Abstract

Background: Producing, distributing or discussing child sexual abuse materials (CSAM) is often committed through the dark web in order to remain hidden from search engines and regular users. Additionally, on the dark web, the CSAM creators employ various techniques to avoid detection and conceal their activities. The large volume of CSAM on the dark web presents a global social problem and poses a significant challenge for helplines, hotlines and law enforcement agencies.

Objective: Identifying CSAM discussions on the dark web and uncovering associated metadata insights into characteristics, behaviours and motivation of CSAM creators.

Participants and Setting: We have conducted an analysis of more than 353,000 posts generated by 35,400 distinct users and written in 118 different languages across eight dark web forums in 2022. Out of these, approximately 221,000 posts were written in English and contributed by around 29,500 unique users.

Method: We propose a CSAM detection intelligence system. The system uses a manually labelled dataset to train, evaluate and select an efficient CSAM classification model. Once we identify CSAM creators and victims through CSAM posts on the dark web, we proceed to analyze, visualize and uncover information concerning the behaviors of CSAM creators and victims.

Result: The CSAM classifier, based on Support Vector Machine model, exhibited good performance, achieving the highest precision of 92.3%, accuracy of 87.6% and recall of 84.2%. Its prediction time is fast, taking only 0.3 milliseconds to process a single post on our laptop. While, the Naive Bayes combination is the best in term of recall, achieving 89%, and its prediction time is just 0.1 microseconds per post. Across the eight forums in 2022, our Support Vector Machine model detected around 63,000 English CSAM posts and identified near 10,500 English CSAM creators. The analysis of metadata of CSAM posts revealed meaningful information about CSAM creators and their victims, such as: (1) the ages and nationalities of the victims typically mentioned by CSAM creators, (2) forum topics where the CSAM creators assign their posts, and (3) online platforms preferred by CSAM creators for sharing or uploading CSAM.

Conclusion: Our CSAM detection system exhibits high performance in precision, recall, and accuracy in real-time when classifying CSAM and non-CSAM posts. Additionally, it can extract and visualize valuable and unique insights about CSAM creators and victims by employing advanced statistical methods. These insights prove beneficial to our partners, i.e. national hotlines and child agencies.

Keywords: Child sexual abuse material, forums, artificial intelligence, child victim, abuser

1. Introduction

Child Sexual Abuse Material (CSAM) encompasses various forms of visual, written or audio content that depicts or describes sexual abuse of children. This can include photographs, videos, stories, chats, comments, drawings or any other form of media that portrays or discusses such abusive acts.¹ The production and distribution of CSAM have profound and detrimental impacts on both the victims and society as a whole. The victims of CSAM often endure long-lasting psychological, emotional, and physical harm as a result of the abuse they have experienced [Ngo et al. \(2022\)](#). A high volume of CSAM is generated and shared on a daily basis, not only on surface web platforms like social network sites but also within dark web forums. The sheer volume of this content makes it impractical for human experts to manually investigate, detect, and prevent CSAM effectively [Lee et al. \(2020\)](#). Indeed, automatically detecting and analysing online CSA text poses significant challenges and can be an exceedingly time-consuming task, due to language complexity, contextual ambiguity, dynamic nature of language and large volume of data. The challenges are particularly pronounced when it comes to CSAM shared in the dark web. The dark web prioritizes privacy and anonymity, making it a breeding ground for illicit activities, including the dissemination of CSAM. In addition, CSAM creators on the dark web employ various techniques to evade detection and conceal their activities. They may resort to using code words, slang, or other forms of obfuscation to camouflage their communication and intentions. This deliberate effort to disguise their actions adds another layer of complexity to the detection and analysis process. Efforts to combat CSAM in the dark web necessitate ongoing research and development of advanced technologies, collaboration between law enforcement agencies and technology experts.

In this context, we propose a CSAM detection intelligence system based on Machine Learning (ML) or Deep Learning (DL) techniques. Our system aims to address the challenges associated with detecting CSAM, particularly in real-time, while ensuring a high level of precision and recall. By accomplishing this, we can significantly improve the protection of children from harmful content online. To achieve an accurate and effective CSAM detection intelligence system, we have created a manually labeled dataset that includes both CSAM and non-CSAM content. This dataset serves as a crucial resource in building and refining the classification model of the system, ensuring it performs at its best to detect CSAM posts and non-CSAM posts in the dark web. Our system holds tremendous potential as it goes beyond merely detecting CSAM and the CSAM creators responsible for creating such content. It can also identify CSAM creators' behaviors, gather critical forensic evidence, and extract valuable insights. These capabilities will be invaluable to various stakeholders, including child protection agencies, hotlines, educational programs, law enforcement agencies, and policy makers. By delivering comprehensive and actionable information, our model aims to make a substantial contribution to the fight against CSAM, actively working to safeguard children from online harm. Its implementation can play a pivotal role in creating a safer digital environment for our young people.

The remainder of the paper is organised as follows. In Section 2, we review the related work. Section 3 outlines how we collected the dark web data and describes our system architecture. Section 4 presents the ML and DL algorithms, training and testing datasets, evaluation methodology, and experimental results for CSAM detection model of the system. In Section 5, we focus on quantitative information extraction and discussion about CSAM creators, victims and social media platforms mentioned in CSAM posts. Finally, we conclude and offer some future directions in Section 6.

2. Related Work

Disturbingly, there is a significant distribution of videos, images, and text depicting or discussing children engaged in sexual activities across the internet. To address this issue, research works [Gangwar et al. \(2021\)](#), [Guerra and Westlake \(2021\)](#), [Vitorino et al. \(2018\)](#), [Laranjeira et al. \(2022\)](#) and [Struppek et al. \(2022\)](#) applied deep convolutional neural network models or deep perceptual hashing algorithms with the goal of removing CSAM from social media sites. With the exception of [Gangwar et al. \(2021\)](#), papers [Guerra and Westlake \(2021\)](#), [Vitorino et al. \(2018\)](#), [Laranjeira et al. \(2022\)](#) and [Struppek et al. \(2022\)](#) used datasets from third-parties to train and test their models. However, these papers only considered CSA images and not text. Similar to our work, research works [Islam et al. \(2020\)](#), [Borj et al. \(2021\)](#), [Akhter et al. \(2022\)](#), [Cecillon et al. \(2021\)](#) and [Ngejane et al. \(2021\)](#) applied ML and DL models to process CSA text. In [Islam et al. \(2020\)](#), Naive Bayes (NB), Support Vector Machine (SVM) and Random Forest (RF) were applied to detect online abusive and bullying comments on Facebook and Twitter. In [Borj et al. \(2021\)](#), the histogram gradient boosted decision trees were exploited for predatory chat conversation detection. In [Akhter et al. \(2022\)](#), Convolutional Neural Network (CNN) and Long Short Term Memory (LSTM) were applied for YouTube comments. In [Cecillon et al. \(2021\)](#), deepWalk model and graph embedding representations were used to detect abuse chat logs in French on the SpaceOrigin game. In [Ngejane et al. \(2021\)](#), Logistic Regression (LR), XGBoost and Multi Layer Perceptron (MLP) were exploited to detect sexual predatory chats in social networks. To train and test ML/DL models, the papers [Islam et al. \(2020\)](#) and [Cecillon et al. \(2021\)](#) created their own datasets and the papers [Borj et al. \(2021\)](#), [Akhter et al. \(2022\)](#) and [Ngejane et al. \(2021\)](#) used datasets of third-parties. However, these papers considered the clear web, not the dark web.

Challenging more than the clear web, the dark web not only contains complex and unclear data, but it is also difficult to access. The papers [Owen and Savage \(2015\)](#), [Schäfer et al. \(2019\)](#), [Kokolaki et al. \(2020\)](#), [Nazah et al. \(2021\)](#) and [Woodhams et al. \(2021\)](#) processed the dark web data in text format. However, the approaches did not automatically detect CSA text in the dark web by using post contents and artificial intelligence. In [Owen and Savage \(2015\)](#), the 450 authorised hidden service sites were manually classified. In [Schäfer et al. \(2019\)](#), the authors analysed seven popular dark web sites to monitor the sites by using their metadata, e.g. the number of users, site names and common users in sites. In [Kokolaki et al. \(2020\)](#), the authors statistically analysed some simple metadata e.g. victim ages and the number of CSAM reports per year. In [Nazah et al. \(2021\)](#), K-Means algorithm was applied to cluster the forum comments into the selected seven labels, i.e. breach, financial, drug, vendor, account, product and other. In [Woodhams et al. \(2021\)](#), the authors manually analysed transcripts of 53 anonymous suspects in United Kingdom to understand suspects' interaction behaviors and sexual interests.

3. Method

3.1. Collecting Data on the Dark Web

In order to gain insights into CSAM in the dark web, our N-Light project has established a collaboration with Hotline.ie and Web-IQ. Web-IQ has developed the DarkCloud system² specifically designed for the detection, investigation, and monitoring of the hidden areas of the internet. This system efficiently collects and organizes cached pages from dark web forums involved in CSAM sharing. The collected data is then stored in an ATLAS dataset for further analysis and research purposes. Hotline.ie has received the ATLAS dataset from Web-IQ and subsequently transferred it to the N-Light project.

The ATLAS dataset encompasses a vast array of valuable information regarding posts within the dark web. This includes the text content of the posts, timestamps indicating when they were created, the language used in the posts, the names of the forums where the posts originated, the topics discussed within those forums, the online platforms mentioned in the posts, and even details about the nationalities of the victims mentioned in the posts. The information is very useful for various entities such as law enforcement,

²<https://web-iq.com/solutions/darkcloud>

government agencies, and educational institutions. Specially, N-Light project can apply artificial intelligence algorithms to discover child sexual CSAM creators' behaviors and preferences.

In 2022, the ATLAS dataset comprised a total of 353,218 posts from eight distinct forums, namely *boyvids-V6*, *boysrus*, *amorzinho*, *resistance*, *nymphetomania*, *pedo-support*, *naughtykids*, and *pharos*. These forums and their corresponding post counts are presented in Figure 1. Among them, *boyvids-V6* has the most number of posts with 205,444 posts, approximately 58.3% of all posts from the eight forums. The next three forums, *boysrus*, *amorzinho* and *resistance*, have a similar number of posts, each comprising approximately 9% of the total. On the other hand, *pharos* only has 1,837 posts, approximately 0.5%. Out of the total 353,218 posts, Web-IQ successfully identified the languages used in 266,517 posts, covering 118 different languages. Among these detected posts, the distribution of the top 6 languages is as shown in Figure 2: English, Russian, Portuguese, Spanish, German and French. English has the highest number of posts, with 221,876 posts, approximately 83.25% of the identified posts. Russian ranks second, with 24,415 posts, accounting for approximately 9.16%, and French ranks the last, with only 775 posts, approximately 0.29%. In this paper, we solely focus on analyzing the 221,876 English posts (for more details, please refer to Section 5.1).

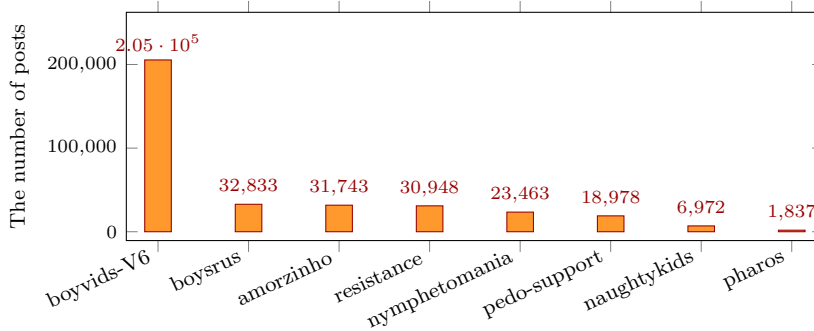

Figure 1: The number of posts of eight forums in 2022

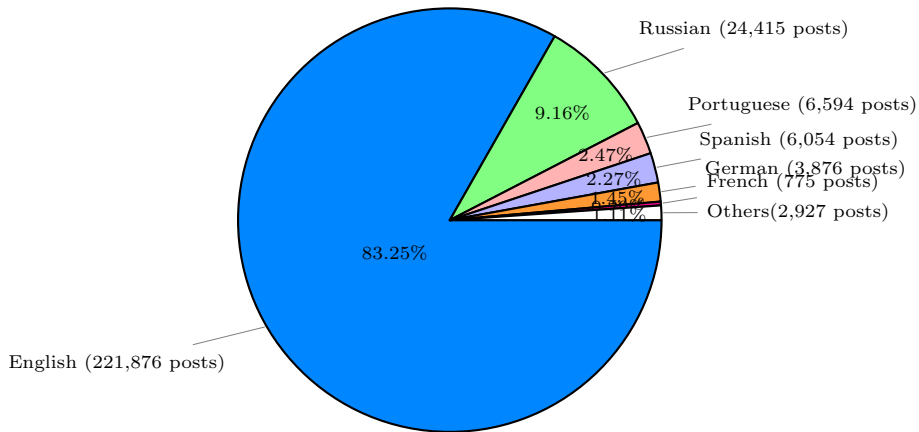

Figure 2: The number of posts of languages in 2022

3.2. System Architecture

Supervised learning in ML and DL models is a prevalent method for text classification, as it involves learning patterns from labeled training samples [Tran et al. \(2014\)](#); [Russell and Norvig \(2022\)](#); [Dang et al. \(2023\)](#). Each supervised learning algorithm possesses its own set of strengths and weaknesses. Therefore, to identify a suitable algorithm to classify CSAM post contents, we evaluate the three most popular classical

ML algorithms, NB, LR and SVM, alongside the three most popular DL algorithms, CNN, LSTM and BERT (Bidirectional Encoder Representations from Transformers). More comprehensive information about these algorithms can be found in Sections 4.1 and 4.2.

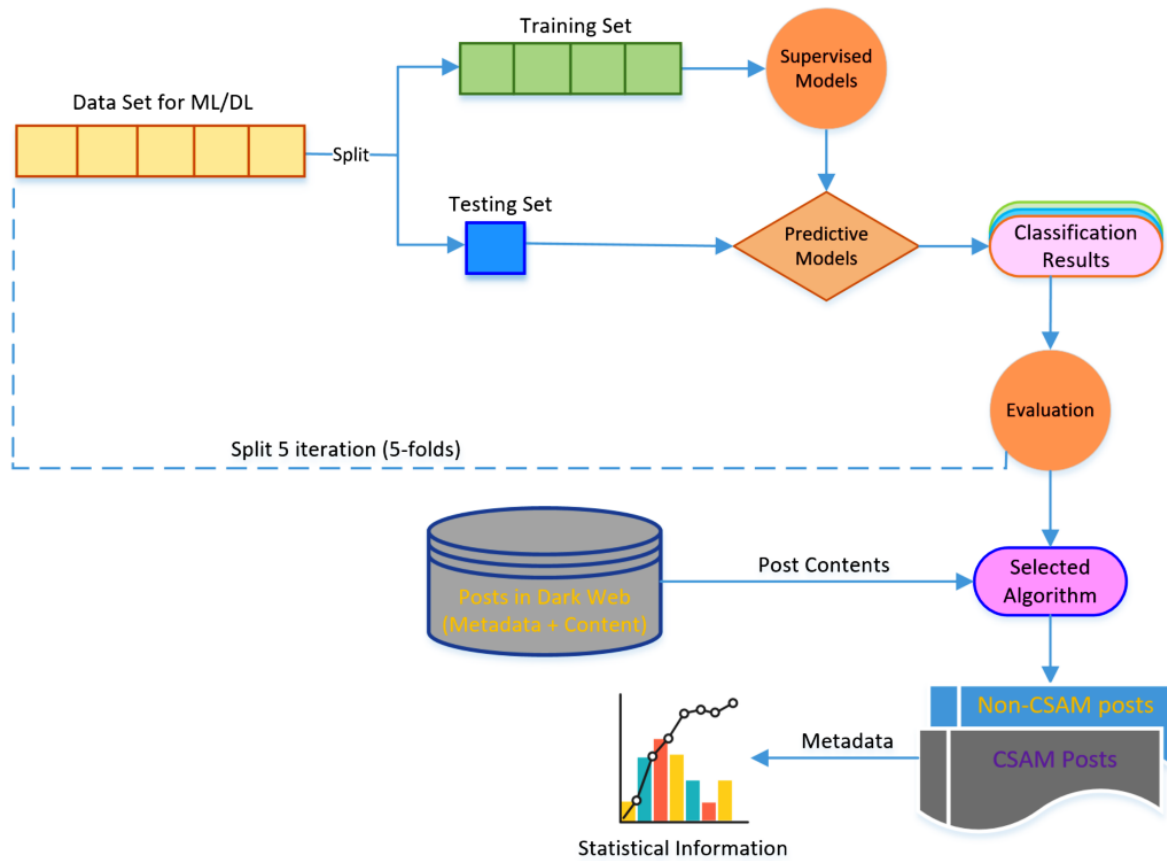

Figure 3: The architecture of the CSAM classification system

Figure 3 illustrates our system architecture, which is employed to design and implement our novel algorithm for CSAM text classification. Additionally, the system enables the analysis of CSAM posts to discover information related to CSAM creators and victims. In that, the **Supervised Models** component implements several ML and DL algorithms, including NB, LR, SVM, CNN, LSM and BERT algorithms. These algorithms tokenize the post texts and convert them into vector representation using TF.IDF³ in the case of NB, LR and SVM, and embedding layers⁴ for CNN, LSTM and BERT.

The **Evaluation** component serves the purpose of determining the execution times, including training time and prediction time, as well as the classification performance metrics, such as precision, recall, and accuracy, for each combination of algorithms. For more details about the metrics, please refer to Section 4.4. To mitigate the risk of overfitting, we employ a 5-fold cross-validation approach on our dataset. This involves dividing the dataset into five subsets or folds, where four folds are used for training the algorithm, and the remaining fold is used for testing. This process is repeated until each fold serves as the testing set. The recorded classification measures from five rounds are then averaged to obtain the algorithm’s classification performance measures. Finally, we analyse experimental results on the data set to determine the best algorithm for CSAM text classification on the dark web, and make recommendations based on these findings.

³https://scikit-learn.org/stable/modules/generated/sklearn.feature_extraction.text.TfidfVectorizer.html

⁴https://www.tensorflow.org/api_docs/python/tf/keras/layers/Embedding

Using our most effective CSAM classifier, posts in the dark web are categorized into two distinct sets: CSAM post set and non-CSAM post set, based on their contents. Along with the content itself, each CSAM post is accompanied by associated metadata, including factors such as (1) nationalities and ages of victims mentioned within the post’s content, (2) the specific forum topic where the post was uploaded under the appropriate topic of the forum, (3) any online platforms referenced within the post’s content, and (4) the unique identifier code of the individual who created the post, referred to as the CSAM creator’s ID. These metadata are then analyzed to uncover and visualize valuable information that can aid in CSAM prevention and investigation efforts.

4. CSAM Detection

4.1. Machine Learning Algorithms

NB is a specific type of probabilistic classifier that operates by applying Bayes’ theorem with certain simplifying assumptions. It finds extensive use in natural language processing, spam filtering, and other applications where categorizing items into different classes based on probabilistic features is essential. One key assumption of NB is that the features are strongly independent, which allows for simplified computations during classification. We employed the Gaussian Naive Bayes algorithm, implemented by using the library [Scikit-learn \(2023c\)](#), with the following parameters: $\alpha = 1$ and $fit_prior = \text{True}$. Here, α represents the additive smoothing parameter, and fit_prior determines whether to learn the prior probabilities of the classes or not.

Logistic Regression (LR) is a statistical model used to predict the probability of a binary outcome based on one or more independent variables (also called features). It works by transforming the linear combination of independent variables using a logistic function (also known as the Sigmoid function), which maps the linear output to a value between 0 and 1. We used the Logistic Regression implemented in [Scikit-learn \(2023b\)](#), with parameters: $penalty = 'l2'$ and $solver = 'lbfgs'$. Where, $penalty$ refers to a regularization technique that is applied to the model’s coefficients to prevent overfitting. The $solver$ term refers to the optimization algorithm used to estimate the optimal coefficients for the model.

The SVM algorithm represents patterns as points in space and effectively separates data points with a clear gap. It constructs a maximum margin separator, which maximizes the distance between the separating hyperplane and the nearest data points of each class. Additionally, SVM can handle non-linearly separable data by employing the "kernel trick." This technique allows SVM to transform the original feature space into a higher-dimensional space, where the data becomes linearly separable. By doing so, SVM can perform non-linear classification with accuracy and efficiency. We utilized the C-support vector classification algorithm, implemented by using the library [Scikit-learn \(2023a\)](#), with the following parameters: $C = 1.0$, $kernel = 'linear'$, $degree = 3$ and $gamma = 'auto'$. Where, C represents the regularization parameter and $kernel$ denotes the type of kernel used. The $degree$ term refers to the degree of the polynomial kernel function, while the $gamma$ term represents the kernel coefficient.

with no SAP and approximately 44,000 English posts containing at least one SAP. This provides us with a high level grouping of posts, but with refinement required to allow for CSAM posts that does not contain any SAPs, and vice versa. Figure 4 presents the word clouds of single words and two-word phrases related to sexual abuse, extracted from post contents in dark web forums. The size of each word in the clouds corresponds to its frequency within the forums.

From the group of 177,000 posts with no SAP, experts randomly selected 2,000 non-CSAM posts and 500 CSAM posts. Similarly, from the group of 44,000 posts with at least one SAP, experts randomly selected 2,000 CSAM posts and 100 non-CSAM posts. As a result, our manually labelled dataset comprises 4,600 posts from the dark web, consisting of 2,500 CSAM posts and 2,100 non-CSAM posts.

4.4. Experiment Setup and Quality Measures

The algorithms were implemented using Python 3.10. For LR, NB, and SVM, we used the scikit-learn library version 1.2.2. For CNN, LSTM, and BERT, we utilized the keras library version 1.1.2, running on top of the tensorflow library version 2.10.0. All experiments were run under Windows 10 (64-bit) on a Dell laptop with an Intel Core i7 CPU (3.00 GHz) and 16 GB memory.

For the purpose of measuring the quality of the predicted classes of posts compared to the correct classes, we apply the most commonly used metrics namely accuracy, precision and recall (Ngo et al. (2021a); Tharwat (2021)). The metrics are derived from four categories in the confusion matrix: True Positive (TP), False Positive (FP), True Negative (TN) and False Negative (FN) as follows:

- TP: Posts in which the algorithm predicted CSAM and the correct class was also CSAM.
- FP: Posts in which the algorithm predicted CSAM, but the correct class was non-CSAM.
- TN: Posts in which the algorithm predicted non-CSAM and the correct class was non-CSAM.
- FN: Posts in which the algorithm predicted non-CSAM, but the correct class was CSAM.

Accuracy (ACC) in binary classification is defined as a ratio between the correctly classified samples to the total number of samples: $ACC = \frac{TP+TN}{TP+FP+TN+FN}$. The accuracy puts the same emphasis on all these factors. However, when categorising pairs, there is usually a bias: it is much easier to identify true negatives correctly, due to their large number. So, we also look at the the precision $P = \frac{TP}{TP+FP}$ and the recall $R = \frac{TP}{TP+FN}$.

4.5. Experiment Results

Using the 5-fold cross-validation methodology, each experimental round includes a training set of 3,680 posts (2,000 CSAM and 1,680 non-CSAM) and a testing set of 920 posts (500 CSAM and 420 non-CSAM). Table 1 presents the average training time, average prediction time, average precision, average recall and average accuracy of six algorithm combinations as follows:

1. NB: The training time and prediction time were 0.5 and 0.001 seconds, respectively. The precision was 76.1%, recall was 89%, and accuracy was 78.8%.
2. LR: The training time and prediction time were 0.5 seconds and 0.4 milliseconds, respectively. The precision archived 91.4%, the recall rate was 85%, and accuracy reached 87.5%.
3. SVM: The training time and prediction time were recorded as 1.8 and 0.27 seconds, respectively. The algorithm demonstrated a precision of 92.3%, a recall of 84.2%, and an accuracy of 87.6%.
4. CNN: The training time and prediction time were recorded as 21.47 and 0.223 seconds, respectively. The precision achieved by the algorithm was 88.8%, with a recall rate of 85.4% and an accuracy of 86.2%.
5. LSTM: The training process took approximately 32.5 seconds, while the prediction time was recorded as 1.01 seconds. The precision achieved by the algorithm was 90.3%, with a recall rate of 85.6% and an accuracy of 87.2%.

6. BERT: The training process took a significant amount of time, specifically 4,261 seconds (or approximately 1 hour and 11 minutes), while the prediction time was 215.3 seconds (around 3.6 minutes). The precision achieved by BERT was 85.9%, with a recall rate of 83% and an accuracy of 83.4%.

Table 1: Average execution time and binary classification performance of the NB, LR, SVM, CNN, LSTM and BERT algorithms

Results	Algorithms					
	NB	LR	SVM	CNN	LSTM	BERT
Training time ¹	0.5	0.5	1.8	21.47	32.5	4,261
Prediction time ¹	0.001	0.0004	0.27	0.223	1.01	215.3
# True Positive	445	425	421	427	428	415
# False Positive	140	40	35	54	46	68
# True Negative	280	380	385	366	374	352
# False Negative	55	75	79	73	72	85
Precision	76.1%	91.4%	92.3%	88.8%	90.3%	85.9%
Recall	89%	85%	84.2%	85.4%	85.6%	83%
Accuracy	78.8%	87.5%	87.6%	86.2%	87.2%	83.4%

¹ second.

The combination of the LR algorithm has the fastest execution time, taking approximately 0.43 microseconds to detect a post (or roughly 0.4 milliseconds to detect 920 posts) based on our laptop’s capabilities. The NB algorithm follows as the second-best performing algorithm, with an average detection time of around 0.1 microseconds. The SVM algorithm comes in third place, taking approximately 0.3 milliseconds to detect a post. The DL algorithms have longer training and prediction times compared to the ML algorithms. These fast prediction times make our ML models well-suited for processing CSA text in real-time on social networks. Additionally, the ML models can run on edge devices with limited computational resources and power supply.

In terms of classification precision, the SVM combination performs the best with 92.3%. Following closely behind are LR and LSTM, ranked as the second and third-best performers with precision rates of 91.4% and 90.3% respectively. On the other hand, in terms of recall rate, the NB combination has the highest recall rate of 89%, followed by LSTM and CNN as the second and third-best performers with 85.6% and 85.4% respectively. When it comes to accuracy, SVM is the best with 87.6% which is slightly higher than LR and LSTM with accuracy rates of 87.5% and 87.2%. Among the listed algorithms, BERT exhibits the lowest recall rate of 83% and also has the second-lowest precision and accuracy rates, with values of 85.9% and 83.4% respectively, surpassing only the NB algorithm. This indicating that BERT is not suitable for binary classification of CSAM posts in the dark web. The DL models have a classification performance lower than the ML models. This could be due to our dataset being small, which is not suitable for DL models that typically require a large amount of data to achieve optimal performance.

NB aims to prioritize maximizing true positives, which proves valuable in the identification and removal of CSAM posts from online platforms. This proactive approach is crucial for protecting potential victims, as it helps prevent harmful content from spreading and reaching vulnerable individuals. On the other hand, SVM focuses on minimizing false positives, enabling the identification of CSAM posts to gather information about potential abusers and victims for investigative purposes. Investigators can use the algorithm’s results with more confidence to target and apprehend offenders, as well as to support efforts to rescue victims and prevent future abuse.

5. Quantitative Information Extraction and Discussion

5.1. Our Dark Web Data

We only analyse quantitative information of English posts for our paper. Therefore, when we refer to CSAM posts, non-CAM posts, or forum posts, we specifically mean English CSAM posts, English non-

CSAM posts, or English forum posts. The size of each forum on the dark web can be determined by the number of CSAM posts, forum posts, CSAM creators, victim nationalities described in the CSAM posts, online platforms mentioned in the CSAM posts and forum topics including the CSAM posts. All metrics for the crawled forums are presented in Table 2. In 2022, the eight forums on the dark web contained 63,008 CSAM posts, equivalent to 28.4% of 221,876 forum posts. These CSAM posts were created by 10,490 CSAM creators. Additionally, these CSAM posts referenced 119 victim nationalities, 110 platforms and 12 topics.

The three forums with the largest number of CSAM posts are `boyvids-V6`, `pedo-support` and `amorzinho` which contain 37,158, 8,458 and 6,338 CSAM posts out of 132,274, 18,617 and 21,588 forum posts, respectively. This corresponds to 28.1%, 45.4% and 29.4% of the percentages of the CSAM posts out of the forum posts of the respective forums. While, the three forums with the moderate number of CSAM posts are `resistance`, `boysrus` and `naughtykids` which contain 5,874, 4,079 and 917 CSAM posts out of 23,695, 18,166 and 5,508 forum posts, respectively. This corresponds to 24.8%, 22.5% and 16.6%, of the percentages of the CSAM posts out of the forum posts of the respective forums. The remaining two forums, `pharos` and `nymphetomania`, have the fewest CSAM posts. The `pharos` forum has 138 CSAM posts out of 1,641 forum posts (equivalent to 8.4%). The `nymphetomania` forum has 46 CSAM posts out of 387 forum posts (equivalent to 11.9%).

The number of CSAM creators and victim nationalities are 3,675 and 117 for `boyvids-V6`, 864 and 74 for `pedo-support`, 2,171 and 62 for `amorzinho`, 1,136 and 79 for `resistance`, 60 and 6 for `boysrus`, and 28 and 9 for `naughtykids`, respectively. In term of the number of platforms and topics, there are 100 and 8 for `boyvids-V6`, 68 and 2 `pedo-support`, 73 and 10 for `amorzinho`, 75 and 10 `resistance`, 60 and 6 for `boysrus`, and 28 and 9 for `naughtykids`, respectively. However, the remaining two forums, `pharos` and `nymphetomania`, have either a small number of or no available information regarding the number of CSAM creators, victim nationalities, platforms and topics.

Table 2: Statistical information of some metadata of 221,876 English posts of 8 dark web forums in 2022

Forum names	# CSAM posts ¹	# forum posts ²	% CSAM in forum ³	# CSAM creators ⁴	# victim nationalities ⁵	# platforms ⁶	# topics ⁷
boyvidsV6	37,158	132,274	28.1%	3,675	117	100	8
pedosupport	8,458	18,617	45.4%	864	74	68	2
amorzinho	6,338	21,588	29.4%	2,171	62	73	10

¹ The number of English CSAM posts.

² The number of all English posts in the forum which include English CSAM posts and English non-CSAM posts.

³ The percentage of the CSAM posts out of the forum posts.

⁴ The numbers of different CSAM creators writing, uploading or sharing the CSAM posts.

⁵ The numbers of different victim nationalities described in the CSAM posts.

⁶ The numbers of different online platforms mentioned in the CSAM posts. Online platforms refer to digital spaces or websites that facilitate various activities, interactions, or services over the internet.

⁷ The numbers of different forum topics containing CSAM posts.

5.2. CSAM Creator Profiles

Among 10,490 CSAM creators on the dark web in 2022, we have compiled data on the 20 most active CSAM creators. For our analysis, we have selected three informative classifications (Figures 5, 6 and 7) for discussion. Figure 5 presents the statistics on the number of CSAM posts and forum posts made by the 20 most active CSAM creators, along with the corresponding percentage relationship between the two. This information sheds light on the posting behavior of these individuals and provides insights into their activities. All of the identified CSAM creators belong to the forum group known for having the largest number of CSAM posts, namely `boyvids-V6`, `pedo-support` and `amorzinho`. Specifically, there are

16 CSAM creators associated with `boyvids-V6`, 3 CSAM creators associated with `pedo-support`, and 1 CSAM creator associated with `amorzinho`. The most active CSAM creator is identified as a creator within `boyvids-V6` with `id_10068` who posted 1,818 CSAM posts out of a total of 2,011 forum posts (equivalent to 91%). The identified CSAM creator within `amorzinho` is only the 3rd ranking in the number of CSAM posts, but his percentage of CSAM posts out of the total posts is the highest with 99%. While, the CSAM creator with ID `boyvids-V6:id_7931` has the lowest percentage of CSAM posts out of the total posts is lowest, at 23%, and is ranked 14th.

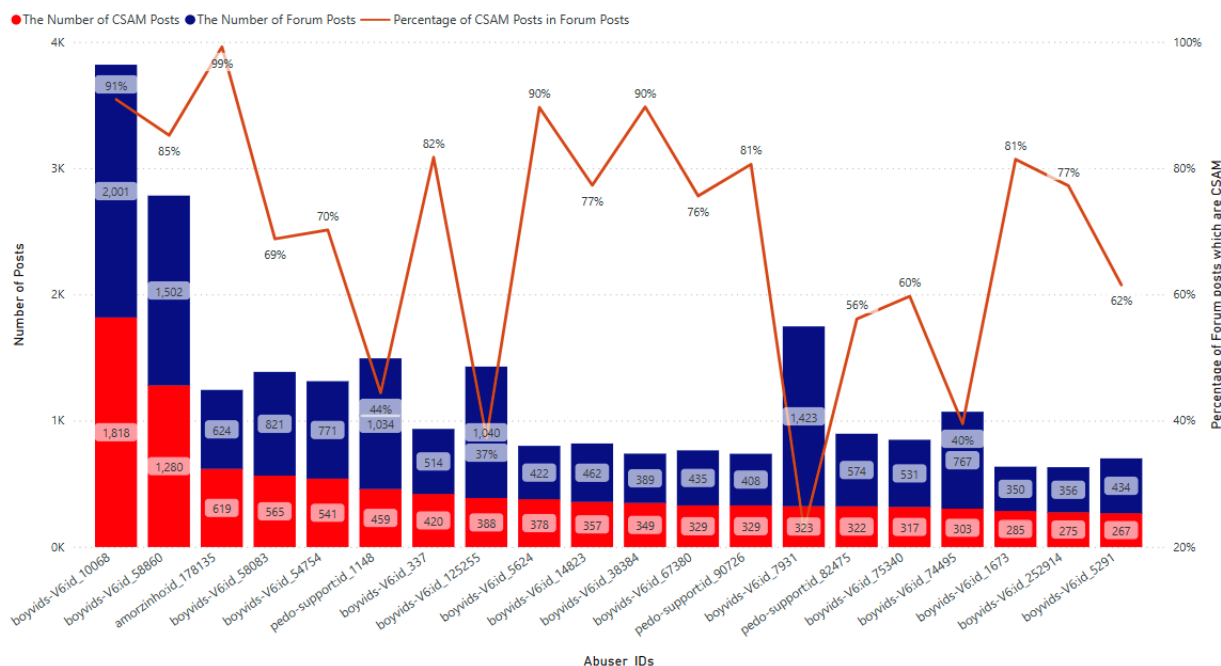

Figure 5: The number of CSAM posts and forum posts by the 20 most active CSAM creators in 2022

On the dark web, numerous forum topics are available where users can upload their posts under the appropriate topic. There are the 9 topics collected, namely `Chat`, `General`, `Girl`, `Hardcore`, `Photo`, `Softcore`, `Video`, `Webcam` and `Other`. In Figure 6, the percentages of CSAM posts out of forum topics of the top 20 CSAM creators are presented for each topic. The top-ranked CSAM creator, identified as `boyvids-V6:id_10068`, uploaded CSAM posts in a total of 7 topics. Notably, the percentages of CSAM posts out of forum topics in the `Video` and `Webcam` categories are 50% and 43% respectively. The second ranked CSAM creator, `boyvids-V6:id_58860`, and the third ranked CSAM creator, `amorzinho:id_178135`, uploaded CSAM posts in only 2 topics. In each of these topics, the percentage of CSAM posts out of forum topics was 50%. Specifically, `boyvids-V6:id_58860` utilized `Video` and `General` topics, while `amorzinho:id_178135` used `Girl` and `Webcam` topics. Among the remaining CSAM creators, it was observed that although they used multiple topics, they frequently focused on two specific topics. Among the top 20 CSAM creators, the most common topic for posting CSAM content was `Video`, followed by `Webcam` as the second most utilized topic.

Figure 6: Percentages of the CSAM posts in forum topics uploaded by the 20 most active CSAM creators of the topics in 2022

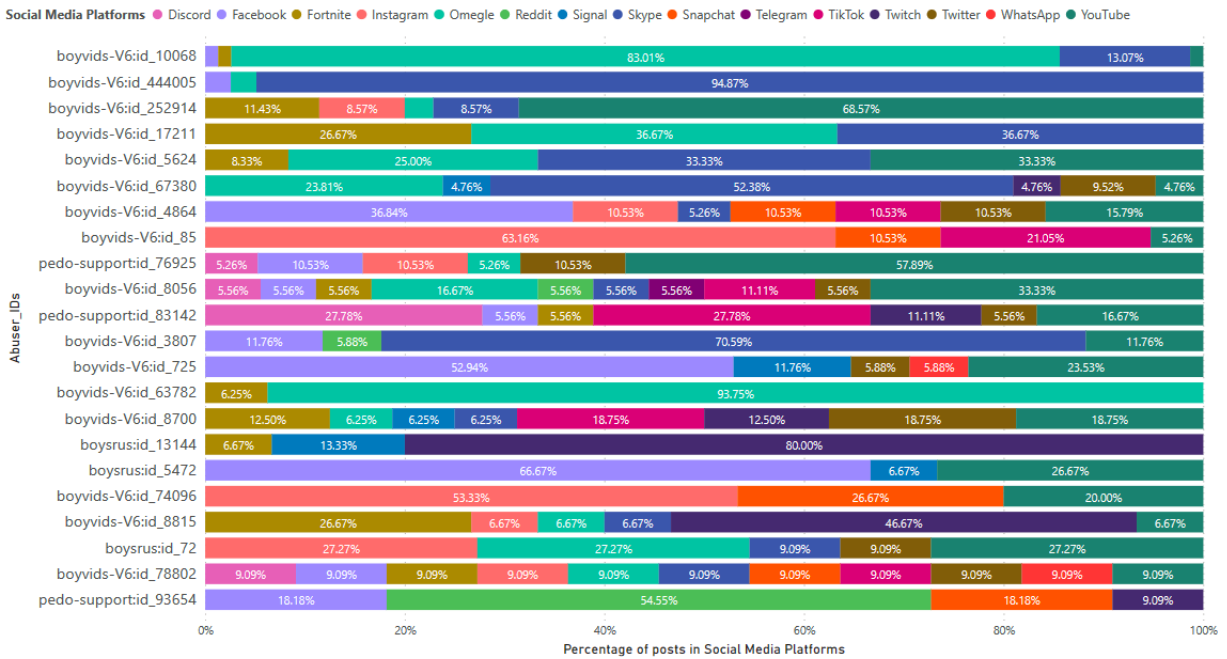

Figure 7: Percentages of the CSAM posts in social media platforms mentioned by the 22 most active CSAM creators of the platforms in 2022

CSAM creators frequently engage in the creating, uploading and/or sharing of CSAM on various online platforms, with a particular emphasis on social media platforms. These individuals often include links to such platforms within their posts in the dark web. Figure 7 presents the distribution of CSAM posts mentioning

different social media platforms, specifically focusing on the 22 most active CSAM creators of these platforms. The analysis encompasses famous social media platforms, e.g. Facebook, Instagram, Skype, TikTok, Twitter, WhatsApp and YouTube. Certain CSAM creators exhibit a significant concentration of their CSAM posts on a specific social media platform, accounting for over 80% of their total CSAM posts. The top CSAM creator (boyvids-V6:id_10068) and the 14th ranked CSAM creator (boyvids-V6:id_63782) allocated 83.01% and 93.75% of their CSAM posts to Omegle, respectively. The second highest CSAM creator, identified as boyvids-V6:id_444005, attributed 94.87% of their CSAM posts to Skype. On the other hand, some CSAM creators utilized multiple social media platforms to distribute their CSAM posts. For example, CSAM creators identified as boyvids-V6:id_8056, boyvids-V6:id_8700 and boyvids-V6:id_78802, ranked 10th, 15th and 21th respectively, mentioned 10, 8 and 11 social media platforms respectively in their posts.

5.3. Victim Profiles

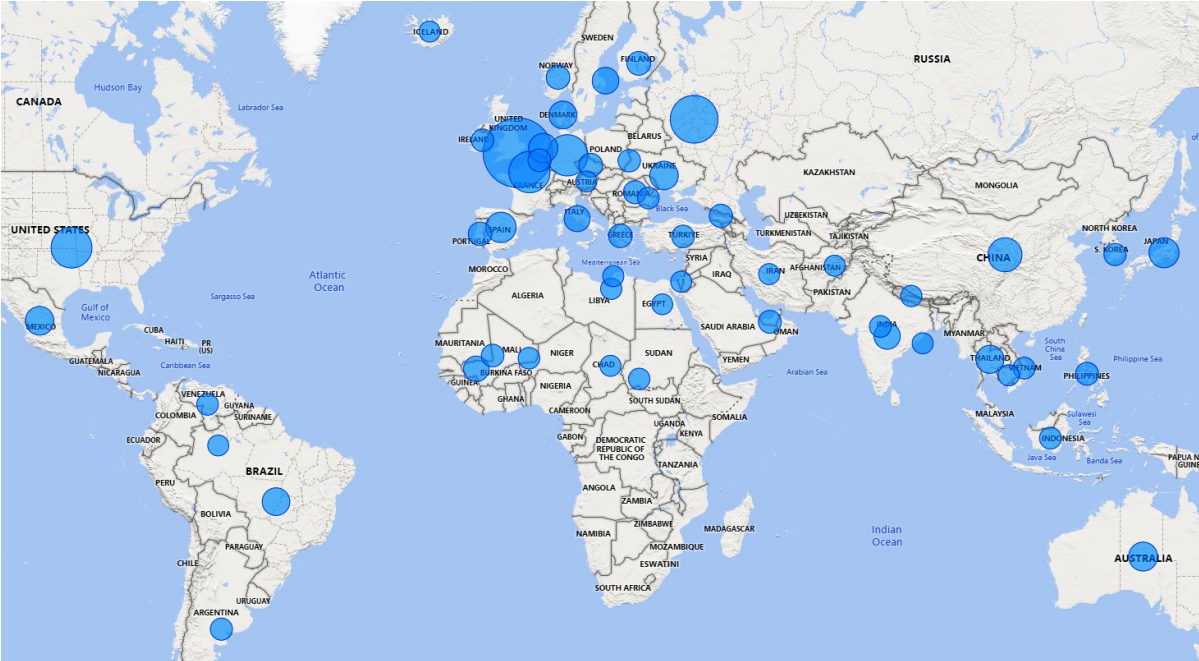

Figure 8: The number of CSAM posts and victim countries described in CSAM posts in 2022

The nationalities of victims are often described in CSAM posts. Figure 8 depicts a world map illustrating the countries of the victims mentioned in 2022, with the size of the circle indicating the number of CSAM posts associated with that particular country. Thus, countries with larger circle sizes indicate a higher number of CSAM posts that mentions those locations. Based on the visualization, it is evident that the top 5 countries with the highest number of CSAM mentions are Great Britain, Russia, German, France and United States. We can zoom-in view of the visualization that allows for a closer examination of the number of CSAM posts specifically mentioning each country. Figure 9 provides valuable insights into the prevalence of CSAM posts referencing these countries within the European context in 2022. Specifically, Great Britain was mentioned in 1,164 CSAM posts, while France, Germany, and Spain were mentioned in 496, 495, and 327 CSAM posts, respectively.

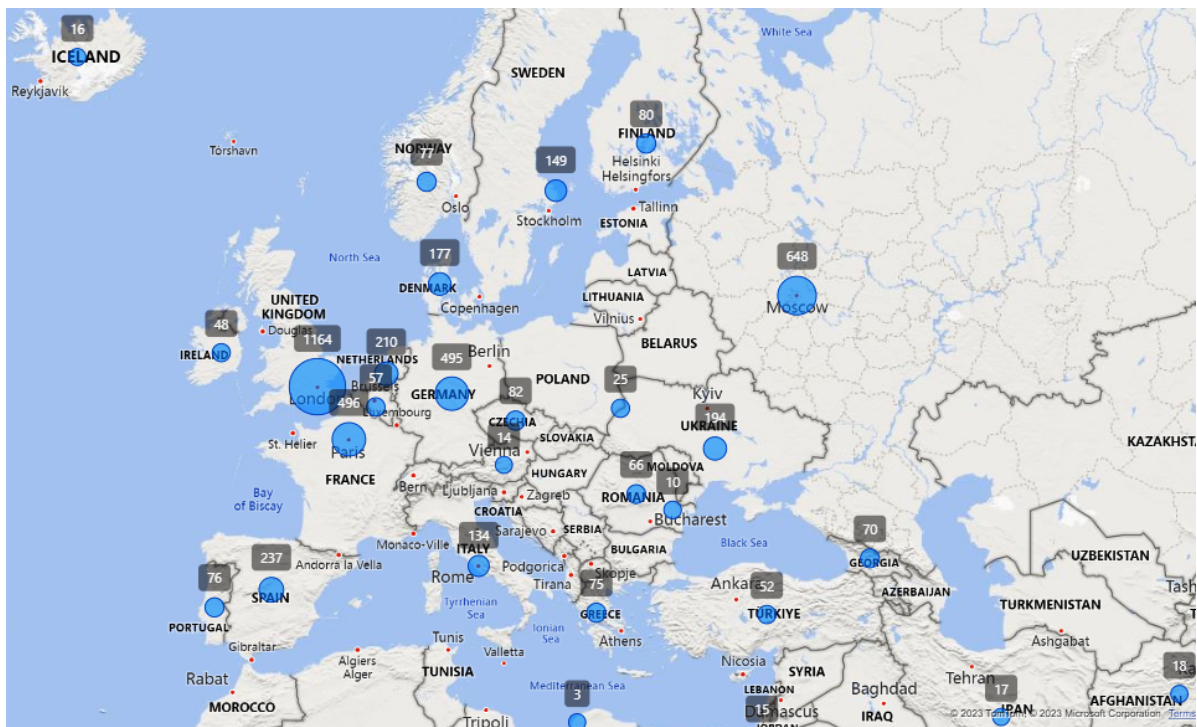

Figure 9: The number of CSAM posts and victim countries in Europe described in CSAM posts

Figure 10: Percentages of CSAM posts per victim age in the top 18 victim nationalities described in the posts

Figure 10 displays distribution of CSAM posts based on the percentages per victim age, ranging from 1 to 17 years old, for the top 18 victim nationalities. Among these nationalities, victims at the age of 12 were most frequently mentioned in 12 out of 18, specifically British, Russian, German, French, Dutch, Thai, Italian, Chinese, Spanish, Brazilian, Japanese and Belgian. The most commonly mentioned ages for Polish victims were 12 and 14 years old. In contract, victims at the age of 13 were most prevalent among American, Australian and Danish. Indian victims were most frequently mentioned at the age of 14, while Canadian victims were most commonly mentioned at 16 years old.

The chord diagram in Figure 11 presents relationships between the top ten victim nationalities and the top ten social media platforms. Certain nationalities were exclusively mentioned on specific social media platforms. For example, Chinese victims were mentioned only on Twitter and Telegram, while Mexican victims were exclusively mentioned on YouTube and Facebook. Conversely, certain social media platforms were used exclusively for specific nationalities. For instance, TikTok was solely used for Russian and Ukrainian victims. Whereas, Omegle was utilized for British, Australian, Italian, Brazilian, Belgian and German victims.

Figure 11: Relationships between the top ten victim nationalities and the top ten social media platforms

5.4. Social Media Platform Profiles

In 2022, among the 110 online platforms used by CSAM creators on the dark web, there were 15 notably popular social media platforms. These platforms include Discord, Facebook, Fortnite, Instagram, Omegle, Reddit, Signal, Skype, Snapchat, Telegram, TikTok, Twitch, Twitter, WhatsApp and YouTube. Some selected information associated with these platforms are presented in Figures 12, 13 and 14. Figure 12 displays the monthly count of CSAM posts per social media platform in 2022. Omegle recorded the highest values in November and April, with 93 and 52 CSAM posts respectively. Conversely, the lowest number of CSAM posts on Omegle was observed in September, with only 2 CSAM posts. Meanwhile, the highest number of CSAM posts on YouTube was recorded in March, with 54 posts, while Skype had its highest

number of CSAM posts in November, with 44 posts. From a different perspective, it is worth noting that in September, these platforms had a relatively low number of CSAM posts. Among them, YouTube had the highest value, with only 10 CSAM posts recorded during that month.

Figure 12: The number of CSAM posts per social media platform per month in 2022

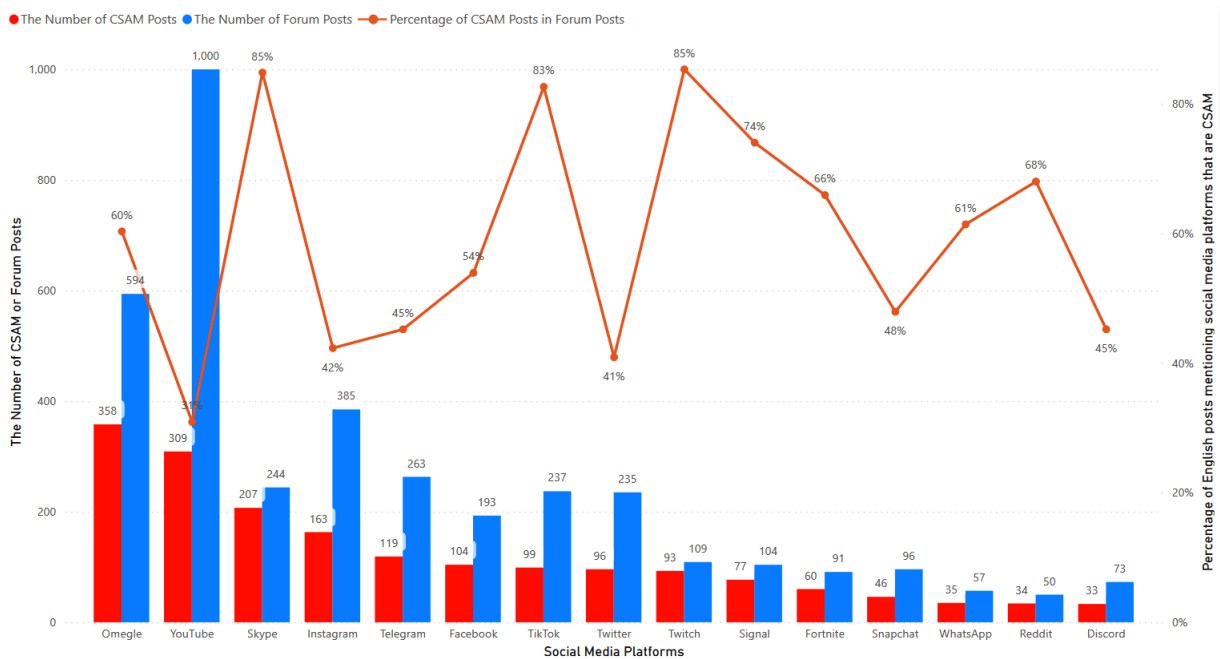

Figure 13: The number of CSAM posts and forum posts, and the percentages between them in the top 15 social media platforms

Figure 13 illustrates the number of CSAM posts and forum posts, along with the corresponding percentage, for each platform. The leading social media platform mentioned in CSAM posts is Omegle, with 358 CSAM posts out of 594 forum posts, accounting for approximately 60% of the total. The second and third social media platforms, YouTube and Skype, recorded 309 and 207 CSAM posts, respectively. Some platforms with a high percentage of CSAM posts compared to forum posts include Skype, TikTok, and Twitch, with percentages of 85%, 83% and 85%, respectively. On the other hand, YouTube, Instagram and Twitter has the lowest percentages, with less than 45%.

Figure 14: The number of CSAM posts per type of link per social media platform

Figure 14 presents the number of CSAM posts categorized as having no link, containing photo links, and containing video links. Omegle had 225 CSAM posts without any links, 133 CSAM posts with photo links, and a mere 5 CSAM posts with video links. YouTube had the highest number of CSAM posts with both photo links and video links, with a total of 136 with photo links and 19 posts with video links, respectively. The number of posts with no link and photo links in Skype is similar, with approximately 100 posts each. Three platforms, namely Fortnite, Reddit, and Discord, did not have any CSAM posts with video links.

6. Conclusion and Future Work

We proposed and implemented a novel algorithm based on machine learning and natural language processing to automatically detect and classify CSAM text post content in the dark web. In the experimental evaluation on the dataset of 4,600 CSAM and non-CSAM posts with 5-fold cross-validation, the combination of NB algorithm performed the best in terms of classification recall with 89%, and it was the second best in execution time with 0.1 microsecond/post. On the other hand, the SVM combination performed the best in terms of classification precision and accuracy with 92.3% and 87.6% respectively, and it was the third-best in execution time with 0.3 milliseconds/post. The choice of NB and SVM depends on the specific goals and requirements of the CSAM classification task. NB aims to maximize the number of true positives, which could be useful in identifying and removing CSAM posts from online platforms to protect potential victims. In contrast, SVM aims to minimize false positives, which could be useful for identifying CSAM posts to extract information about potential predators and victims for investigative purposes.

We also applied and analysed the statistics on CSAM creators, victim nationalities, online platforms, and forum topics in each forums on the dark web in 2022. In particular, we extracted, analyzed and discussed the preferences of CSAM creators regarding children’s age and nationality, online platforms, and forum topics that allows us to gain valuable insights into CSAM creators’ behaviors and motivations. By exploring the intricate relationships between these factors, we supplied a deeper understanding of the patterns and trends associated with CSAM activities on the dark web.

As part of our future work, CSAM detection APIs will be designed and implemented to seamlessly integrate into the websites of hotlines and helplines. This integration will facilitate the direct reporting of CSAM incidents to online platforms, ensuring swift removal of harmful content. These APIs will also enable the creation of visualizations that provide efficient CSAM information for educational and legal agencies. Additionally, we plan to conduct more in-depth investigations into activities of CSAM creators and victims on the dark web. This includes exploring the complex relationships between CSAM creators and victims, identifying potential collaborations among CSAM creators, and assessing the extent of victims’ losses.

Moreover, we will focus on recognizing named entities in CSA text to provide crucial concepts for our ML models [Ngo et al. \(2021b\)](#). By enhancing our ML model’s understanding of post contents, we can further improve its efficiency and accuracy in detecting and classifying CSAM content. Overall, our future endeavors aim to strengthen the fight against CSAM on the dark web by developing practical tools and gaining a deeper understanding of the dynamics involved. Through these efforts, we strive to protect vulnerable individuals and contribute to a safer online environment for all.
