**Document status and date:**

Published: 01/01/1971

**Document Version:**

Publisher's PDF, also known as Version of Record (includes final page, issue and volume numbers)

**Please check the document version of this publication:**

- A submitted manuscript is the version of the article upon submission and before peer-review. There can be important differences between the submitted version and the official published version of record. People interested in the research are advised to contact the author for the final version of the publication, or visit the DOI to the publisher's website.
- The final author version and the galley proof are versions of the publication after peer review.
- The final published version features the final layout of the paper including the volume, issue and page numbers.

LETTER TO THE EDITOR

THE CONSISTENT SOLUTION OF THE UNDAMPED CYCLOTRON-  
WAVE PROPAGATION PROBLEM

D. C. SCHRAM

Association Euratom-FOM, FOM-Instituut voor Plasma-Fysica,  
Rijnhuizen, Jutphaas, Nederland

Received 26 March 1971

In a recent publication<sup>1)</sup> the nonlinear dielectric behaviour of a cold plasma drifting along a static magnetic field ( $B_0$ ) in a large amplitude E.M. wave ( $\hat{E}$ ,  $\omega$ ,  $k$ ) near and at cyclotron resonance has been treated. The permittivity,  $\epsilon$ , of the plasma has been calculated from the reactive current; this current has been found by the summation over velocity space of the appropriate velocity component of the individual particles. To that end, the characteristic quantities, which define the individual motion of the particles such as the amplitude and the period of the energy oscillation have been expressed as functions of  $\hat{E}$ ,  $B_0$  and, close to the resonance, of the index of refraction,  $n$ . As a result, also the expressions for the reactive currents are functions of the permittivity, and close to the resonance:

$$n = \sqrt{\epsilon_r} = n(\tilde{g}, \beta, \tilde{\alpha}, n) \quad (1)$$

(cf. eqs. (2) and (34) of ref. 1), where the symbols have the same meaning as in ref. 1:

$$\tilde{g} = \frac{e\hat{E}}{\gamma_0 m \omega c (1 - v_{z0}/v_p)} = \frac{g}{\gamma_0 (1 - v_{z0}/v_p)},$$

the E.M. field-strength parameter<sup>†</sup>,

$$\beta = \frac{eB_0}{\gamma_0 m \omega (1 - v_{z0}/v_p)} - 1,$$

the magnetic-field parameter,

$$\tilde{\alpha} = \frac{\omega_p^2}{\gamma_0 \omega^2} = \frac{n_e e^2}{m \epsilon_0 \omega^2 \gamma_0},$$

the electron-density parameter.

<sup>†</sup> For convenience a slightly different E.M. field parameter  $\tilde{g}$  instead of  $g$  has been used: the parameter  $\tilde{g}$  contains a small correction factor due to the zero-order drift velocity along the static magnetic field. As in ref. 1 the zero-order transverse velocity is supposed to be zero, so  $\gamma_0 \equiv m(0)/m = 1/(1 - v_{z0}^2/c^2)^{1/2}$ .

Fig. 1. The dielectric function  $j_2$  as a function of the normalized magnetic-field parameter  $\beta/\beta_{ac}$ .

In ref. 1 an elaborate numerical procedure is described for the solution of eq. (1) in terms of  $n = n(\beta)$  for a given set of values of  $\tilde{g}$  and of  $\tilde{\alpha}$  (cf. fig. 8 of ref. 1). Once this has been done, also the characteristic quantities of the motion can be calculated as functions of  $\beta$ . Though, in principle, the solution of eq. (1) can be obtained, one is forced to solve the problem again for any new set of values of the E.M. field strength and density, *i.e.* the parameters  $\tilde{g}$  and  $\tilde{\alpha}$ . To avoid this cumbersome numerical procedure, an alternative, approximate, procedure is presented here which results in generalized expressions for all quantities.

It has been established, that under the condition that  $\tilde{\alpha}' \gg$  the quantity  $\tilde{g}^2 [(1 - \epsilon)/\tilde{\alpha}] C$  is a function of  $\beta/\beta_{ac}$  only (cf. fig. 1):

$$[(1 - \epsilon)/\tilde{\alpha}] C = j_2(\beta/\beta_{ac}), \quad (2)$$

where

$$C = (\tilde{\alpha}\tilde{g}^2)^{\frac{1}{2}}, \quad \text{and} \quad \beta_{ac} = 0.73 C; \quad (3)$$

$\beta_{ac}$  is the width of the nonlinear resonance.

This is the consistent solution of  $\epsilon - 1$  as a function of  $\beta$  for any set of values of  $\tilde{g}$  and  $\tilde{\alpha}$ . Now it is possible to substitute this solution in the expressions for the energy oscillation (cf. eqs. (18)–(23) of ref. 1). This enables

Fig. 2. The normalized energy amplitude as a function of the magnetic-field parameter  $\beta/\beta_{ac}$ .

Fig. 3. Oscillation-time functions  $j_0$  and  $j_1$  as functions of magnetic-field parameter  $\beta/\beta_{ac}$ .

us to express the energy-amplitude oscillation time and length in new functions of  $\Delta$ ,  $j_0$  and  $j_1$  which depend only on  $\beta/\beta_{ac}$ . In terms of these functions which are shown in figs. 2 and 3 we find as a complete solution of the problem the following:

the energy amplitude:

$$\gamma_{\text{extr}} - \gamma_0 \approx \frac{\Delta(\beta/\beta_{ac})}{C} \gamma_0 (1 - v_{z0}/v_p) \tilde{g}^2; \quad (4)$$

the oscillation time:

$$\omega t_{os} = \tau_{os} = \frac{2j_0}{C} \left[ \frac{1}{1 - v_{z0}/v_p} + \frac{j_1}{j_0} \frac{C^2}{\tilde{\alpha}} \right]; \quad (5)$$

the oscillation length:

$$kz_{os} = \left\{ \frac{2v_{z0}/v_p}{1 - v_{z0}/v_p} \frac{j_0}{C} + 2j_1 \left[ \frac{C}{\tilde{\alpha}} - j_2 \right] \right\}. \quad (6)$$

This work was performed under the association agreement of Euratom and FOM with financial support from ZWO and Euratom.
