## **Acknowledgements**

This project could not have proceeded without the assistance and guidance from a number of people. Special thanks to the University of New England and the University of Adelaide for facilitating this research.

Thanks to the Poultry CRC who supported this project through research funding, scholarship funding and professional development and guidance.

I would also like to thank Dr Matt Tighe and Dr Rebecca Haling for their assistance with the initial CT scanning and developing the scan parameters.

Finally and most significantly I would like to thank my supervisors Julie Roberts, Kapil Chousalkar and Richard Flavel. Without their support and guidance this project could not have proceeded.

## Summary

This project sought to correlate external shell features with underlying shell structures and examine if these structures are indicative of increased incidence of eggshell penetration by *Salmonella Typhimurium*.

Eggs are an important nutrient and protein source in most cultures around the world, and the importance of food safety in intensive food production industries is likely to increase. Microbial infection of eggs is the source of approximately 49% of *Salmonella* food poisoning cases in Australia each year. The most significant source of these infections in Australia is *Salmonella Typhimurium*. Eggshell translucency is a phenomenon observed when an egg is candled over a light source; the underlying cause and incidence of eggshell translucency form the basis of our investigations of shell structures. In order to image eggshell structure, both Computed Tomography and Scanning Electron Microscopy were used to examine different structural components of the shell.

Shell structures were found to be different among shells, even consecutive shells from the same bird. There was a clear relationship between refrigerated storage and the appearance of translucency, and that there were significant differences in the type of mammillary bodies and pore formations between low and high translucency shells. There was no consistent relationship between translucency and eggshell penetration; however, there were some significant correlations. This experiment also identified a number of structural features that were potentially conducive to bacterial entry.

Although there was no clear relationship between higher incidence of eggshell translucency and increased rates of bacterial penetration, this project has confirmed a number of shell structures that are more commonly associated with bacterial penetration of intact table eggs.
