Abstract: Intraplate faulting and the resultant earthquakes are not well understood because of their complex distribution, long period of seismic recurrence, and poor exposure of surface rupture. Pre-existing weaknesses should be studied to understand intraplate faulting and earthquakes. We are developing a long-term project to understand Korean-type intraplate fault behavior and recurrence intervals. As the first step, we will establish an integrated system for production, analysis, and management of fault data related to active crustal deformation. Here we propose a new format for fault data description and management.
keywords: Intraplate faulting, earthquake, pre-existing weakness, fault data description and management

1. Introduction

Plate boundary faults, loaded by steady-state relative plate motion, quasi-periodically release strain energy causing concentration of earthquake along plate boundary (Liu et al., 2011). In contrast, intraplate faults with a high degree of complexity and connectivity tend to be selectively reactivated in response to far field stress (Liu et al., 2011). Therefore, earthquakes in intraplate region are spatiotemporally much less regular than those in interplate region (Liu et al., 2011). Although some of the most destructive earthquakes in the world have occurred in intraplate region (England and Jackson, 2011), potentially active seismogenic structures are unfortunately not well exposed at surface due to coverage by thick recent sediments. In addition, moderate earthquakes within intraplate region commonly accompanied with rupture propagation beneath the surface. Earthquake behavior of blind active faults could be underestimated, until the occurrence of damaging earthquakes (Yule and Sieh, 2003 and references therein).

Most intraplate earthquakes occur along pre-existing weaknesses (Wibberley et al., 2008 and references therein). Under a homogeneous stress field, preferential reactivation is controlled by (1) attitudes of pre-existing fractures to imposed stress, (2) presence of anomalously low-friction material along particular faults, (3) heterogeneous distribution of fluid overpressure, and (4) fault distribution complexity, such as fault segment, connectivity, and discontinuity (e.g. Barka and Kadinsky-Cade, 1988; Sibson, 1995; Kelly et al., 1999). We therefore need to study pre-existing weaknesses (e.g., basement faults) in detail to understand intraplate faulting and the resultant earthquakes. The Geology Division at the Korea Institute of Geoscience and Mineral Resources (KIGAM) is developing a long-term project to build a Korean-type intraplate fault behavior and recurrence model. This project, referred to as the

Intraplate Setting Active Fault behavior & Earthquake recurrence or IntraSAFE, will establish an integrated system for production, analysis, and management of highly reliable fault data. To do this, we need to compile already-published fault data using a standardized description format and then manage additional data to be produced in the same format.

We therefore propose a new simplified format for fault outcrop descriptions in the integrated system (Fig. 1). We also present an example (Fig. 2) of a re-written fault outcrop description in the suggested format, using the data from the main core of the northern Yangsan Fault, originally produced by Cheon et al. (2019).

2. Why Do We Need Integrated Fault Data?

The widely accepted conceptual definition of a fault is any surface or narrow zone with visible shear displacement along it (Fossen, 2010). Although the term fault covers both brittle and ductile slip discontinuities, many geologists implicitly restrict the term to refer only to slip discontinuities dominated by brittle behavior (Fossen, 2010). Generally, a brittle fault zone can be divided into a fault core of cataclastic rocks, where most of the displacement is accommodated, and a surrounding damage zone of subsidiary structures (e.g. Chester et al., 1993; Caine et al., 1996; Billi et al., 2003; Faulkner et al., 2010). Additionally, a physically-discrete mixed zone could develop between fault core and damage zone (e.g. Rawling and Goodwin, 2003, 2006). Materials and structural complexity within a fault zone play an important role in controlling its hydrological, mechanical, and seismological properties and behaviors (e.g. Rawling et al., 2001; Wibberley et al., 2008; Faulkner et al., 2010). Thus, detailed quantitative information on the complex internal structure of a fault zone is definitely required to understand its earthquake behavior. A collection of fault outcrop information could provide significant data to understand fault segmentation. During the last several decades, many Korean researchers have studied the structure and evolutionary history of Quaternary and basement faults. Recently, the damage caused by two moderate earthquakes (2016 Gyeongju and 2017 Pohang earthquakes; e.g. Kim Y et al., 2016; Kim K-H et al., 2016, 2017; Choi et al., 2019) in the southeastern part of Korea have led to an increase in personal and national interest in fault activity. As a result, several research projects concerning faults and earthquakes are being conducted. However, there are still no standardized formats for fault outcrop description and data acquisition, and a large amount of information on faults in the Korean peninsula is still distributed. It is thus necessary to build a database in a unified format via standardization and systematization. The integration and advancement of fault-to-earthquake information will contribute to a reliable archive of crustal deformation information and can be used as concrete data for earthquake disaster assessment.

3. Summary Of The Fault Outcrop Description Form

The proposed description format contains a series of fault outcrop information, which is divided into basement fault information and Quaternary movement information. The items are as follows:

[Basement Fault Information]

(1) Investigation Name

: Describe name of fault outcrop.

(2) Researcher or Reference

: Describe researcher (or reference) who conducts fault investigation.

(3) Investigation Locality

(Administrative District, GPS coordinates)

: Describe the place where fault outcrop is situated.

(4) Photo

: Insert representative picture or photograph of fault outcrop.

(5) Fault Strike

: Describe fault strike, which is the direction of a line created by the intersection of a fault plane and a horizontal surface, 0° to 360° clockwise relative to North. All orientation data is described in azimuth notation.

(6) Fault Dip

: Describe dip of fault surface. It is angle of inclination measured from the horizontal.

(7) Fault Type

: Describe kinematics of fault. It is described as "RL (right-lateral (dextral) fault)", "LL (left-lateral (sinistral) fault)", "N (normal fault)", "R (reverse fault)", If it is oblique fault, it can be described as combination of lateral slip and dip slip, such as RL+N, RL+R, N+LL, R+RL, etc. If the fault has multiple movement kinematics, describe the dominant kinematics and then minor kinematics.

(8) Fault Striation

: Describe striation on fault surface. Striations are linear furrows, or linear marks on fault surface. It reveals the direction of movement along the fault. It can be described as "trend/plunge".

(9) Internal Structure

(Width, Kinematic Indicator, Deformation Characteristics)

: Describe characteristics of internal structure of fault zone (fault core, fault damage zone, mixed zone, fault rock type and material, alteration, microstructure, fault rock K-Ar age, and so on).

(10) Basement rocks Information

(Lithology, Stratigraphy, Radiometric Age)

: Describe information on basement rocks transected by fault.

[Quaternary Movement Information]

(11) Quaternary Movement Type

: Describe fault kinematics during the Quaternary.

(12) Quaternary offset Indicator

(Marker, Offset, Formation Age)

: Describe Quaternary displacement indicators. Markers of the Quaternary offset indicator are mainly geomorphic surface and/or sediment.

(13) Age of Last Movement

: Describe the latest movement of fault (ky BP) based on offset marker whose age can be estimated.

(14) Slip Rate

: Describe the slip rate (mm/yr) of fault during the Quaternary, determined from displacement and age of offset marker.

4. Acknowledgements

This research was supported by a grant (2018M3D7A1052897) from the Research on Geologic Hazard Assessment of Large Fault System Focusing on the Central Region of the Yangsan Fault from Basic Research Project of the Institute of Geoscience and Mineral Resources (KIGAM) funded by the National Research Foundation of Korea. We gratefully thank Prof. Park, S.I. and Prof. Cho. H. for valuable reviews.
