

ADAPTIVE BACKGROUND SUBTRACTION TECHNIQUE WITH UNIQUE  
FEATURE REPRESENTATION FOR VEHICLE COUNTING

MOHAMED ATEF ABD EL MONIEM EL IMAM EL KHOREBY

A thesis submitted in fulfilment of the  
requirements for the award of the degree of  
Doctor of Philosophy

School of Electrical Engineering  
Faculty of Engineering  
Universiti Teknologi Malaysia

MARCH 2022

**DEDICATION**

*Dedicated to Mom  
Thank you so much*

*To Dad  
I hope to be proud*

*To my Wife  
You deserve a lot*

*To my Sons  
I love you so much*

## ACKNOWLEDGEMENT

I am very grateful to **ALLAH** Subhanahu Wa Ta'ala who gave me an excellent family to live with and provided me the environment where I could finish my PhD and without whose it will would have been impossible to complete my degree.

Second only to **ALLAH**, thanks to my parents for what they have contributed towards my education. Their unconditional love, constant support, great advice and prayers over the years are something that I cannot thank them for enough. Additionally, knowing that my success in completing my PhD would be a source of happiness for them, I was further motivated to work hard.

I must also thank my supervisors, **Prof. Dr. Syed Abdul Rahman Bin Syed Abu Bakar** and **Associate Prof. Dr. Musa Mohd Mokji** for their continuous guidance and support.

My deepest appreciation goes to my advisor **Prof. Dr. Syed Abdul Rahman Bin Syed Abu Bakar** for his active contribution to refining my research work and in filling the gaps. At times, when things looked difficult, he was the one who gave me hope. Whether it was studying existing research or writing articles, he was there to listen to my concerns, review the material, provide feedback and show direction.

I would like to express my heartily thanks to my friends. They always encouraged me in this challenge. This goes especially for **Ismail Elbadawy and Mohamed Gamal** for their support and friendship that we have through many years.

Finally, my thanks to everyone who has in some way or other helped me in completing this work successfully.

## ABSTRACT

Vehicle detection is the first step towards a successful traffic monitoring system. Although there were many studies for vehicle detection, only a few methods dealt with a complex situation especially in traffic jams. In addition, evaluation under different weather conditions (rainy, foggy and snowy) is so important for some countries but unfortunately it is rarely performed. Presently, vehicle detection is mainly performed using background subtraction method, yet it still faces many challenges. In this thesis, an adaptive background model based on the approximate median filter (AMF) is developed. To demonstrate its potential, the proposed method is further combined with two proposed feature representation techniques to be employed in either global or local vehicle detection strategy. In the global approach, an adaptive triangle-based threshold method is applied following the proposed adaptive background method. As a consequence, a better segmented foreground can be differentiated from the background regardless of the different weather conditions (i.e., rain, fog and snowfall). Comparisons with the adaptive local threshold (ALT) and the three frame differencing methods show that the proposed method achieves the average recall value of 85.94% and the average precision value of 79.53% with a negligible processing time difference. In the local approach, some predefined regions, instead of the whole image, will be used for the background subtraction operation. Subsequently, two feature representations, i.e. normalized object-area occupancy and normalized edge pixels are computed and formed into a feature vector, which is then fed into the  $k$ -means clustering technique. As illustrated in the results, the proposed method has shown an increment of at least 10% better in terms of the precision and 4.5% in terms of F1 score when compared to the existing methods. Once again, even with this significant improvement, the proposed method does not incur noticeable difference in the processing time. In conducting the experiments, different standard datasets have been used to show the performance of the proposed approach. In summary, the proposed method has shown better performances compared to three frame differencing and adaptive local threshold methods.

## ABSTRAK

Pengesanan kenderaan merupakan langkah permulaan kepada kejayaan sistem pengawasan trafik. Walaupun terdapat banyak kajian mengenai pengesanan kenderaan, hanya beberapa kaedah sahaja yang memfokuskan kepada situasi yang kompleks terutamanya ketika kesesakan lalu lintas. Tambahan pula, penilaian dalam keadaan cuaca yang berbeza (hujan, kabus dan salji) adalah penting untuk sesetengah negara, namun malangnya amat jarang dilaksanakan. Pada masa ini, pengesanan kenderaan adalah berdasarkan kaedah penolakan latar belakang, namun ianya masih berhadapan dengan pelbagai cabaran. Dalam tesis ini, model latar belakang berdasarkan penapis median anggaran adaptif (AMF) dibangunkan. Bagi mempamerkan potensi model ini, kaedah yang dicadangkan kemudiannya digabungkan dengan dua teknik perwakilan ciri iaitu dengan strategi pengesanan kenderaan secara global atau secara lokal. Di dalam pendekatan secara global, kaedah berdasarkan segitiga ambang adaptif diterapkan diikuti dengan kaedah latar belakang adaptif. Sebagai hasil, segmentasi latar hadapan yang lebih baik dapat dibezakan dengan latar belakang walaupun dalam keadaan cuaca yang berbeza (sebagai contoh: hujan, kabus dan salji). Perbandingan dengan ambang lokal adaptif (ALT) dan kaedah perbezaan tiga-kerangka menunjukkan bahawa strategi yang dicadangkan mencapai nilai purata pulangan sebanyak 85.94% dan nilai purata ketepatan sebanyak 79.53% dengan perbezaan masa pemrosesan yang boleh diabaikan. Bagi pendekatan secara lokal pula, hanya beberapa kawasan tertentu digunakan untuk operasi penolakan latar belakang, bukannya keseluruhan imej. Selanjutnya, dua perwakilan ciri, iaitu penghunian kawasan-objek dinormalisasi dan piksel sisi dinormalisasi, dikira dan dibentuk menjadi vektor ciri, yang kemudiannya dimasukkan ke dalam teknik pengklusteran *k-means*. Seperti mana yang digambarkan di dalam keputusan, kaedah yang dicadangkan telah menunjukkan peningkatan sekurang-kurangnya 10% lebih baik dari segi ketepatan dan 4.5% dari segi skor F1 apabila dibandingkan dengan kaedah-kaedah yang sedia ada. Demikian juga, walaupun dengan peningkatan yang ketara ini, kaedah yang dicadangkan tidak menunjukkan perbezaan yang nyata dalam masa pemrosesan. Dalam menjalankan eksperimen, set data piawai yang berbeza telah digunakan untuk menunjukkan prestasi kaedah yang dicadangkan. Sebagai kesimpulan, kaedah yang dicadangkan telah menunjukkan prestasi yang lebih baik berbanding dengan kaedah perbezaan tiga-kerangka dan kaedah ambang lokal adaptif.

## LIST OF ABBREVIATIONS

ITS	-	Intelligent Transportation System
BS	-	Background Subtraction
SVM	-	Support Vector Machine
SIFT	-	Scale-Invariant Feature Transform
HOG	-	Histogram of Oriented Gradient
GMM	-	Gaussian Mixture Model
ALT	-	Adaptive Local Threshold
AMF	-	Approximate Median Filter
MI	-	Motion Index
TTD	-	Three Temporal Differencing
EM	-	Expectation Maximization
TP	-	True Positive
FP	-	False Positive
FN	-	False Negative
SD	-	Sigma Delta
MDPS	-	Motion Detection With Pyramid Structure
FCDH	-	Fuzzy Color Difference Histogram
CDH	-	Color Difference Histogram
MCC	-	Mathew's Correlation Coefficient
PCC	-	Percentage OF Correct Classification
ACTC	-	Average Computational Time Per Pixel Per Clock
ROI	-	Region of Interest
PTRF	-	Preset Threshold Based Region Filling Method
GDVM	-	Grey Level Differential Value Method
HE	-	Histogram Estimation
MRF	-	Markov Random Filed
CRF	-	Conditional Random Filed
JRF	-	Joint Random Filed
NR	-	Actual Number of Vehicles
ND	-	Number of Detected Vehicles
NOAO	-	Normalized object area occupancy
NAEP	-	Normalized aggregate edge pixel

## LIST OF SYMBOLS

$t$	-	Frame number
$b_g$	-	Final background model
$vg$	-	Brightness value
$N_{ref}$	-	Number of pixels inside reference region
$N$	-	Number of pixels inside detection region
$C$	-	Current Frame
$\alpha$	-	Learning rate for minimum value
$\beta$	-	Learning rate for maximum value
$L'$	-	Compensated image
$Fl$	-	Floor value
$Ce$	-	Ceiling value
$L_{max}$	-	Maximum intensity value
$L_{min}$	-	Minimum intensity value
$c$	-	Hypotenuse of the right angle
$d$	-	Maximum distance
$h(b_{max})$	-	Maximum histogram brightness value
$h(b_{min})$	-	Minimum histogram brightness value
$R_i$	-	Detection region number $i$
$z_i^k$	-	Local maximum point
$E$	-	Total edge pixels
$J$	-	Objective function
$C_j$	-	The center of cluster $j$
$w_{opt}$	-	Optimum frame number
$f$	-	Time needed to model background
$gt$	-	Ground truth
$y$	-	The output of multiplying the processing time with the difference between the background model output and the ground truth
$P$	-	Precision
$R$	-	Recall
$F$	-	F-measure

$th$	-	Threshold value
$D_c$	-	Binary motion detection mask
$H$	-	Height
$W$	-	Width

# CHAPTER 1

## INTRODUCTION

### 1.1 Overview

Intelligent Transportation Systems (ITS) can be defined as an application of new information and communication technologies of vehicles and roads for monitoring and managing traffic flow, decreasing congestion, improving security and optimizing the use of roads and transportation. In addition, it is useful in informing the drivers with the best route and the travel time for their destination in real-time [1]. Consequently, the development of ITS that extracts information from the traffic surveillance systems plays an important role in traffic management. It can ensuring better safety, directing smoother traffic flow, improving better traffic control in a congested urban area, and maintaining law and order of traffic and traffic signals [1,2].

One of the primary keys to ITS is the video-based surveillance system. It can be used for extracting some useful information such as vehicle counting, detection, tracking and recognition [3]. Traditionally, such information can be extracted by utilizing induction loops, passive magnetic sensors or pneumatic tubes under the road. These methods, in general, have limitations such as unable to detect stationary vehicles in addition to being highly complex in the hardware design, which translates to high cost [4]. Moreover, it can only extract local information from a specific location, causing limitation of the effectiveness of traffic management [5]. Therefore, the vision-based traffic monitoring system has attracted many researchers due to its two-fold advantages: less costly and easier to deploy [6]. Moreover, the advancement in the development of computational technologies has made vision-based vehicle counting an extremely attractive option for ITS. Nevertheless, such a system does face some challenges, such as changing lighting conditions, occlusion, and unfavorable weather conditions. Such problems have opened up a new horizon of research

opportunities. Therefore, vehicle detection based on video camera becomes an active research field.

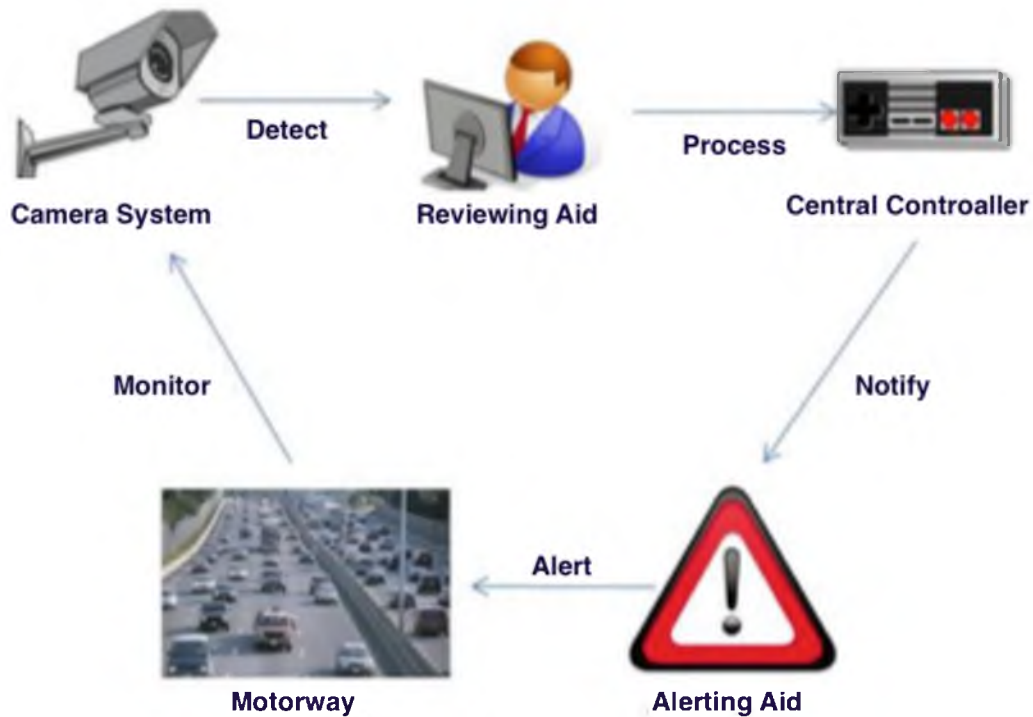

Figure 1.1 Main components in traffic management based on CCTV system [7].

Figure 1.1 shows the main components for a traffic management system based on a CCTV system. Two types of cameras can be used; analog or digital. A digital camera has an advantage over the analog as it has high storage capacity and high resolution. The captured video can be reviewed in real-time or recorded to manage the traffic flow. A central controller is responsible for some pre-processing steps such as shadow removal, noise removal, and other processing steps such as feature extraction and background subtraction processes. In addition, post-processing steps such as morphological operations can be included for better vehicle detection performance.

Monocular cameras are usually deployed for the human operator; however, stereo cameras can provide more depth information about the scene [8]. In monocular vision-based monitoring systems, a stationary camera is mounted at a high position, such as on the traffic lights or bridges to capture the passing vehicles. As a consequence, detecting vehicles can be affected by many challenges such as occlusion, changing lane and illumination conditions [9].

Conversely, stereo cameras and 3D modeling are deployed mainly to overcome the occlusion problem by improving the scene analysis obtained from the extracted depth information. These models, however, are computationally intensive, which, in return, affect the real-time speed and require prior tracking information [9]. For a typical surveillance system, a traffic camera network is used to analyze and extract parameters from the captured scene and then transmit them in real-time [10].

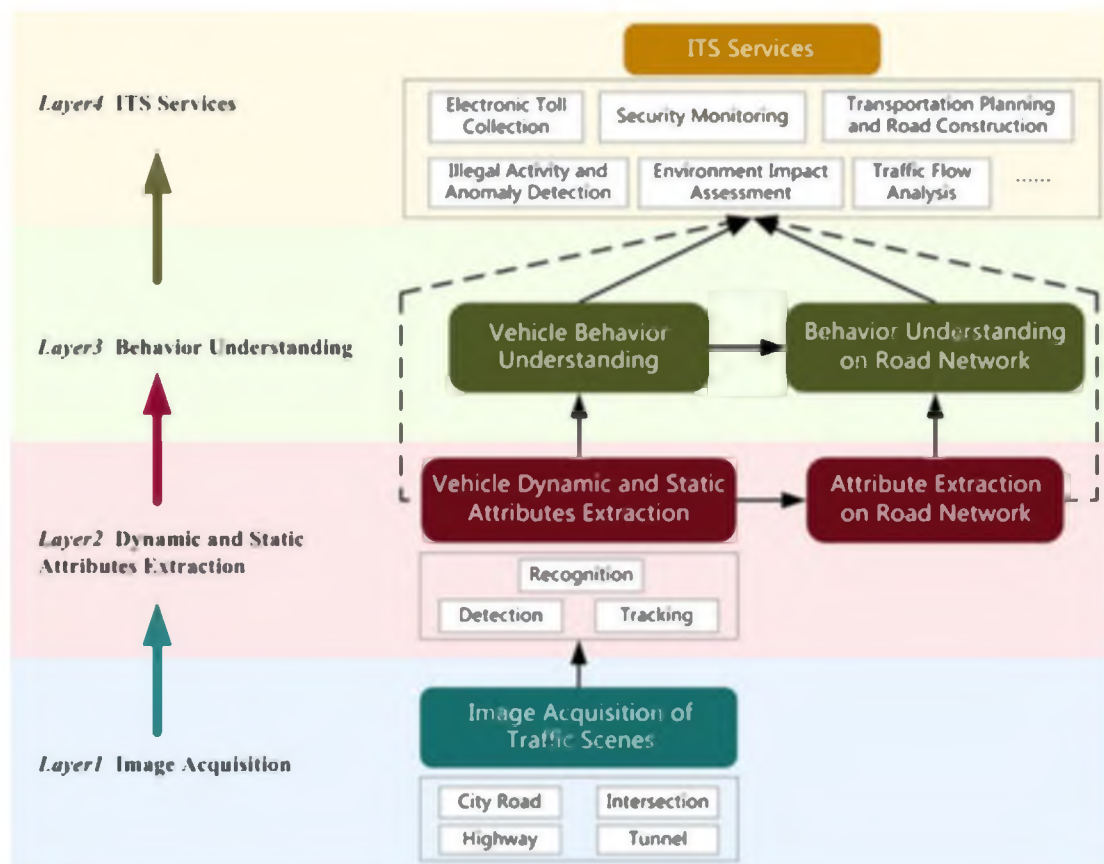

Figure 1.2 Main components of video surveillance systems [3].

Figure 1.2 illustrates the main components of a video surveillance system that consists of four layers:

- Layer 1: Image acquisition
- Layer 2: Dynamic and static attributes extraction
- Layer 3: Behavior understanding
- Layer 4: ITS services

The main function of layer 1 is to capture the traffic scene and extract images based on visual sensors. The purpose of layer 2 is to extract the dynamic attributes of vehicles such as velocity, vehicle trajectories and direction of movement, and static attributes of vehicles, which include its color, shape, and type. For layer 3, it aims to analyze and understand the dynamic and static attributes extracted from layer 2. Based on the extracted information, layer 4 provides ITS services such as traffic flow analysis, security monitoring, and transportation planning and road construction [3].

### **1.1.1 Vehicle Counting**

Vehicle counting is a key feature in traffic flow estimation, which is one of the crucial features in the ITS [4]. Estimating the number of vehicles in ITS based on traffic video sequences is an important task, as it can provide reliable information for traffic management and control [11]. It can be used for understanding the traffic status, such as road-traffic density, lane occupancy, and congestion level, which helps drivers to avoid traffic congestion and spend less time in traffic. Subsequently, development authorities can use such information to design a better solution for road traffic.

### **1.1.2 Vehicle Detection**

In any ITS, reliable vehicle detection is the first step to be achieved [12]. Subsequent applications such as vehicle counting, speed estimation and traffic flow depend on this first step. Hence, increasing the accuracy of the vehicle detection process will result in enhancing the efficiency of traffic control. Additionally, this will lead to improving the accuracy of other processes following it, such as vehicle tracking, vehicle trajectory, and behavior understanding, which is common in traffic surveillance systems [5].

## 1.2 Problem Statement

One of the main reasons for traffic congestion is the exponential increase in the number of vehicles concerning the number of roads [13]. In such a situation, developing a robust and reliable system that can estimate the traffic measurements in any weather conditions is necessary.

Vehicle detection can be considered as the first step for any ITS system. However, some challenges still remain particularly during adverse weather conditions. In such a situation, the exact shape or size of the moving vehicle may not be clearly detected leading to miscounting. The same problem is faced when one vehicle is being occluded by another vehicle.

Therefore, many approaches have been proposed for vehicle detection. However, a number of these approaches cannot be implemented in real-time due to their high computational complexity, such as the optical flow approach. On the other hand, some algorithms are so simple that they do not provide reliable reliable with a sufficient level of accuracy, such as the frame differencing approach. Additionally, the background subtraction (BS) approach still faces some challenges and the most challenging of all is in modeling of the background scene with acceptable degree of accuracy. Moreover, the performance of these algorithms decreases under unfavourable environment situations such as different weather conditions. As in many previous works, the worst accuracy for vehicle detection occurs when the visibility in the scene is poor or low such as during heavy rain condition.

Although there were many studies for vehicle detection, only a few methods dealt with the abnormal situation, especially in traffic jams [8,14,15]. In addition, evaluation under different weather conditions (Rainy, Foggy and Snowy) is so important for some countries, but unfortunately, it is rarely performed [8]. Furthermore, urban traffic is more challenging than highway traffic due to lower camera angles, which leads to occlusion and traffic density [8].

Moreover, the algorithm used for vehicle detection must be computationally efficient so that it can be implemented in real-time. This is essential so that the

extracted information can be delivered to traffic users on time. Therefore, having an accurate algorithm, which can cope with these challenges and can be used in real-time, is very important.

### **1.3 Objectives**

The undertaken research has the following objectives:

1. To propose an accurate vehicle detection and counting method that is robust under different conditions such as different weather conditions (sunny, rainy, foggy and snowy), and different traffic landscapes (urban and highway). An adaptive background modelling with feature representation techniques covering global and local approach is proposed.
2. To propose a detection model that is computationally efficient for possible real-time implementation. The proposed background method along with the local feature representation technique is further explored and analysed.

### **1.4 Scope**

The scope of this research includes the followings:

- a) This work will focus on vehicle detection and counting in urban and highway traffic under different illumination and weather conditions (Foggy, Rainy, Snowy and Sunny) using handcrafted methods.
- b) The datasets used are standard datasets used by other researchers [17-20]. Additionally, data collected from urban roads in Malaysia, especially in the rainy condition, will also be used. This is because public dataset on different rainy condition is not currently available.

- c) The collected videos were recorded from a stationary camera placed above the road so as to obtain two views; either the traffic is facing towards or away from the camera.
- d) MATLAB software is used for testing the developed algorithms using Intel i5 core processor, 2.3 GHz speed and 4GB RAM operated under Windows 10.

## **1.5 Thesis Outline**

This thesis is organized as follows: Chapter 1 presents an overview of the thesis. In this chapter the problem statement is presented along with the research objectives and scopes. Chapter 2 gives a survey of the existing techniques in vehicle detection and counting along with a summary of the existing methods. Chapter 3 details out the proposed background modeling in addition to the details of the two proposed feature representation techniques (global and local). The primary key technique is the adaptive background modelling based on Aproximate Median Filter (AMF). To proof the efficacy of the proposed method, it will then be applied to both global and local vehicle detection and counting methods. In the global method, the triangle threshold technique is implemented after the background subtraction operation to obtain foreground objects representing moving vehicles. While in the local method, two additional features are extracted from the background subtraction result performed in a predefined region. Next, k-means clustering technique is then applied for the vehicle detection and counting. Chapter 4 presents the results of the proposed adaptive background modelling accompanied by a comparison with some existing methods using existing benchmarks datasets and self-collected videos from different weather conditions. The results show the potential of the proposed methods compared to some existing methods in terms of accuracy and computational efficient. Finally, Chapter 5 summarizes the main contribution achieved by this thesis with suggestions for future work.
