#### Abstract

: For a nonempty subset X of a group G and a positive integer m , the product of X , denoted by $\mathrm{X}^{\mathrm{m}}$, is the set $$
\mathrm{X}^{\mathrm{m}}=\left\{\prod_{i=1}^{m} x_{i}: x_{i} \in X\right\}
$$

That is, $\mathrm{X}^{\mathrm{m}}$ is the subset of G formed by considering all possible ordered products of $m$ elements form $X$. In the symmetric group $S_{n}$, the class $C_{n}$ ( $n$ odd positive integer) split into two conjugacy classes in $\mathrm{A}_{\mathrm{n}}$ denoted $\mathrm{C}_{\mathrm{n}}{ }^{+}$and $\mathrm{C}_{\mathrm{n}}{ }^{-} . \mathrm{C}^{+}$and $\mathrm{C}^{-}$were used for these two parts of $\mathrm{C}_{\mathrm{n}}$. This work we prove that for some odd n , the class C of 5-cycle in $\mathrm{S}_{\mathrm{n}}$ has the property that $C^{\frac{n-3}{2}}=\mathrm{A}_{\mathrm{n}} \mathrm{n} \geq 7$ and $\mathrm{C}^{+}$has the property that each element of $\mathrm{C}^{+}$is conjugate to its inverse, the square of each element of it is the element of $\mathrm{C}^{-}$, these results were used to prove that $\mathrm{C}^{+} \mathrm{C}^{-}=\mathrm{A}_{\mathrm{n}}$ exceptional of I (I the identity conjugacy class), when $\mathrm{n}=5+4 \mathrm{k}, \mathrm{k}>=0$.

Key words: conjugacy classes ,split, Alternating Group, Product

## Introduction:

The product of conjugacy classes of the symmetric group $S_{n}$ is found to be a linear combination of conjugacy classes of the symmetric group with integer coefficients,[1]. Dvir in [2] developed a theory of the product of the conjugacy classes in $A_{n}$ and $S_{n}$, $n \geq 5$ which satisfy $C^{3}=A_{n}$. Brenner proved that for the conjugacy class C of n - cycle of the Alternating group $\mathrm{A}_{\mathrm{n}}, \quad \mathrm{CCC}=\mathrm{A}_{\mathrm{n}}, \mathrm{n}=4 \mathrm{k}-1$ and $\mathrm{CC}=\mathrm{A}_{\mathrm{n}}$, $\mathrm{n}=4 \mathrm{k}+1>5$.[3] Lamia H.R. in [3] proved that for $n=5+8 k, C^{+} C^{+} C^{+}=A_{n}$, In the Symmetric group $\mathrm{S}_{\mathrm{n}}$, the class C $\in \mathrm{S}_{\mathrm{n}}$ splits into two conjugacy classes of the same order $\mathrm{C}^{+}$and $\mathrm{C}^{-}$, these splitting happens with respect to the conjugator if it is even or odd. For each $\mathrm{x}, \mathrm{y} \in \mathrm{C}, \delta \notin \mathrm{A}_{\mathrm{n}}$ we have $\delta^{-1} \mathrm{x}$ $\delta=y \in C^{-}$when $x \in C^{+}$. After splitting we can see if $x^{-1} \in C^{+}$or not by using the formula [(n-l)/2] which gives the number of transposition in the standard
conjugator, if it is even then $\mathrm{x}^{-1} \in \mathrm{C}^{+}$ and otherwise $\mathrm{x}^{-1} \notin \mathrm{C}^{+},[4]$.

The Conjugacy Classes of the Alternating Group $\mathbf{A}_{\mathbf{n}}$
In this section, some basic definitions and fundamental results which are necessary for the main results are given.

## Proposition (1), [4]:

Let $\mathrm{C}_{\alpha}$ be the conjugacy class of $\mathrm{S}_{\mathrm{n}}$. Then $\mathrm{C}_{\alpha}$ splits into two $\mathrm{A}_{\mathrm{n}}$-classes of equal order if and only if $\mathrm{n}>1$ and the non-zero parts of $\alpha$ are pair wise different and odd. In all other cases $\mathrm{C}_{\alpha}$ does not split. We denote these two split classes $\mathrm{C}^{+}$and $\mathrm{C}^{-}$.
Proposition (2), [2]:
For n odd, the cycle (12...n) is conjugate to its inverse in $A_{n}$ if and only if $n \equiv 1 \quad(\bmod 4)$.

[^0]
## Lemma (3), [5]:

If a finite subgroup $H$ of a group $G$ is the union of conjugacy classes in G, then H is a normal subgroup of G .

## Results:

This section depends on two type of conjugacy classes of the symmetric group $\mathrm{S}_{\mathrm{n}}$
1- The conjugacy class $C$ of type $51^{n-5}$ For $S_{7}$ the class $C$ of type $51^{\text {n-5 }}$ has the property that $\mathrm{CC}=\mathrm{A}_{7}$. The same for $\mathrm{S}_{9}$ the class $\mathrm{CCC}=\mathrm{A}_{9}$ and so on.
2- The conjugacy class which split into two classes $\mathrm{C}^{+}$and $\mathrm{C}^{-}$.
By using proposition (2.1), the class C of length n ( n odd positive integer) split into two classes, this split happened with respect to $n$ (proposition 2.2), for example in $\mathrm{A}_{5}$
$\mathrm{C}^{+}=$
[(12345),(15432),(13254),(14523),(13
425),(15243), 12453), (12534) , (14352), (13542), (15324), (14235)] $\mathrm{C}^{-}=\quad[(13524), \quad(14253), \quad(12435)$, (15342), (14532), (12354), (14325), (15423), (13245), (15234), 13452), (12543)] .
these two type of classes were used to prove some results of this paper as in the following:
Lemma (1)
Let C be the class of the 5 - cycle in $\mathrm{S}_{7}$, then $\mathrm{C}^{2}=\mathrm{A}_{7}$.

## Proof

Since each element of the class C of $\mathrm{S}_{5}$ contains in the class C of $\mathrm{S}_{7}$
Then CC contains some elements of $\mathrm{A}_{7}$ For the other elements of $\mathrm{A}_{7}$ we have:

| $(12345)(12346)=(136)(245)$ | $\in \mathrm{A}_{7}$ |
| :--- | :--- |
| $(12345)(12463)=(1452)(36)$ | $\in \mathrm{A}_{7}$ |
| $(12345)(12467)=(1452367)$ | $\in \mathrm{A}_{7}$ |
| $(12345)(14267)=(167)(23)(45)$ | $\in \mathrm{A}_{7}$ |

So CC contains all elements of $\mathrm{A}_{7}$
Then $\mathrm{C}^{2}=\mathrm{A}_{7}$.
Lemma (2)
Let $n \geq 7$ be odd, let $C$ be the class of 5 - cycle in $\mathrm{S}_{\mathrm{n}}$ then $C^{\frac{n-3}{2}}=\mathrm{A}_{\mathrm{n}}$.

## Proof

The proof is by induction on n :
For $\mathrm{n}=7$ we have from lemma (1), $\mathrm{C}^{2}=$ $\mathrm{A}_{7}$, which implies that CC is the normal subgroup of $\mathrm{S}_{7}$. Since n is odd, assume its true for $\mathrm{n}-2$ which is odd, $\mathrm{C}^{\frac{n-5}{2}}=\mathrm{A}_{\mathrm{n}}$ ${ }_{2}, \mathrm{C}^{\frac{n-5}{2}}$ is the normal subgroup of $\mathrm{S}_{\mathrm{n}}$ 2. Now we prove it true for $n$, since $\mathrm{C}^{\frac{n-5}{2}}$ is the normal subgroup of $\mathrm{S}_{\mathrm{n}-2}$ which contains all even conjugacy classes by product $\mathrm{C}^{\frac{n-5}{2}} \mathrm{C}$ we get the conjugacy classes of $A_{n-2}$ as well as anther even conjugacy classes, since $\mathrm{C}^{\frac{n-5}{2}}$ is normal subgroup so the product $\mathrm{C}^{\frac{n-5}{2}} \mathrm{C}$ which equal two $C^{\frac{n-3}{2}}$ is also normal subgroup , then $C^{\frac{n-3}{2}}=\mathrm{A}_{\mathrm{n}}$.
Lemma (3)
Let $\mathrm{n}=5+4 \mathrm{k},(\mathrm{k}=0,1,2, \ldots)$, let $\mathrm{C}^{+}$be the class of $(12 \ldots \mathrm{n}), \mathrm{C}^{-}$be the class of (21...n) in $\mathrm{A}_{\mathrm{n}}$ then $\mathrm{C}^{+} \mathrm{C}^{-}$contains the conjugacy classes of period 2 .

## Proof

For $\mathrm{n}=5$, we have for any two elements of $\mathrm{C}^{+} \& \mathrm{C}^{-}$of $\mathrm{A}_{5}$ $(12345)(12354)=(13)(25)$
So the class of type $2^{2}$ contains in $\mathrm{C}^{+} \mathrm{C}^{-}$
The same for $\mathrm{n}=9$, we have
(123456789) $\mathrm{C}^{+}$,(123985674)
$\mathrm{C}^{-} \quad\left(12345, \epsilon_{89}\right)(123985674): \in$
(13)(29)(46)(57)

For any two elements of the conjugacy classes $\mathrm{C}^{+}, \mathrm{C}^{-}$we have
$(12 \ldots \mathrm{n})(\mathrm{n} . . .54123)=(13)(24)$
(12...n) (n...85674123) = (13)(2n)(46)(57)

So $\mathrm{C}^{+} \mathrm{C}^{-}$contains the conjugacy classes of period two.
Lemma (4)
Let $\mathrm{n}=5+4 \mathrm{k}$. Let $\mathrm{C}^{+}$be the class of ( $12 \ldots \mathrm{n}$ ), $\mathrm{C}^{-}$be the class of $(21 \ldots \mathrm{n})$ in $\mathrm{A}_{\mathrm{n}}$ then $\mathrm{C}^{+} \mathrm{C}^{-}$contains the conjugacy class of a 3- cycle.

## Proof

By the same way of lemma (3)
We have ,for any two elements of $\mathrm{C}^{+}$, $\mathrm{C}^{-}$we have
$(12 \ldots \mathrm{n})(\mathrm{n} . . .54312)=(1 \mathrm{n} 2)$
Then $\mathrm{C}^{+} \mathrm{C}^{-}$contains the conjugacy class of 3-cycle
Theorem (5)
In the Alternating group $\mathrm{A}_{\mathrm{n}}$, if $\mathrm{n}=5+4 \mathrm{k}$ $\geq 5,(\mathrm{k}=0,1, \ldots)$, then $\mathrm{C}^{+} \mathrm{C}^{-}=\mathrm{A}_{\mathrm{n}}$ exceptional of I.

## Proof

Let $C$ be the conjugacy class of $A_{n}$ of length n which split into $\mathrm{C}^{+}$and $\mathrm{C}^{-}$ .Since by lemma [2.2]
Then the inverse of each element of $\mathrm{C}^{+}$ is belonging to $\mathrm{C}^{+} . \mathrm{So}^{+} \mathrm{C}^{-}$doesn't contain the identity.
Now we prove that $\mathrm{C}^{+} \mathrm{C}^{-}$contain all other conjugacy classes of $A_{n}$.
The prove is by induction on n , for $\mathrm{n}=5$, let $\mathrm{a}=(12345) \in \mathrm{C}^{+}$for each element of $\mathrm{C}^{-}$we have :
$(13452) \in \mathrm{C}^{-} \longrightarrow(12345)(13452)=$ (24) (35) $\in \mathrm{A}_{5}$
(15342) $\in \mathrm{C}^{-} \longrightarrow$ (12345)
$(15342)=(243) \quad \in \mathrm{A}_{5}$
(14253) $\in \mathrm{C}^{-} \longrightarrow$ (12345)
$(14253)=(15432) \in \mathrm{A}_{5}$
(13524) $\in \mathrm{C}^{-} \longrightarrow$ (12345)
$(13524)=(14253) \in \mathrm{A}_{5}$
Since all conjugacy classes contain in $\mathrm{A}_{5}$, this implies that $\mathrm{C}^{+} \mathrm{C}^{-}=\mathrm{A}_{5}$ except for I . The theorem is valid for $\mathrm{n}=5$.
Now for $\mathrm{n}-2$, since n is odd so $\mathrm{n}-2$ is odd, assume its true for $\mathrm{n}-2$ which implies that $\mathrm{C}^{+} \mathrm{C}^{-}=\mathrm{A}_{\mathrm{n}-2}$.
We want to prove it for $n$
Let $S \neq I$ be a permutation of $A_{n}$. If the largest cycle in $S$ is a 2 - cycle, then by using [lemma 3], $\mathrm{C}^{+} \mathrm{C}^{-}=\mathrm{A}_{\mathrm{n}}$.
If S is a single 3-cycle, then by using [lemma 4] $\mathrm{C}^{+} \mathrm{C}^{-}=\mathrm{A}_{\mathrm{n}}$.
Next we must show that $S=k_{1} k_{2}$ and $\mathrm{k}_{1}, \mathrm{k}_{2}$ are n -cycles belonging to different classes in $\mathrm{A}_{\mathrm{n}}$. To see this write $\mathrm{d}_{1}=$ (123...n-2), $\mathrm{d}_{2}=$ (135...n-2 $24 \ldots \mathrm{n}-3$ ) in different classes in $\mathrm{A}_{\mathrm{n}-2}$. By using $\mathrm{t}=(\mathrm{n} \mathrm{n}-1 \mathrm{n}-3)$ such that
$d_{1} \mathrm{t}^{-1}=(123 \ldots \mathrm{n}-2)(\mathrm{n}-3 \mathrm{n}-1 \mathrm{n})=(123 \ldots \mathrm{n}-$ $1 \mathrm{nn}-3) \in \mathrm{A}_{\mathrm{n}}$.
$\mathrm{d}_{2}$ ( n n-2 $\mathrm{n}-1$ ) $=(135 \ldots \mathrm{n}-2 \quad 24 \ldots \mathrm{n}-$ $3)=(135 \ldots n-1 n n-2) \in A_{n}$.

The two cycles displayed on the right - hand sides are in different classes in $A_{n}$, since $d_{1}, d_{2}$ are in different classes in $\mathrm{A}_{\mathrm{n}-2}$ so the theorem follows.

## Conclusions :

From this work some conclusions are drown ; they listed below:
1- The product of conjugacy classes $C$ of type $51^{\mathrm{n}-5}, C^{\frac{n-3}{2}}=$ $\mathrm{A}_{\mathrm{n}}$, for $\mathrm{n} \mathrm{n} \geq 7$
2- The product of split conjugacy classes $\mathrm{C}^{+} \mathrm{C}^{-}$contains the conjugacy class of period 2 when $\mathrm{n}=5+4 \mathrm{k}$.
3- The product of split conjugacy classes $\mathrm{C}^{+} \mathrm{C}^{-}$contains the conjugacy class of a 3- cycle when $\mathrm{n}=5+4 \mathrm{k}$.
4- The product of split conjugacy classes $\mathrm{C}^{+} \mathrm{C}^{-}=\mathrm{A}_{\mathrm{n}}, \mathrm{n}=5+4 \mathrm{k} \geq 5$, exceptional of I.
5- In future we can study the split conjugacy class $C_{\alpha}^{ \pm}$with the property $\alpha_{i} \equiv 3 \quad(\bmod 4)$ is even.
