### Abstract

Observed charge transfer cross sections are compiled in an energy region from a few to tens keV for multiply charged Ne, Ar, Kr and Xe ions on rare gas targets, where projectile ions are produced by using an "ion-impact ion source" (IIIS). The values are compared with the results of other research workers.

### 1. Introduction

During the past ten years, many theoretical and experimental works have been carried out concerning charge transfer collisions between multiply charged slow ions with various atoms and molecules. The reason is that these collisions are fundamental processes in atomic physics, chemistry, radiation physics, astrophysics<sup>1)</sup> and fusion researches<sup>2)</sup>. Pre- and post-electronic states of both projectile and target, collision energy, interaction range, emitted radiations and electrons, and cross section magnitude are necessary quantities to be studied, but the observations are not easy.

It was in 1978 that we started the project "low energy ion-atom collisions", because we succeeded in extracting multiply charged recoil ions. When rare gas atoms were bombarded with an accelerator beam of heavy ions and the charge spectra of recoil ions were analyzed with the use of a Wien filter, amounts of highly ionized ions having energies of approximately a few eV width were detected<sup>3)</sup>. This system was immediately turned to an ion source applicable to ion-atom collisions in a low energy

\*\* Department of Nuclear Engineering.

region. Thereafter, we named this the "ion-impact ion source" (IIIS), and the feature of the revised system has been reported elsewhere<sup>4)</sup>.

In an earlier stage of our project, the single- and double-electron captures of  $\text{He}^{2+}$  ions from He, Ne, Ar, Kr, Xe and  $\text{N}_2$  had been studied in the energy region of 0.7–4.5 keV<sup>3,5)</sup>. The detection method for charge-transferred ions was rather simple. Fortunately, since we received the 1979–1981 Scientific Research Expenditure of the Ministry of Education, the experimental apparatus and techniques have been remarkably improved. New data have been rapidly accumulated, which are quite important in considering collision mechanism.

Among very many observed results, we present here the charge transfer cross sections for variously stripped Ne, Ar, Kr and Xe ions on rare gas targets. The projectile-target combinations and the collision energies are listed in Table 1. Our cross section values, tabulated and depicted in many figures, are compared with those of other research workers.

Table 1. Combination of projectile-target in charge transfer experiment.

Ion	Projectile Charge $q$	Collision energy	Target atom
$\text{Ne}^{q+}$	2~5	1.5 $q$ –12 $q$ keV	He
$\text{Kr}^{q+}$	4, 8	1.5 $q$ –12 $q$ keV	He
$\text{Ar}^{q+}$	2~7	11.4 keV (0.286 keV/amu)	He
$\text{Kr}^{q+}$	2~9	24 keV (0.286 keV/amu)	He, Ne, Ar, Kr, Xe
$\text{Xe}^{q+}$	2~11	37.6 keV* (0.286 keV/amu)	He, Ne, Ar, Kr, Xe

\* A few  $\text{Xe}^{2+}$ -target combinations were measured at about 34.5 keV in energy (0.262 keV/amu) to prevent an electrical breakdown in ion acceleration.

## 2. Experimental

The experimental arrangement is schematically shown in Fig. 1, which is fundamentally the same as reported elsewhere<sup>4)</sup>, but is briefly described here.

### 2.1. Collision system

A beam of molecular nitrogen ions ( $\text{N}_2^+$ ) with 1 MeV in energy, extracted from a Van de Graaff accelerator of Kyoto University, was sharply collimated up to about 0.2mm×3mm in size and introduced into an ionization chamber with a beam intensity of 0.05–1.5  $\mu\text{A}$ . In this chamber was constructed the IIIS, which was composed of two parallel plates, a central gas nozzle, a focusing lens and four accelerating electrodes. When gas atoms ejected from the nozzle were bombarded with the nitrogen beam, highly charged recoil ions were produced. By imposing appropriate electric potentials to the plates, lens and electrodes, recoil ions could be drawn out toward the grounded side.

Fig. 1. Schematic diagram of the experimental arrangement.

The charge and energy of these ions were analyzed in a Wien filter ( $E \times B$  field) and then the course was adjusted slightly by two pairs of steering electrodes. However, in order to prevent a heavy mixing of neutral components, it was necessary to arrange a "neutral particle rejector", which consisted of electrostatic deflectors and a movable shutter. Thus, a well resolved ion beam with the desired ionicity and energy could be introduced into a collision cell. The ion intensities were typically  $\sim 10$  kcps for  $\text{Ne}^+$ ,  $\text{Ar}^+$ ,  $\text{Kr}^+$  and  $\text{Xe}^+$ , but  $10 \sim 100$  cps for  $\text{Ne}^{5+}$ ,  $\text{Ar}^{7+}$ ,  $\text{Kr}^{9+}$  and  $\text{Xe}^{11+}$ . Therefore, the time of data acquisition becomes longer as the projectile ionicity increases.

The collision cell was a SUS cylinder of  $30 \text{ mm}\phi \times 40 \text{ mm}$  with a  $0.5 \text{ mm}\phi$  entrance and  $3.5 \text{ mm}\phi$  exit apertures. Target gas was fed into this cell through a variable leak valve and the gas pressure was monitored with the use of a sensitive Pirani gauge, which had been calibrated by a capacitance manometer (Baratron). The main chamber was evacuated up to the base pressure of less than  $2 \times 10^{-7}$  Torr ( $2.7 \times 10^{-5}$  Pa), the pumping system of which consisted of a  $250 \text{ l/s}$  turbomolecular pump and a  $6''$  oil diffusion pump plus a liquid nitrogen trap,

## 2.2. System of particle detection

The charge-transferred outgoing ions were electrostatically deflected and hit on a position sensitive detector (PSD) separately according to their charges. This PSD was made of a rectangular ( $46 \text{ mm} \times 13 \text{ mm}$ ) tandem microchannel plate (MCP)\*, onto which a resistive anode was attached. The output signals were processed in an analog decoder and also in a digital decoder, and so the position (charge) spectrum could be obtained with a good resolution. The details of the present MCP-PSD device have been reported elsewhere<sup>9)</sup>.

## 2.3. Determination of cross sections and uncertainties

The cross section values were derived by applying a growth rate method based

\* Specially manufactured by Hamamatsu TV. Co., Ltd.

on the so-called rate equations. When ions of  $q+$  ionicity pass through the collision cell, the peak corresponding to  $(q-k)+$  ions ( $k=0, 1, 2, \dots$ ) appears on the PSD profile where  $k$  is the number of transferred electrons. If the fraction is denoted as  $F_{q,q-k}$ , it is a function of target thickness  $\pi$  (gas pressure  $\times$  cell length), and we obtain its approximate expression in a low  $\pi$  region

$$F_{q,q-k} = \sigma_{q,q-k} \cdot \pi + C_k \cdot \pi^2,$$

where  $\sigma_{q,q-k}$  is the cross section for  $k$ -electron transfer and  $C_k$  is a coefficient including several cross sections.

We measured a set of fraction curves for a given projectile-target combination and derived the  $\sigma_{q,q-k}$  values by the least squares method. To examine the reliability of the above procedure, we solved the rate equations by using the  $\sigma_{q,q-k}$  results. The reproductions were found satisfactory in most cases, and an example is shown in Fig. 2 for  $\text{Ne}^{4+}$  ions on He,

Each statistical deviation of  $\sigma_{q,q-k}$  is easily obtained by the fitting procedure stated

above, and typically a few % for  $k=1, 2$  and 3. Other experimental uncertainties which affect the cross section values are listed in Table 2. The total experimental uncertainties for the absolute values of the cross section were obtained by the quadrature sum of these uncertainties. The reason for ion impurity is that our Wien filter is a  $(q/m)^{1/2}$  analyzer and cannot separate ions with close  $q/m$  values. Therefore, contaminant  $^{16}\text{O}^{4+}$  and  $^{12}\text{C}^{3+}$  ions in  $^{20}\text{Ne}^{5+}$ ,  $\text{O}^{2+}$  in  $\text{Ar}^{5+}$ ,  $\text{OH}^+$  and  $\text{O}^+$  in  $\text{Kr}^{5+}$  and  $\text{Xe}^{8+}$ ,  $\text{N}^+$  in  $\text{Kr}^{6+}$  and  $\text{Xe}^{9+}$ ,  $\text{C}^+$  in  $\text{Kr}^{7+}$  and  $\text{Xe}^{11+}$ , and  $\text{O}_2^+$  in  $\text{Xe}^{4+}$  were inevitably mixing. The amounts of these impurities were usually negligibly small or at most less than 5%. A large amount of contaminant  $\text{C}^+$  ions, however, was found in  $\text{Xe}^{11+}$  ions and estimated to be about 39% in the case of  $\text{Xe}^{11+}$ -He collision. These contributions were corrected in deriving the final  $\sigma_{q,q-k}$  values.

Fig. 2. Variations of charge fractions as a function of target gas pressure for 24 keV  $\text{Ne}^{4+}$  ions on He. Solid curves are the calculated fractions by using the experimental  $\sigma_{q,q-k}$  values.

Table 2. List of systematic uncertainties.

Origin	Uncertainty (%)
Measurements of gas pressure	7
Effective collision length	5
Temperature	3
Target gas impurity	< 5
Ion impurity*	5 for Kr <sup>5-7+</sup>
	4 for Ar <sup>5+</sup>
	3 for Xe <sup>8,9+</sup>
	2 for Xe <sup>4+</sup>
Charge separation in PSD and error of dividing processor	< 1 for other ions except Xe <sup>11+</sup>
	< 10 for Xe <sup>11+</sup>
	< 5 for other ions

\* The impurity contents in Xe<sup>11+</sup> ions were estimated to be 8~40%, the contributions of which are corrected in deriving the cross section values.

### 3. Results and comparison with other data

The present charge transfer cross sections are given in Tables 3 to 7 and are depicted in Figs. 3 to 15. The values obtained by other research workers are inserted in these figures for the sake of comparison.

#### 3.1. Ne<sup>q+</sup> ( $q=2\sim 5$ ) ions on He

The energy range adopted is 1.5–12 keV/ $q$  as listed in Table 3, and the present data together with those of others are plotted in Fig. 3. Our  $\sigma_{2,1}$  results stay around

Table 3. Charge transfer cross sections for Ne<sup>q+</sup> ( $q=2\sim 5$ ) ions on He.

Ion <sup>q+</sup>	Target	Energy (keV)	Cross section (cm <sup>2</sup> )	
			$\sigma_{q,q-1}$	$\sigma_{q,q-2}$
Ne <sup>2+</sup>	He	3.0	2.99±0.37(-17)	1.97±0.32(-18)
		6.0	5.01±0.66(-17)	4.65±0.85(-18)
		12.0	5.78±0.67(-17)	9.69±2.27(-18)
		24.0	8.50±1.00(-17)	1.17±0.16(-17)
Ne <sup>3+</sup>	He	5.3	1.49±0.17(-16)	9.42±1.41(-18)
		9.0	1.28±0.15(-16)	8.22±1.22(-18)
		18.0	9.30±1.17(-17)	1.03±0.16(-17)
		36.0	1.11±0.15(-16)	1.06±0.20(-17)
Ne <sup>4+</sup>	He	6.0	1.14±0.13(-15)	7.91±1.06(-17)
		12.0	9.60±1.13(-16)	7.21±0.86(-17)
		24.0	7.11±0.83(-16)	5.57±0.66(-17)
		48.0	7.27±0.85(-16)	3.78±0.49(-17)
Ne <sup>5+</sup>	He	15.0	2.08±0.54(-15)	—
		55.0	1.69±0.40(-15)	—

the mean of the values obtained by Flaks *et al.*<sup>1)</sup>, Cocke *et al.*<sup>8)</sup> and Salzborn *et al.*<sup>9)</sup>, and can be connected with the higher energy data of Bloemen *et al.*<sup>10)</sup> and Suk *et al.*<sup>11)</sup>. The present  $\sigma_{2,0}$  results are rather consistent with those of Flaks *et al.*<sup>1)</sup>. Both  $\sigma_{2,1}$  and  $\sigma_{2,0}$  increase steeply with an increasing impact energy. This means that the electron transfer range,  $R_z$ , is rapidly increasing since  $\sigma \propto \pi R_z^2$  is approximated,

The present values for  $\text{Ne}^{3+}$  to  $\text{Ne}^{5+}$  ions are rather monotone against ion energy, and are generally consistent with those of Cocke *et al.*<sup>8)</sup> and Salzborn *et al.*<sup>9)</sup>.

### 3.2. $\text{Kr}^{q+}(q=4, 8)$ ions on He

The measurements were done in an energy range from 1.5 to 12 keV/q, as tabulated in Table 4 and represented in Fig. 4. The present data are original and are comparable with only the observations of Cocke *et al.*<sup>8)</sup> at a lower impact energy. The cross section magnitudes are monotone against ion energy except for the present  $\sigma_{4,3}$  values.

### 3.3. $\text{Ar}^{q+}(q=2\sim 7)$ , $\text{Kr}^{q+}(q=2\sim 9)$ and $\text{Xe}^{q+}(q=2\sim 11)$ ions on He

The projectile  $q$ -dependence of the charge transfer cross section is quite important from the points of empirical scaling law and theoretical

Fig. 3 Charge transfer cross sections for 1.5–12 keV/q  $\text{Ne}^{q+}$  ( $q=2\sim 5$ ) ions on He. Solid symbols and crosses denote single-electron transfer and open symbols stand for double-electron transfer.

Ion	q	Target	Cross section (cm <sup>2</sup> )	
			$\sigma_{q,q-1}$	$\sigma_{q,q-2}$
$\text{Ar}^{q+}$	2	He	$4.72 \pm 0.57$ (-16)	$< 0.7$ (-18)
	3		$4.67 \pm 0.56$ (-16)	$5.81 \pm 3.24$ (-18)
	4		$1.02 \pm 0.13$ (-15)	$3.41 \pm 1.15$ (-17)
	5		$1.85 \pm 0.23$ (-15)	$2.46 \pm 0.33$ (-16)
	6		$2.28 \pm 0.27$ (-15)	$6.59 \pm 0.78$ (-16)
	7		$2.26 \pm 0.29$ (-15)	$5.94 \pm 0.70$ (-16)
	$\text{Kr}^{q+}$		2	He
3		$1.19 \pm 0.15$ (-15)	$3.20 \pm 1.15$ (-18)	
4		$5.67 \pm 0.70$ (-16)	$3.29 \pm 0.73$ (-17)	
5		$1.26 \pm 0.17$ (-15)	$9.10 \pm 1.15$ (-17)	
6		$1.54 \pm 0.20$ (-15)	$1.68 \pm 0.25$ (-16)	
7		$2.24 \pm 0.31$ (-15)	$7.94 \pm 1.14$ (-16)	
8		$1.79 \pm 0.22$ (-15)	$5.58 \pm 0.98$ (-16)	
9		$2.64 \pm 0.33$ (-15)	$1.31 \pm 0.50$ (-16)	
$\text{Xe}^{q+}$		2	He	
	3	$4.19 \pm 0.49$ (-16)		$1.90 \pm 0.47$ (-18)
	4	$1.57 \pm 0.19$ (-15)		$4.66 \pm 1.04$ (-18)
	5	$1.02 \pm 0.13$ (-15)		$1.36 \pm 0.42$ (-17)
	6	$2.22 \pm 0.26$ (-15)		$1.30 \pm 0.17$ (-16)
	7	$2.64 \pm 0.31$ (-15)		$5.28 \pm 0.75$ (-16)
	8	$2.38 \pm 0.29$ (-15)		$6.30 \pm 0.77$ (-16)
	9	$3.27 \pm 0.41$ (-15)		$2.61 \pm 0.51$ (-16)
	10	$4.00 \pm 0.84$ (-15)		$1.55 \pm 0.43$ (-16)
	11	$5.34 \pm 0.99$ (-15)*		$1.56 \pm 0.61$ (-16)*

\* These values are corrected for a 39% C<sup>+</sup> contamination mixing in Xe<sup>11+</sup> ions.

Fig. 5. Charge transfer cross sections for 0.286 keV/amu  $\text{Ar}^{q+}$  ( $q=2\sim 7$ ) ions on He. Solid and open symbols denote single- and double-electron transfer, respectively.

●, ○: present-Kyoto, ■, □: Salzborn *et al.*<sup>9,12),</sup>, ▲: Bliman *et al.*<sup>13),</sup>, ◆: Cocke *et al.*<sup>14).</sup>  
 Solid lines are drawn to guide the eye.

consideration. The present results are listed in Table 5 and are also illustrated in Figs. 5, 6 and 7 for  $\text{Ar}^{q+}$ ,  $\text{Kr}^{q+}$  and  $\text{Xe}^{q+}$  ions, respectively.

Our  $\sigma_{q,q-1}$  data for  $\text{Ar}^{q+}$  ions are in general agreement with those of Salzborn<sup>9,12)</sup> (at 30 keV), Bliman<sup>13)</sup> (mean values in the energy range from  $2q$  to  $10q$  keV) and Cocke<sup>14)</sup> (at 0.5 keV/ $q$ ) for  $q \geq 4$ . The scatter of these observations would be attributable to the ion-energy dependence of the cross section. The present  $\sigma_{q,q-2}$  values are consistent with those obtained by Salzborn *et al.*<sup>12).</sup>

Fig. 6. Charge transfer cross sections for 0.286 keV/amu  $\text{Kr}^{q+}$  ( $q=2\sim 9$ ) ions on He. For symbols, see Fig. 5.

Fig. 7. Charge transfer cross sections for 0.286 keV/amu  $\text{Xe}^{q+}$  ( $q=2\sim 11$ ) ions on He. For symbols, see Fig. 5.

In Fig. 6 are compared our  $\sigma_{q,q-1}$  measurements and those of Cocke *et al*<sup>14)</sup> for  $\text{Kr}^{q+}$  ions, and an accordance is seen except for  $q=4$ . The deviation of  $\sigma_{4,3}$  values also seems to be attributable to the energy dependence of the cross section. The  $\sigma_{q,q-2}$  data have never been reported and we find a  $\sigma$  maximum at  $q=7$  in the present study. Similarly, the results for  $\text{Xe}^{q+}$  ions are represented in Fig. 7, where the  $\sigma_{q,q-1}$  values of Salzborn *et al*<sup>9)</sup> are compared. The  $\sigma_{q,q-2}$  measurements in the  $\text{Xe}^{q+}$ —He collision had been firstly done by our study group.

### 3.4. $\text{Kr}^{q+}(q=2\sim 9)$ ions on Ne, Ar, Kr and Xe

It is very interesting to survey the charge transfer collisions of multiply vacant ions with multi-electron targets at a given energy. The  $\sigma_{q,q-k}$  data for  $\text{Kr}^{q+}$  ions on Ne, Ar, Kr and Xe are compiled in Table 6 and graphically shown in Figs. 8, 9, 10 and 11, respectively.

The comparable observations are quite poor, and there have been reported only the  $\sigma_{q,q-1}$  data of Salzborn *et al*<sup>9)</sup> for the  $\text{Kr}^{q+}$ —Ar case at 30 keV, which are consistent with ours. The feature is that the  $\sigma_{q,q-k}$  values have a similar trend against  $q$  as

Fig. 8. Charge transfer cross sections for 0.286 keV/amu  $\text{Kr}^{q+}(q=2\sim 9)$  ions on Ne.  $\bullet$ ,  $\blacktriangle$ ,  $\blacksquare$ ,  $\blacktriangledown$ : present-Kyoto. The notation  $k$  means the number of transferred electrons. Solid lines are served to guide the eye.

Fig. 9. Charge transfer cross sections for 0.286 keV/amu  $\text{Kr}^{q+}(q=2\sim 9)$  ions on Ar.  $\bullet$ ,  $\blacktriangle$ ,  $\blacksquare$ ,  $\blacktriangledown$ ,  $\blacklozenge$ : present-Kyoto,  $\circ$ : Salzborn *et al*<sup>9)</sup>. Other notations are the same as in Fig. 8.

Table 6. Charge transfer cross sections for  $\text{Kr}^{q+}$  ( $q=2\sim 9$ ) ions on Ne, Ar, Kr and Xe at 0.286 keV/amu in energy.

Ion $q$ Target	Cross section ( $\text{cm}^2$ )

well as  $k$ , the case for  $\text{Kr}^{q+}$ -Ne being slightly different. The maxima of  $\sigma_{q,q-k}$  are seen for large  $k$  numbers.

### 3.5. $\text{Xe}^{q+}$ ( $q=2\sim 11$ ) ions on Ne, Ar, Kr and Xe

Referring to the  $\sigma_{q,q-k}$  results for  $\text{Kr}^{q+}$  ions, those for  $\text{Xe}^{q+}$  ions on multi-electron targets at the same velocity as before become important. Therefore, our measurements

Fig. 10. Charge transfer cross sections for 0.286 keV/amu  $\text{Kr}^{q+}$  ( $q=2\sim 9$ ) ions on Kr. Symbols and notations are the same as in Fig. 9.

Fig. 11. Charge transfer cross sections for 0.286 keV/amu  $\text{Kr}^{q+}$  ( $q=2\sim 9$ ) ions on Xe. Symbols and notations are the same as in Fig. 9.

are listed in Table 7 and are depicted in Figs. 12, 13, 14 and 15 for Ne, Ar, Kr and Xe, respectively. The Salzborn data<sup>9)</sup> obtained at 30 keV are inserted, which show a systematic overestimation from our results. Again, there are seen remarkable behaviors whereby the  $\sigma_{q,q-k}$  results have a similar trend against  $q$  and  $k$ , but no significant  $\sigma$  maxima are seen.

#### 4. Summary

We have measured the cross sections of single- to multiple-electron transfer for slow multiply ionized Ne, Ar, Kr and Xe ions on rare gas targets, and the results are compiled here. The features are summarized as follows:

- (1) The cross sections for single-electron transfer,  $\sigma_{q,q-1}$ , have oscillations against  $q$ . This fact is consistent with the prediction of a "classical one electron model" (COEM)<sup>15)</sup>.
- (2) The  $\sigma$  data of Salzborn's group<sup>9,12)</sup> are in general accordance with the present results, but deviate for targets with small ionization potentials. Therefore, the reported scaling law<sup>9)</sup> for  $\sigma_{q,q-1}$  should be reexamined.
- (3) The double-electron transfer cross sections,  $\sigma_{q,q-2}$ , for  $\text{Ar}^{q+}$ ,  $\text{Kr}^{q+}$  and  $\text{Xe}^{q+}$

Table 7. Charge transfer cross sections for Xe<sup>q+</sup> (q=2~11) ions on Ne, Ar, Kr and Xe at 0.286 keV/amu in energy.

Ion	q	Target	Cross section (cm <sup>2</sup> )

\* Only these collisions were measured at 0.262 keV/amu in energy to prevent an electrical breakdown in ion acceleration,

\* These values are corrected by considering the 28.8 and 20.4% C<sup>+</sup> contaminations in Xe<sup>11+</sup> ions on Ar and Kr, respectively,

Fig. 12. Charge transfer cross sections for 0.286 keV/amu  $Xe^{q+}$  ( $q=2\sim 11$ ) ions on Ne. Symbols and notations are the same as in Fig. 9.

Fig. 13. Charge transfer cross sections for 0.286 keV/amu  $Xe^{q+}$  ( $q=2\sim 11$ ) ions on Ar. Symbols and notations are the same as in Fig. 9.

on He show a very similar dependence on  $q$  and have clear maxima at around  $q=7$ .

(4) The multiple-electron transfer cross sections for  $Kr^{q+}$  and  $Xe^{q+}$  ions on Ar, Kr and Xe behave very similarly irrespective of target gas. A comparison with the "classical absorbing sphere model" (CASM)<sup>16)</sup> could be done, but at present, it is only a measure to know the  $\sigma_{q,q-k}$  behaviors and magnitudes. A new treatment of the "statistical electron transfer model" (SETM)<sup>17)</sup> proposed by our study group seems useful.

(5) The compiled data include many important facts to be profoundly examined, which are to be discussed elsewhere.

### Acknowledgements

The authors would like to express their sincere gratitude to Prof. F. Fukuzawa and Mr. M. Tomita for their encouragement and useful comments. The cooperative works of Messers K. Norizawa, N. Ide and T. Yamauchi are heartfully appreciated. This work was supported by the Scientific Research Expenditure of the Ministry of Education in Japan.
