Document status and date: Published: 01/01/2014

## Document Version:

Accepted manuscript including changes made at the peer-review stage

# Please check the document version of this publication:

• A submitted manuscript is the version of the article upon submission and before peer-review. There can be important differences between the submitted version and the official published version of record. People interested in the research are advised to contact the author for the final version of the publication, or visit the DOI to the publisher's website.

• The final author version and the galley proof are versions of the publication after peer review.

• The final published version features the final layout of the paper including the volume, issue and page numbers.

Ionic liquids (ILs) are defined as organic compounds consisting entirely of ions and are characterized by melting points below 100 °C, with many of them being liquid at room temperature (RTILs). ILs feature often unique property profiles, which can be tuned by design, such as viscosity, density, solubility, conductivity or high thermal and chemical stability, just to name the most important ones. With these versatile properties they may have a major impact on many promising applications. In this context, our focus is on  $CO_2$  capture.

The current process to capture  $CO_2$  is based on highly corrosive, volatile and smelly aqueous amine solutions (e.g. MEA). Due to their ability to retain  $CO_2$  - both physically (physical sorption) and chemically (chemisorption)<sup>[1]</sup> ILs can be used for the direct capture of  $CO_2$ . This should lead to a reduction of[ul][li]water consumption,[/li][li]release of solvents and strong odors to atmosphere, [/li][li]corrosion of plant components.[/li][ul]

A major advantage is that absorption/stripping rates and CO<sub>2</sub> loading can be elevated at the same time.

It turns out that some ILs, *i.e.* 1-alkyl-3-methylimidazolium tricyanomethanides exhibit a considerable increase of both,  $CO_2$  solubility and the diffusivity in binary systems consisting of IL and water in comparison to dry solvents. This is a considerable improvement over most of the  $CO_2$  absorbing ionic liquids where water impairs the efficiency of the  $CO_2$  capture.<sup>[2]</sup>

 $CO_2$  captured by such a process can be consecutively used for conversion into other products such as methane (Sabatier-process)<sup>[3]</sup> again in the presence of ILs, where they can be used because of their low vapor pressure, thermal stability, tunable miscibility and polarity ILs as reaction medium and heat transfer fluids.
