Abstract

The first part of this paper gives an algebraic semantics for Place/Transition nets in terms of an algebra which is based on the process algebra ACP. The algebraic semantics is such that a P/T net and its term representation have the same operational behavior. As opposed to other approaches in the literature, the actions in the algebra do not correspond to the firing of a transition, but to the consumption or production of tokens. Equality of P/T nets can be determined in a purely equational way.

The second part of this paper extends the results to hierarchical P/T nets. It gives a compositional algebraic semantics for both their complete operational behavior and their high-level, observable behavior. By means of a non-trivial example, the Alternating-Bit Protocol, it is shown that the notions of abstraction and verification in the process algebra ACP can be used to verify in an equational way whether a hierarchical P/T net satisfies some algebraic specification of its observable behavior. Thus, the theory in this paper can be used to determine whether two hierarchical P/T nets have the same observable behavior. As an example, it is shown that the Alternating-Bit Protocol behaves as a simple one-place buffer. The theory forms a basis for a modular, top-down design methodology based on Petri nets.

Key words: Place/Transition nets – hierarchical Petri nets – process algebra – algebraic semantics – abstraction – verification – top-down design

1 Introduction

Motivation. The theory of Petri nets (see for example [31]) has been developed to design and analyze distributed systems. In order to support the design of large, complex systems, high-level Petri nets [21, 23] have been defined, which include hierarchy, data, and time. Based on high-level Petri nets, automated tools, such as Design/CPN [26] and ExSpect [1], have been developed. The most important reasons for the widespread use of Petri nets in the area of system design, are their intuitive graphical representation and the simplicity of the main concepts of the theory. Unfortunately, the class of Place/Transition nets, which underlies all other classes of Petri nets, also lacks one important property, which is essential to top-down, modular design: *compositionality*.

Several other theories for describing concurrent systems do have this property. For example, process algebras, such as CCS [27], CSP [22], and ACP [4], all support compositionality. Therefore, it is not surprising that several attempts have been made to integrate P/T nets and process algebra. Some approaches give a net semantics for some process algebra; others describe an algebraic semantics for (some subclass of) P/T nets. All approaches have in common that there is a one-to-one correspondence between actions in the calculus and transitions in the P/T nets. Usually, only flat P/T nets are considered. Below, a brief survey is given of some recent results described in the literature.

This paper presents a different approach. First, it gives an algebraic semantics for flat P/T nets in terms of an ACP-like process algebra [4] in which atomic actions correspond to the consumption or production of a single token. This correspondence is the essential idea that allows for a straightforward extension to hierarchical nets. The algebraic semantics is such that the two transition systems which form the operational semantics of a P/T net and its algebraic representation are equivalent. The process algebra ACP is chosen,

*An extended abstract of this report appeared as [6]

because it emphasizes equational reasoning as opposed to model-based reasoning. An equational theory is given which can be used to determine equality of P/T nets, without referring to their operational semantics. Second, this paper gives an algebraic semantics for both the complete behavior and the observable behavior of hierarchical P/T nets. The complete behavior of a hierarchical P/T net is the behavior of the flat net which is obtained when the hierarchical net is unfolded; the observable behavior of a hierarchical net is the behavior after hiding the internal behavior. The algebraic semantics for the observable behavior of hierarchical P/T nets can be used to verify whether a net satisfies some algebraic specification of its behavior, and, as a result, to determine whether two hierarchical nets have the same observable behavior. All this can be done in a purely equational and compositional way. The theory thus forms the basis for a top-down design methodology based on hierarchical Petri nets. Figure 1 gives an example, which is used to further explain and motivate the research described in this paper.

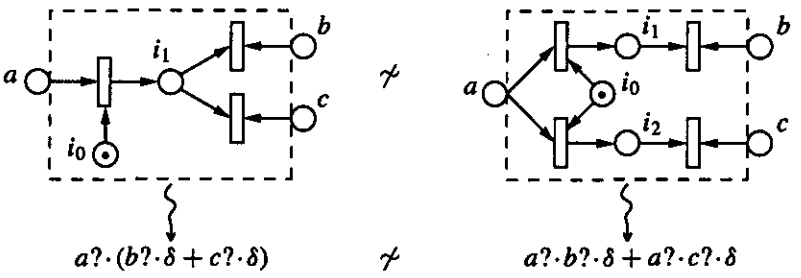

Figure 1: Motivating example.

The two nets shown in Figure 1 look like ordinary P/T nets. However, the dashed boxes divide the set of places into *pins* and *internal places*. The idea is that pins are connectors to an environment, which can remove tokens from or add tokens to the pins. The internal structure of the net is hidden as in a black box. Thus P/T nets with pins are a very simple form of hierarchical nets. It is straightforward to extend such P/T nets with pins to more general hierarchical P/T nets. Besides places and transitions, the internal structure of a high-level, hierarchical net can also contain subnets, whose pins are connected to internal places or pins from the high-level net. Essentially, this is the hierarchy construct underlying the high-level nets described in [21]. It is also one of the constructs used to build hierarchical nets as described in [23]. Furthermore, it is supported by tools as Design/CPN and ExSpect.

The main objective of this paper is to give an algebraic semantics for the observable behavior of hierarchical nets, that is, their behavior projected onto pins. Therefore, it seems most appropriate to define the behavior of a net in terms of production and consumption of tokens. Consider, for example, the left net in Figure 1. Assuming that the environment provides sufficiently many tokens, it is easy to see that it first consumes a token from a, then, either consumes a token from b or from c, after which it deadlocks. In an ACP-like process algebra, one could express this kind of behavior by the term $a?\cdot(b?\cdot\delta + c?\cdot\delta)$, where a question mark denotes the consumption of a token, $\cdot$ denotes sequential composition, $+$ denotes a choice, and δ denotes deadlock.

In order to compare hierarchical nets, some suitable notion of equivalence is needed. In the context of this paper, two hierarchical nets are considered equivalent if and only if their observable behavior is the same. For example, consider the right net in Figure 1. From the environment, it looks the same as the other net. However, it does not have the same observable behavior. Obviously, like the other net, it first consumes a token from a. But after that, its behavior is different. If the uppermost transition consumed the token from a, after that, it will only consume a token from b but not from c. The consumption of a token from a implies a choice between b and c. For the left net, this is not the case. After consuming a token from a, it is still able to consume a token from either b or c. The behavior of the nets is different, because their *moments of choice* are different.

So, an appropriate notion of equivalence should capture the moments of choice in a process, often called the *branching structure of the process*. In [15], Van Glabbeek formally defines the branching structure of a process. He shows that an equivalence notion captures the branching structure if and only if it distinguishes more processes than *bisimulation equivalence*. Two processes are *bisimilar* if and only if, at any time, they can copy, or simulate, each others actions. Therefore, in this paper, two hierarchical P/T nets are considered equivalent if and only if their observable behavior is bisimilar. Consequently, the two nets of Figure 1 are not equivalent. In their survey on refinement of Petri nets, Brauer, Gold, and Vogler [12] propose bisimulation equivalence for similar reasons as explained above. It also appears in the survey on equivalence notions for Petri nets by Pomello, Rozenberg, and Simone [30]. Note that in this paper bisimulation is not used explicitly to determine equivalence of nets. Instead, an equational theory is given which can be used for this purpose. Since it is not the main subject of this paper to investigate equivalences on Petri nets, it is left for future work to investigate other notions of equivalence which might be of interest in the context of this paper. True concurrency equivalences seem to be interesting candidates.

Note that the notion of equivalence of hierarchical nets introduced above has an interesting consequence. For example, adding an *internal* output place to any of the transitions of a net in Figure 1 does not change its observable behavior. This behavior is even independent of the number of initial tokens in such an additional place. This means that nets with different reachable states can have equivalent observable behavior.

Summarizing, this paper gives an algebraic semantics for hierarchical P/T nets, in which atomic actions correspond to the consumption or production of tokens. An equational theory is given which can be used to determine equivalence of hierarchical nets.

Related work. One way to integrate P/T nets with process algebra is to give a net semantics for terms in the algebra, thus providing the process algebra with a true concurrency semantics. Examples of this approach are Best, Devillers, and Hall [10], Degano, De Nicola, and Montanari [13], Van Glabbeek and Vaandrager [16], Goltz [19], Montanari and Yankelevich [28], Olderog [29], and Taubner [33]. As explained, this paper does the converse. It gives an algebraic semantics for P/T nets. Examples of this approach are Baeten and Bergstra [2], Boudol, Roucairol, and De Simone [11], and Dietz and Schreibert [14]. All three approaches are discussed briefly.

Dietz and Schreibert [14] give an algebraic semantics for P/T nets which reflects the parallelism in their dynamic behavior. The parallel components in the algebraic representation of a net do not correspond to its structural components. Such a relationship does exist in the other two papers. Boudol, Roucairol, and De Simone [11] give an algebraic term for each place and each transition of a P/T net. The complete behavior of the net is the parallel composition of all these terms. The communication between these terms corresponds to the flow of tokens. A similar approach is taken by Baeten and Bergstra [2]. Atomic actions in the algebra correspond to transitions in the P/T nets. So-called input and output causes are added to these actions, corresponding to input and output places. The behavior of a net is the parallel composition of all actions corresponding to its transitions. A so-called causal state operator is used to restrict the behavior in such a way that it corresponds to the flow of tokens in the net. As opposed to Boudol, Roucairol, and De Simone, Baeten and Bergstra emphasize equational reasoning.

The approach pursued in this paper is most closely related to the work of Baeten and Bergstra. The algebraic semantics given is very similar to theirs. However, as mentioned before, an important difference between this paper and all other approaches is that, in this paper, actions in the algebraic semantics correspond to the consumption or production of tokens, whereas, in the other approaches, there is a correspondence between actions and transitions. In the latter case, there is no straightforward extension to hierarchical nets. As this paper shows, there is a straightforward extension when actions correspond to the consumption or production of tokens.

Organization. The paper is organised as follows. Section 2 introduces a framework of transition systems which serve as the operational semantics for both P/T nets and terms in the process algebra. In Section 3, P/T nets with pins and their operational behavior are defined. Section 4 introduces the equational theory PTNA, for *Place/Transition-Net Algebra*, and its operational semantics. The algebraic semantics of a P/T net with pins is a closed PTNA term. It has the same operational semantics as the P/T net. Section 5 introduces the distinction between internal and observable behavior. It extends the algebraic semantics to general hierarchical nets. In Section 6, a fairness principle and a recursion principle are introduced, which are needed in Section 7, where the theory is applied to the example of the Alternating-Bit Protocol. Finally, Section 8 ends with some concluding remarks and a discussion of future work. The appendices give some proofs which are not essential to the understanding of the paper, as well as some large and complicated proofs.

Notation. For any set X, the notation $\mathbf{P}\,X$ denotes the powerset of X and $\mathbb{B}\,X$ denotes the set of all bags over X, where a bag is a finite multi-set. The standard operators minus $(-)$ and union $(\cup)$ on sets are also used on bags. Minus binds stronger than union. Set inclusion $(\subseteq)$ is also extended to bags. Furthermore, restriction of some set or bag X to some domain D is denoted $X \restriction D$. Restriction binds stronger than minus and union. The emptyset symbol $(\emptyset)$ is also used to denote the empty bag. A non-empty bag is written as a sequence of its elements in arbitrary order, where each element appears only once and a superscript denotes its cardinality. Furthermore, for an *associative* binary operator $\otimes$, some function f, some $n \in \mathbb{N}$, and operands $x_0, \ldots, x_n$, the quantifier notation $(\otimes i : 0 \leq i \leq n : f(x_i))$ is used as a shorthand notation for $f(x_0) \otimes \ldots \otimes f(x_n)$. For an associative binary operator $\oplus$ that is also *commutative*, the notation $(\oplus x : x \in X : f(x))$, where X is some bag of operands, is sometimes used.

2 Processes

This section introduces a general framework of labeled transition systems. It serves as the process domain in which the operational semantics of both P/T nets and algebraic terms are defined. In this way, the behavior of P/T nets and algebraic terms can be compared in an unambiguous way. For now, there is no distinction between internal and observable behavior.

Definition 2.1. (Process space) A *process space* over some set of *actions* $\mathcal{A}ct$ is a pair $(\mathcal{P}, \longrightarrow)$, where $\mathcal{P}$ is a set of processes, and $\_ \xrightarrow{\_} \_ : \mathbf{P}(\mathcal{P} \times \mathcal{A}ct \times (\mathcal{P} \cup \{\surd\}))$ a ternary transition relation.

Intuitively, for any $p, p' \in \mathcal{P}$ and $\alpha \in \mathcal{A}ct$, the predicate $p \xrightarrow{\alpha} p'$ means that process p can perform an action α, thus transiting into a process p'. The predicate $p \xrightarrow{\alpha} \surd$ means that process p terminates successfully upon executing an action α. In P/T-net theory, no distinction is made between successful and unsuccessful termination (deadlock). However, in the process algebra ACP, such a distinction does exist. Hence, the distinction is made in the process domain. Of course, P/T nets should represent processes which cannot terminate successfully.

An equivalence on processes which captures their branching structure is defined as follows. Let $(\mathcal{P}, \longrightarrow)$ be some process space over $\mathcal{A}ct$.

Definition 2.2. (Bisimulation) A binary relation $\mathcal{R} : \mathbf{P}(\mathcal{P} \times \mathcal{P})$ is called a *bisimulation* if and only if, for any $p, p', q, q' \in \mathcal{P}$ and $\alpha \in \mathcal{A}ct$,

i) $p\mathcal{R}q \wedge p \xrightarrow{\alpha} p' \Rightarrow (\exists\, q' : q' \in \mathcal{P} : q \xrightarrow{\alpha} q' \wedge p'\mathcal{R}q')$,

ii) $p\mathcal{R}q \wedge q \xrightarrow{\alpha} q' \Rightarrow (\exists\, p' : p' \in \mathcal{P} : p \xrightarrow{\alpha} p' \wedge p'\mathcal{R}q')$,

iii) $p \mathcal{R} q \Rightarrow p \xrightarrow{\alpha} \surd \Leftrightarrow q \xrightarrow{\alpha} \surd$.

Two processes p and q are called *bisimilar*, denoted $p \sim q$, if and only if there exists a bisimulation $\mathcal{R}$ such that $p \mathcal{R} q$.

3 P/T Nets with Pins

This section formalizes the notion of P/T nets with pins and their operational semantics. No distinction is made between observable and internal behavior. This means that the dashed box in the graphical representation of P/T nets with pins merely is a *glass box* instead of a black box. Let L_p be some universe of place labels and L_t a universe of transition labels.

Definition 3.1. (P/T net with pins) A *P/T-net structure with pins* is a 5-tuple $(P, T, \mathbf{i}, \mathbf{o}, I)$, where $P \subseteq \mathsf{L}_\mathsf{p}$ is a finite, non empty set of places, $T \subseteq \mathsf{L}_\mathsf{t}$ is a finite, non empty set of transitions, $\mathbf{i} : T \to \mathbb{B}\, P$ a function which gives the input places for each transition, $\mathbf{o} : T \to \mathbb{B}\, P$ a function which gives the output places for each transition, and $I \subseteq P$ the set of internal places. The set $P - I$ is the set of *pins*. The functions $\mathbf{i}$ and $\mathbf{o}$ must satisfy the following two conditions: *(i)* for any $p \in P$, there must exist a $t \in T$ such that $p \in \mathbf{i}t \cup \mathbf{o}t$, which means that there are no isolated places; *(ii)* for any $t \in T$, $\mathbf{i}t \cup \mathbf{o}t$ is not empty, which means that there are no isolated transitions. A *P/T net with pins*, in the remainder simply called P/T net or net, is a pair (N, s), where N is its structure as defined above and $s : \mathbb{B}\, I$ is its *state* or *marking*.

Note that, when the set of pins is empty, a P/T net with pins is just an ordinary P/T net. The state of a P/T net with pins is a bag of *internal* places. As usual, an element a of the state of a P/T net is often referred to as a *token* residing in place a. The reason for not considering *pins* in the state of a net is that we want to determine the behavior of a P/T net under the assumption that the environment is responsible for producing tokens on and consuming tokens from pins.

The dynamic behavior of a P/T net is a process space in which the P/T nets are the processes and the transition relation determines what actions a P/T net can perform. To formalize this definition, some terminology and definitions are given first.

Let (N, s) be a P/T net, where $N = (P, T, \mathbf{i}, \mathbf{o}, I)$. A transition $t \in T$ is *enabled* if and only if, for each *internal* place $a \in I$ with positive cardinality n in $\mathbf{i}t$, there are at least n tokens in a available in s. More concisely, a transition t is enabled if and only if $\mathbf{i}t \upharpoonright I \subseteq s$. If a transition is enabled, it can *fire*. Upon firing, a transition t removes n tokens from each of its input places a, where n is again the cardinality of a in $\mathbf{i}t$; it adds m tokens to each of its output places b, where m is the cardinality of b in $\mathbf{o}t$. This means that upon firing t, the P/T net (N, s) evolves into another P/T net $(N, s - \mathbf{i}t \cup \mathbf{o}t \upharpoonright I)$. Note that it follows from the standard definition of "$-$" that it is not necessary to restrict $\mathbf{i}t$ to I. The tokens that are removed from the net when firing a transition are often referred to as *consumed* tokens or the *consumption* of a transition; tokens that are added are referred to as the *production* of a transition. If I is chosen equal to P, that is, all places are internal, the definitions above are the usual ones for P/T nets without pins. Or, from a different viewpoint, the definitions given here are the usual ones *provided that the environment supplies sufficiently many tokens on the input pins*. It is assumed that transitions cannot fire simultaneously. However, as explained in Section 8, this is not a real restriction. All results can be extended to P/T nets with an operational semantics that allows transitions to fire simultaneously. The reason for not doing so, is that it unnecessarily complicates the theory and examples that follow, and thus distracts the reader from the essential points of this paper.

The definitions given so far are sufficient to formalize the operational semantics of P/T nets. Let $\mathcal{PTN}$ be the set of all P/T nets. A single action of a net, which is the firing of a single transition, is determined by two bags, the consumption and the production of the transition. Therefore, let $\mathcal{A}ct$ be $\mathbb{B}\, \mathsf{L}_\mathsf{p} \times \mathbb{B}\, \mathsf{L}_\mathsf{p}$. The transition relation $\_ \xrightarrow{\_} \_ : \mathbb{P}(\mathcal{PTN} \times \mathcal{A}ct \times (\mathcal{PTN} \cup \{\surd\}))$ is the smallest relation satisfying, for any net structure $N = (P, T, \mathbf{i}, \mathbf{o}, I)$, bags $s, s' \in \mathbb{B}\, I$, and transition $t \in T$,

$$(N, s \cup \mathbf{it} \restriction I) \xrightarrow{(\mathbf{it},\mathbf{ot})} (N, s \cup \mathbf{ot} \restriction I).$$

Note that, according to this definition, P/T nets have no successful termination. If a P/T net cannot perform any actions anymore, it is deadlocked. This conforms to the usual semantics for nets, where no distinction is made between successful and unsuccessful termination.

Example 3.2. Let $PTN_0 = (N_0, i_0)$ and $PTN_1 = (N_1, i_0)$ be the left and right P/T net in Figure 1 respectively. Figure 2 visualizes the transition relations of both nets. Since internal activity is visible, and hence the two nets perform different actions, they are obviously not bisimilar.

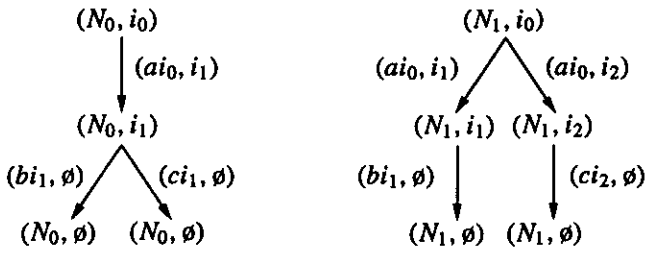

Figure 2: The transition relations of PTN_0 and PTN_1.

4 An Algebraic Semantics for P/T Nets

This section introduces an ACP-like equational theory and its operational semantics. It gives an algebraic semantics for P/T nets such that a P/T net and its term representation have the same operational behavior.

The theory PTNA. An *equational theory* consists of a *signature* and a set of *axioms*. The signature defines the *sorts* of a theory and its *functions*. A 0-ary function is often called a *constant*.

The equational theory used in this paper is PTNA, *Place/Transition-Net Algebra*. The signature and the axioms are given in Table 1. The theory is parameterized by a set of constants $\mathsf{L_p}$, which is the set of place labels introduced in the previous section. The first part of Table 1 lists the sorts of PTNA; the second part defines the functions and the third part the axioms. An informal explanation is given below.

Intuitively, A is the set of *atomic actions*, AC the set of *actions*, and P the set of *processes*. Each atomic action is either the consumption of a token or the production of a token. A consumption is denoted by "?" and a production by "!." An action is the simultaneous consumption and/or production of one or more tokens. Actions are constructed by the synchronous-merge operator $|$. In an equational theory, nothing is an element of a subsort unless explicitly stated. This yields the following property.

Property 4.1. *For any $a \in \mathsf{A}$, there exists a $b \in \mathsf{L_p}$, such that $a = b?$ or $a = b!$. For any $b \in \mathsf{L_p}$, $b? \in \mathsf{A}$ and $b! \in \mathsf{A}$. For any $e \in \mathsf{AC}$, there exist $a_0, \ldots, a_n \in \mathsf{A}$, for some $n \in \mathbb{N}$, such that $e = (|\, i : 0 \leq i \leq n : a_i)$. For any $a_0, \ldots, a_n \in \mathsf{A}$, where $n \in \mathbb{N}$, $(|\, i : 0 \leq i \leq n : a_i) \in \mathsf{AC}$.*

The synchronous merge is a very simple form of the communication merge as defined in [8]. There, the axioms $S1$ and $S2$ appear as $C1$ and $C2$ respectively. The reason for changing the names is that there is no communication in PTNA. The operators $+$ and $\cdot$ denote choice and sequential composition respectively. Axiom $A4$ states the *right distributivity* of sequential composition over choice. To be able to distinguish between processes with different moments of choice, the converse, left distributivity, is not an axiom of the

Table 1: Place/Transition-Net Algebra.

theory. As expressed by axioms $A6$ and $A7$, the special process δ can be interpreted as *inaction* or *deadlock*. The merge operator $\parallel$ can be interpreted as parallel execution. It is axiomatized using an auxiliary operator $\lfloor\!\lfloor$, called the left merge. The left merge has the same meaning as the merge except that the left process must execute the first action. Axioms $ASC1$ and $ASC2$ are the so-called *axioms of standard concurrency*. Often, they are derivable for *closed* terms and omitted from the theory. However, in combination with the binary Kleene star (*) they are not derivable for closed terms and hence included. The binary Kleene star adds a simple form of recursion to the theory. It is the original star operator as introduced by Kleene [24]. In [7], where the axioms $BKS1$–3 are given, it was introduced into process algebra. Because of its simplicity, the binary Kleene star is preferred over general recursion (see for example [4]). The remainder of this paper shows that it is powerful enough to capture the behavior of P/T nets. Finally, the *causal state operator* λ is a special version of the state operator as described in [4]. It is very similar to the causal state operator as defined in [2]. A state operator has a parameter, the superscript, and a certain state space, the subscript. The state space of the causal state operator can be interpreted as the state or marking of some P/T net and its parameter as the set of internal places. For I, s and x as in Table 1, the term $\lambda^I_s(x)$ can be thought of as the P/T net x with internal places I and state s. Using Property 4.1, the auxiliary functions $\mathbf{c}, \mathbf{p} : \mathsf{AC} \to \mathbb{B}\,\mathsf{L_p}$, for consumption and production respectively, can be defined as follows. For all $a \in \mathsf{L_p}$ and $e \in \mathsf{AC}$, $\mathbf{c}a? = a$, $\mathbf{c}a! = \emptyset$, $\mathbf{c}(a? \mid e) = a \cup \mathbf{c}e$, and $\mathbf{c}(a! \mid e) = \mathbf{c}e$; $\mathbf{p}a? = \emptyset$, $\mathbf{p}a! = a$, $\mathbf{p}(a? \mid e) = \mathbf{p}e$, and $\mathbf{p}(a! \mid e) = a \cup \mathbf{p}e$.

The binding precedence of the above operators is as follows. Unary operators bind stronger than binary operators. Sequential composition and Kleene star bind stronger than all other binary operators. Choice binds weaker than all other operators.

The main purpose of a theory as PTNA is that it can be used to reason about processes in a purely equational way. For any processes x and y, $\mathrm{PTNA} \vdash x = y$ denotes that $x = y$ can be derived from the axioms.

In order to formalize the intuitive notions given above and to be able to compare processes defined by PTNA terms to processes defined by P/T nets, the next paragraph gives an operational semantics for PTNA.

Operational semantics for PTNA. A *semantics* or *model* of a theory is an interpretation in a, usually well known and well understood, mathematical domain, such that the axioms are valid in the interpretation. An *operational* semantics is a model obtained by giving a process space as defined in Section 2.

To obtain a model of the theory PTNA, interpretations of the sorts A, AC, and P must be given. Define the interpretation of the set of processes P as the set of *closed* PTNA terms, denoted $\mathcal{C}$(PTNA). Since it follows from Property 4.1 that A is a subset of all closed terms, the interpretation of A is simply A itself. For the same reason, the interpretation of AC is AC itself. Obviously, these definitions satisfy $\mathsf{A} \subseteq \mathsf{AC} \subseteq \mathsf{P}$.

It remains to define the transition relation for processes in $\mathcal{C}$(PTNA). First, the set $\mathcal{A}ct$ must be defined. Intuitively, processes in $\mathcal{C}$(PTNA) can execute an action in AC, thus transiting into another process in $\mathcal{C}$(PTNA). Therefore, elements in $\mathcal{A}ct$ should be interpretations of actions which serve as the labels of the transition relation. Let $\phi : \mathsf{AC} \to \mathcal{A}ct$ be a function that maps actions in AC to actions in $\mathcal{A}ct$. The semantics given in the previous section for P/T nets suggests that the semantics of an algebra of P/T nets should have pairs of bags as transition labels, where the first element is the consumption and the second element the production of an action. The auxiliary functions **c** and **p** exactly define the consumption and production of each action in AC. Therefore, let $\mathcal{A}ct$ be equal to $\mathbf{B}\,\mathsf{L_p} \times \mathbf{B}\,\mathsf{L_p}$ and let for any $e \in \mathsf{AC}$, $\phi(e) = (\mathbf{c}e, \mathbf{p}e)$. The transition relation $\_ \xrightarrow{\_} \_ : \mathbf{P}(\mathcal{C}(\text{PTNA}) \times \mathcal{A}ct \times (\mathcal{C}(\text{PTNA}) \cup \{\surd\}))$ can now be defined as the smallest relation satisfying the derivation rules in Table 2.

$\alpha : \mathcal{A}ct$; $e : \mathsf{AC}$; $s : \mathbf{B}\,\mathsf{L_p}$; $I : \mathbf{P}\,\mathsf{L_p}$; $p, p', q, q' : \mathcal{C}(\text{PTNA})$

$$e \xrightarrow{\phi(e)} \surd$$

$$\frac{p \xrightarrow{\alpha} p'}{p \cdot q \xrightarrow{\alpha} p' \cdot q} \qquad \frac{p \xrightarrow{\alpha} \surd}{p \cdot q \xrightarrow{\alpha} q}$$

$$\frac{p \xrightarrow{\alpha} p'}{p + q \xrightarrow{\alpha} p'} \qquad \frac{q \xrightarrow{\alpha} q'}{p + q \xrightarrow{\alpha} q'} \qquad \frac{p \xrightarrow{\alpha} \surd}{p + q \xrightarrow{\alpha} \surd} \qquad \frac{q \xrightarrow{\alpha} \surd}{p + q \xrightarrow{\alpha} \surd}$$

$$\frac{p \xrightarrow{\alpha} p'}{p \parallel q \xrightarrow{\alpha} p' \parallel q} \qquad \frac{q \xrightarrow{\alpha} q'}{p \parallel q \xrightarrow{\alpha} p \parallel q'} \qquad \frac{p \xrightarrow{\alpha} \surd}{p \parallel q \xrightarrow{\alpha} q} \qquad \frac{q \xrightarrow{\alpha} \surd}{p \parallel q \xrightarrow{\alpha} p}$$

$$\frac{p \xrightarrow{\alpha} p'}{p \between q \xrightarrow{\alpha} p' \parallel q} \qquad \frac{p \xrightarrow{\alpha} \surd}{p \between q \xrightarrow{\alpha} q}$$

$$\frac{p \xrightarrow{\alpha} p'}{p^* q \xrightarrow{\alpha} p' \cdot (p^* q)} \qquad \frac{q \xrightarrow{\alpha} q'}{p^* q \xrightarrow{\alpha} q'} \qquad \frac{p \xrightarrow{\alpha} \surd}{p^* q \xrightarrow{\alpha} p^* q} \qquad \frac{q \xrightarrow{\alpha} \surd}{p^* q \xrightarrow{\alpha} \surd}$$

$$\frac{p \xrightarrow{\phi(e)} p'}{\lambda^I_{s \cup \mathbf{c}e \setminus I}(p) \xrightarrow{\phi(e)} \lambda^I_{s \cup \mathbf{p}e \setminus I}(p')} \qquad \frac{p \xrightarrow{\phi(e)} \surd}{\lambda^I_{s \cup \mathbf{c}e \setminus I}(p) \xrightarrow{\phi(e)} \surd}$$

Table 2: The transition relation for PTNA.

It remains to show that the process space as defined above is indeed a model of the theory PTNA. Recall that a process space is a model if and only if all equations that can be derived from the axioms are valid in the process space. The notion of validity is formalized as follows. In Section 2, bisimulation is defined, which is an equivalence relation on processes. Therefore, it is possible to look at equivalence classes of closed PTNA terms modulo bisimulation, denoted $\mathcal{C}(\text{PTNA})/\sim$. For closed terms p and q, the equation $p = q$ is *valid*, denoted $\mathcal{C}(\text{PTNA})/\sim \models p = q$, if and only if $p \sim q$. That is, if and only if p and q are bisimilar and thus

elements of the same equivalence class. The following theorem states that if equality of two processes can be derived from the axioms, then the processes are bisimilar, and thus the equality is valid. This means that one can indeed use equational reasoning instead of model-based reasoning.

Theorem 4.2. *The set of closed* PTNA *terms modulo bisimulation is a model for* PTNA. *That is, for any* $p, q \in \mathcal{C}(\text{PTNA})$, $\text{PTNA} \vdash p = q \Rightarrow \mathcal{C}(\text{PTNA})/\sim \models p = q$.

Proof. It follows from the format of the derivation rules in Table 2 that bisimulation equivalence is a *congruence* on $\mathcal{C}(\text{PTNA})$ [3]. Therefore, it suffices to verify the validity of each axiom of PTNA to prove the theorem. The validity of an axiom can be shown by constructing a bisimulation. The details can be found in Appendix A. □

An algebraic semantics for P/T nets. The following definition associates a closed PTNA term to each P/T net. The idea is to define first the unrestricted behavior of a net. That is, its behavior when every transition is always enabled. Then, the causal state operator instantiated with the initial marking is used to restrict the behavior to all possible firing sequences. The unrestricted behavior of a single transition is the infinite iteration of its consumption and production of tokens. The unrestricted behavior of a net is the parallel execution of all its transitions.

Definition 4.3. (Algebraic semantics for P/T nets) Let $PTN = (N, s)$ be a P/T net, where $N = (P, T, \mathbf{i}, \mathbf{o}, I)$. The algebraic semantics of PTN, denoted $\mathcal{N}[\![PTN]\!]$, is defined as follows:

$\mathcal{N}[\![PTN]\!] = \lambda_s^I(\|\ t :\ t \in T :\ \mathcal{T}[\![t]\!])$,

where, for any $t \in T$,

$\mathcal{T}[\![t]\!] = ((|\ i :\ i \in \mathbf{i}t :\ i?) \mid (|\ o :\ o \in \mathbf{o}t :\ o!))^*\delta$.

Empty quantifications should be simply omitted.

The following theorem states that a net and its algebraic representation have the same operational behavior. That is, any step that a net can make can be simulated by its algebraic semantics and vice versa. Furthermore, since a P/T net cannot terminate successfully, its algebraic semantics cannot terminate successfully either. Recall that $(\mathcal{PTN}, \longrightarrow)$ and $(\mathcal{C}(\text{PTNA}), \longrightarrow)$ are the operational semantics for P/T nets and PTNA respectively. The set $\mathcal{A}ct$ is equal to $\mathbf{B}\,\mathsf{L}_\mathsf{p} \times \mathbf{B}\,\mathsf{L}_\mathsf{p}$.

Theorem 4.4. *For any P/T nets* (N, s) *and* (N, s'), *where* $N = (P, T, \mathbf{i}, \mathbf{o}, I)$, *closed* PTNA *term* p, *and* $\alpha \in \mathcal{A}ct$,

i) $(N, s) \xrightarrow{\alpha} (N, s') \Rightarrow \mathcal{N}[\![(N, s)]\!] \xrightarrow{\alpha} \mathcal{N}[\![(N, s')]\!]$,

ii) $\mathcal{N}[\![(N, s)]\!] \xrightarrow{\alpha} p \Rightarrow (\exists\, s' :\ s' \in \mathbf{B}\, I :\ p = \mathcal{N}[\![(N, s')]\!] \wedge (N, s) \xrightarrow{\alpha} (N, s'))$,

iii) $\mathcal{N}[\![(N, s)]\!] \not\xrightarrow{\alpha} \surd$.

Proof.

i) Assume that $(N, s) \xrightarrow{\alpha} (N, s')$. Then, according to the operational semantics for P/T nets given in Section 3, there exists a $\bar{t} \in T$ such that $\alpha = (\mathbf{i}\bar{t}, \mathbf{o}\bar{t})$, $\mathbf{i}\bar{t} \lceil I \subseteq s$, and $s' = s - \mathbf{i}\bar{t} \cup \mathbf{o}\bar{t} \lceil I$. Let e be an abbreviation of $(|\ i :\ i \in \mathbf{i}\bar{t} :\ i?) \mid (|\ o :\ o \in \mathbf{o}\bar{t} :\ o!)$. Hence, the algebraic semantics of transition $\bar{t}$, $\mathcal{T}[\![\bar{t}]\!]$, is equal to $e^*\delta$. It is easy to see that $\phi(e) = (\mathbf{c}e, \mathbf{p}e) = (\mathbf{i}\bar{t}, \mathbf{o}\bar{t}) = \alpha$. Now, the rules in Table 2 yield

$e \xrightarrow{\alpha} \surd$

and hence

$e^*\delta \xrightarrow{\alpha} e^*\delta$.

Since $\mathcal{T}[\![\bar{t}]\!] = e^*\delta$ and $\bar{t} \in T$,

$(\|\ t :\ t \in T :\ \mathcal{T}[\![t]\!]) \xrightarrow{\alpha} (\|\ t :\ t \in T :\ \mathcal{T}[\![t]\!])$.

It follows from $\mathbf{i}\bar{t} \upharpoonright I \subseteq s$ and $\mathbf{i}\bar{t} = \mathbf{ce}$, that $\mathbf{ce} \upharpoonright I \subseteq s$. Since also $s' = s - \mathbf{i}\bar{t} \cup \mathbf{o}\bar{t} \upharpoonright I = s - \mathbf{ce} \cup \mathbf{pe} \upharpoonright I$,

$\lambda_s^I(\|\ t :\ t \in T :\ \mathcal{T}[\![t]\!]) \xrightarrow{\alpha} \lambda_{s'}^I(\|\ t :\ t \in T :\ \mathcal{T}[\![t]\!])$.

Finally, because $\mathcal{N}[\![(N, s)]\!] = \lambda_s^I(\|\ t :\ t \in T :\ \mathcal{T}[\![t]\!])$ and $\mathcal{N}[\![(N, s')]\!] = \lambda_{s'}^I(\|\ t :\ t \in T :\ \mathcal{T}[\![t]\!])$, we may conclude that

$\mathcal{N}[\![(N, s)]\!] \xrightarrow{\alpha} \mathcal{N}[\![(N, s')]\!]$.

ii) Assume $\mathcal{N}[\![(N, s)]\!] \xrightarrow{\alpha} p$. The definition of $\mathcal{N}[\![.]\!]$ yields that

$\lambda_s^I(\|\ t :\ t \in T :\ \mathcal{T}[\![t]\!]) \xrightarrow{\alpha} p$.

It follows from the derivation rules for the causal state operator in Table 2 that there exists an $e \in \mathsf{AC}$, and $q \in \mathcal{C}(\mathrm{PTNA})$, such that $\alpha = \phi(e) = (\mathbf{ce}, \mathbf{pe})$, $\mathbf{ce} \upharpoonright I \subseteq s$,

$p = \lambda_{s-\mathbf{ce}\cup\mathbf{pe}\upharpoonright I}^I(q)$,

and

$(\|\ t :\ t \in T :\ \mathcal{T}[\![t]\!]) \xrightarrow{\alpha} q$.

Let $s' = s - \mathbf{ce} \cup \mathbf{pe} \upharpoonright I$. We can show that s' is the bag of internal places such that $p = \mathcal{N}[\![(N, s')]\!]$ and $(N, s) \xrightarrow{\alpha} (N, s')$.

The derivation rules for the merge operator yield that there must exist a $\bar{t} \in T$ and $r \in \mathcal{C}(\mathrm{PTNA})$, such that

$q = r \parallel (\|\ t :\ t \in T \wedge t \neq \bar{t} :\ \mathcal{T}[\![t]\!])$,

and

$\mathcal{T}[\![\bar{t}]\!] \xrightarrow{\alpha} r$.

Since $\mathcal{T}[\![\bar{t}]\!] = ((|\ i :\ i \in \mathbf{i}\bar{t} :\ i?) \mid (|\ o :\ o \in \mathbf{o}\bar{t} :\ o!))^*\delta$ and since $\alpha = \phi(e)$, it follows that $e = (|\ i :\ i \in \mathbf{i}\bar{t} :\ i?) \mid (|\ o :\ o \in \mathbf{o}\bar{t} :\ o!)$ and that $r = \mathcal{T}[\![\bar{t}]\!]$. As a result, $q = (\|\ t :\ t \in T :\ \mathcal{T}[\![t]\!])$ and $p = \lambda_{s'}^I((\|\ t :\ t \in T :\ \mathcal{T}[\![t]\!]))$. The definition of $\mathcal{N}[\![.]\!]$ yields that

$p = \mathcal{N}[\![(N, s')]\!]$,

which proves the first proof obligation. Since $\alpha = \phi(e) = (\mathbf{ce}, \mathbf{pe}) = (\mathbf{i}\bar{t}, \mathbf{o}\bar{t})$, $\mathbf{ce} \upharpoonright I \subseteq s$, and $s' = s - \mathbf{ce} \cup \mathbf{pe} \upharpoonright I$, it follows that $\mathbf{i}\bar{t} \upharpoonright I \subseteq s$ and $s' = s - \mathbf{i}\bar{t} \cup \mathbf{o}\bar{t} \upharpoonright I$. We may conclude from the operational semantics for P/T nets given in Section 3, that

$(N, s) \xrightarrow{\alpha} (N, s')$.

iii) Assume $\mathcal{N}[\![(N, s)]\!] \xrightarrow{\alpha} \surd$, where $N = (P, T, \mathbf{i}, \mathbf{o}, I)$. It follows from the definition of $\mathcal{N}[\![.]\!]$ that

$\lambda_s^I(\|\ t :\ t \in T :\ \mathcal{T}[\![t]\!]) \xrightarrow{\alpha} \surd$.

It follows from the rules in Table 2 that

$(\|\ t :\ t \in T :\ \mathcal{T}[\![t]\!]) \xrightarrow{\alpha} \surd$

and thus that T must be a singleton $\{\bar{t}\}$, for some $\bar{t} \in \mathsf{L_t}$, such that

$\mathcal{T}[\![\bar{t}]\!] \xrightarrow{\alpha} \surd$.

It follows from the definition of $\mathcal{T}[\![.]\!]$ and the rules in Table 2 that this is a contradiction. Hence,

$\mathcal{N}[\![(N, s)]\!] \not\xrightarrow{\alpha} \surd$.

□

Theorem 4.4 states that, in the union of the two process spaces $\mathcal{PTN}$ and $\mathcal{C}(\mathrm{PTNA})$, the P/T net (N, s) is bisimilar to its algebraic representation $\mathcal{N}[\![(N, s)]\!]$.

Expansion. The following results are useful for simplifying many calculations. Their proofs can be found in Appendix A.

Theorem 4.5. (Expansion) *For any* $x_0, \ldots, x_n \in \mathsf{P}$, $n \in \mathbb{N} - \{0\}$
$(\|\, i : 0 \leq i \leq n : x_i) = (+i : 0 \leq i \leq n : x_i \between (\|\, j : 0 \leq j \leq n \wedge j \neq i : x_j))$.

Property 4.6. *For any non empty bag* $E \in \mathbb{B}\,\mathsf{AC}$,
$(\|\, e : e \in E : e^*\delta) = (+e : e \in E : e \cdot (\|\, f : f \in E : f^*\delta))$.

Example 4.7. Let $PTN_0 = (N_0, i_0)$ be the left P/T net in Figure 1. Let X_0 be the algebraic representation of PTN_0, that is, $X_0 = \mathcal{N}[\![PTN_0]\!]$. This example shows how a simple expression can be derived for X_0, which is an algebraic term for the behavior of PTN_0. In the derivation below, the causal state operator is written without the superscript $\{i_0, i_1\}$.

$$
\begin{aligned}
& X_0 \\
= \quad & \{\ X_0 = \mathcal{N}[\![PTN_0]\!];\ \text{Definition 4.3 (Algebraic semantics for P/T nets)}\ \} \\
& \lambda_{i_0}((a? \mid i_0? \mid i_1!)^*\delta \parallel (b? \mid i_1?)^*\delta \parallel (c? \mid i_1?)^*\delta) \\
= \quad & \{\ \text{Property 4.6; Let } X = (a? \mid i_0? \mid i_1!)^*\delta \parallel (b? \mid i_1?)^*\delta \parallel (c? \mid i_1?)^*\delta\ \} \\
& \lambda_{i_0}((a? \mid i_0? \mid i_1!) \cdot X + (b? \mid i_1?) \cdot X + (c? \mid i_1?) \cdot X) \\
= \quad & \{\ \text{Axiom } CSO5;\ \text{Axiom } CSO4\ (3\times)\ \} \\
& \lambda_{i_0}(a? \mid i_0? \mid i_1!) \cdot \lambda_{i_1}(X) + \lambda_{i_0}(b? \mid i_1?) \cdot \lambda_{i_0}(X) + \lambda_{i_0}(c? \mid i_1?) \cdot \lambda_{i_0}(X) \\
= \quad & \{\ \text{Axiom } CSO2;\ \text{Axiom } CSO3\ (2\times)\ \} \\
& (a? \mid i_0? \mid i_1!) \cdot \lambda_{i_1}(X) + \delta \cdot \lambda_{i_0}(X) + \delta \cdot \lambda_{i_0}(X) \\
= \quad & \{\ \text{Axiom } A7\ (2\times);\ \text{Axiom } A6\ (2\times);\ \text{Let } X_1 = \lambda_{i_1}(X)\ \} \\
& (a? \mid i_0? \mid i_1!) \cdot X_1
\end{aligned}
$$

A derivation similar to the one above yields the following result for X_1.

$X_1 = (b? \mid i_1?) \cdot \delta + (c? \mid i_1?) \cdot \delta$.

It is straightforward to verify that the transition relation of X_0 is the same as the transition relation of PTN_0 that is directly obtained from the operational semantics for nets given in Section 3 (See Figure 2). It is left to the reader to verify that also for the right P/T net in Figure 1, the transition relations for the net and its representation are the same.

5 An Algebraic Semantics for Hierarchical P/T Nets

In this section, hierarchical P/T nets are defined and an algebraic semantics for their complete operational behavior is given. Then, the notion of internal behavior is introduced in the process domain as well as in the theory PTNA. The abstraction mechanism from the process algebra ACP is adapted to give an algebraic semantics for the observable behavior of hierarchical P/T nets. This algebraic semantics indirectly specifies an operational semantics for the observable behavior of hierarchical nets.

5.1 Hierarchical P/T nets

In addition to places and transitions, a hierarchical P/T net has subnets which, in turn, are hierarchical P/T nets.

Definition 5.1. (Hierarchical P/T nets) A *hierarchical P/T net* is a 7-tuple $(P, T, S, \mathbf{i}, \mathbf{o}, I, s)$, where $P \subseteq \mathsf{L}_\mathsf{p}$ is a finite, non empty set of places, $T \subseteq \mathsf{L}_\mathsf{t}$ is a finite set of transitions, and S a finite set of hierarchical

P/T nets, such that $T \cup S$ is not empty; function $\mathbf{i} : (T \cup S) \to \mathbb{B}\, P$ gives the input places for each transition and each subnet, $\mathbf{o} : (T \cup S) \to \mathbb{B}\, P$ gives the output places, $I \subseteq P$ is the set of internal places, and $s : \mathbb{B}\, I$ is the marking of the hierarchical net. It is assumed that there are no isolated places, transitions, or subnets. Set S must be such that for each subnet the set of input and output places is equal to the set of pins of the subnet. The set of places of a hierarchical P/T net and the sets of internal places of all its subnets must be mutually disjoint. A hierarchical P/T net can be unfolded in the usual way. The unfolding of a hierarchical net must be finite.

Figure 5 in Section 7 shows an example of a hierarchical net. The two nets in Figure 1 are also examples of simple hierarchical nets. A hierarchical net without any subnets is a P/T net as defined in Definition 3.1. The *complete* operational behavior of a hierarchical P/T net is the operational semantics of its unfolding. This semantics can be obtained algebraically as follows.

Definition 5.2. (Complete behavior of hierarchical P/T nets) Let $HN = (P, T, S, \mathbf{i}, \mathbf{o}, I, s)$. Extend the function $\mathcal{N}[\![.]\!]$, as defined in Definition 4.3, inductively as follows. As before, empty quantifications should be omitted.

$$\mathcal{N}[\![HN]\!] = \lambda_s^I((\|\ t :\ t \in T :\ \mathcal{T}[\![t]\!]) \parallel (\|\ sn :\ sn \in S :\ \mathcal{N}[\![sn]\!])).$$

Note that the unfolding of a net must be finite, because only then the net has a finite algebraic representation.

5.2 Processes with Silent Actions.

In Section 2, a process is defined as a labeled transition system over some set of actions. A process can execute actions, thus transiting into some other process. An action that is executed by a process is part of its observable behavior. To be able to distinguish between observable and internal behavior, *silent actions* are introduced. Usually, silent actions are denoted τ. Only a single symbol is needed, since all internal actions are equal in the sense that they do not have any visible, external effects. The notion of silent actions in an algebraic setting was first introduced by Milner [27].

The definition of a process space given in Section 2 can still be used in a context with silent actions. However, since bisimulation does not distinguish between observable and silent actions, the notion of equality on processes needs to be changed. Processes with the same observable behavior, but with different internal behavior should be equal. As before, the equivalence relation on processes should distinguish processes with different moments of choice. In [15], Van Glabbeek shows that *(rooted) branching bisimulation* is exactly the equivalence that satisfies these two requirements. Branching bisimulation is a slightly finer equivalence than the better known observation equivalence [27]. That is, it distinguishes more processes than observation equivalence.

Let $(\mathcal{P}, \longrightarrow)$ be some process space over $\mathcal{A}ct$ equal to $\mathcal{A} \cup \{\tau\}$, for some set of action symbols $\mathcal{A}$. The following auxiliary relation expresses that a process can evolve into another process by executing a sequence of zero or more τ actions. For the sake of simplicity, the termination symbol $\surd$ is treated as a process.

Definition 5.3. The relation $\_ \twoheadrightarrow \_ : \mathbb{P}((\mathcal{P} \cup \{\surd\}) \times (\mathcal{P} \cup \{\surd\}))$ is defined as the smallest relation satisfying, for any $p, p', p'' \in \mathcal{P} \cup \{\surd\}$,

$p \twoheadrightarrow p$,

$p \twoheadrightarrow p' \wedge p' \xrightarrow{\tau} p'' \ \Rightarrow\ p \twoheadrightarrow p''$.

Let, for any $p, p' \in \mathcal{P} \cup \{\surd\}$ and $\alpha \in \mathcal{A}ct$, $p \xrightarrow{(\alpha)} p'$ be an abbreviation of $p \xrightarrow{\alpha} p' \vee (\alpha = \tau \wedge p = p')$. That is, $p \xrightarrow{(\tau)} p'$ means zero or one τ steps and, for any $a \in \mathcal{A}$, $p \xrightarrow{(a)} p'$ is simply $p \xrightarrow{a} p'$.

Definition 5.4. ((Rooted) Branching Bisimulation) A binary relation $\mathcal{R} : \mathbf{P}((\mathcal{P} \cup \{\surd\}) \times (\mathcal{P} \cup \{\surd\}))$ is called a *branching bisimulation* if and only if, for any $p, p', q, q' \in \mathcal{P} \cup \{\surd\}$ and $\alpha \in \mathcal{A}ct$,

i) $p\mathcal{R}q \wedge p \xrightarrow{\alpha} p' \Rightarrow (\exists q', q'' : q', q'' \in \mathcal{P} \cup \{\surd\} : q \longrightarrow\!\!\!\!\!\rightarrow q'' \xrightarrow{(\alpha)} q' \wedge p\mathcal{R}q'' \wedge p'\mathcal{R}q')$,

ii) $p\mathcal{R}q \wedge q \xrightarrow{\alpha} q' \Rightarrow (\exists p', p'' : p', p'' \in \mathcal{P} \cup \{\surd\} : p \longrightarrow\!\!\!\!\!\rightarrow p'' \xrightarrow{(\alpha)} p' \wedge p''\mathcal{R}q \wedge p'\mathcal{R}q')$,

iii) $p\mathcal{R}q \Rightarrow p \longrightarrow\!\!\!\!\!\rightarrow \surd \Leftrightarrow q \longrightarrow\!\!\!\!\!\rightarrow \surd$.

A branching bisimulation $\mathcal{R}$ is called a *rooted* branching bisimulation between p and q in $\mathcal{P}$ if and only if $p\mathcal{R}q$ and, for any $p', q' \in \mathcal{P} \cup \{\surd\}$ and $\alpha \in \mathcal{A}ct$,

iv) $p \xrightarrow{\alpha} p' \Rightarrow (\exists q' : q' \in \mathcal{P} \cup \{\surd\} : q \xrightarrow{\alpha} q' \wedge p'\mathcal{R}q')$,

v) $q \xrightarrow{\alpha} q' \Rightarrow (\exists p' : p' \in \mathcal{P} \cup \{\surd\} : p \xrightarrow{\alpha} p' \wedge p'\mathcal{R}q')$.

Two processes p and q are called *rooted branching bisimilar*, denoted $p \sim_{rb} q$, if and only if there exists a rooted branching bisimulation between p and q.

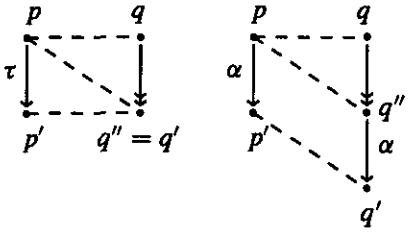

Figure 3: Branching bisimulation.

Figure 3 shows the essence of branching bisimulation. The root condition is introduced, because branching bisimulation is not a congruence for the algebraic choice operator, whereas rooted branching bisimulation is. This property is needed in the next section, where rooted branching bisimulation is used to give an operational semantics for PTNA extended with silent actions.

Note that the definition given here differs from the original definition given by Van Glabbeek and Weijland in [17]. In fact, it is the definition of *semi*-branching bisimulation, which was first defined in [18], as it appears in [5]. It can be shown that the two notions are equivalent [18, 5]. The reason for using the alternative definition is that it is more concise and more intuitive than the original definition. It also yields shorter proofs. A comparison of the two definitions can be found in [5].

Property 5.5. *Rooted branching bisimulation, $\sim_{rb}$, is an equivalence on processes.*

Proof. It must be shown that rooted branching bisimulation is reflexive, symmetric, and transitive.

Reflexivity: Let $\mathcal{I}$ be the identity relation on $\mathcal{P} \cup \{\surd\}$. Obviously, $\mathcal{I}$ is a rooted branching bisimulation. Hence, for any $p \in \mathcal{P}$, $p \sim_{rb} p$.

Symmetry: Let p and q be processes in $\mathcal{P}$. Let $\mathcal{R}$ be a rooted branching bisimulation between p and q. It follows from the symmetry in the definition of rooted branching bisimulation that the inverse of $\mathcal{R}$ is a rooted branching bisimulation between q and p. Hence, for any $p, q \in \mathcal{P}$, $p \sim_{rb} q \Rightarrow q \sim_{rb} p$.

Transitivity: Let p, q, and r be processes in $\mathcal{P}$. Let $\mathcal{Q}$ and $\mathcal{R}$ be rooted branching bisimulations between p and q, and q and r respectively. It is straightforward to verify by means of a case analysis that $\mathcal{Q} \circ \mathcal{R}$, where $\circ$ denotes relation composition, is a rooted branching bisimulation between p and r. Hence, for any $p, q, r \in \mathcal{P}$, $p \sim_{rb} q \wedge q \sim_{rb} r \Rightarrow p \sim_{rb} r$. □

5.3 Place/Transition-Net Algebra with Silent Actions.

The theory PTNA$^\tau$. In this paragraph, the silent action τ and an abstraction operator are added to the theory PTNA, yielding the theory PTNA$^\tau$, for PTNA *with silent actions*. Table 3 gives a definition of PTNA$^\tau$. Recall that $\mathsf{L_p}$ is the set of place labels. The first entry of Table 3 means that PTNA$^\tau$ is a modular extension of PTNA. That is, PTNA$^\tau$ has all sorts, functions, and axioms given in Tables 1 and 3. The auxiliary functions $\mathbf{c}, \mathbf{p} : \mathsf{AC} \to \mathbf{B}\,\mathsf{L_p}$ that appear in Table 1 are extended to τ as follows: $\mathbf{c}\tau = \mathbf{p}\tau = \emptyset$.

PTNA$^\tau$($\mathsf{L_p}$)			
PTNA($\mathsf{L_p}$)			
$\tau : \mathsf{AC}$		$\tau\_ : \mathbf{P}\,\mathsf{L_p} \to (\mathsf{P} \to \mathsf{P})$	
$a : \mathsf{L_p}$; $e, f : \mathsf{AC}$; $x, y, z : \mathsf{P}$; $I : \mathbf{P}\,\mathsf{L_p}$			
$e \mid \tau = e$	AT	$x \cdot \tau = x$	$B1$
		$x \cdot (\tau \cdot (y + z) + y) = x \cdot (y + z)$	$B2$
$a \in I \Rightarrow \tau_I(a?) = \tau$	$TAC1$	$a \in I \Rightarrow \tau_I(a!) = \tau$	$TAP1$
$a \notin I \Rightarrow \tau_I(a?) = a?$	$TAC2$	$a \notin I \Rightarrow \tau_I(a!) = a!$	$TAP2$
$\tau_I(\delta) = \delta$	TAD	$\tau_I(e \mid f) = \tau_I(e) \mid \tau_I(f)$	$TA1$
$\tau_I(\tau) = \tau$	TAT	$\tau_I(x + y) = \tau_I(x) + \tau_I(y)$	$TA2$
		$\tau_I(x \cdot y) = \tau_I(x) \cdot \tau_I(y)$	$TA3$
		$\tau_I(x * y) = \tau_I(x) * \tau_I(y)$	$TA4$

Table 3: Place/Transition-Net Algebra with silent actions.

For any set of place labels I, the abstraction operator τ_I simply renames actions from I to τ. The axioms $B1$ and $B2$ are an axiomatization of branching bisimulation [17]. Axiom AT states that only the visible part of the simultaneous execution of some action and τ is observed. It is different from the normal axioms for τ in ACP with silent actions. There, for any action e, $e \mid \tau$ is equal to δ. The reasoning behind this is that $\mid$ means communication. Since an invisible action cannot communicate, every attempt to communicate with τ results in deadlock.

Operational semantics for PTNA$^\tau$. Let the set of processes be the set of closed PTNA$^\tau$ terms, $\mathcal{C}$(PTNA$^\tau$). As before, let $\mathcal{A}ct$ be equal to $\mathbf{B}\,\mathsf{L_p} \times \mathbf{B}\,\mathsf{L_p}$; let $\phi : \mathsf{AC} \longrightarrow \mathcal{A}ct$, for any $e \in \mathsf{AC}$, be defined as $\phi(e) = (\mathbf{c}e, \mathbf{p}e)$. Note that $\phi(\tau) = (\emptyset, \emptyset)$. This means that, in the process domain, the action $(\emptyset, \emptyset)$ is the silent action. As mentioned in the previous subsection, the silent action in the process domain is usually called τ as well. The reason for this is that actions in the theory often coincide with actions in the process domain. In the remainder, τ always refers to the silent action in the theory, except in Appendix B, where τ is also used as an abbreviation for $(\emptyset, \emptyset)$. The transition relation $\_ \xrightarrow{\ } \_ : \mathbf{P}(\mathcal{C}(\text{PTNA}^\tau) \times \mathcal{A}ct \times (\mathcal{C}(\text{PTNA}^\tau) \cup \{\surd\}))$ is the smallest relation satisfying the rules in Tables 2 and 4. In Table 2, let p, p', q, q' range over $\mathcal{C}$(PTNA$^\tau$).

Property 5.6. *Rooted branching bisimulation, $\sim_{rb}$, is a congruence on closed* PTNA$^\tau$ *terms.*

Proof. Property 5.5 states that $\sim_{rb}$ is an equivalence relation. It remains to show that for each n-ary PTNA$^\tau$ operator f on processes and closed PTNA$^\tau$ terms $p_1, \ldots, p_n, q_1, \ldots, q_n$ such that $p_1 \sim_{rb} q_1, \ldots, p_n \sim_{rb} q_n$, $f(p_1, \ldots, p_n) \sim_{rb} f(q_1, \ldots, q_n)$. The details can be found in Appendix A. □

$$e : \mathsf{AC};\ I : \mathbf{PL_p};\ p, p' : \mathcal{C}(\mathrm{PTNA}^\tau)$$

$$\frac{p \xrightarrow{\phi(e)} p'}{\tau_I(p) \xrightarrow{\phi(\tau_I(e))} \tau_I(p')} \qquad \frac{p \xrightarrow{\phi(e)} \surd}{\tau_I(p) \xrightarrow{\phi(\tau_I(e))} \surd}$$

Table 4: The transition relation for the abstraction operator.

The following theorem states that if equality of two processes can be derived from the axioms of PTNA^τ, then the two processes are rooted branching bisimilar. Hence, equational reasoning can be used instead of model-based reasoning.

Theorem 5.7. *The set of closed* PTNA^τ *terms modulo rooted branching bisimulation is a model for* PTNA^τ. *That is, for any* $p, q \in \mathcal{C}(\mathrm{PTNA}^\tau)$, $\mathrm{PTNA}^\tau \vdash p = q \Rightarrow \mathcal{C}(\mathrm{PTNA}^\tau)/{\sim_{rb}} \models p = q$.

Proof. It follows from Property 5.6 that it suffices to verify the validity of each axiom of PTNA^τ. It is straightforward to construct a rooted branching bisimulation for each axiom. See Appendix A for more details. □

An algebraic semantics for hierarchical P/T nets. The algebraic semantics for the observable behavior of a hierarchical P/T net strongly resembles the algebraic semantics which describes its complete behavior. The essential difference is that the abstraction operator is used to hide the internal behavior of the net itself and its components.

Definition 5.8. (Observable behavior of hierarchical P/T nets) Let $HN = (P, T, S, \mathbf{i}, \mathbf{o}, I, s)$ be a hierarchical P/T net. The algebraic semantics for its observable behavior, $\mathcal{H}[\![HN]\!]$, is defined as follows. As before, omit empty quantifications.

$\mathcal{H}[\![HN]\!] = \tau_I \circ \lambda_s^I((\|\ t :\ t \in T :\ \mathcal{T}[\![t]\!]) \,\|\, (\|\ sn :\ sn \in S :\ \mathcal{H}[\![sn]\!]))$,
where $\circ$ denotes function composition and $\mathcal{T}[\![.]\!]$ is as in Definition 4.3.

Example 5.9. Again, let $PTN_0 = (N_0, i_0)$ be the left P/T net in Figure 1. In Example 4.7, the following expression is derived for its complete behavior $X_0 = \mathcal{N}[\![PTN_0]\!]$:

$X_0 = (a? \mid i_0? \mid i_1!) \cdot ((b? \mid i_1?) \cdot \delta + (c? \mid i_1?) \cdot \delta)$.

Since PTN_0 is a flat P/T net, its observable behavior $\mathcal{H}[\![PTN_0]\!]$ is equal to $\tau_{I_0}(X_0)$, where $I_0 = \{i_0, i_1\}$. Use the axioms $TA1$–3, AT and TAD to derive the following result.

$\tau_{I_0}(X_0) = (a? \mid \tau \mid \tau) \cdot ((b? \mid \tau) \cdot \tau_{I_0}(\delta) + (c? \mid \tau) \cdot \tau_{I_0}(\delta)) = a? \cdot (b? \cdot \delta + c? \cdot \delta)$.

The transition relation of $\tau_{I_0}(X_0)$ is shown in Figure 4. The expression $a? \cdot (b? \cdot \delta + c? \cdot \delta)$ describes the behavior of PTN_0 projected onto its pins. It corresponds to the expression already given in the motivating example (Figure 1). In a similar way, it is possible to derive the expression $a? \cdot b? \cdot \delta + a? \cdot c? \cdot \delta$ for the observable behavior of the right P/T net in Figure 1, PTN_1. The transition relation of this term is also shown in Figure 4. Obviously, the two processes are not (rooted branching) bisimilar, which is the desired result.

6 Recursion and Fairness

In order to apply the theory developed so far to non-trivial examples, we must be able to reason about *recursion* and *fairness*. The theory PTNA^τ already includes a recursion operator, namely the binary Kleene star. In this section, we give a fairness principle for the binary Kleene star and a recursion principle that gives for a

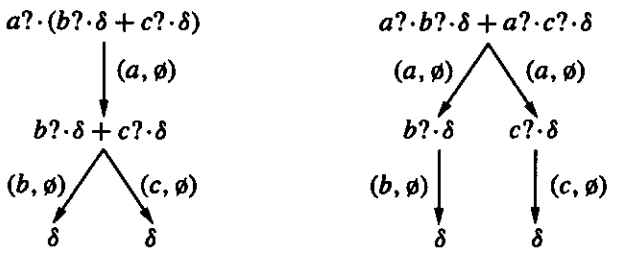

Figure 4: The transition relations of $\mathcal{H}[\![PTN_0]\!]$ and $\mathcal{H}[\![PTN_1]\!]$.

restricted set of recursive equations a solution in terms of the binary Kleene star. The reason for not including these principles in the theory PTNA$^\tau$ is that, depending on the application, it might be desirable to extend the theory with different fairness and recursion principles.

Fairness of the binary Kleene star can be expressed by a single axiom: the *Fair Iteration Rule* (*FIR*). It states that a sequence of silent steps cannot be infinitely long. In terms of P/T nets, it means that, in an internal conflict situation, it is not possible that one transition is always chosen.

$$\frac{}{x : \mathsf{P}} \qquad \frac{}{\tau^* x = x + \tau\cdot x} \; FIR$$

Property 6.1. *The Fair Iteration Rule is valid in the model of closed* PTNA$^\tau$ *terms modulo rooted branching bisimulation. That is, for any* $p \in \mathcal{C}(\text{PTNA}^\tau)$, $\mathcal{C}(\text{PTNA}^\tau)/{\sim_{rb}} \models \tau^* p = p + \tau\cdot p$.

Proof. It is straightforward to verify that, for any $p \in \mathcal{C}(\text{PTNA}^\tau)$, the following relation is a rooted branching bisimulation between $\tau^* p$ and $p + \tau\cdot p$.

$\{(\tau^* p,\, p+\tau\cdot p) \mid p \in \mathcal{C}(\text{PTNA}^\tau)\} \cup \{(\tau^* p,\, p) \mid p \in \mathcal{C}(\text{PTNA}^\tau)\} \cup \{(p,\, p) \mid p \in \mathcal{C}(\text{PTNA}^\tau) \cup \{\surd\}\}$. □

The *Recursive Specification Principle* for the binary Kleene star (*RSP**) is a derivation rule which gives a solution for some restricted set of recursive equations. Such a rule is necessary since many processes are inherently recursive. *RSP** uses the notion of a guard which is defined as follows.

Definition 6.2. (Guard) A *closed* PTNA$^\tau$ term p is a *guard* if and only if, using the axioms of PTNA$^\tau$, it can be rewritten into an equivalent term of any of the following forms:

i) δ or e, for any $e \in \mathsf{AC} - \{\tau\}$;

ii) $q\cdot r$, for closed PTNA$^\tau$ terms q and r where either q or r or both are guards;

iii) $q + r$, for any closed PTNA$^\tau$ terms q and r where both q and r are guards.

$$\frac{}{x, y, z : \mathsf{P}} \qquad \frac{x = y\cdot x + z, \quad y \text{ is a guard}}{x = y^* z} \; RSP^*$$

Informally, the requirement "y is a guard" means that y cannot terminate successfully without executing at least one visible action.

Property 6.3. *The derivation rule RSP* is valid in the model of closed* PTNA$^\tau$ *terms modulo rooted branching bisimulation. That is, for any* $p, q, r \in \mathcal{C}(\text{PTNA}^\tau)$ *such that* q *is a guard,* $\mathcal{C}(\text{PTNA}^\tau)/{\sim_{rb}} \models p = q\cdot p + r \Rightarrow \mathcal{C}(\text{PTNA}^\tau)/{\sim_{rb}} \models p = q^* r$.

Proof. Let p, q, and r be closed terms such that q is a guard; let $\mathcal{R}$ be a rooted branching bisimulation between p and $q \cdot p + r$. It can be shown that the following relation which uses the transitive closure of $\mathcal{R}$, denoted $\mathcal{R}^+$, is a rooted branching bisimulation between p and q^*r. An explanation of this relation and the details of the proof can be found in Appendix B.

$$\mathcal{Q} = \{(p, q^*r)\} \cup \mathcal{R}^+ \cup \{(s, q^*r) \mid s \in \mathcal{C}(\mathrm{PTNA}^\tau) \cup \{\surd\} \wedge s\mathcal{R}^+p\}$$
$$\cup \{(s, t \cdot (q^*r)) \mid s \in \mathcal{C}(\mathrm{PTNA}^\tau) \cup \{\surd\} \wedge t \in \mathcal{C}(\mathrm{PTNA}^\tau) \wedge s\mathcal{R}^+t \cdot p\}.$$

□

7 Example: The Alternating-Bit Protocol

In this section, the theory developed in this paper is applied to a non-trivial example, namely the Alternating-Bit Protocol (ABP). The version of the ABP considered here consists of four components: a sender, a receiver, a message channel, and an acknowledgement channel. Both messages and acknowledgments can be corrupted. In order to identify messages and acknowledgements, they are marked alternatingly with a zero and a one bit. Each time the sender sends a message, it waits for an acknowledgment from the receiver.

The example of the ABP is used to show two applications of the theory developed in this paper. First, it can be used to verify the behavior of a hierarchical P/T net against an algebraic specification. At each hierarchical level, the algebraic terms describing the observable behavior of the subnets can, on the one hand, be seen as the specification of the level below, and, on the other hand, as the implementation of the level above. The theory of this paper can be used to verify such implementations against their specifications in a purely equational and compositional way. Second, the theory can be used to show that different hierarchical nets have the same observable behavior. In a hierarchical P/T net, one can exchange subnets with the same observable behavior, without influencing the observable behavior at higher levels of abstraction.

Figure 5 gives a three-level hierarchical P/T net of the ABP which conforms to the informal description given above. Since for each net it is clear what are pins and what are internal places, dashed boxes are omitted. Table 5 explains the names of the subnets, transitions, and places.

To demonstrate the first application of the theory, a bottom-up verification of the ABP is given, which consists of four steps. First, simple algebraic expressions are derived for the behavior of the four nets at the most detailed level. Second, the abstraction operator is used to hide their internal behavior. Third, the results of these two steps are used to derive an expression for the behavior of the net at the intermediate level. Finally, by hiding the internal behavior of the intermediate net, it is shown that the subnet "abp" satisfies its specification given in Figure 5. To demonstrate the other application of the theory, it is shown that, on the highest level of abstraction, the ABP behaves as a one-place buffer. A P/T net of the one-place buffer is given in Figure 6. The observable behavior of the ABP is the same as the observable behavior of this net.

The verification of the ABP. In the following, a transition name t is used as an abbreviation of $(\mid i : i \in \mathbf{i}t : it?) \mid (\mid o : o \in \mathbf{o}t : ot!)$. For example, $0t$ is an abbreviation of $(it? \mid 0s? \mid 0w! \mid 0m1!)$. Furthermore, the following abbreviations are introduced:

$$S = 0t^*\delta \parallel 0rt1^*\delta \parallel 0rt2^*\delta \parallel 0a^*\delta \parallel 1t^*\delta \parallel 1rt1^*\delta \parallel 1rt2^*\delta \parallel 1a^*\delta,$$
$$R = 0a^*\delta \parallel 0na1^*\delta \parallel 0na2^*\delta \parallel 1a^*\delta \parallel 1na1^*\delta \parallel 1na2^*\delta,$$
$$M = f0m^*\delta \parallel c0m^*\delta \parallel f1m^*\delta \parallel c1m^*\delta,$$
$$A = f0a^*\delta \parallel c0a^*\delta \parallel f1a^*\delta \parallel c1a^*\delta.$$

The first part of the verification is to derive expressions for $\mathcal{H}[\![\mathrm{sen}]\!]$, $\mathcal{H}[\![\mathrm{rec}]\!]$, $\mathcal{H}[\![\mathrm{mc}]\!]$, and $\mathcal{H}[\![\mathrm{ac}]\!]$. It consists of two steps. First, expressions are derived for the complete behavior of each component; second, their internal behavior is hidden. To start with, expressions are calculated for the two channels. Applying Property 4.6 and the axioms for the causal state operator yields the following result.

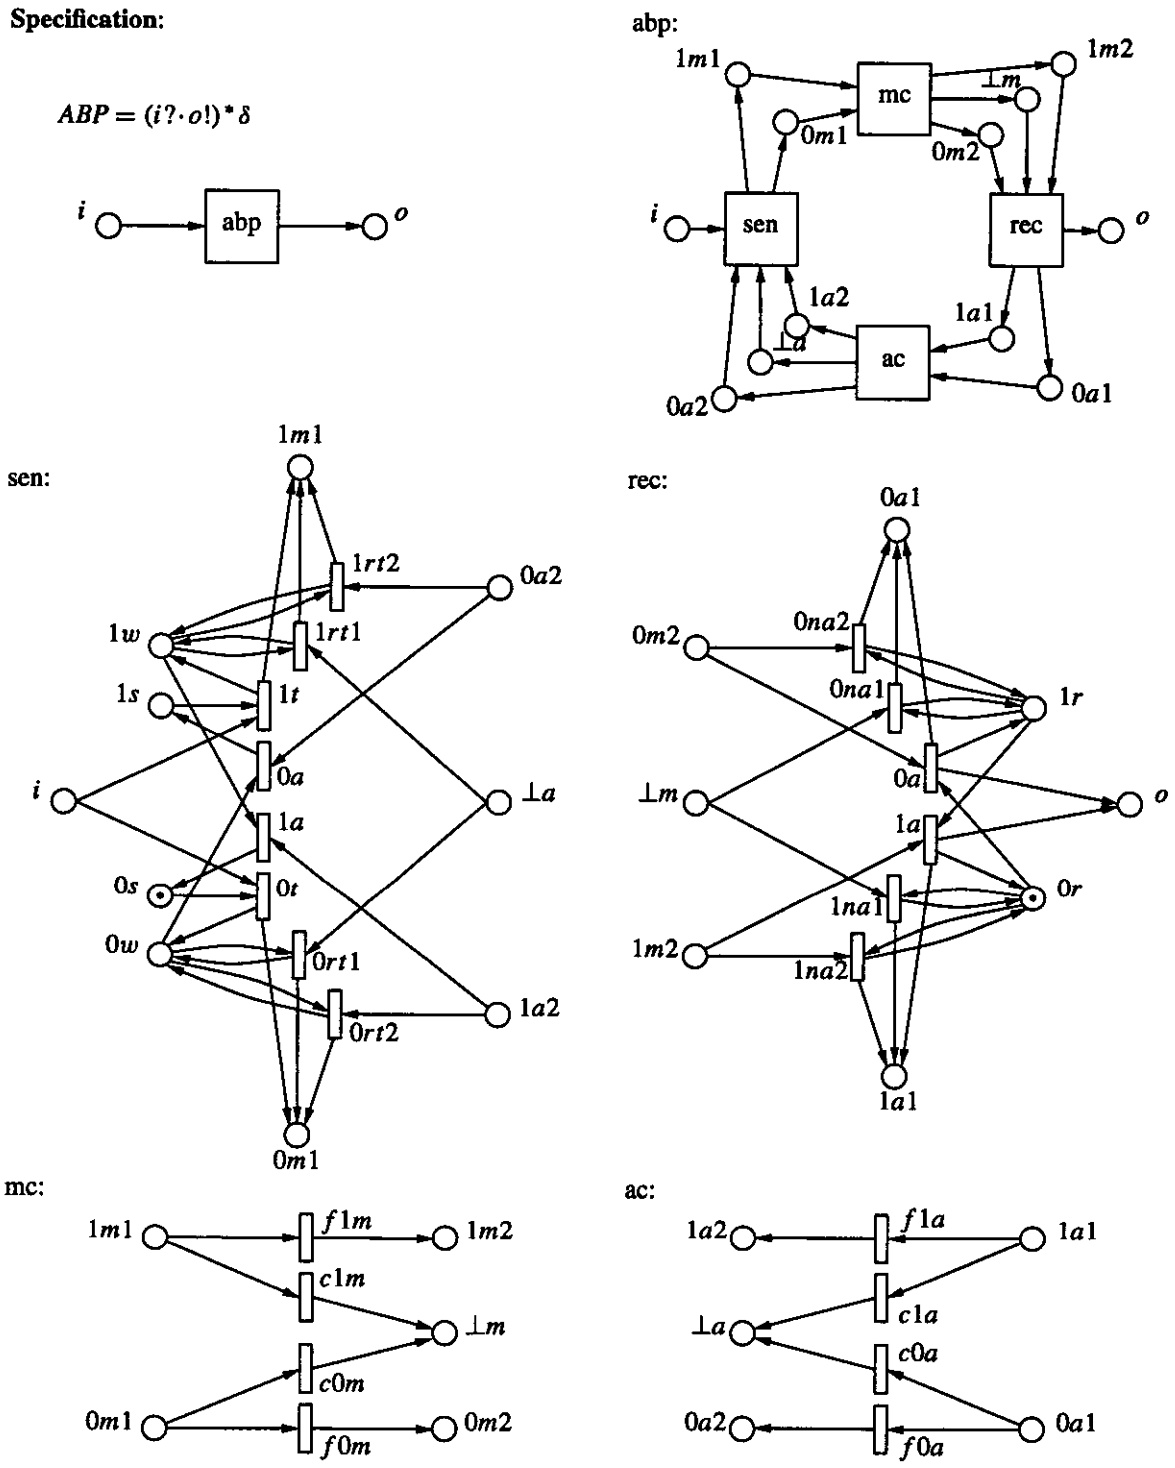

Figure 5: A hierarchical P/T net of the alternating-bit protocol.

$j \in \{0, 1\}$		
Specification:		
i, o	:	input/output pin for messages from/to the environment;
abp	:	the system that implements the ABP.
System abp:		
sen, rec	:	the sender and receiver;
mc, ac	:	the message channel and acknowledgement channel;
$jm1/2$	:	places for messages with bit j;
$\perp m$	:	corrupted messages;
$ja1/2, \perp a$	:	idem for acknowledgements.
System sen:		
js	:	the sender is ready to send a j message.
jw	:	the sender has sent a j message and is waiting for an ack.;
$jt, jrt1/2$	:	(re)transmit a j message;
ja	:	receive an acknowledgement of a j message;
System rec:		
jr	:	the receiver is ready to receive a j message;
$ja, jna1/2$	:	acknowledge a j message; send a negative j ack.;
Systems mc, ac:		
$fjm/a, cjm/a$	:	forward resp. corrupt message/acknowledgement.

Table 5: Informal explanation of the Alternating-Bit Protocol

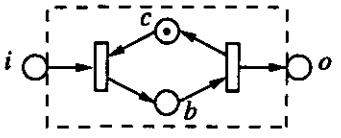

Figure 6: A one-place buffer.

$$M_0 = \lambda_\emptyset^\emptyset(M) = f0m \cdot M_0 + c0m \cdot M_0 + f1m \cdot M_0 + c1m \cdot M_0.$$

*RSP** yields:

$$M_0 = (f0m + c0m + f1m + c1m)^* \delta.$$

Similarly,

$$A_0 = \lambda_\emptyset^\emptyset(A) = (f0a + c0a + f1a + c1a)^* \delta.$$

Next, an expression is calculated for the sender. The state operator is written without the superscript $\{0s, 0w, 1s, 1w\}$.

$$S_0 = \lambda_{0s}(S) = 0t \cdot S_1,$$
$$S_1 = \lambda_{0w}(S) = 0rt1 \cdot S_1 + 0rt2 \cdot S_1 + 0a \cdot S_2,$$
$$S_2 = \lambda_{1s}(S) = 1t \cdot S_3, \text{ and}$$
$$S_3 = \lambda_{1w}(S) = 1rt1 \cdot S_3 + 1rt2 \cdot S_3 + 1a \cdot S_0.$$

Applying *RSP** and *BKS2* on the last equation yields:

$$S_3 = (1rt1 + 1rt2)^*(1a \cdot S_0) = ((1rt1 + 1rt2)^* 1a) \cdot S_0$$

Substituting this result and repeatedly applying *RSP** and *BKS2* gives:

$$S_0 = (0t \cdot ((0rt1 + 0rt2)^* 0a) \cdot (1t \cdot ((1rt1 + 1rt2)^* 1a)))^* \delta$$

Observe that this equation conforms to the intuitive notion of what the sender should do. First, it sends a

zero message; if necessary, it retransmits this message until it receives an acknowledgement; then, it repeats this behavior for a one message, after which it starts all over again. Similar to the calculations above, the following equation can be derived for the receiver:

$$R_0 = \lambda_{0r}^{\{0r,1r\}}(R) = (0a \cdot ((0na1 + 0na2)^* 1a) + 1na1 + 1na2)^* \delta$$

The second step is to hide the internal behavior of the sender and receiver in order to obtain their observable behavior. Since the two channels do not have internal places, their observable behavior is already given by the expressions above. The axioms for the abstraction operator plus *AT* yield the following results:

$$\begin{aligned}
TS_0 &= \tau_{\{0s,0w,1s,1w\}}(S_0) \\
&= ((i? \mid 0m1!) \cdot ((\bot a? \mid 0m1! + 1a2? \mid 0m1!)^* 0a2?) \cdot \\
&\quad (i? \mid 1m1!) \cdot ((\bot a? \mid 1m1! + 0a2? \mid 1m1!)^* 1a2?))^* \delta \\
TR_0 &= \tau_{\{0r,1r\}}(R_0) \\
&= ((0m2? \mid 0a1! \mid o!) \cdot ((\bot m? \mid 0a1! + 0m2? \mid 0a1!)^* (1m2? \mid 1a1! \mid o!)) \\
&\quad + \bot m? \mid 1a1! + 1m2? \mid 1a1!)^* \delta
\end{aligned}$$

This completes the first part of the verification. Summarizing, $\mathcal{H}[\![\text{sen}]\!] = TS_0$, $\mathcal{H}[\![\text{rec}]\!] = TR_0$, $\mathcal{H}[\![\text{mc}]\!] = M_0$, and $\mathcal{H}[\![\text{ac}]\!] = A_0$.

The second part of the verification is to use the expressions derived for $\mathcal{H}[\![\text{sen}]\!]$, $\mathcal{H}[\![\text{rec}]\!]$, $\mathcal{H}[\![\text{mc}]\!]$, and $\mathcal{H}[\![\text{ac}]\!]$ to determine an expression for $\mathcal{H}[\![\text{abp}]\!]$, the observable behavior of the subnet "abp." The result should satisfy the specification given in Figure 5. As the first part, $\mathcal{H}[\![\text{abp}]\!]$ is calculated in two steps. First, an expression is calculated for $X_0 = \lambda_\emptyset^I(TS_0 \parallel M_0 \parallel TR_0 \parallel A_0)$, where I is equal to $\{0m1, 1m1, 0m2, \bot m, 1m2, 0a1, 1a1, 0a2, \bot a, 1a2\}$. Second, the internal behavior of X_0 is hidden. The calculations of the first step are tedious, but not very complicated. In principle, one just repeatedly applies the expansion theorem (Theorem 4.5) and the axioms of PTNA. Figure 7 shows the transition relation of X_0. With *RSP** and *BKS2*, the following equations are obtained for X_0–X_9:

$$\begin{aligned}
X_0 &= (i? \mid 0m1!) \cdot X_1 \\
X_1 &= (((0m1? \mid \bot m!) \cdot (\bot m? \mid 1a1!) \cdot ((1a1? \mid 1a2!) \cdot (1a2? \mid 0m1!) \\
&\quad + (1a1? \mid \bot a!) \cdot (\bot a? \mid 0m1!)))^* (0m1? \mid 0m2!)) \cdot X_2 \\
X_2 &= (0m2? \mid 0a1! \mid o!) \cdot X_3 \\
X_3 &= (((0a1? \mid \bot a!) \cdot (\bot a? \mid 0m1!) \cdot ((0m1? \mid 0m2!) \cdot (0m2? \mid 0a1!) \\
&\quad + (0m1? \mid \bot m!) \cdot (\bot m? \mid 0a1!)))^* (0a1? \mid 0a2!)) \cdot X_4 \\
X_4 &= 0a2? \cdot X_5 \\
X_5 &= (i? \mid 1m1!) \cdot X_6 \\
X_6 &= (((1m1? \mid \bot m!) \cdot (\bot m? \mid 0a1!) \cdot ((0a1? \mid 0a2!) \cdot (0a2? \mid 1m1!) \\
&\quad + (0a1? \mid \bot a!) \cdot (\bot a? \mid 1m1!)))^* (1m1? \mid 1m2!)) \cdot X_7 \\
X_7 &= (1m2? \mid 1a1! \mid o!) \cdot X_8 \\
X_8 &= (((1a1? \mid \bot a!) \cdot (\bot a? \mid 1m1!) \cdot ((1m1? \mid 1m2!) \cdot (1m2? \mid 1a1!) \\
&\quad + (1m1? \mid \bot m!) \cdot (\bot m? \mid 1a1!)))^* (1a1? \mid 1a2!)) \cdot X_9 \\
X_9 &= 1a2? \cdot X_0
\end{aligned}$$

The final step is to hide the internal places I. Use the axioms for the abstraction operator plus *AT*, *B*1, *A*3, and *FIR* to obtain the following result:

$$\begin{aligned}
ABP &= \tau_I(X_0) \\
&= i? \cdot ((\tau \cdot \tau \cdot (\tau \cdot \tau + \tau \cdot \tau))^* \tau) \cdot \tau_I(X_2) \\
&= i? \cdot (\tau^* \tau) \cdot \tau_I(X_2) \\
&= i? \cdot (\tau + \tau \cdot \tau) \cdot \tau_I(X_2) \\
&= i? \cdot \tau_I(X_2)
\end{aligned}$$

Repeating this derivation for X_2–X_9 and substituting the result in the equation above yields:

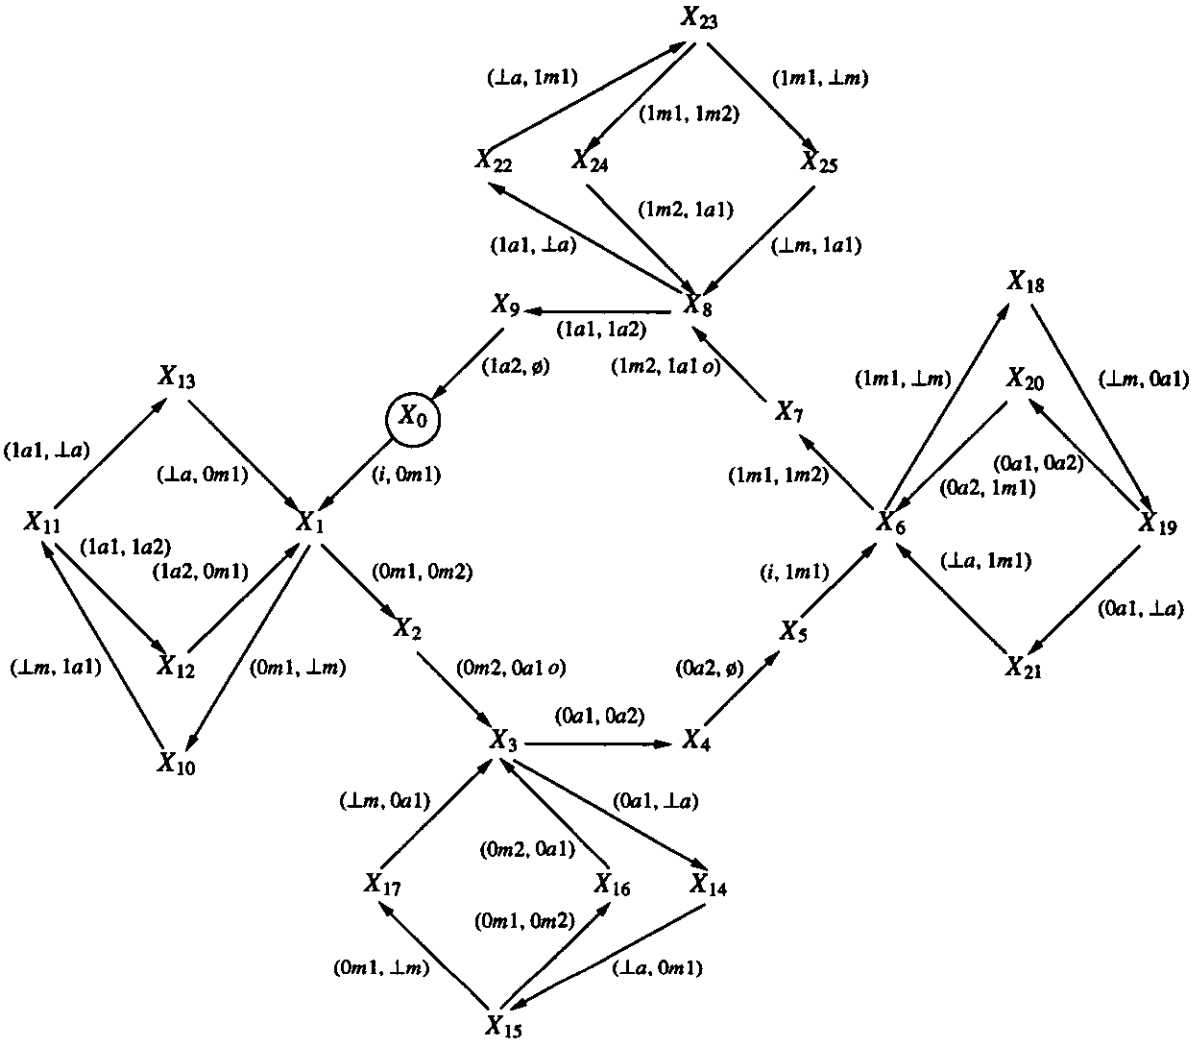

Figure 7: The transition relation of the Alternating-Bit Protocol.

$$ABP = i?\cdot o!\cdot i?\cdot o!\cdot ABP$$

So, by *RSP**,

$$ABP = (i?\cdot o!\cdot i?\cdot o!)^*\delta$$

From the observation that, for any process x,

$$x^*\delta = x\cdot(x^*\delta)+\delta = x\cdot(x\cdot(x^*\delta)+\delta)+\delta = x\cdot(x\cdot(x^*\delta))+\delta = (x\cdot x)\cdot(x^*\delta)+\delta,$$

which by *RSP** implies that $x^*\delta = (x\cdot x)^*\delta$, it follows that

$$ABP = (i?\cdot o!)^*\delta.$$

This completes the verification of the ABP. The algebraic term which is derived for its observable behavior satisfies the specification given in Figure 5.

The ABP and the one-place buffer. As mentioned, the theory developed in this paper can be used to determine whether two hierarchical P/T nets have the same observable behavior. In the previous paragraph, an algebraic expression has been derived for the observable behavior of the ABP. In this paragraph, it is shown

that the one-place buffer of Figure 6 has the same observable behavior. Thus, on a high level of abstraction, the one-place buffer and the ABP are equivalent.

Let BUF denote the observable behavior of the one-place buffer, $\mathcal{H}[\![\text{buf}]\!]$, where "buf" is the net shown in Figure 6. Let $I = \{b, c\}$ and let $B = (i? \mid c? \mid b!)^* \delta \parallel (b? \mid c! \mid o!)^* \delta$. As usual, the state operator is written without superscript I. Use Property 4.6 and the axioms for the causal state operator.

$$B_0 = \lambda_c(B) = (i? \mid c? \mid b!) \cdot \lambda_b(B) = (i? \mid c? \mid b!) \cdot (b? \mid c! \mid o!) \cdot B_0$$

*RSP**yields:

$$B_0 = ((i? \mid c? \mid b!) \cdot (b? \mid c! \mid o!))^* \delta$$

Hiding the internal places gives:

$$BUF = \tau_I(B_0) = ((i? \mid \tau \mid \tau) \cdot (\tau \mid \tau \mid o!))^* \delta = (i? \cdot o!)^* \delta$$

It follows that BUF equals ABP as derived in the previous paragraph. It means that the ABP and the one-place buffer have indeed the same observable behavior, and are thus equivalent.

High-level Petri nets. So far, only P/T nets have been considered. However, in practice, high-level nets, or colored nets, extended to data are used. In colored nets, tokens have values. As long as the values of tokens range over a finite domain, the results presented in this paper can be simply extended to data. For example, if messages in the ABP are taken from some finite data domain D, one could specify its behavior as follows: $ABP = (+ d : d \in D : (i(d)? \cdot o(d)!)^* \delta)$, where $i(d)?$ means the consumption of a token (message) with value d from place i, and $o(d)!$ means the production of a token with value d. All calculations given above can be easily adapted to incorporate data. Furthermore, the P/T net of the ABP can be simplified by adding the bit which is used to mark messages and acknowledgements to the value of the tokens. Thus, the explicit distinction made in the current net is not necessary anymore.

In case of infinite data domains, the results of this paper must be adapted to an algebraic formalism which supports data, such as for example μCRL [20] or PSF [25].

8 Concluding Remarks and Future Work

The first part of this paper gives an algebraic semantics for P/T nets which is consistent with their usual interleaving semantics. The second part gives an algebraic semantics for the complete operational behavior of hierarchical P/T nets, as well as a semantics for their high-level, observable behavior. The latter can be used to determine whether a hierarchical net satisfies some algebraic specification of its observable behavior and, thus, to determine whether two hierarchical nets can be considered equivalent.

Although the first results appear to be promising, it is necessary to further investigate the theoretical foundation and applicability of the approach presented in this paper. It is interesting to study the meaning of an arbitrary PTNA$^{(\tau)}$ term in P/T-net theory. Furthermore, it is worthwile to investigate the meaning of results from Petri-net theory, such as place and transition invariants, in the theories PTNA$^{(\tau)}$.

There are several interesting ways to extend the results presented in this paper. It has already briefly been mentioned how they can be extended to colored nets. Furthermore, it seems worthwile to investigate other hierarchical constructs than the one presented in this paper, and maybe time or stochastic aspects.

Finally, it is interesting to look at other semantics than the interleaving semantics. It is straightforward to extend the results to a step semantics, in which multiple transitions can fire simultaneously. It is only necessary to define the synchronous-merge operator on processes in the same way as the communication merge is defined in [2]. A true concurrency semantics appears to be another interesting candidate for future investigation.

Acknowledgements. The authors want to thank Wil van der Aalst, Jos Baeten, Roland Bol, Pedro D'Argenio, Kees van Hee, Sjouke Mauw, Paul Rambags, and Michel Reniers for the many fruitful discussions and their valuable suggestions. Special thanks go to Paul Rambags for his careful reading of an earlier version of this paper.

A Some Proofs

Theorem 4.2. *The set of closed* PTNA *terms modulo bisimulation is a model for* PTNA. *That is, for any* $p, q \in \mathcal{C}(\text{PTNA})$, $\text{PTNA} \vdash p = q \Rightarrow \mathcal{C}(\text{PTNA})/\sim \models p = q$.

Proof. Since it follows from the format of the derivation rules in Table 2 that bisimulation equivalence is a congruence on $\mathcal{C}(\text{PTNA})$ [3], it suffices to verify the validity of each axiom of PTNA. Below, for each axiom, a bisimulation is given. It is left to the reader to verify that the relations are indeed bisimulations. Let $\mathcal{D}(\mathcal{C}(\text{PTNA}))$ be an abbreviation of $\{(p, p) \mid p \in \mathcal{C}(\text{PTNA})\}$.

Axiom	Bisimulation
$A1$	$\{(p+q, q+p) \mid p, q \in \mathcal{C}(\text{PTNA})\} \cup \mathcal{D}(\mathcal{C}(\text{PTNA}))$
$A2$	$\{((p+q)+r, p+(q+r)) \mid p, q, r \in \mathcal{C}(\text{PTNA})\} \cup \mathcal{D}(\mathcal{C}(\text{PTNA}))$
$A3$	$\{(p+p, p) \mid p \in \mathcal{C}(\text{PTNA})\} \cup \mathcal{D}(\mathcal{C}(\text{PTNA}))$
$A4$	$\{((p+q)\cdot r, p\cdot r + q\cdot r) \mid p, q, r \in \mathcal{C}(\text{PTNA})\} \cup \mathcal{D}(\mathcal{C}(\text{PTNA}))$
$A5$	$\{((p\cdot q)\cdot r, p\cdot(q\cdot r)) \mid p, q, r \in \mathcal{C}(\text{PTNA})\} \cup \mathcal{D}(\mathcal{C}(\text{PTNA}))$
$A6$	$\{(p+\delta, p) \mid p \in \mathcal{C}(\text{PTNA})\} \cup \mathcal{D}(\mathcal{C}(\text{PTNA}))$
$A7$	$\{(\delta\cdot p, \delta) \mid p \in \mathcal{C}(\text{PTNA})\}$
$S1$	$\{(e \mid f, f \mid e) \mid e, f \in \mathsf{AC}\}$
$S2$	$\{((e \mid f) \mid g, e \mid (f \mid g)) \mid e, f, g \in \mathsf{AC}\}$
$M1$	$\{(p \between q, p \between q + q \between p) \mid p, q \in \mathcal{C}(\text{PTNA})\} \cup \{(p \between q, q \between p) \mid p, q \in \mathcal{C}(\text{PTNA})\} \cup \mathcal{D}(\mathcal{C}(\text{PTNA}))$
$M2$	$\{(d \between p, d\cdot p) \mid d \in \mathsf{AC} \cup \{\delta\} \wedge p \in \mathcal{C}(\text{PTNA})\} \cup \mathcal{D}(\mathcal{C}(\text{PTNA}))$
$M3$	$\{(d\cdot p \between q, d\cdot(p \between q)) \mid d \in \mathsf{AC} \cup \{\delta\} \wedge p, q \in \mathcal{C}(\text{PTNA})\} \cup \mathcal{D}(\mathcal{C}(\text{PTNA}))$
$M4$	$\{((p+q) \between r, p \between r + q \between r) \mid p, q, r \in \mathcal{C}(\text{PTNA})\} \cup \mathcal{D}(\mathcal{C}(\text{PTNA}))$
$ASC1,2$	$\{((p \between q) \between r, p \between (q \between r)) \mid p, q, r \in \mathcal{C}(\text{PTNA})\} \cup \{((p \between q) \between r, p \between (q \between r)) \mid p, q, r \in \mathcal{C}(\text{PTNA})\} \cup \mathcal{D}(\mathcal{C}(\text{PTNA}))$
$CSO1$	$\{(\lambda_s^I(\delta), \delta) \mid I \in \mathbb{P}\,\mathsf{L_p} \wedge s \in \mathbb{B}\,\mathsf{L_p}\}$
$CSO2$	$\{(\lambda_s^I(e), e) \mid I \in \mathbb{P}\,\mathsf{L_p} \wedge s \in \mathbb{B}\,\mathsf{L_p} \wedge e \in \mathsf{AC} \wedge ce\restriction I \subseteq s\}$
$CSO3$	$\{(\lambda_s^I(e), \delta) \mid I \in \mathbb{P}\,\mathsf{L_p} \wedge s \in \mathbb{B}\,\mathsf{L_p} \wedge e \in \mathsf{AC} \wedge ce\restriction I \not\subseteq s\}$
$CSO4$	$\{(\lambda_s^I(e\cdot p), \lambda_s^I(e)\cdot\lambda_{s-ce\cup pe\restriction I}^I(p)) \mid I \in \mathbb{P}\,\mathsf{L_p} \wedge s \in \mathbb{B}\,\mathsf{L_p} \wedge e \in \mathsf{AC} \wedge p \in \mathcal{C}(\text{PTNA})\} \cup \mathcal{D}(\mathcal{C}(\text{PTNA}))$
$CSO5$	$\{(\lambda_s^I(p+q), \lambda_s^I(p) + \lambda_s^I(q)) \mid I \in \mathbb{P}\,\mathsf{L_p} \wedge s \in \mathbb{B}\,\mathsf{L_p} \wedge p, q \in \mathcal{C}(\text{PTNA})\} \cup \mathcal{D}(\mathcal{C}(\text{PTNA}))$
$BKS1$	$\{(p^*q, p\cdot(p^*q)+q) \mid p, q \in \mathcal{C}(\text{PTNA})\} \cup \mathcal{D}(\mathcal{C}(\text{PTNA}))$
$BKS2$	$\{(p^*(q\cdot r), (p^*q)\cdot r) \mid p, q, r \in \mathcal{C}(\text{PTNA})\} \cup \{(p'\cdot(p^*(q\cdot r)), (p'\cdot(p^*q))\cdot r) \mid p, p', q, r \in \mathcal{C}(\text{PTNA})\} \cup \mathcal{D}(\mathcal{C}(\text{PTNA}))$
$BKS3$	$\{(p^*(q\cdot((p+q)^*r)+r), (p+q)^*r) \mid p, q, r \in \mathcal{C}(\text{PTNA})\} \cup \{(p'\cdot(p^*(q\cdot((p+q)^*r)+r)), p'\cdot((p+q)^*r)) \mid p, p', q, r \in \mathcal{C}(\text{PTNA})\} \cup \mathcal{D}(\mathcal{C}(\text{PTNA}))$

□

Theorem 4.5. (Expansion) *For any* $x_0, \ldots, x_n \in \mathsf{P}, n \in \mathbb{N} - \{0\}$
$(\between i : 0 \le i \le n : x_i) = (+i : 0 \le i \le n : x_i \between (\between j : 0 \le j \le n \wedge j \neq i : x_j))$.

Proof. The proof is by induction on n. The basic case where $n = 1$ is simply axiom $M1$. Assume $n > 1$.

$$
\begin{aligned}
& (\between i : 0 \le i \le n : x_i) \\
= \quad & \{ \text{Associativity of the merge } (ASC2) \}
\end{aligned}
$$

$$
\begin{aligned}
& (\|\, i : 0 \le i < n : x_i) \,\|\, x_n \\
= \quad & \{ \text{Axiom } M1 \} \\
& (\|\, i : 0 \le i < n : x_i) \,\mathbin{\mathbb{L}}\, x_n + x_n \,\mathbin{\mathbb{L}}\, (\|\, i : 0 \le i < n : x_i) \\
= \quad & \{ \text{Induction} \} \\
& (+i : 0 \le i < n : x_i \,\mathbin{\mathbb{L}}\, (\|\, j : 0 \le j < n \wedge j \neq i : x_j)) \,\mathbin{\mathbb{L}}\, x_n + x_n \,\mathbin{\mathbb{L}}\, (\|\, i : 0 \le i < n : x_i) \\
= \quad & \{ \text{Axioms } M4 \text{ and } ASC1 \} \\

= \quad & \{ \text{Associativity of the merge } (ASC2); \text{ dummy change; calculus} \} \\
& (+i : 0 \le i < n : x_i \,\mathbin{\mathbb{L}}\, (\|\, j : 0 \le j \le n \wedge j \neq i : x_j)) + x_n \,\mathbin{\mathbb{L}}\, (\|\, j : 0 \le j \le n \wedge j \neq n : x_j) \\
= \quad & \{ \text{Associativity of the choice } (A2) \} \\
& (+i : 0 \le i \le n : x_i \,\mathbin{\mathbb{L}}\, (\|\, j : 0 \le j \le n \wedge j \neq i : x_j))
\end{aligned}
$$

□

Property 4.6. *For any non empty bag* $E \in \mathbf{B}\,\mathsf{AC}$,
$(\|\, e : e \in E : e^*\delta) = (+e : e \in E : e \cdot (\|\, f : f \in E : f^*\delta))$.

Proof. If E is a singleton containing only one action e, then the above equation reduces to $e^*\delta = e \cdot (e^*\delta)$, which follows immediately from $BKS1$ and $A6$. So assume, E contains at least two different actions.

$$
\begin{aligned}
& (\|\, e : e \in E : e^*\delta) \\
= \quad & \{ \text{Expansion} \} \\
& (+e : e \in E : (e^*\delta) \,\mathbin{\mathbb{L}}\, (\|\, f : f \in E \wedge e \neq f : f^*\delta)) \\
= \quad & \{ \text{Axioms } BKS1 \text{ and } A6 \} \\
& (+e : e \in E : (e \cdot (e^*\delta)) \,\mathbin{\mathbb{L}}\, (\|\, f : f \in E \wedge e \neq f : f^*\delta)) \\
= \quad & \{ \text{Axiom } M3 \} \\
& (+e : e \in E : e \cdot ((e^*\delta) \,\|\, (\|\, f : f \in E \wedge e \neq f : f^*\delta))) \\
= \quad & \{ \text{Associativity of the merge } (ASC2) \} \\
& (+e : e \in E : e \cdot (\|\, f : f \in E : f^*\delta))
\end{aligned}
$$

□

Property 5.6. *Rooted branching bisimulation,* $\sim_{rb}$*, is a congruence on closed* PTNA^τ *terms.*

Proof. Property 5.5 states that $\sim_{rb}$ is an equivalence relation. It remains to show that for each n-ary PTNA^τ operator f on processes and closed PTNA^τ terms $p_1, \ldots, p_n, q_1, \ldots, q_n$ such that $p_1 \sim_{rb} q_1, \ldots, p_n \sim_{rb} q_n$, $f(p_1, \ldots, p_n) \sim_{rb} f(q_1, \ldots, q_n)$.

For the constants of PTNA^τ the desired result follows trivially from the reflexivity of the $\sim_{rb}$ relation. There is one operator on actions only, the synchronous merge $|$. Let $e_1, e_2, f_1, f_2 \in \mathsf{AC}$ such that $e_1 \sim_{rb} f_1$ and $e_2 \sim_{rb} f_2$. Let $\mathcal{Q}$ be defined as $\{(e_1 | e_2, f_1 | f_2), (\surd, \surd)\}$. Obviously, $\mathcal{Q}$ is a rooted branching bisimulation. Hence, $\sim_{rb}$ is a congruence for the synchronous merge.

There are seven operators on processes, five binary operators and two unary ones. Let p_1, p_2, q_1, q_2 be closed PTNA^τ terms. Let $\mathcal{R}_1$ and $\mathcal{R}_2$ be rooted branching bisimulations such that $p_1 \mathcal{R}_1 q_1$ and $p_2 \mathcal{R}_2 q_2$. It must be shown that there exist rooted branching bisimulations $\mathcal{Q}_1, \ldots, \mathcal{Q}_7$, such that $(p_1 + p_2)\mathcal{Q}_1(q_1 + q_2)$, $(p_1 \cdot p_2)\mathcal{Q}_2(q_1 \cdot q_2)$, $(p_1\, {}^*\, p_2)\mathcal{Q}_3(q_1\, {}^*\, q_2)$, $(p_1 \,\|\, p_2)\mathcal{Q}_4(q_1 \,\|\, q_2)$, $(p_1 \,\mathbin{\mathbb{L}}\, p_2)\mathcal{Q}_5(q_1 \,\mathbin{\mathbb{L}}\, q_2)$, and, such that for any $I \in \mathbf{P}\,\mathsf{L}_\mathsf{p}$ and $s \in \mathbf{B}\,\mathsf{L}_\mathsf{p}$, $\lambda_s^I(p_1)\mathcal{Q}_6\lambda_s^I(q_1)$, and $\tau_I(p_1)\mathcal{Q}_7\tau_I(p_2)$. The seven rooted branching bisimulations are given below. It is left to the reader to verify that the relations are indeed rooted branching bisimulations. To avoid unnecessarily complex formulas, some notational abbreviations are introduced. Let, for any $p \in \mathcal{C}(\mathrm{PTNA}^\tau) \cup \{\surd\}$, $\surd \cdot p = p$ and $\surd \,\|\, p = p \,\|\, \surd = p$, and, for any $I \in \mathbf{P}\,\mathsf{L}_\mathsf{p}$ and $s \in \mathbf{B}\,\mathsf{L}_\mathsf{p}$, $\lambda_s^I(\surd) = \surd$ and $\tau_I(\surd) = \surd$.

$\mathcal{Q}_1 = \mathcal{R}_1 \cup \mathcal{R}_2 \cup \{(p_1 + p_2, q_1 + q_2)\}$
$\mathcal{Q}_2 = \mathcal{R}_2 \cup \{(p \cdot p_2, q \cdot q_2) \mid p \mathcal{R}_1 q\}$
$\mathcal{Q}_3 = \mathcal{R}_2 \cup \{(p_1 \,{}^* p_2, q_1 \,{}^* q_2)\} \cup \{(p \cdot (p_1 \,{}^* p_2), q \cdot (q_1 \,{}^* q_2)) \mid p \mathcal{R}_1 q\}$
$\mathcal{Q}_4 = \{(p \parallel p', q \parallel q') \mid p \mathcal{R}_1 q \wedge p' \mathcal{R}_2 q'\}$
$\mathcal{Q}_5 = \mathcal{Q}_4 \cup \{(p_1 \between p_2, q_1 \between q_2)\}$
$\mathcal{Q}_6 = \{(\lambda_s^I(p), \lambda_s^I(q)) \mid p \mathcal{R}_1 q \wedge I \in \mathbf{P}\mathsf{L}_\mathsf{p} \wedge s \in \mathbf{B}\mathsf{L}_\mathsf{p}\}$
$\mathcal{Q}_7 = \{(\tau_I(p), \tau_I(q)) \mid p \mathcal{R}_1 q \wedge I \in \mathbf{P}\mathsf{L}_\mathsf{p}\}$ □

Theorem 5.7. *The set of closed* PTNA$^\tau$ *terms modulo rooted branching bisimulation is a model for* PTNA$^\tau$. *That is, for any* $p, q \in \mathcal{C}(\text{PTNA}^\tau)$, $\text{PTNA}^\tau \vdash p = q \Rightarrow \mathcal{C}(\text{PTNA}^\tau)/{\sim_{rb}} \models p = q$.

Proof. It follows from Property 5.6 that it suffices to verify the validity of each axiom of PTNA$^\tau$. Since any bisimulation as defined in Definition 2.2, extended with the pair $(\surd, \surd)$, is a rooted branching bisimulation, the axioms given in Table 1 are valid in $\mathcal{C}(\text{PTNA}^\tau)/{\sim_{rb}}$. Therefore, it remains to verify the validity of the axioms given in Table 3. The table below gives a rooted branching bisimulation for each of these axioms. Again, it is left to the reader to verify that the relations are indeed rooted branching bisimulations. Let $\mathcal{D}(\mathcal{C}(\text{PTNA}^\tau) \cup \{\surd\}) = \{(p, p) \mid p \in \mathcal{C}(\text{PTNA}^\tau) \cup \{\surd\}\}$.

Axiom	Bisimulation
AT	$\{(e \mid \tau, e) \mid e \in \mathsf{AC}\} \cup \{(\surd, \surd)\}$
*B*1	$\{(p \cdot \tau, p) \mid p \in \mathcal{C}(\text{PTNA}^\tau)\} \cup \{(\tau, \surd), (\surd, \surd)\}$
*B*2	$\{(p \cdot (\tau \cdot (q + r) + q), p \cdot (q + r) \mid p, q, r \in \mathcal{C}(\text{PTNA}^\tau)\} \cup$ $\{(\tau \cdot (p + q) + p), p + q) \mid p, q \in \mathcal{C}(\text{PTNA}^\tau)\} \cup \mathcal{D}(\mathcal{C}(\text{PTNA}^\tau) \cup \{\surd\})$
*TAC*1	$\{(\tau_I(a?), \tau) \mid I \in \mathbf{P}\mathsf{L}_\mathsf{p} \wedge a \in I\} \cup \{(\surd, \surd)\}$
*TAC*2	$\{(\tau_I(a?), a?) \mid I \in \mathbf{P}\mathsf{L}_\mathsf{p} \wedge a \in \mathsf{L}_\mathsf{p} - I\} \cup \{(\surd, \surd)\}$

*TAP*2	$\{(\tau_I(a!), a!) \mid I \in \mathbf{P}\mathsf{L}_\mathsf{p} \wedge a \in \mathsf{L}_\mathsf{p} - I\} \cup \{(\surd, \surd)\}$
TAD	$\{(\tau_I(\delta), \delta) \mid I \in \mathbf{P}\mathsf{L}_\mathsf{p}\}$
TAT	$\{(\tau_I(\tau), \tau) \mid I \in \mathbf{P}\mathsf{L}_\mathsf{p}\} \cup \{(\surd, \surd)\}$
*TA*1	$\{(\tau_I(e \mid f), \tau_I(e) \mid \tau_I(f)) \mid e, f \in \mathsf{AC} \wedge I \in \mathbf{P}\mathsf{L}_\mathsf{p}\} \cup \{(\surd, \surd)\}$
*TA*2	$\{(\tau_I(p + q), \tau_I(p) + \tau_I(q)) \mid p, q \in \mathcal{C}(\text{PTNA}^\tau) \wedge I \in \mathbf{P}\mathsf{L}_\mathsf{p}\} \cup \mathcal{D}(\mathcal{C}(\text{PTNA}^\tau) \cup \{\surd\})$
*TA*3	$\{(\tau_I(p \cdot q), \tau_I(p) \cdot \tau_I(q)) \mid p, q \in \mathcal{C}(\text{PTNA}^\tau) \wedge I \in \mathbf{P}\mathsf{L}_\mathsf{p}\} \cup \mathcal{D}(\mathcal{C}(\text{PTNA}^\tau) \cup \{\surd\})$
*TA*4	$\{(\tau_I(p^* q), \tau_I(p)^* \tau_I(q)) \mid p, q \in \mathcal{C}(\text{PTNA}^\tau) \wedge I \in \mathbf{P}\mathsf{L}_\mathsf{p}\} \cup$ $\{(\tau_I(p \cdot (q^* r)), \tau_I(p) \cdot (\tau_I(q)^* \tau_I(r))) \mid p, q, r \in \mathcal{C}(\text{PTNA}^\tau) \wedge I \in \mathbf{P}\mathsf{L}_\mathsf{p}\} \cup$ $\mathcal{D}(\mathcal{C}(\text{PTNA}^\tau) \cup \{\surd\})$

□

B Proving the Validity of *RSP**

Recall that *RSP** has been defined as follows.

$$\frac{x, y, z : \mathsf{P} \qquad \dfrac{x = y \cdot x + z, \quad y \text{ is a guard}}{x = y^* z}}{} \; RSP^*$$

One way to prove the validity of *RSP** is to show that the model satisfies the so-called *Approximation Induction Principle AIP*. *AIP* states that any processes with the same finite prefixes are equivalent. If a model satisfies *AIP*, or a slightly weaker variant of *AIP* called AIP^-, then it also satisfies *RSP*, which is the Recursive Specification Principle for general recursion. This line of proof is used in for example [4] to show that the models introduced there satisfy *RSP*.

Since a model that satisfies *RSP* also satisfies *RSP**, the same line of reasoning could be used to prove the validity of *RSP** in this paper. However, the validity of *RSP** can also be shown directly by constructing a rooted branching bisimulation. The advantage of such a proof is that it is not necessary to introduce any auxiliary notions as *AIP*. Furthermore, once the idea behind the construction of the rooted branching bisimulation is understood, the proof is rather straightforward.

The following two lemmas are useful in the proof.

Lemma B.1. *Let p be a closed* PTNA^τ *term. If p is a guard, then $p \not\twoheadrightarrow \surd$.*

Proof. Since p is a guard, it can be rewritten into an equivalent closed PTNA^τ term q which is of any of the forms given in Definition 6.2. Using the operational rules given in Table 2, it is straightforward to prove by means of stuctural induction that $q \not\twoheadrightarrow \surd$. Since $\mathrm{PTNA}^\tau \vdash p = q$, the soundness of the PTNA^τ axioms yields that $p \sim_{rb} q$. It follows immediately from the definition of rooted branching bisimulation, Definition 5.4, that $p \not\twoheadrightarrow \surd$. □

Lemma B.2. *Let $(\mathcal{P}, \longrightarrow)$ be a process space over Act equal to $\mathcal{A} \cup \{\tau\}$, for some set of action symbols $\mathcal{A}$. Let $\mathcal{R}$ be a branching bisimulation. For any $p, p', q, q' \in \mathcal{P} \cup \{\surd\}$,*

$$p \twoheadrightarrow p' \wedge p \mathcal{R} q \;\Rightarrow\; (\exists\, q' : q' \in \mathcal{P} \cup \{\surd\} \wedge q \twoheadrightarrow q' : p' \mathcal{R} q') \text{ and}$$
$$q \twoheadrightarrow q' \wedge p \mathcal{R} q \;\Rightarrow\; (\exists\, p' : p' \in \mathcal{P} \cup \{\surd\} \wedge p \twoheadrightarrow p' : p' \mathcal{R} q')$$

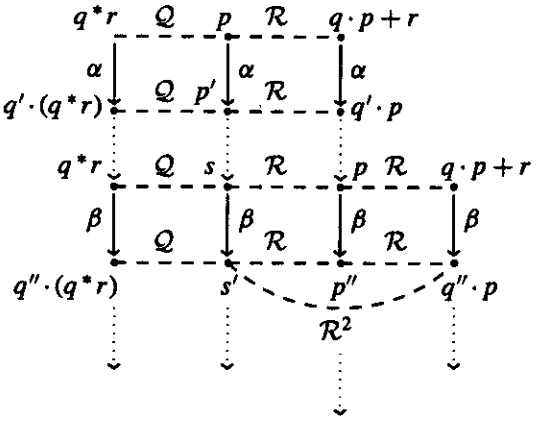
Proof. Straightforward by induction to the number of τ steps from p to p' and q to q' respectively. See also [5]. □

Property 6.3. *The derivation rule RSP* is valid in the model of closed* PTNA^τ *terms modulo rooted branching bisimulation. That is, for any $p, q, r \in \mathcal{C}(\mathrm{PTNA}^\tau)$ such that q is a guard, $\mathcal{C}(\mathrm{PTNA}^\tau)/{\sim_{rb}} \models p = q \cdot p + r \Rightarrow \mathcal{C}(\mathrm{PTNA}^\tau)/{\sim_{rb}} \models p = q^* r$.*

Proof. Let p, q, and r be closed terms such that q is a guard; let $\mathcal{R}$ be a rooted branching bisimulation between p and $q \cdot p + r$. It must be shown that there exists a rooted branching bisimulation $\mathcal{Q}$ between p and $q^* r$. In the construction of $\mathcal{Q}$, the transitive closure of $\mathcal{R}$, denoted $\mathcal{R}^+$, is used.

$$\mathcal{Q} = \{(p, q^* r)\} \cup \mathcal{R}^+ \cup \{(s, q^* r) \mid s \in \mathcal{C}(\mathrm{PTNA}^\tau) \cup \{\surd\} \wedge s \mathcal{R}^+ p\}$$
$$\cup \{(s, t \cdot (q^* r)) \mid s \in \mathcal{C}(\mathrm{PTNA}^\tau) \cup \{\surd\} \wedge t \in \mathcal{C}(\mathrm{PTNA}^\tau) \wedge s \mathcal{R}^+ t \cdot p\}.$$

The example depicted below shows the idea behind the construction of $\mathcal{Q}$. In this example, $\mathcal{R}$ is depicted from left to right, whereas $\mathcal{Q}$ is depicted from right to left. Obviously, it is required that $p \mathcal{Q} q^* r$. Since $\mathcal{R}$ is a rooted branching bisimulation between p and $q \cdot p + r$, $q \cdot p + r$ can simulate any step that p can make. Therefore, if p can evolve into some process p' by executing an α step, then $q \cdot p + r$ can simulate this step



and evolve into, for example, $q' \cdot p$. However, this means that also $q^* r$ can do an α step, in which case it evolves into $q' \cdot (q^* r)$. This means that all pairs of the form $(p', q' \cdot (q^* r))$ must be added to $\mathcal{Q}$. This explains the basic form of $\mathcal{Q}$.

The reason why the transitive closure of $\mathcal{R}$ is needed, can be explained as follows. Assume that after a number of steps p' evolves into some process s and $q' \cdot p$ simulates these steps evolving into p. Then, $s \mathcal{R} p$ and since $q' \cdot (q^* r)$ evolves into $q^* r$ again, also $s \mathcal{Q} q^* r$. Note that the definition of $\mathcal{Q}$ indeed implies that it contains the element $(s, q^* r)$. Now assume that s can execute some β step evolving into s'. For the sake of simplicity, also assume that p can simulate this step without executing any preceding τ steps. Then, also $q \cdot p + r$ can do a β step evolving into, for example, $q'' \cdot p$. However, this implies that $q^* r$ can do a β step to $q'' \cdot (q^* r)$, which means that $\mathcal{Q}$ must relate s' to $q'' \cdot (q^* r)$. The example shows that this would not necessarily have been the case if the definition of $\mathcal{Q}$ would have used $\mathcal{R}$ instead of $\mathcal{R}^+$, because $\mathcal{R}$ does not relate s' directly to $q'' \cdot p$. However, $\mathcal{R}^2$, the relation composition of $\mathcal{R}$ with itself, does relate s' to $q'' \cdot p$. Since the process sketched here can repeat itself, this example suggests to use the transitive closure of $\mathcal{R}$ instead of $\mathcal{R}$ itself in the construction of $\mathcal{Q}$. Below, it is shown that $\mathcal{Q}$ is indeed a rooted branching bisimulation between p and $q^* r$.

The proof uses the fact that $\mathcal{R}^+$ is a rooted branching bisimulation between p and $q \cdot p + r$. This follows from the observation that the relation composition as well as the union of two branching bisimulations is again a branching bisimulation (see the proof of Property 5.5 and [5]). Furthermore, if a branching bisimulation satisfies the root condition for two processes, then also any larger branching bisimulation satisfies the root condition for these two processes, where "larger" is defined by means of the superset relation.

First, we show that $\mathcal{Q}$ satisfies the root condition for p and $q^* r$. The $\equiv$ sign is used to denote syntactical equivalence on closed PTNA$^\tau$ terms plus $\surd$. Recall that τ is used as an abbreviation of $(\emptyset, \emptyset)$.

i) Assume $p \xrightarrow{\alpha} p'$ for some $\alpha \in Act$ and $p' \in \mathcal{C}(\text{PTNA}^\tau) \cup \{\surd\}$. It must be shown that there exists a $v' \in \mathcal{C}(\text{PTNA}^\tau) \cup \{\surd\}$ such that $q^* r \xrightarrow{\alpha} v'$ and $p' \mathcal{Q} v'$.

Since $\mathcal{R}$ satisfies the root condition for p and $q \cdot p + r$, it follows from the operational rules for choice and sequential composition in Table 2 that three cases can be distinguished.

(a) First, $q \xrightarrow{\alpha} q'$, for some $q' \in \mathcal{C}(\text{PTNA}^\tau)$, and $q \cdot p + r \xrightarrow{\alpha} q' \cdot p$ such that $p' \mathcal{R} q' \cdot p$. It follows immediately from the operational rules for the binary Kleene star in Table 2 and the definition of $\mathcal{Q}$ that $q^* r \xrightarrow{\alpha} q' \cdot (q^* r)$ and $p' \mathcal{Q} q' \cdot (q^* r)$.

(b) Second, $q \xrightarrow{\alpha} \surd$ and $q \cdot p + r \xrightarrow{\alpha} p$ such that $p' \mathcal{R} p$. It follows immediately that $q^* r \xrightarrow{\alpha} q^* r$ and $p' \mathcal{Q} q^* r$.

(c) Third, $r \xrightarrow{\alpha} r' \in \mathcal{C}(\text{PTNA}^\tau) \cup \{\surd\}$ and $q \cdot p + r \xrightarrow{\alpha} r'$ such that $p' \mathcal{R} r'$. It follows immediately that $q^* r \xrightarrow{\alpha} r'$ and $p' \mathcal{Q} r'$.

ii) Assume $q^* r \xrightarrow{\alpha} v'$ for some $\alpha \in \mathcal{A}ct$ and $v' \in \mathcal{C}(\text{PTNA}^\tau) \cup \{\surd\}$. It must be shown that there exists a $p' \in \mathcal{C}(\text{PTNA}^\tau) \cup \{\surd\}$ such that $p \xrightarrow{\alpha} p'$ and $p' \mathcal{Q} v'$. Again, three cases can be distinguished.

(a) First, $q \xrightarrow{\alpha} q' \in \mathcal{C}(\text{PTNA}^\tau)$ and $q^* r \xrightarrow{\alpha} v' \equiv q' \cdot (q^* r)$. It follows that $q \cdot p + r \xrightarrow{\alpha} q' \cdot p$. Since $p \mathcal{R} q \cdot p + r$ and $\mathcal{R}$ satisfies the root condition for p and $q \cdot p + r$, $p \xrightarrow{\alpha} p' \in \mathcal{C}(\text{PTNA}^\tau) \cup \{\surd\}$ such that $p' \mathcal{R} q' \cdot p$. Hence, $p \xrightarrow{\alpha} p'$ and $p' \mathcal{Q} v' \equiv q' \cdot (q^* r)$.

(b) Second, $q \xrightarrow{\alpha} \surd$ and $q^* r \xrightarrow{\alpha} v' \equiv q^* r$. It follows that $q \cdot p + r \xrightarrow{\alpha} p$. Since $p \mathcal{R} q \cdot p + r$ and $\mathcal{R}$ satisfies the root condition for p and $q \cdot p + r$, $p \xrightarrow{\alpha} p' \in \mathcal{C}(\text{PTNA}^\tau) \cup \{\surd\}$ such that $p' \mathcal{R} p$. Hence, $p \xrightarrow{\alpha} p'$ and $p' \mathcal{Q} v' \equiv q^* r$.

(c) Third, $r \xrightarrow{\alpha} r' \in \mathcal{C}(\text{PTNA}^\tau) \cup \{\surd\}$ and $q^* r \xrightarrow{\alpha} v' \equiv r'$. It follows that $q \cdot p + r \xrightarrow{\alpha} r'$ and therefore $p \xrightarrow{\alpha} p' \in \mathcal{C}(\text{PTNA}^\tau) \cup \{\surd\}$ such that $p' \mathcal{R} r'$. Hence, $p \xrightarrow{\alpha} p'$ and $p' \mathcal{Q} v' \equiv r'$.

The above two cases show that $\mathcal{Q}$ satisfies the root condition for p and $q \cdot p + r$.

Second, assume that for any $\alpha \in \mathcal{A}ct$ and $u, u', v \in \mathcal{C}(\text{PTNA}^\tau) \cup \{\surd\}$, $u \xrightarrow{\alpha} u'$ and $u \mathcal{Q} v$. It must be shown that there exist $v', v'' \in \mathcal{C}(\text{PTNA}^\tau) \cup \{\surd\}$ such that $v \longrightarrow\!\!\!\!\!\rightarrow v'' \xrightarrow{(\alpha)} v'$, $u \mathcal{Q} v''$, and $u' \mathcal{Q} v'$. Using the definition of $\mathcal{Q}$, three cases can be distinguished.

i) First, $u \mathcal{R}^+ v$. Since $\mathcal{R}^+$ is a rooted branching bisimulation, it follows immediately that there exist $v', v'' \in \mathcal{C}(\text{PTNA}^\tau) \cup \{\surd\}$ such that $v \longrightarrow\!\!\!\!\!\rightarrow v'' \xrightarrow{(\alpha)} v'$, $u \mathcal{R}^+ v''$, and $u' \mathcal{R}^+ v'$, and hence also $u \mathcal{Q} v''$, and $u' \mathcal{Q} v'$.

ii) Second, $v \equiv q^* r$ and $u \mathcal{R}^+ p$. Two cases can be distinguished, corresponding to whether or not p does at least one τ step before possibly doing an α step.

(a) Assume $p \xrightarrow{(\alpha)} p' \in \mathcal{C}(\text{PTNA}^\tau) \cup \{\surd\}$ such that $u' \mathcal{R}^+ p'$. According to the definition of $p \xrightarrow{(\alpha)} p'$ again two cases can be distinguised.

- First, $\alpha = \tau$ and $p' \equiv p$. It follows immediately from the assumptions and $u' \mathcal{R}^+ p' \equiv p$ that $v \equiv q^* r \longrightarrow\!\!\!\!\!\rightarrow q^* r \xrightarrow{(\tau)} q^* r$, $u \mathcal{Q} q^* r$, and $u' \mathcal{Q} q^* r$.
- Second, $p \xrightarrow{\alpha} p'$. Since $p \mathcal{R} q \cdot p + r$ and $\mathcal{R}$ satisfies the root condition for p and $q \cdot p + r$, as above, three cases can be distinguished.
  - Assume $q \xrightarrow{\alpha} q' \in \mathcal{C}(\text{PTNA}^\tau)$ and $q \cdot p + r \xrightarrow{\alpha} q' \cdot p$ such that $p' \mathcal{R} q' \cdot p$. The assumption $u \mathcal{Q} v$ and $u' \mathcal{R}^+ p' \mathcal{R} q' \cdot p$ yield immediately $v \equiv q^* r \longrightarrow\!\!\!\!\!\rightarrow q^* r \xrightarrow{\alpha} q' \cdot (q^* r)$, $u \mathcal{Q} q^* r$, and $u' \mathcal{Q} q' \cdot (q^* r)$.
  - Assume $q \xrightarrow{\alpha} \surd$ and $q \cdot p + r \xrightarrow{\alpha} p$ such that $p' \mathcal{R} p$. It follows immediately that $v \equiv q^* r \longrightarrow\!\!\!\!\!\rightarrow q^* r \xrightarrow{\alpha} q^* r$, $u \mathcal{Q} q^* r$, and $u' \mathcal{Q} q^* r$.
  - Assume $r \xrightarrow{\alpha} r' \in \mathcal{C}(\text{PTNA}^\tau) \cup \{\surd\}$ and $q \cdot p + r \xrightarrow{\alpha} r'$ such that $p' \mathcal{R} r'$. It follows immediately that $v \equiv q^* r \longrightarrow\!\!\!\!\!\rightarrow q^* r \xrightarrow{\alpha} r'$, $u \mathcal{Q} q^* r$, and $u' \mathcal{Q} r'$.

(b) Assume $p \xrightarrow{\tau} p''' \longrightarrow\!\!\!\!\!\rightarrow p'' \xrightarrow{(\alpha)} p'$, for some $p', p'', p''' \in \mathcal{C}(\text{PTNA}^\tau) \cup \{\surd\}$ such that $u \mathcal{R}^+ p''$ and $u' \mathcal{R}^+ p'$. Since $p \mathcal{R} q \cdot p + r$, $\mathcal{R}$ satisfies the root condition for p and $q \cdot p + r$, and q is a guard, which by Lemma B.1 excludes the possibility that $q \xrightarrow{\tau} \surd$, it follows that $q \xrightarrow{\tau} q''' \in \mathcal{C}(\text{PTNA}^\tau)$ such that $p''' \mathcal{R} q''' \cdot p$. Lemmas B.1 and B.2 yield that $q''' \longrightarrow\!\!\!\!\!\rightarrow q'' \in \mathcal{C}(\text{PTNA}^\tau)$ such that $p'' \mathcal{R} q'' \cdot p$. Two cases can be distinguished.

- First, $\alpha = \tau$ and $p' \equiv p''$. Then, $v \equiv q^*r \longrightarrow\!\!\!\!\!\rightarrow q'' \cdot (q^*r) \xrightarrow{(\tau)} q'' \cdot (q^*r)$. Furthermore, $u\mathcal{R}^+ p''\mathcal{R}q'' \cdot p$ and $u'\mathcal{R}^+ p' \equiv p''\mathcal{R}q'' \cdot p$ yield that $u\mathcal{Q}q'' \cdot (q^*r)$ and $u'\mathcal{Q}q'' \cdot (q^*r)$.
- Second, $p'' \xrightarrow{\alpha} p'$. Since q is a guard and $q \longrightarrow\!\!\!\!\!\rightarrow q''$, Lemma B.1 yields that $q'' \not\longrightarrow\!\!\!\!\!\rightarrow \surd$. Since $p''\mathcal{R}q'' \cdot p$, again two cases can be distinguished.
  - First, $q'' \longrightarrow\!\!\!\!\!\rightarrow \tilde{q} \xrightarrow{(\alpha)} q'$, for some $\tilde{q}, q' \in \mathcal{C}(\text{PTNA}^\tau)$, $p''\mathcal{R}\tilde{q} \cdot p$, and $p'\mathcal{R}q' \cdot p$. It follows that $v \equiv q^*r \longrightarrow\!\!\!\!\!\rightarrow \tilde{q} \cdot (q^*r) \xrightarrow{(\alpha)} q' \cdot (q^*r)$. Since $u\mathcal{R}^+ p''\mathcal{R}\tilde{q} \cdot p$ and $u'\mathcal{R}^+ p'\mathcal{R}q' \cdot p$, also $u\mathcal{Q}\tilde{q} \cdot (q^*r)$ and $u'\mathcal{Q}q' \cdot (q^*r)$.
  - Second, $q'' \longrightarrow\!\!\!\!\!\rightarrow \tilde{q} \xrightarrow{\alpha} \surd$, for some $\tilde{q} \in \mathcal{C}(\text{PTNA}^\tau)$, $p''\mathcal{R}\tilde{q} \cdot p$, and $p'\mathcal{R}p$. It follows immediately that $v \equiv q^*r \longrightarrow\!\!\!\!\!\rightarrow \tilde{q} \cdot (q^*r) \xrightarrow{(\alpha)} q^*r$. Furthermore, $u\mathcal{R}^+ p''\mathcal{R}\tilde{q} \cdot p$ and $u'\mathcal{R}^+ p'\mathcal{R}p$ yield $u\mathcal{Q}\tilde{q} \cdot (q^*r)$ and $u'\mathcal{Q}q^*r$.

iii) Third, $v \equiv t \cdot (q^*r)$ and $u\mathcal{R}^+ t \cdot p$, for some $t \in \mathcal{C}(\text{PTNA}^\tau)$. Since $\mathcal{R}^+$ is a rooted branching bisimulation and $u \xrightarrow{\alpha} u'$, three cases can be distinguished.

(a) First, $t \longrightarrow\!\!\!\!\!\rightarrow t'' \xrightarrow{(\alpha)} t'$, for some $t', t'' \in \mathcal{C}(\text{PTNA}^\tau)$ such that $u\mathcal{R}^+ t'' \cdot p$ and $u'\mathcal{R}^+ t' \cdot p$. It follows that $v \equiv t \cdot (q^*r) \longrightarrow\!\!\!\!\!\rightarrow t'' \cdot (q^*r) \xrightarrow{(\alpha)} t' \cdot (q^*r)$, $u\mathcal{Q}t'' \cdot (q^*r)$, and $u'\mathcal{Q}t' \cdot (q^*r)$.

(b) Second, $t \longrightarrow\!\!\!\!\!\rightarrow t'' \xrightarrow{\alpha} \surd$, for some $t'' \in \mathcal{C}(\text{PTNA}^\tau)$ such that $u\mathcal{R}^+ t'' \cdot p$ and $u'\mathcal{R}^+ p$. It follows that $v \equiv t \cdot (q^*r) \longrightarrow\!\!\!\!\!\rightarrow t'' \cdot (q^*r) \xrightarrow{(\alpha)} q^*r$, $u\mathcal{Q}t'' \cdot (q^*r)$, and $u'\mathcal{Q}q^*r$.

(c) Third, $t \longrightarrow\!\!\!\!\!\rightarrow \surd$ and $p \longrightarrow\!\!\!\!\!\rightarrow p'' \xrightarrow{(\alpha)} p'$, for some $p', p'' \in \mathcal{C}(\text{PTNA}^\tau) \cup \{\surd\}$ such that $u\mathcal{R}^+ p''$ and $u'\mathcal{R}^+ p'$. In this case, the proof proceeds along the lines of case *ii)* immediately above.

The above three cases show that for any $\alpha \in \mathcal{A}ct$ and $u, u', v \in \mathcal{C}(\text{PTNA}^\tau) \cup \{\surd\}$, such that $u \xrightarrow{\alpha} u'$ and $u\mathcal{Q}v$, there exist $v', v'' \in \mathcal{C}(\text{PTNA}^\tau) \cup \{\surd\}$ such that $v \longrightarrow\!\!\!\!\!\rightarrow v'' \xrightarrow{(\alpha)} v'$, $u\mathcal{Q}v''$, and $u'\mathcal{Q}v'$.

Third, assume that for any $\alpha \in \mathcal{A}ct$ and $u, v, v' \in \mathcal{C}(\text{PTNA}^\tau) \cup \{\surd\}$, $v \xrightarrow{\alpha} v'$ and $u\mathcal{Q}v$. It must be shown that there exist $u', u'' \in \mathcal{C}(\text{PTNA}^\tau) \cup \{\surd\}$ such that $u \longrightarrow\!\!\!\!\!\rightarrow u'' \xrightarrow{(\alpha)} u'$, $u''\mathcal{Q}v$, and $u'\mathcal{Q}v'$. Using the definition of $\mathcal{Q}$, as before, three cases can be distinguished.

i) First, $u\mathcal{R}^+ v$. Since $\mathcal{R}^+$ is a rooted branching bisimulation, the desired result follows immediately.

ii) Second, $v \equiv q^*r$ and $u\mathcal{R}^+ p$. Since $p\mathcal{R}q \cdot p + r$ and $\mathcal{R}$ satisfies the root condition for p and $q \cdot p + r$, three cases can be distinguished.

(a) First, $q \xrightarrow{\alpha} q' \in \mathcal{C}(\text{PTNA}^\tau)$ and $p \xrightarrow{\alpha} p' \in \mathcal{C}(\text{PTNA}^\tau) \cup \{\surd\}$ such that $p'\mathcal{R}q' \cdot p$. Since $u\mathcal{R}^+ p$, it follows that $u \longrightarrow\!\!\!\!\!\rightarrow u'' \xrightarrow{(\alpha)} u'$, for some $u', u'' \in \mathcal{C}(\text{PTNA}^\tau) \cup \{\surd\}$ such that $u''\mathcal{R}^+ p$, and $u'\mathcal{R}^+ p'$. Hence, it follows from $v \equiv q^*r \xrightarrow{\alpha} q' \cdot (q^*r) \equiv v'$ and $u'\mathcal{R}^+ p'\mathcal{R}q' \cdot p$ that $u''\mathcal{Q}v \equiv q^*r$, and $u'\mathcal{Q}v' \equiv q' \cdot (q^*r)$.

(b) Second, $q \xrightarrow{\alpha} \surd$ and $p \xrightarrow{\alpha} p' \in \mathcal{C}(\text{PTNA}^\tau) \cup \{\surd\}$ such that $p'\mathcal{R}p$. Since $u\mathcal{R}^+ p$, it follows that $u \longrightarrow\!\!\!\!\!\rightarrow u'' \xrightarrow{(\alpha)} u'$, for some $u', u'' \in \mathcal{C}(\text{PTNA}^\tau) \cup \{\surd\}$ such that $u''\mathcal{R}^+ p$, and $u'\mathcal{R}^+ p'$. Hence, it follows from $v \equiv q^*r \xrightarrow{\alpha} q^*r \equiv v'$ and $u'\mathcal{R}^+ p'\mathcal{R}p$ that $u''\mathcal{Q}v \equiv q^*r$, and $u'\mathcal{Q}v' \equiv q^*r$.

(c) Third, $r \xrightarrow{\alpha} r' \in \mathcal{C}(\text{PTNA}^\tau) \cup \{\surd\}$ and $p \xrightarrow{\alpha} p' \in \mathcal{C}(\text{PTNA}^\tau) \cup \{\surd\}$ such that $p'\mathcal{R}r'$. Since $u\mathcal{R}^+ p$, it follows that $u \longrightarrow\!\!\!\!\!\rightarrow u'' \xrightarrow{(\alpha)} u'$, for some $u', u'' \in \mathcal{C}(\text{PTNA}^\tau) \cup \{\surd\}$ such that $u''\mathcal{R}^+ p$, and $u'\mathcal{R}^+ r'$. Hence, it follows from $v \equiv q^*r \xrightarrow{\alpha} r' \equiv v'$ that $u''\mathcal{Q}v \equiv q^*r$, and $u'\mathcal{Q}v' \equiv r'$.

iii) Third, $v \equiv t \cdot (q^*r)$ and $u\mathcal{R}^+ t \cdot p$, for some $t \in \mathcal{C}(\text{PTNA}^\tau)$. Two cases can be distinguished.

(a) First, $t \xrightarrow{\alpha} t' \in \mathcal{C}(\text{PTNA}^\tau)$. Since $u\mathcal{R}^+t \cdot p$, there exist $u', u'' \in \mathcal{C}(\text{PTNA}^\tau) \cup \{\surd\}$ such that $u \twoheadrightarrow u'' \xrightarrow{(\alpha)} u'$, $u''\mathcal{R}^+t\cdot p$, and $u'\mathcal{R}^+t'\cdot p$. Hence, it follows from $v \equiv t \cdot (q^* r) \xrightarrow{\alpha} t' \cdot (q^* r) \equiv v'$ that $u''\mathcal{Q}v \equiv t \cdot (q^* r)$, and $u'\mathcal{Q}v' \equiv t' \cdot (q^* r)$.

(b) Second, $t \xrightarrow{\alpha} \surd$ Since $u\mathcal{R}^+t\cdot p$, there exist $u', u'' \in \mathcal{C}(\text{PTNA}^\tau)\cup\{\surd\}$ such that $u \twoheadrightarrow u'' \xrightarrow{(\alpha)} u'$, $u''\mathcal{R}^+t\cdot p$, and $u'\mathcal{R}^+p$. Hence, it follows from $v \equiv t\cdot(q^*r) \xrightarrow{\alpha} q^*r \equiv v'$ that $u''\mathcal{Q}v \equiv t\cdot(q^*r)$, and $u'\mathcal{Q}v' \equiv q^*r$.

The above three cases show that for any $\alpha \in \mathcal{A}ct$ and $u, v, v' \in \mathcal{C}(\text{PTNA}^\tau) \cup \{\surd\}$ such that $v \xrightarrow{\alpha} v'$ and $u\mathcal{Q}v$, there exist $u', u'' \in \mathcal{C}(\text{PTNA}^\tau) \cup \{\surd\}$ such that $u \twoheadrightarrow u'' \xrightarrow{(\alpha)} u'$, $u''\mathcal{Q}v$, and $u'\mathcal{Q}v'$.

Finally, for any $u, v \in \mathcal{C}(\text{PTNA}^\tau) \cup \{\surd\}$ such that $u\mathcal{Q}v$, it must be shown that $u \twoheadrightarrow \surd \Leftrightarrow v \twoheadrightarrow \surd$. As before, three cases can be distinguised.

i) First, $u\mathcal{R}^+v$. Since $\mathcal{R}^+$ is a rooted branching bisimulation, the desired result follows immediately.

ii) Second, $v \equiv q^* r$ and $u\mathcal{R}^+p$. Assume $u \twoheadrightarrow \surd$. Since $u\mathcal{R}^+p\mathcal{R}q\cdot p + r$, $q\cdot p + r \twoheadrightarrow \surd$. Since q is a guard, Lemma B.1 yields that $r \twoheadrightarrow \surd$. Hence, $v \equiv q^* r \twoheadrightarrow \surd$. Assume $v \equiv q^* r \twoheadrightarrow \surd$. This implies that $r \twoheadrightarrow \surd$. Since $u\mathcal{R}^+p\mathcal{R}q\cdot p + r$, $u \twoheadrightarrow \surd$.

iii) Third, $v \equiv t \cdot (q^* r)$ and $u\mathcal{R}^+t \cdot p$, for some $t \in \mathcal{C}(\text{PTNA}^\tau)$. Assume $u \twoheadrightarrow \surd$. Since $u\mathcal{R}^+t \cdot p$, $t \twoheadrightarrow \surd$ and $p \twoheadrightarrow \surd$. Since $p\mathcal{R}q\cdot p + r$, using the same argument as in the previous case, it follows that $r \twoheadrightarrow \surd$. Since also $t \twoheadrightarrow \surd$, $v \equiv t\cdot(q^*r) \twoheadrightarrow \surd$. Assume $v \equiv t\cdot(q^*r) \twoheadrightarrow \surd$. Therefore, $t \twoheadrightarrow \surd$ and $r \twoheadrightarrow \surd$. Since $p\mathcal{R}q\cdot p + r$, also $p \twoheadrightarrow \surd$. Finally, it follows from $u\mathcal{R}^+t\cdot p$ that $u \twoheadrightarrow \surd$.

These two cases show that also the last requirement of a branching bisimulation is satisfied, which concludes the proof of the validity of *RSP**. □
