Publisher's PDF, also known as Version of Record (includes final page, issue and volume numbers)

Please check the document version of this publication:

- A submitted manuscript is the version of the article upon submission and before peer-review. There can be important differences between the submitted version and the official published version of record. People interested in the research are advised to contact the author for the final version of the publication, or visit the DOI to the publisher's website.
- The final author version and the galley proof are versions of the publication after peer review.
- The final published version features the final layout of the paper including the volume, issue and page numbers.

EXPERIMENTAL INVESTIGATION OF THE EFFECT OF GAS PERMEATION THROUGH VERTICAL MEMBRANE ON THE ONSET OF TRANSITION VELOCITY FROM BUBBLING TO TURBULENT REGIME IN FLUIDIZED BED**Congress:** ECCE10**Topic:** Chemical reaction engineering**Presenting author:** Solomon Assefa Wassie**Authors and affiliations :** Solomon Assefa Wassie:Department of Energy and Process Engineering,Norwegian University of Science and Technology,Trondheim,Norway;Department of Chemical Engineering and Chemistry,Eindhoven University of Technology,Eindhoven,Netherlands|Abdelghafour Zaabout:SINTEF Materials and Chemistry,Flow Technology ,Trondheim,Norway|Schalk Cloete:SINTEF Materials and Chemistry,Flow Technology ,Trondheim,Norway|Fausto Gallucci:Department of Chemical Engineering and Chemistry,Eindhoven University of Technology,Eindhoven,Netherlands|Martin Van Sint Annaland:Department of Chemical Engineering and Chemistry,Eindhoven University of Technology,Eindhoven,Netherlands|Shahriar Amini:SINTEF Materials and Chemistry,Flow Technology ,Trondheim,Norway;Department of Energy and Process Engineering,Norwegian University of Science and Technology,Trondheim,Norway**Abstract:**

Membrane-assisted (MA) fluidized beds have recently emerged as a cutting-edge technology for intensification of a number of industrial chemical processes. MA-fluidized bed reactors combine the benefits of the separation properties of membranes and the advantages of fluidized bed reactors known for their excellent heat and mass transport characteristics; the presence of membranes maximises the volumetric production rate by reducing equilibrium limitations. Hydrogen production from methane reforming is one of the main applications of MA-fluidized beds. Particularly, the Chemical Switching Reforming (CSR) (figure 1) reactor concept has recently been introduced as a promising reactor concept for cost effective pure hydrogen production from steam-methane reforming with integrated CO₂ separation. CSR operates under transient behaviour where methane/steam and air are alternatively fed into a single reactor with a bed of oxygen carrier material (which acts both as a catalyst and heat carrier) in order to directly convert methane to high-purity H₂. This is achieved through the insertion of hydrogen perm-selective membranes into the reactor, which extract the produced H₂ while simultaneously shifting the steam reforming and water-gas shift reactions equilibria towards complete conversion. Relative to conventional chemical looping configurations, CSR offers simpler process design, scale-up and operation, especially under the pressurized conditions required by membrane reactors.

Understanding the effect of vertically inserted membranes on the hydrodynamic behaviour of the fluidized bed reactor is of high importance for the design and optimization of the CSR process. This work presents the experimental results of the effect of gas extraction through vertically inserted membranes on the transition velocity from bubbling to turbulent fluidization regime. A pseudo 2D experimental setup (figure 2) is used where a multi-chamber area with porous plates on the front was constructed and mounted at the bottom of the back plate in order to simulate vertical membranes. Gas can be extracted in specific areas on the back of the set-up through vertically mounted porous plates, thus the influence of the gas extraction, membrane configuration, and particle sizes on the onset of transition gas superficial velocity from bubbling to turbulent fluidization regime is investigated. Absolute and differential pressure fluctuations measured using fast pressure transducers mounted at different heights of the bed are employed to determine the transition velocity. In addition, local solid volume fraction and bubble behaviour determined using the DIA (Digital Image Analysis) technique is employed to highlight the differences in the bed behaviour in the two fluidization regimes.
