Publisher's PDF, also known as Version of Record (includes final page, issue and volume numbers)

Please check the document version of this publication:

- A submitted manuscript is the version of the article upon submission and before peer-review. There can be important differences between the submitted version and the official published version of record. People interested in the research are advised to contact the author for the final version of the publication, or visit the DOI to the publisher's website.
- The final author version and the galley proof are versions of the publication after peer review.
- The final published version features the final layout of the paper including the volume, issue and page numbers.

Biomedical Engineering, Eindhoven University of Technology, Eindhoven, Netherlands

ABSTRACT

Calcium is the main regulator of skeletal muscle metabolic activity. The question has been addressed whether the highly structured spatial organization of sites of Ca²⁺ release, uptake and action in skeletal muscle substantially impacts the dynamics of cytosolic Ca²⁺ handling and thereby the physiology of the cell. Hereto, the spatiotemporal dynamics of the free calcium distribution in a fast-twitch muscle sarcomere was studied using a reaction-diffusion computational model.

The model was based on the model of Baylor and Hollingworth (*J Gen Physiol*. 1998 112:297-316), but was adapted to handle local calcium dynamics in mouse EDL fast twitch muscle at 35°C. Furthermore, the Ca²⁺ mass balance was closed by adding a mathematical representation of the sarcoplasmic reticulum. Experimental calcium time courses (high time resolution, but spatially averaged) obtained under physiological conditions (35°C, 125 Hz stimulation frequency) were used for model validation.

The model showed that subtle changes in sarcomere microstructure influenced the local calcium concentration. Furthermore, local calcium concentration sensed by mitochondria was higher than average calcium concentration and also above the activation constant of the mitochondria, whereas the local concentration was not. Furthermore, the free Ca²⁺ concentration was higher at the positions with troponin C than without troponin C.
