**Abstract** We present for the first time 160Gb/s all-optical contention resolution with prioritization using integrated photonic devices. Error-free operation verifies that complex photonic systems are possible and could play a central role in future high-capacity networks.

## Introduction

The realization of advanced photonic integrated components has fuelled new research for realizing more advanced and larger all-optical processing systems [1,2]. Driven by the potential for larger integration scale, smaller footprint and lower power consumption of photonics, research now turns to the design of novel architectures and the implementation of all-optical processing systems. These novel architectures would allow to perform more complex network functionalities serially, on the fly and at bit-rates not possible by electronics. In this paper we present an optical circuit capable of resolving contention in space and wavelength domain between 160 Gb/s packets at the same wavelength  $\lambda_1$ , also taking into account priority flags embedded into optical labels. Packet priority information is transmitted alongside with the packets at  $\lambda_2$  (pulse = high, no\_pulse = low priority) and can be in-band with the data increasing the overall bandwidth utilization [2]. The system operates at 160Gb/s, does not require any electronics and performs all processing on-the-fly. The circuit was implemented by fiber-interconnecting photonic integrated devices, making the system integrable using hybrid integration of III-V with Silica-on-Silicon platform. Due to the use of packet-level signal processing and high-speed wavelength conversion [3] the bit-rate could be extended to rates >320 Gb/s.

Fig. 1 shows the functional diagram of the circuit, consisting of two 1x2 switches (Switch\_1 and 2), an Optical Flip-Flop (OFF), a Packet Envelope Detection circuit (PED) and a 160 Gb/s all-optical Wavelength Converter (WC). Packet A enters the circuit from input 1 and its priority flag is extracted using narrowband optical filtering. The extracted label is fed to the OFF to generate an optical pulse at  $\lambda_3$  with length slightly higher than the data packets. This signal is used to control the state of Switch\_1 and route packet B: In the presence of  $\lambda_3$  (i.e. packet A has priority) packet

B exits from output\_2 of Switch\_1 and thus is routed to O/P1 ("contention" port), otherwise packet B exits from output\_1 and thus from O/P2 (main output). Output\_1 of Switch\_1 is split and introduced to the PED circuit generating packet envelope signals at  $\lambda_4$ . The PED output is used to control Switch\_2 so that packet A is routed to output\_3 and exits from O/P1 when the PED is on (ie. packet B exists and packet A has low priority), otherwise packet A is routed to output\_4 and exits from O/P2. Outputs 1 and 4 of the 1x2 switches are combined to the circuit output (O/P2) whereas outputs 2 and 3 are combined to point 5 thus resolving the contention in the space domain. Contention resolution in the wavelength domain is performed by wavelength converting the data packets appearing at point 5 to wavelength  $\lambda_5$ .

## Experimental setup and results

Fig. 2 shows the circuit experimental setup. A 10 GHz mode-locked laser generated 1.8ps pulses that were modulated into data packets containing a  $2^7-1$  PRBS pattern. This signal was rate-multiplexed to 160Gb/s in a fiber multiplexer and generated a sequence of three data packets with 52ns duration followed by an empty packet slot. This signal was split in 2 parts to provide the 2 incoming packet streams. Packet stream A was combined with the priority flag and was delayed by 90ns with respect to packet stream B (Fig. 3(a,b)). The priority flag was generated in a second modulator and had 1.6ns duration. Packet stream A was separated from the priority flag using an optical filter. The extracted flag was split in 2 parts separated

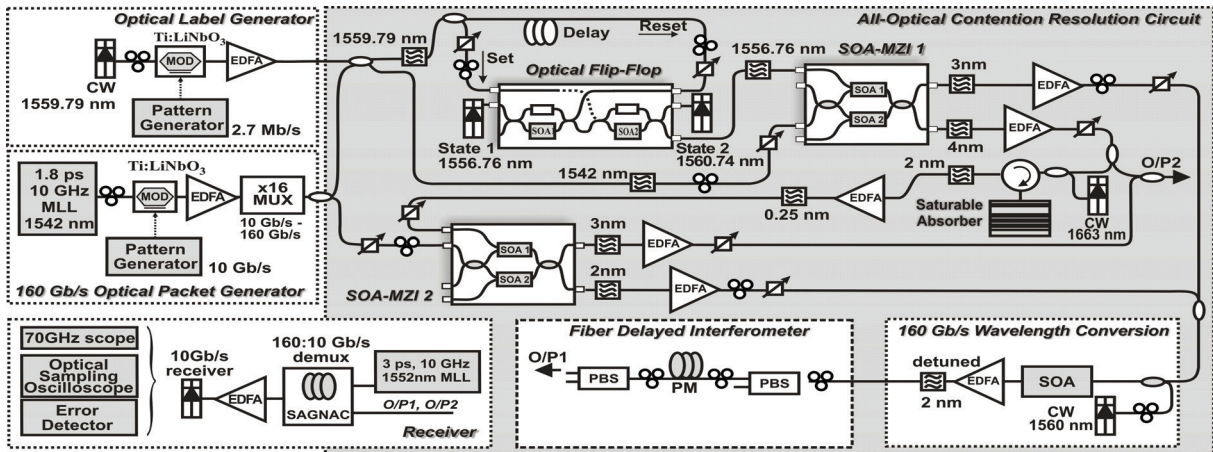

Figure 2: Experimental set-up.

by 60ns to provide the Set and Reset signals for the OFF, which generated 60ns pulses with 1.4dB fluctuation (Fig 3(c)). In parallel, packet streams A and B were introduced to Switch\_2 and Switch\_1 respectively. Both switches were hybridly integrated SOA – Mach-Zehnder Interferometers and were biased with co-propagating assist CW beams to reduce the SOA ASE. Output\_1 of Switch\_1 was introduced to the PED circuit, consisting of a passive slow saturable absorber-based vertical-cavity semiconductor gate powered by a 1564nm CW [4]. Output pairs 1,4 and 2,3 were time-synchronized and

combined at the main output and contention output respectively (Fig. 3(k,j)). The contention output was combined with a 1560nm CW and was launched in the WC, consisting of a 1.1mm long SOA followed by a 1.5nm filter and a delayed interferometer (Fig 3(i,l)). The 160Gb/s streams were demultiplexed to 10Gb/s in a Sagnac optical switch and the BER performance of the 10Gb/s tributary channels was evaluated. Fig. 4 shows the BER of the input, O/P1 and O/P2 demultiplexed signals as well as the corresponding eye diagrams. The obtained power penalties were 4.5dB and 7.8dB at O/P2 and O/P1 at log(BER)=10-9.

Figure 3 Experimental results. (a) Packet A, (b) packet B, (c) OFF (d) output\_2, (e) output\_1, (f) PED, (g) output\_3, (h) output\_4, (j) low-priority contending packets (output\_5), (k) O/P2, (i) SOA-filter output (inverting WC) and (l) WC output (O/P1). Time scale: 38 ns/div

**Conclusions**

We present 160Gb/s contention resolution in space and wavelength domain with prioritization. The circuit includes photonic integrated devices, verifying the potential of photonics in large-scale systems-on-chip.
