† Deceased

**One Sentence Summary:** A single dose of a clinically-relevant adenovirus-based vaccine induces a strong and functional antibody response against group B meningococcus.

**Abstract:** Adenoviral-vectored vaccines are licensed for prevention of severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) and Ebola virus, but, for bacterial proteins, expression in a eukaryotic cell may impact the antigen's localization, conformation, or lead to unwanted glycosylation. Here, we investigated the potential use of an adenoviral-vectored vaccine platform for capsular group B meningococcus (MenB). Vector-based candidate vaccines expressing MenB antigen factor H binding protein (fHbp) were generated, and immunogenicity was assessed in mouse models, including the functional antibody response by serum bactericidal assay (SBA) using human complement. All adenovirus-based vaccine candidates induced high

1063 antigen-specific antibody and T cell responses. A single dose induced functional serum  
1064 bactericidal responses with titers superior or equal to those induced by two doses of proteinbased  
1065 comparators, as well as longer persistence and a similar breadth. The fHbp transgene was further  
1066 optimized for human use by incorporating a mutation abrogating binding to the human  
1067 complement inhibitor factor H. The resulting vaccine candidate induced high and persistent SBA  
1068 responses in transgenic mice expressing human factor H. The optimized transgene was inserted  
1069 into the clinically-relevant ChAdOx1 backbone, and this vaccine has now progressed to clinical  
1070 development. The results of this preclinical vaccine development study underline the potential of  
1071 vaccines based on genetic material to induce functional antibody responses against bacterial  
1072 outer membrane proteins.

1073

1074 **Main Text:**

## 1075 INTRODUCTION

1076 *Neisseria meningitidis* is a leading cause of childhood meningitis and septicemia in several  
1077 countries, including the United Kingdom. Effective conjugate vaccines against the capsular  
1078 groups A, C, W and Y, are licensed, For the serogroup B (MenB), the licensed vaccines  
1079 4component MenB vaccine (4CMenB, Bexsero, GlaxoSmithKline) and recombinant lipoprotein  
1080 2086 (rLP2086, Trumenba, Pfizer) are based on subcapsular protein antigens (1–5). 4CMenB  
1081 also contains outer membrane vesicles (OMV), used to control a previous outbreak in New  
1082 Zealand (6). Both vaccines are licensed for adolescents and adults in a two-dose schedule (4), but  
1083 the persistence of the protective response appears limited(7), and there is no evidence that  
1084 4CMenB can reduce bacterial colonization within an organism (8). These factors negatively  
1085 affect the cost-effectiveness of an adolescent program for MenB vaccines (9). A low cost,  
1086 singledose MenB vaccine capable of inducing sustained protective immune responses would be  
1087 well positioned (10).

1088 Viral-based vaccine platforms such as adenoviral and poxviral vectors induce both innate and  
1089 adaptive immune responses in mammalian hosts (11, 12). Although they were originally  
1090 developed for their well-recognized ability to induce potent cellular immunity, a single dose of  
1091 an adenovirus-based vaccine is able to induce potent neutralizing antibodies against some  
1092 pathogens, as demonstrated with vaccines against rabies (13), severe acute respiratory syndrome  
1093 coronavirus 2 (SARS-CoV-2) (14, 15), malaria (16) and Ebola virus (17). Their capacity to  
1094 induce strong interferon (IFN)- $\gamma$  producing T cell responses should provide the ideal conditions  
1095 for class switching to complement-fixing bactericidal antibody against MenB (18).

1096 The use of viral vectors to induce antibody responses to bacterial outer membrane proteins is  
1097 complicated by the differences between prokaryotic and eukaryotic expression systems, which  
1098 may result in incorrect or sub-optimal expression of bacterial antigens in mammalian cells. If  
1099 successfully expressed, there may still be a loss of protective epitopes due to misfolding or  
1100 aberrant post-transcriptional modifications (19). However, some successes at eliciting functional  
1101 responses were described for bacterial antigens from *Streptococcus pneumoniae* (20) and  
1102 *Yersinia pestis* (21). In the current study, a series of vectors were constructed expressing the  
1103 MenB protective antigen factor H binding protein (fHbp) (22–25). The vectors were assessed for  
1104 antigen expression in mammalian cells, and for immunogenicity and induction of protective

1105 bactericidal activity in mouse models. One candidate was selected and optimized for human use  
1106 by incorporating a point mutation, which abrogates binding of fHbp to the human complement  
1107 inhibitor factor H. The resulting vaccine candidate is now in clinical development.

1108

## 1109 **RESULTS**

### 1110 **Adenoviral vaccine vectors encoding fHbp induce bactericidal activity in mice.**

1111 Recombinant replication-deficient human adenovirus 5 (HuAd5) vectors encoding a full length  
1112 (immature sequence including the signal sequence), or a truncated version (without the signal  
1113 sequence) of fHbp were created (HuAd5 fHbp and HuAd5 fHbp-truncated, respectively). Both  
1114 vectors induced antibody responses in BALB/c mice as soon as two weeks post a single  
1115 intramuscular injection, as evidenced by antibodies detected against whole H44/76 bacteria  
1116 containing a homologous fHbp variant (Fig. 1A). The antibody titers were of similar magnitude  
1117 to those induced by a single dose of native H44/76 OMVs containing the same fHbp variant as  
1118 well as many more antigens including the immunodominant PorA protein. Endpoint  
1119 enzymelinked immunosorbent assay (ELISA) titers reached 32,000 to 256,000 at week 6 post  
1120 HuAd5 fHbp injection, and 16,000 to 128,000 with native OMVs (Fig. 1A). An analysis of the  
1121 IgG subclasses at week 6 indicated that HuAd5 fHbp induced IgG1 and IgG2a mainly, whereas  
1122 the native H44/76 OMVs induced responses that also included high IgG2b and IgG3 antibodies  
1123 (Fig.

1124 1B). The latter could be directed against any of the immunogenic antigens comprised within  
1125 OMVs, in particular the immunodominant PorA. Both the full length and truncated  
1126 fHbpencoding adenoviruses elicited T cell responses (Fig 1C).

1127 Importantly, both vectors were able to induce functional antibody responses, as evidenced by the  
1128 bactericidal activity detected in pooled mouse serum samples at week 42 (Fig. 1D). Individual  
1129 SBA titers and T-cell responses were similar when a tissue plasminogen activator (tPA) signal  
1130 sequence was used instead or in addition of the wild type fHbp signal sequence (fig. S1A and  
1131 S1B). The vector comprising both the tPA signal sequence followed by the full-length  
1132 (immature) bacterial signal sequence (HuAd5 fHbp) was selected for further analysis and  
1133 optimization. Induction of bactericidal response was confirmed in a second mouse inbred strain  
1134 (NIH Swiss) against strain H44/76-SL as well as against another bacterial strain expressing a  
1135 lower amount of fHbp variant 1.1 (BZ83, Fig. 1E), and also after intranasal and sublingual  
1136 delivery (fig. S1C). A dose response experiment suggested that bactericidal responses appeared  
1137 highest after vaccination with  $10^9$  infectious units (IU) per mouse (Fig. 1F), a relatively high  
1138 dose in mice. Finally, a longitudinal study was performed. As a single dose OMV vaccines is  
1139 poorly immunogenic, and OMVs are not used as single dose in humans, a single dose adenovirus  
1140 was compared with two doses OMV in order to better represent real use (Fig. 1G). We observed  
1141 that a single injection with HuAd5 fHbp elicited SBA titers that were consistently equivalent to  
1142 or higher than OMV-induced responses, at different time points, included when compared with  
1143 two doses of OMVs (Fig. 1H). The quantitative antibody responses, detected by ELISA, were  
1144 similar between a single dose HuAd5 fHbp, expressing a single antigen, and two doses of  
1145 OMVs, containing many more antigens (Fig. 1I). Moreover, the SBA titers remained stable up to  
1146 32 weeks post the single injection with HuAd5 fHbp (Fig. 1H). Altogether these results confirm

1147 the capacity of the adenoviral-vector platform to elicit functional antibody responses after a  
1148 single dose in mice.

1149

1150 **The adenovirus-induced SBA response is not increased with a prime-boost regimen.**

1151 Heterologous prime-boost regimens using a vectored vaccine construct have been shown to  
1152 induce higher antibody responses than single dose or homologous prime-boost modalities (26).  
1153 Combinations of HuAd5 fHbp and native (n) OMVs from strain H44/76 were assessed in mice  
1154 (Fig. 2A and B). The SBA responses induced by two-dose approaches (homologous and  
1155 heterologous) did not induce higher SBA titers than those observed at 6 weeks post a single  
1156 injection (Fig. 2C). Remarkably, the SBA assay against strain H44/76-SL detects bactericidal  
1157 antibodies directed to all antigens present in the OMVs, including the immunodominant and  
1158 protective antigen PorA, and thus may advantage the OMV vaccine, due to this PorA-specific  
1159 response, as well as potential bactericidal responses to other lesser known antigens. Therefore,  
1160 strain BZ83 was used as target in the SBA assay as it contains low amounts of homologous fHbp  
1161 variant 1.1, and a PorA (P1.5-2,10) heterologous to the OMVs used for immunizing mice (P1.7,  
1162 16), and thus allows a fairer comparison of the fHbp-specific bactericidal antibodies in this  
1163 study. Only HuAd5 fHbp was able to elicit SBA responses against this strain, whereas nOMVs  
1164 did not (Fig. 2D).

1165 One of the most immunogenic vaccine regimens with regard to induction of T cell responses is  
1166 based on heterologous adenovirus prime-poxvirus boost regimen (27). A Th1-biased T cell  
1167 response may be associated with better functional responses to protein-based meningococcal  
1168 vaccines (18). Therefore, the heterologous vectored prime-boost approach was explored, using a  
1169 modified vaccinia Ankara (MVA) vector encoding the same fHbp 1.1 sequence as in the  
1170 adenovirus prime (Fig. 2E). MVA was a poorer primer of antibody responses as compared with  
1171 HuAd5, as evidenced by the lower and slower induction of SBA response after a single dose  
1172 (Fig. 2F). The prime-boost regimen, whether HuAd5-MVA or MVA-HuAd5, did not induce  
1173 substantially higher SBA titers than HuAd5 alone, (Fig. 2F). The SBA responses persisted in all  
1174 groups up to week 50 (Fig. 2F). Addition of an adjuvant previously shown to increase the  
1175 immunogenicity of adenoviral vectors (AddaVax) also did not impact the SBA response induced  
1176 by HuAd5 fHbp (Fig. 2F), nor the amount of binding antibodies as detected by ELISA at week  
1177 50 (Fig. 2G). At week 50 post the single injection or prime, bone marrow B cell responses were  
1178 explored in a subset of groups as these are associated with longer persistence of circulating  
1179 antibodies. The results did not suggest that the heterologous prime-boost elicited higher B cell  
1180 responses (Fig. 2H). Similar results were observed in an independent experiment using bone  
1181 marrow and spleens of mice immunized with each vector alone or immunized with a prime-boost  
1182 regimen, where higher numbers of fHbp-specific B cells were detected in the mice that received  
1183 at least one HuAd5 injection (HuAd5 alone, HuAd5-MVA or MVA-HuAd5, fig. S2A).  
1184 Altogether, these results suggests that the SBA response induced in this model by a single  
1185 HuAd5 fHbp injection may be at a plateau at that dose and time points.

1186

1187 **A single dose of HuAd5 fHbp compares favorably with 4CMenB.**

1188 The adenovirus-based vaccine candidate was compared with one, two and three doses of  
1189 4CMenB, which contains detergent-extracted OMVs from strain NZ98/254 (PorA P1.7-2,4), and  
1190 a recombinant fHbp protein variant 1.1 (Fig. 3A). 4CMenB was assessed at one-tenth and  
1191 onefifth of the human dose, the latter administered intraperitoneally because the volume  
1192 exceeded the permitted volume for intramuscular injection. At week 20, antibody responses  
1193 measured by ELISA were higher after two or three doses of the licensed vaccine as compared  
1194 with a single dose of adenoviral vaccine (Fig. 3B). However, the SBA responses against a strain  
1195 containing an homologous fHbp (H44/76-SL) were equivalent or higher with the adenovirus  
1196 vaccine (Fig. 3C, top panels). 4CMenB administration schedule is two or three doses, and indeed  
1197 the SBA response induced by a single dose of 4CMenB in mice was low (Fig. 3C, first time  
1198 point a week 3). SBA responses against strain NZ98/254 (homologous to the OMV in 4CMenB)  
1199 were also explored. This strain expresses intermediate amounts of heterologous fHbp ID 14.  
1200 Results showed that the adenoviral vaccine was able to induce SBA responses against that  
1201 heterologous fHbp with titers in the same range as 4CMenB except for the latest time points  
1202 (from 40 weeks post prime, Fig. 3C, bottom panels). At week 56, a terminal bleed was  
1203 performed and allowed the assessment of individual SBA responses and their persistence over a  
1204 year post vaccination. The results mirrored the SBA titers obtained with the pooled serum  
1205 samples. A single dose of adenovirus vaccine elicited higher or similar SBA titers than two or  
1206 three doses of 4CMenB, with titers comprised between 1:128 and 1:1,024 at 56 weeks after a  
1207 single injection (Fig. 3D). Enumeration of antigen-specific B cells in the bone marrow and  
1208 spleen suggested that a single adenoviral vaccine induced persistence of B cell responses in these  
1209 organs as well as two or three doses of 4CMenB (Fig. 3E). An exploration of the CD45RA+  
1210 CD19+ B cells in lymph nodes and spleens two weeks after injection with a single dose of  
1211 HuAd5 fHbp, 4CMenB or OMVs confirmed the capacity of the viral vector to induce early high  
1212 B cell responses in mice, that may explain the persistence of protective SBA titers for up to a  
1213 year in mice after a single dose (fig. S2B).

1214 In an independent longitudinal experiment (Fig. 3F), assessment of the SBA response was  
1215 compared with a higher dose of 4CMenB (two-fifths of a human dose). In this study, a single  
1216 dose of HuAd5 fHbp induced similar SBA titers to those induced by three doses of 4CMenB  
1217 against strain H44/76-SL (Fig. 3G), and also induced SBA responses against strain BZ198 (PorA  
1218 P1.7-2,4, similar to the one in the 4CMenB vaccine, and fHbp 1.5), albeit lower than three doses  
1219 of 4CMenB containing a homologous PorA to that strain (Fig. 3H).

1220 Lastly, immunogenicity was confirmed in outbred mice (CD-1, Fig. 3I). The single dose  
1221 adenovirus vaccine induced similar SBA titers to those elicited by three doses of 4CMenB, and  
1222 induced better persistence from six months post first injection against strain H44/76-SL (Fig. 3J).  
1223 Altogether, these results demonstrate that a single dose adenovirus-based vaccine is sufficient to  
1224 induce immunity in mouse models.

1225

### 1226 **HuAd5 fHbp induces bactericidal responses against different strains.**

1227 Many variants of fHbp circulate in invasive meningococcal strains (28); therefore the capacity of  
1228 the vaccine candidate to induce serological evidence of protection against strains expressing  
1229 different fHbp variants in different quantities was measured by SBA using pooled serum samples  
1230 at different time points post injection with a single dose of the adenovirus vaccine, or one, two or

1231 up to three doses of the licensed vaccines, 4CMenB or rLP2086. Twelve target strains were  
1232 selected, varying either by the variant expressed or by the putative quantity of fHbp expressed on  
1233 their surface (Table 1). The SBA responses induced by a single dose of the protein-based  
1234 vaccines was absent, or very low (titer of 1:4) against a single strain out of the 12 tested (Table 1,  
1235 week 2). None of the vaccines induced SBA against a strain expressing a low amount of fHbp  
1236 1.1 (Table 1, M08 0240375). However, a single dose of HuAd5 fHbp induced earlier SBA  
1237 responses than those generated by the protein-based vaccines against strains expressing medium  
1238 and high amount of homologous fHbp 1.1 (Table 1, M08 0240063 and M07 40800, respectively)  
1239 despite the fact that 4CMenB contains other antigens able to induce SBA responses. Both  
1240 HuAd5 fHbp and 4CMenB were able to induce SBA responses against strains expressing  
1241 variants 1.13 and 1.15, but not against 1.14 (Table 1). Responses were induced against strains  
1242 expressing low and medium amounts of variant 1.4. Only rLP2086 was able to induce SBA  
1243 responses against strains containing fHbp variant 3.187 and 3.45, as expected (Table 1). rLP2086  
1244 appeared to induce limited SBA against some of the variant 1 strains included in this panel,  
1245 despite containing a variant 1 fHbp, but this may be an artefact of the small number of strain  
1246 assessed in this study. Altogether, these results show that the strain coverage induced by a single  
1247 dose of fHbp inserted in the adenovirus delivery platform was similar to that induced by three  
1248 doses of 4CMenB when tested using this particular panel of strains.

1249

#### 1250 **Modifications of the vaccine candidate were designed to increase clinical potential.**

1251 Pre-existing immunity to human adenovirus serotypes such as the serotype 5 has the potential to  
1252 neutralize the vaccine and thus dampen its immunogenicity. One solution is to use adenoviruses  
1253 that do not circulate in humans, such as chimpanzee serotypes, including ChAdOx1 and  
1254 ChAdOx2 (29, 30). In addition, the influence of two different CMV promoters on antigen  
1255 expression was explored, a long and a shorter version described previously (31). The vectors  
1256 were assessed at suboptimal doses in order to detect differences that may not be observed when  
1257 using the higher dose of  $10^9$  IU/mouse (Fig. 4). There was no statistically significant difference  
1258 ( $p>0.05$ ) between the two clinically-relevant backbones at week 20 post vaccination and  
1259 ChAdOx1 was selected (Fig. 4).

1260

#### 1261 **Mutations of the fHbp transgene to prevent binding to human factor H increases the** 1262 **bactericidal response.**

1263 In humans, *N. meningitidis* fHbp binds to the human complement inhibitor factor H (fH), thus  
1264 decreasing the innate response to the invading bacteria and allowing its survival in the  
1265 bloodstream (32). This interaction may affect the anti-fHbp antibody repertoire when fHbp is  
1266 used as vaccine antigen, and decrease SBA due to fH covering important epitopes when binding  
1267 on fHbp in the vaccine (33). Therefore, mutant fHbp proteins with lower binding to human fH  
1268 have been generated (34–36), and are associated with higher SBA titers in the presence of human  
1269 fH (34, 37). We thus explored if the same would occur when fHbp is expressed within the host  
1270 cells by an adenoviral vector. Two vectors were constructed, HuAd5 fHbp-H248L and -S223R,  
1271 containing previously described mutations that decrease fH binding (38). The expression of the  
1272 fHbp mutants in cells infected with the vectored vaccines was at least equivalent to the

1273 expression of the wild type antigen in infected HeLa cells (21 to 32% of infected cells, Fig. 5A,  
1274 top panels). The fHbp mutants expressed in infected HeLa cells had reduced binding to human  
1275 factor H present in human serum, as well as to recombinant human fH, and the reduction was  
1276 independent of the adenoviral backbone used (Fig. 5A, middle and bottom panels, respectively).  
1277 Mouse fH does not bind to fHbp, and we verified that both mutants induced SBA responses  
1278 comparable with those elicited by the wild-type fHbp in BALB/c mice (Fig. 5B and C) and in  
1279 outbred mice (Fig. 5D). SBA titers were assessed in transgenic mice expressing human fH and  
1280 were at similar amounts to those found in healthy humans in the two experiments described  
1281 previously (34) (fig. S3A and B). In this model, the vector expressing the mutant S223R induced  
1282 superior SBA titers as compared with vectors containing the wild type sequence or the H248L  
1283 mutation (Fig. 5E and 5F). In a longitudinal study using human fH-expressing transgenic mice, a  
1284 single HuAd5 fHbp-S223R dose elicited comparable or higher titers than three injections of  
1285 4CMenB that persisted up to 17 weeks post-injection (Fig. 5G). The S223R mutation was  
1286 therefore introduced in the ChAdOx1 backbone (ChAdOx1 fHbp-S223R). Induction of SBA  
1287 responses by a single dose of ChAdOx1 fHbp-S223R was confirmed in three strains of mice,  
1288 including an outbred strain (Fig. 6A). Dose responses in BALB/c and CD-1 highlighted the  
1289 higher variability observed in outbred mice, where a higher dose is required to obtain 100%  
1290 seroconversion. SBA responses induced by a single dose ChAdOx1 fHbp-S223R were similar to  
1291 those induced by 4CMenB administered 3 times in the presence of human fH, and persisted up to  
1292 week 21 (Fig. 6B). Altogether, these results highlight the potential of an adenoviral-based  
1293 vaccine expressing a mutated fHbp for use in humans.

1294

## 1295 **DISCUSSION**

1296 In this study, we explored the immunogenicity of adenovirus-based vaccine candidates  
1297 expressing fHbp. Screening of different transgene designs was performed using HuAd5 and  
1298 allowed a comprehensive exploration of different signal sequence and mutations. The optimal  
1299 transgene was inserted into the clinically-relevant ChadOx1 vector. We demonstrate that a single  
1300 dose of ChAdOx1 fHbp-S223R induces higher SBA responses in mice than three doses of  
1301 4CMenB in the presence of human factor H. This MenB vaccine is now in phase I human  
1302 clinical trials. Although the expression of CMV-driven transgenes in adenovirus vectors was  
1303 shown to be dose-dependent, it is not known if the quantity of antigen expressed, the timing, or  
1304 the pattern recognition or danger signals provided after infection with the adenovirus are  
1305 responsible for the response after a single dose. The capacity of adenoviral vaccines to induce T  
1306 cell responses may also support higher B cell responses and contribute to better persistence as  
1307 compared with conventional adjuvants, such as aluminum.

1308 Mouse IgG isotypes differ in their capacity to promote bactericidal activity (39). We quantified  
1309 the antigen-specific IgG1, IgG2a, IgG2b, and IgG3 induced by fHbp-expressing vectors. HuAd5  
1310 fHbp induced IgG responses dominated by IgG2a, whereas the nOMV vaccines also induced  
1311 IgG2b and IgG3. Induction of IgG2a has been observed with adenoviral vectors encoding  
1312 different antigens (viral, parasitic, and bacterial) in mouse models (40–42), suggesting that this  
1313 induction of this IgG2a subclass is not driven by the antigen itself, but by the adenovirus vector.  
1314 IgG1 is not reported as a primary driver of bactericidal activity, but this observation was made  
1315 for antibodies against the outer membrane PorA protein only, and only in mice (39). It is not

1316 known if fHbp-specific subclass antibodies would behave similarly and which subclass is  
1317 responsible for SBA responses after HuAd5 injection. The IgG1 and IgG2a induced by the  
1318 nOMV vaccine may be against other antigens (as shown by the ELISA used whole cells), or may  
1319 be against other epitopes in fHbp due to the different presentation (OMV versus mouse host  
1320 cells). The titers of binding antibodies was lower after OMV injection than those elicited by  
1321 HuAd5 fHbp by week 26, which supports the hypothesis that the lower SBA at later time points  
1322 may in part be due to lower persistence of antibodies after injection with OMVs.

1323 The fHbp gene was inserted as either the immature protein (bacterial signal sequence followed  
1324 by the protein encoding gene) or the mature protein only (with the bacterial signal sequence  
1325 removed) to manipulate the N-terminal sequence and the resulting folding of the proteins. In  
1326 both cases, we elected to add a tPA signal sequence to target the protein to the secretion pathway  
1327 and to promote antigen presentation on the plasma membrane. Therefore, two signal sequences  
1328 were encoded for the immature construct. The tPA followed by the bacterial sequence is an  
1329 original design compared with other adenoviral vaccines expressing bacterial antigens (43–45).  
1330 The design with the double signal sequence consistently induced higher antibody titers and SBA.

1331 This may suggest that preserving the native fHbp signal sequence contributed to correct  
1332 processing by signal peptidase and supported native folding for this antigen, as previously  
1333 observed with the SARS-CoV-2 spike protein (46). However structural data suggest the same  
1334 folding for fHbp, regardless of presence or absence of leader peptide and regardless of variant  
1335 type; thus, the exact mechanism for when two signal sequences are used is unknown (46).  
1336 Moreover, although it is expected that the expressed fHbp is glycosylated due to the presence of  
1337 the tPA (which may cause issues for bacterial antigens in this type of vaccine platform), we do  
1338 not know if it would be lapidated. The contribution of each element in the signal sequence has  
1339 been explored separately (47).

1340 The lack of boosting of the SBA responses with heterologous prime-boost regimen was  
1341 surprising given existing literature suggesting that such regimen leads to higher immune  
1342 responses (12, 26, 48, 49). The lack of boosting may be a dose effect, as a high dose of  
1343 adenoviral vaccines was used in this study ( $1 \times 10^9$  IU per mouse). In this study, any regimen  
1344 including an adenovirus injection, whether as a prime or a boost, induced high bactericidal  
1345 antibody responses, and a remarkable persistence of antibody titers, linked with higher numbers  
1346 of bone marrow antibody-secreting B cells as compared with protein-based vaccines. Whether a  
1347 single dose will elicit similar high and long-lasting SBA responses in humans is currently being  
1348 explored. Persistence of antibody responses with a single adenoviral vaccine injection in humans  
1349 has been observed for an Ebola virus vaccine. After a single dose in children, the antibody titers  
1350 decreased during the first six months and remained remarkably stable at 12 months (50).

1351 However, higher total responses and better antibody persistence were observed after a second  
1352 dose of ChAdOx1 nCoV-19 (51), suggesting that there are differences in immunogenicity due  
1353 either to the backbone vector in humans, or to the antigen itself. There is induction of  
1354 neutralizing antibody responses against the vector, which increases with increasing numbers of  
1355 doses. However, this induction of neutralizing activity does not seem to affect the antibody  
1356 response to the expressed transgene protein (51). Whether the administration of ChAdOx1  
1357 nCoV-19 interferes with another ChAdOx1-based vaccine will need to be addressed during  
1358 clinical development.

1359 A limitation is that a MenB vaccine based on a single antigen is unlikely to induce sufficiently  
1360 broad protection (52), as the prevalence of different fHbp variants differs across geographical  
1361 regions. The absence of cross-reactivity across families was previously observed in fHbp  
1362 protein-based vaccines (53). The licensed vaccine based solely on fHbp (rLP2086) contains two  
1363 variants (52, 54). However, introducing two fHbp variants in one adenovirus vector is  
1364 challenging, as the homology between the two variants is highly likely to lead to internal  
1365 recombination depending on the position of the transgenes. In this context, a mRNA-based  
1366 approach may be more amenable to mixing several antigens than the adenovirus platform.  
1367 However, the challenges of preserving the correct expression and presentation of bacterial B cell  
1368 epitopes are likely to be similar between adenovirus and mRNA platforms. Our attempts to  
1369 induce bactericidal responses to other protective MenB antigens in adenoviral vectors were  
1370 unsuccessful (19). Therefore, in an attempt to improve the bactericidal antibody response  
1371 induced by a single fHbp variant and produce a clinically-relevant vaccine, we elected to  
1372 introduce a point mutation abrogating binding to human fH (38). In multiple studies, it has been  
1373 suggested that reduced fH-fHbp binding induces higher SBA responses in mouse models (33, 36,  
1374 37, 55). We introduced two mutations described previously (38) and demonstrated that when  
1375 expressed with the adenoviral vaccine platform, the S223R mutation induced the highest SBA  
1376 titers in the presence of human fH in mice. It would be of interest to assess if the mutation  
1377 resulted in higher cross-reactivity as shown for the original insert. This question is being  
1378 addressed in humans as part of the phase I clinical trial, as another limitation of this study is that  
1379 it relies on mouse models using the accepted correlate of protection (SBA).

1380 .

1381 In conclusion, our results demonstrate that outer membrane bacterial antigen targets can be  
1382 expressed in eukaryotic cells from viral vectors and retain a relevant conformation, so that a  
1383 functional antibody response is elicited. Here, fHbp is presented in a relevant conformation when  
1384 expressed by a viral vector, and the resulting vaccine is able to induce a rapid, strong, longlasting  
1385 and functional antibody response. This vaccine is now being tested in a first-in-human phase I  
1386 clinical trial in healthy adults, and has the potential to address the lingering need for a more cost-  
1387 effective vaccine against serogroup B *Neisseria meningitidis* which has low manufacturing costs  
1388 (56), and only requires a single injection to provide sustained protection in adolescents (57). The  
1389 results of these preclinical studies have the potential to be transferable to other gene-based  
1390 vaccine delivery platforms, such as mRNA, and further highlight the potential of such vaccines  
1391 to be used for other bacterial diseases.

1392

## 1393 **MATERIALS AND METHODS**

1394

### 1395 **Study design**

1396 The overall objective of this study was to investigate the potential of a viral-vectored vaccine  
1397 platform to induce functional protective antibody responses against the bacterial disease caused  
1398 by group B meningococcus. The outer membrane protein target selected was known to contain  
1399 protective epitopes. Several vaccine candidates based on replication-deficient adenoviruses were  
1400 constructed and preclinical batches produced. Groups of mice were immunized with defined

1401 doses of vaccines, and the individual mouse experiments within this study were designed to  
1402 address different questions: murine experiments were performed to explore the strength,  
1403 longevity and cross-reactivity of the responses, as described in the corresponding figure. The  
1404 treatments included vaccine comparators and/or naïve animals. The measurement of the immune  
1405 responses included quantitative (ELISA) and qualitative (serum bactericidal activity) antibody  
1406 assays. All data were included in the analysis. Sample size determination was performed based  
1407 on previous experience with immunization with MenB fHbp mutants and number of available  
1408 transgenic animals, the number of animals per group is indicated in the figure legends. Each  
1409 animal was allocated randomly to a treatment group by the animal caretaker. The experimenter  
1410 was not involved in the randomization. Assays included either two (SBA) or three (ELISA)  
1411 technical replicates.

1412

### 1413 **Vaccine candidates**

1414 The nucleotide sequence for the antigen fHbp, variant 1.1 was obtained from the GenBank  
1415 sequence database (<https://www.ncbi.nlm.nih.gov/genbank/>, NMB\_1870). The sequences were  
1416 codon-optimized for expression in mammalian cells. Recombinant adenoviruses (Ad5,  
1417 ChAdOx1 and ChAdOx2) were generated as described previously using a Gateway-compatible  
1418 entry vector (51, 58, 59), using a CMV promoter and a tissue plasminogen activator signal  
1419 sequence (tPA). The antigen was inserted as ‘full length’ using the immature fHbp sequence,  
1420 including the signal sequence that is cleaved in the mature protein, or truncated (labelled t)  
1421 where the bacterial signal sequence was omitted (mature protein). Empty or irrelevant adenoviral  
1422 vectors were used as controls. Although vectors are dosed as viral particles (VP, quantified by  
1423 OD280) in humans, the antigen-specific immunogenicity is due to infectious virus (IU,  
1424 quantified by titration) that leads to transgene expression as opposed to viral particles which also  
1425 measures non-infectious virus. Therefore, dosing as IUs was selected for these preclinical studies  
1426 aiming at comparing different transgene designs. The P:I ratios (particles:infectivity) were  
1427 measured for all batches. All HuAd5 expressing the various designs had P:I ratios below 39. The  
1428 ChAdOx1 and ChAdOx2 preclinical batches had P:I ratios ranging from 195 to 545. The  
1429 modified vaccinia Ankara (MVA) vectors encoding the same antigen were generated as  
1430 described previously (60). Outer membrane vesicles (OMVs) were generated and purified as  
1431 described previously (61, 62).

1432

### 1433 **Immunogenicity experiments in mice**

1434 Procedures were performed according to the UK Animals (Scientific Procedures) Act 1986 and  
1435 were approved by the University of Oxford Animal Care and Ethical Review Committee or the  
1436 Institutional Animal Care and Use Committee at UCSF Benioff Children’s Hospital Oakland.  
1437 Experimental design followed ARRIVE guidelines. Randomized healthy 6- to 8-week-old  
1438 female BALB/c-OlaHsd and NIH-OlaHsd, Hsd:ICR (CD-1)outbred mice (Harlan, UK), or 8 to  
1439 16-week old human factor H transgenic (hfH Tg BALB/c mice of both sexes (Center for  
1440 Immunobiology and Vaccine Development, Children’s Hospital Oakland Research Institute,  
1441 5700 Martin Luther King Jr. Way, Oakland, CA 94609, USA)(35), were housed in specific  
1442 pathogen-free conditions. Sex, age and human fH concentration for the hfH Tg mice were

1443 randomized in each vaccine group. Injections were performed by intramuscular route unless  
1444 otherwise indicated. Blood was collected from tail bleeds or terminal cardiac bleeds at various  
1445 time points and allowed to clot, then centrifuged at 15000 x g for 10 minutes. Sera were  
1446 aliquoted and stored at -20°C until use. Spleen, lymph nodes and bone marrow were harvested  
1447 following cervical dislocation under terminal sedation. Mouse serum samples collected in the  
1448 USA were shipped and assayed in the UK.

1449

#### 1450 **Detection of antibodies by ELISA against whole cells or recombinant proteins**

1451 Immulon 2HB plates (Thermo Fisher Scientific) were coated with heat-killed whole-cell  
1452 preparations of *N. meningitidis* in phosphate-buffered saline (PBS) (optical density (O.D.)  
1453 600nm = 0.1), or with recombinant fHbp protein expressed in *E.coli* using an fHbp expression  
1454 construct as previously described (63), at 2.5 µg/ml in carbonate-bicarbonate buffer (Sigma  
1455 Aldrich). Serum samples were serially diluted in PBS containing 0.5% (v/v) Tween-20 and 1%  
1456 (w/v) bovine serum albumin (BSA). High, medium, and low positive quality controls were used  
1457 in each plate (anti-PorA monoclonal antibody P1.7 or anti-fHbp monoclonal antibody JAR4,  
1458 National Institute of Biological Standards and Controls). Serum from naïve BALB/c mice was  
1459 used as negative control along with buffer only. Antibody binding was detected with horseradish  
1460 peroxidase-conjugated goat anti-mouse IgG (Jackson ImmunoResearch Inc) and visualized with  
1461 3,3',5,5'-Tetramethylbenzidine substrate (TMB, Sigma Aldrich). The reaction was stopped with  
1462 50 µl H<sub>2</sub>SO<sub>4</sub>, and O.D. were measured at 450 nm with a reduction at 600 nm. Endpoint titers  
1463 were defined as the serum dilution corresponding to the O.D. reading above two times the  
1464 average of naïve negative control serum.

1465

#### 1466 **Serum bactericidal assay (SBA)**

1467 SBAs were performed as described previously using 25% (vol/vol) human serum as a  
1468 complement source, from donors screened for no intrinsic SBA (64). Heat-inactivated murine  
1469 serum samples were serially diluted in Hanks Balanced Salt Solution supplemented with 0.5%  
1470 BSA. SBA titer was defined as the reciprocal of the highest dilution of serum that yielded ≥50%  
1471 decrease in colony forming units relative to that of control wells within 60 minutes at 37°C  
1472 without CO<sub>2</sub>. Meningococcal target strains were provided by the Manchester Meningococcal  
1473 reference Unit, UK).

1474

#### 1475 **Enumeration of antigen-specific antibody-secreting B cells by enzyme-linked immune-spot 1476 assay (ELISPOT)**

1477 Ninety-six well filtration ELISPOT plates (Millipore) were coated with recombinant fHbp at 2.5  
1478 µg/ml or 1:1000 dilution of goat-anti-mouse IgG (BioLegend, positive controls), or PBS (blank  
1479 wells). Splenocytes or bone marrow cells (acquired by flushing the bones with PBS through a  
1480 needle) were incubated in duplicates at a concentration of 4x10<sup>5</sup>, 2x10<sup>5</sup> and 1x10<sup>5</sup> cells per well.  
1481 Detection of spots was performed with alkaline phosphatase conjugated goat-anti-mouse IgG  
1482 (Invitrogen) followed by alkaline phosphatase substrate (Bio-RAD). Spot counts were performed  
1483 using an AID ELISpot Reader ELR03 and ELISpot software as described previously (65).

1484 Results were expressed as the number of antigen-specific spots detected per million cells, minus  
1485 the number of spots counted in the absence of antigen (medium only). A negative result was  
1486 recorded as 1.

1487

### 1488 **Detection of fHbp expression and hfH binding by flow cytometry**

1489 Human epithelial HeLa cells (CCL-2, the American Type Culture Collection) were infected with  
1490  $5 \times 10^8$  IU of adenovirus constructs and incubated overnight at 37°C. Infected cells were stained  
1491 with anti-fHbp monoclonal antibody JAR5 (National Institute of Biological Standards and  
1492 Controls) followed by anti-IgG AlexaFluor-488 (Invitrogen, 1:10000 dilution), for 30 minutes at  
1493 4°C. The cells were washed with AutoMacs running buffer (Miltenyi) pre- and post-antibody  
1494 staining, fixed and permeabilized with a Fixation/Permeabilization kit (BD Biosciences). The  
1495 antibody incubation steps with JAR5/anti-IgG AlexaFluor-488 were repeated for intracellular  
1496 staining. The stained cells were then ran on a FACSCalibur flow cytometer (BD Biosciences).  
1497 The percentage of fHbp expressing cells was measured using FlowJo software (BD Biosciences).

1498

### 1499 **Statistics**

1500 Antibody titers as measured by ELISA are presented as median +/- 95% confidence intervals,  
1501 SBA titers are presented as geometric mean titers +/- 95% confidence intervals. Statistical  
1502 analysis of differences between antibody titers were performed using either Kruskal-Wallis test,  
1503 Mann-Whitney test, two-way ANOVA with Bonferroni post-tests, or one-way ANOVA with  
1504 Dunn's multiple comparisons test when appropriate and as stated, using Prism 5 (Graphpad Inc.).  
1505 The experimental units are single animals. No data exclusion was done. Potential confounders  
1506 were minimized by changing orders of treatments and measurements and random cage location.

1865

1866

1867 **Acknowledgments:** The authors thank Ian M. Feavers and Martin C. J. Maiden for support and  
1868 intellectual input including in funding applications; the Viral Vector Core Facility  
1869 (VVCF) for production of all adenovirus vaccine candidates; the Oxford Protein  
1870 Production Facility (OPPF), in particular Jo Flannelly and Raymond Owens for support  
1871 in production of recombinant proteins; Ray Borrow, Jamie Findlow and Jay Lucidarme  
1872 for providing meningococcal strains; and Mariagrazia Pizza for supporting information  
1873 on strains. MCJM, DW, AVH, AJP and CR are Jenner Investigators. CSR is supported  
1874 by the Equal Opportunities Foundation (Hong Kong), the Braithwaite Family Foundation  
1875 and the Bill and Melinda Gates Foundation.

1876

1877 **Funding:** This work was supported by Action Medical Research SP4594 (to CD and CSR);  
1878 MeningitisNow (to LM, GKP, and CSR); Medical Research Council Confidence in  
1879 Concept award – Oxford (to LSR, AJP, and CSR); Oxford Innovation Fund 9534 (to  
1880 LSR, DW, AJP, and CSR); Medical Research Council DPFS MRM0076931 (to CD, LM,  
1881 LSR, AJP, and CSR); and NIHR Oxford Biomedical Research Centre, Oxford, United  
1882 Kingdom, Vaccine theme (to LC, AVH, AJP, and CSR).

1883

1884 **Author contributions:**

1885 CSR, AVH and AJP conceptualized the study. AJP and CSR generated the funding.  
1886 DW, PTB, AJP and CSR led the investigations. CSR, CD, LM, DW and PTB

1887 developed the methodologies. The experiments were performed by CD, LM, NW,  
1888 LSR, EC, GKP for the cloning, generation of vaccine candidates, immunogenicity in  
1889 wild type mice including all readouts, KS and PTB performed the immunogenicity  
1890 studies in transgenic mice. Visualization of the results was performed by CD. CD,  
1891 LM, LC, DW, PTB, AJP and CSR supervised the laboratory work. CSR and CD wrote  
1892 the paper. CD, LM, KS, PTB, AJP and CSR edited the paper. All authors reviewed the  
1893 paper.  
1894

1895 *Competing interests:* AJP is Chair of U.K. Dept. Health and Social Care's (DHSC) Joint  
1896 Committee on Vaccination & Immunisation (JCVI). The views expressed in this article  
1897 do not necessarily represent the views of DHSC, JCVI. CD, LM, DW, CSR, AJP and  
1898 AVH are named inventors on a patent in the field of meningococcal vaccines  
1899 (PCT/GB2021/052692, Compositions And Methods For Inducing An Immune  
1900 Response). AJP waives his rights under any patent. PTB is a named inventor on patents  
1901 related to meningococcal vaccines (Issued U.S. Patent No. 10,995,122 B2). AVH is  
1902 named as an inventor on a patent covering use of simian adenoviral vectored vaccines.  
1903 PB has performed paid consultancy work for Pfizer. CSR has performed paid  
1904 consultancy for Guidepoint. NW, LSR, LC, JPD, KS, and GKP declare that they have no  
1905 competing interests.  
1906

1907 *Data and materials availability:* All data are available in the main text or the supplementary  
1908 materials. Materials transfer agreements (MTAs) will be required for access to the  
1909 materials. All MTA request should be directed to Andrew J. Pollard at  
1910 Andrew.pollard@paediatrics.ox.ac.uk  
1911

## 1913 **Figures**

1914

1915

1916 **Fig. 1. HuAd5 vectors expressing different versions of fHbp are immunogenic in mice.**  
1917 Groups of mice (n=8 to 16) were immunized with HuAd5 expressing fHbp full length or  
1918 truncated, or nOMVs as indicated. **(A)** Serum IgG antibody responses were detected in serum  
1919 samples by ELISA against heat inactivated H44/76 bacteria, 2 and 6 weeks post a single  
1920 injection. **(B)** IgG subclass titers were measured at week 6. In (A and B), the titers for each  
1921 individual mouse, the median and 95% confidence interval of the group, are presented. **(C)**  
1922 Individual (n=6) fHbp-specific T cell responses were assessed in spleens two weeks post a single  
1923 injection of  $10^8$  or  $10^9$  infectious units per mouse. **(D)** Mice (n=4 to 6) were immunized as per  
1924 (A), and SBA responses were measured in pooled serum samples at week 42. **(E)** SBA titers  
1925 were measured in pooled serum samples from BALB/c and NIH Swiss mice (n=4 to 6 per group  
1926 and strain) two weeks post injection with  $10^9$  infectious units of HuAd5 fHbp (blue); white bars  
1927 are titers observed in pooled naïve mouse serum samples. **(F)** Shown is a dose response in  
1928 BALB/c mice. Individual IgG and SBA titers were measured 6 weeks after a single injection

1929 with HuAd5 fHbp at the doses indicated on the x-axis (n=4 to 8). (G) Shown is a schematic of  
1930 the longitudinal study (n=10) assessing the persistence of antibody responses after a single dose  
1931 of HuAd5 fHbp (blue) as compared with two doses of native (n) OMVs (pink). (H and I) SBA  
1932 titers in pooled serum (H) and individual IgG titers (I) at the different time points are shown. In  
1933 (E, F, and H), the horizontal dotted red line denotes the putative threshold associated with  
1934 protection (titer of 1:4). Individual data in (A, B, F left panel and I) are presented as median +/-  
1935 95% confidence intervals, and data in (C and F right panel) are presented as geometric mean  
1936 titers +/- 95% confidence intervals. Data were analyzed by Kruskal Wallis with Dunns multiple  
1937 comparison test.

1938

1939

1940

1941 **Fig. 2. A single adenovirus is sufficient to induce high SBA response in mice.** Shown are the  
1942 effects of prime-boost regimen using HuAd5 and nOMV combinations (A, B, C and D),  
1943 or HuAd5 and MVA combinations (E, F, G and H). Mice (n=5 to 6 per group) were  
1944 immunized with the regimen indicated ( $10^9$  infectious units HuAd5, 5  $\mu$ g nOMV or  $10^7$   
1945 infectious units MVA). (A) Shown is the timeline for the HuAd5 and nOMV  
1946 immunization regimen. (B and C) Individual serum IgG titers are shown. (C) SBA titers  
1947 in pooled serum were measured against strain H44/76-SL expressing the homologous  
1948 fHbp (variant 1.1) (C) or strain BZ83 expressing an homologous fHbp but heterologous  
1949 to the PorA in the nOMV (D). The horizontal dotted red line denotes the putative  
1950 threshold associated with protection (titer of 1:4). (E) Shown is the timeline for the  
1951 HuAd5 and MVA immunization regimen. (F) SBA responses measured in pooled serum  
1952 samples at different time points. (G and H) At week 50, individual serum IgG titers (G)  
1953 and bone marrow B cell responses (H) were measured in each group. Individual data in  
1954 (B and G) are presented as median +/- 95% confidence intervals, and data in (D, F and H)  
1955 are presented as the geometric mean +/- 95% confidence interval of the group as  
1956 indicated. Data in (B, G and H) were analyzed by Kruskal Wallis with Dunns multiple  
1957 comparison test.

1958

1959

1960

1961 **Fig. 3. A single dose of adenovirus vaccine induces a persistent humoral response in mice.**  
1962 Kinetics of SBA responses against different strains and comparison with 4CMenB are  
1963 shown. (A) Groups of mice (n=4 to 8) were immunized as indicated and blood samples  
1964 were collected at different time points. At the termination of experiment, spleens and  
1965 bone marrow were collected. HD, human dose. (B) Individual anti-fHbp endpoint titers  
1966 were measured by ELISA at weeks 6 and 20; data show individual titers, the median and  
1967 95% confidence intervals for each group. (C) SBA using human complement was  
1968 performed using pooled serum samples at the different time points against strain  
1969 H44/76SL expressing the homologous fHbp and strain NZ98/254 expressing a  
1970 heterologous fHbp but homologous for the OMV component in 4CMenB. The titer

1971 obtained for each pooled sample is indicated. **(D)** At week 56, individual SBA titers were  
1972 measured; geometric means and 95% confidence intervals are indicated. **(E)** At week 56,  
1973 individual antibody-secreting cell numbers were calculated in spleens and bone marrow  
1974 samples; geometric means and confidence intervals are indicated for each organ. **(F)** A  
1975 second longitudinal study compared HuAd5 fHbp vaccination with a higher dose of  
1976 4CMenB. **(G and H)** SBA titers were measured at different time points in pooled serum  
1977 samples against strain H44/76 **(G)** and BZ198 **(H)**. **(I and J)** In an independent  
1978 experiment **(I)**, sufficient blood volumes were collected at four time points to measure  
1979 individual SBA titers **(J)**. Individual SBA titers, geometric means, and confidence  
1980 intervals are reported. The horizontal dotted red line in (D, E, G, H, and J) denotes the  
1981 putative threshold associated with protection (titer of 1:4). Data in (B, D, E and J) were  
1982 analyzed by Kruskal Wallis with Dunns multiple comparison test.

1984  
1985  
1986

1987 **Fig. 4. The clinically relevant ChAdOx1 vector encoding the selected antigen design induces**  
1988 **SBA in mice.** The impact of clinically-relevant modifications to the vaccine on the SBA  
1989 response in mice is shown. Groups of BALB/c mice (n= 4 or 6) were immunized with a  
1990 single dose of adenovirus vaccine using different backbones and either a short or a longer  
1991 version of the CMV promoter as indicated. Individual SBA titers, geometric mean and  
1992 95% CI are shown. The horizontal dotted red line denotes the putative threshold  
1993 associated with protection (titer of 1:4).

1994  
1995  
1996

1997 **Fig. 5. A point mutation in the transgene abrogates binding to human fH and increases**  
1998 **SBA responses in the presence of human fH.** Point-mutations were introduced in the  
1999 fHbp transgene (H248L) and (S223R). **(A)** In vitro expression of the resulting protein,  
2000 and capacity to bind human factor H was verified in HeLa cells infected with the  
2001 adenoviruses as mentioned. In the top row, expression of the antigen was measured by  
2002 flow cytometry using an anti-fHbp monoclonal antibody (JAR5), and expressed as  
2003 percentage of positive cells. Middle and bottom rows: HeLa cells were infected with the  
2004 adenoviruses as mentioned, followed by incubation with human serum fH (middle row)  
2005 or with recombinant human fH (bottom row). Detection of bound human fH was  
2006 performed using a commercial anti-human fH antibody by flow cytometry.  
2007 Representative panels from an individual experiment are shown. **(B)** Immunogenicity of  
2008 the mutant-expressing vectors was measured in the absence or presence of human (h) fH.  
2009 Groups of BALB/c, CD-1 or hfH transgenic (Tg) mice (n=5 for BALB/c and CD-1, n=12  
2010 for hfH Tg mice) were immunized once with the adenovirus as mentioned. **(C to E)**  
2011 individual serum SBA titers against strain H44/76-SL were measured at weeks 2, 6 or 14  
2012 in BALB/c **(C)**, CD-1 **(D)**, and hfH Tg BALB/c **(E)** mice. **(F)** Individual SBA titers were

2013 measured in fH Tg mice vaccinated in an independent experiment repeating the  
2014 assessment of HuAd5 fHbp S223R. Individual human fH amounts and correlation with  
2015 SBA titers for both experiments are shown in fig. S3. **(G)** Shown is a comparison of  
2016 immunogenicity between HuAd5 fHbp-S223R and 4CMenB in transgenic mice  
2017 expressing human fH (n=12). Tg mice were immunized once with the vectors expressing  
2018 the S223R mutant, or three times with 4CMenB, and individual SBA titers were  
2019 measured at several time points post injection against strain H44/76-SL. For (C to G),  
2020 geometric means and 95% confidence intervals are indicated. Data were analyzed by  
2021 Kruskal Wallis with Dunns multiple comparison test, except for (D), data were analyzed  
2022 by Mann-Whitney test. The horizontal dotted red line denotes the putative threshold  
2023 associated with protection (titer of 1:4).

2024

2025

2026 **Fig. 6. SBA responses are induced by the clinical vaccine composition ChAdOx1**  
2027 **fHbpS223R in mice.** **(A)** Immunogenicity and dose response experiment results are  
2028 shown for ChAdOx1 fHbp-S223R vaccination in three strains of mice (two inbred and  
2029 one outbred). Individual SBA titers at week 6 are indicated with geometric means and  
2030 95% confidence intervals. **(B)** Longitudinal analysis of SBA responses in the presence of  
2031 hfH are shown. hfH Tg mice (n=10) were immunized as indicated. Individual SBA titers  
2032 geometric means and 95% confidence intervals are shown for mice followed up to 21  
2033 weeks post prime. Data were analyzed by Kruskal Wallis with Dunns multiple  
2034 comparison test. The horizontal dotted red line denotes the putative threshold associated  
2035 with protection (titer of 1:4).

2061 **Table 1. Bactericidal activity was measured against a panel of MenB strains.** The target strains are indicated along with their fHbp variant, relative potency  
 2062 and clonal complex. The table shows the SBA titers elicited in groups of mice immunized with either rLP2086 (after 1, 2 or 3 doses), 4CMenB (after 1, 2 or 3  
 2063 doses) or HuAd5 fHbp (single dose), at the time points indicated. The assays were performed using human complement and pooled serum samples from each  
 2064 group against each of the strain. \* The relative potency for fHbp is reported from the meningococcal antigen typing system (MATS) (Plikaytis *et al.*, 2012). ND,  
 2065 not determined.

2071 **Fig. S1. Immunogenicity of adenoviral vectored vaccine candidates in mice models**

2072 (A) Individual serum bactericidal assay (SBA) titers in mice immunized with a single dose of human adenovirus 5  
 2073 (HuAd5) containing a tissue plasminogen activator (tPA) signal sequence followed by the mature form of the group  
 2074 B meningococcus (MenB) antigen factor H binding protein (fHbp) (referred to as truncated in this study), as  
 2075 compared with the full length fHbp with its own signal sequence, and no tPA (n=4 mice per group) (B) Individual T  
 2076 cell responses in mice immunized with a single dose of HuAd5 containing a tPA signal sequence followed by the  
 2077 mature form of fHbp (referred to as truncated in this study, light blue), as compared with the immature, full length  
 2078 fHbp with its own signal sequence, with or without tPA (both dark blue) (n=6 mice per group). IFN- $\gamma$ , interferon- $\gamma$ ;  
 2079 PBMC, peripheral blood mononuclear cells. (C) Outbred CD-1 mice were immunized by the routes indicated on the  
 2080 X-axis. IU, infectious units. Individual SBA titers were measured at week 6 (n=5 to 6 mice per group). Data in (C)  
 2081 were analyzed by Kruskal Wallis with Dunns multiple comparison test. Geometric mean and 95% confidence  
 2082 intervals (CI) are indicated for all panels. The red dashed lines indicate the protective SBA titer of 4.
