

MoS₂ Nanosheets Uniformly Anchored on NiMoO₄ Nanorods, a Highly Active Hierarchical Nanostructure Catalyst for Oxygen Evolution Reaction and Pseudo-Capacitors

Getachew Solomon, Mojtaba Gilzad Kohan, Raffaello Mazzaro, Matteo Jugovac, Paolo Moras, Vittorio Morandi, Isabella Concina, and Alberto Vomiero*

Hierarchical nanostructures have attracted considerable research attention due to their applications in the catalysis field. Herein, we design a versatile hierarchical nanostructure composed of NiMoO₄ nanorods surrounded by active MoS₂ nanosheets on an interconnected nickel foam substrate. The as-prepared nanostructure exhibits excellent oxygen evolution reaction performance, producing a current density of 10 mA cm⁻² at an overpotential of 90 mV, in comparison with 220 mV necessary to reach a similar current density for NiMoO₄. This behavior originates from the structural/morphological properties of the MoS₂ nanosheets, which present numerous surface-active sites and allow good contact with the electrolyte. Besides, the structures can effectively store charges, due to their unique branched network providing accessible active surface area, which facilitates intermediates adsorptions. Particularly, NiMoO₄/MoS₂ shows a charge capacity of 358 mAhg⁻¹ at a current of 0.5 A g⁻¹ (230 mAhg⁻¹ for NiMoO₄), thus suggesting promising applications for charge-storing devices.

industrial standard of electrolysis, such criteria are critical and still challenging. For energy storage devices, such as supercapacitors, an active catalyst capable of providing high power density and superior cycle life is a necessary condition. Pseudo capacitors exhibit very high-power density similar to that of double-layer capacitor devices. However, they differ from a double-layer capacitor because of their battery-like redox processes of the charge storage principles. Transition metal oxides (TMOs) such as NiCo₂O₄@NiMoO₄,^[6] NiCo-S (Fe-NiCo-S),^[7] CoMxP/CC (M = Fe, Mn, and Ni),^[8] and NiCoFe-P^[9] have been employed as active electrocatalysts for OER and supercapacitors. Pseudocapacitive-type nanomaterials, especially TMOs or hydroxides, such as nickel oxide (NiO),^[10,11] NiMoO₄@Co(OH)₂,^[12] are widely investigated as candidates for supercapacitor applications due to their various oxidation states that contribute to the pseudo capacitance properties.

Hierarchical-structured catalysts have attracted considerable attention in the field of materials for renewable energy applications. These structures can effectively increase the active surface area owing to their morphology. We recently reported the catalytic efficiency of hydrated core NiMoO₄ and shell Co₃O₄

1. Introduction

Numerous alternatives have been explored and developed for advancing the technologies of the renewable energy sector. For overall water splitting, an efficient electrocatalyst capable of splitting water into its components is needed.^[1-5] Low cost, high activity, and long-term stability in the electrolyte are the major criteria for an optimal electrocatalyst. To meet the

heterostructure towards OER, for which we revealed that the high catalytic activity is due to the in situ catalysts reconstruction process and leaching out of Mo atom from crystalline NiMoO₄ structure.^[13] Motivated by that result, we extended the work by wrapping the hydrated NiMoO₄ nanorods with two-dimensional MoS₂ nanosheets. It is known that the presence of MoS₂ together with other nanostructures can enhance the properties of different composites, but modulating the exposed surface area of the nanostructure.^[14,15] It was reported that interconnected hierarchical nanosheets exhibit an improved surface area that enhances the adsorption or intercalation of reaction intermediates, due to the ease of electrolyte diffusion throughout the structure.^[16] MoS₂ nanosheets present a promising catalyst for the hydrogen evolution reaction (HER).^[17] MoS₂ nanosheets are effectively used in altering the surface properties of charge-storing devices due to their outstanding capacitive performance.^[16–19]

Hierarchical nanostructure (like the trees with trunks and branches) provides a perfect contact area with electrolytes. Thanks to the nondestructive synthesis methods of magnetron sputtering, the morphology of NiMoO₄ nanorods was preserved. We believe that this strategy, involving the construction of vertically aligned nanorods with subsequent MoS₂ wrapping on the nanorods, can efficiently improve the electrochemically active surface area, allowing it to be extended to many electrochemical applications. Besides, the use of hierarchical nanostructures can benefit from enhanced electrolyte penetration and avoiding particle agglomeration. NiMoO₄ possesses a very high specific capacitance and conductivity due to its excellent redox activity and the ability to accommodate several oxidation states. The

decorated nanosheet layers can also store charges and induce a faradaic charge transfer process. As a result, the synergistic effect arising from NiMoO₄ and MoS₂ could enhance the electrochemical properties of the hierarchical structure (NiMoO₄/MoS₂). To the best of our knowledge, the OER activity of NiMoO₄/MoS₂ is not explored yet.

2. Results and Discussion

2.1. Structural and Morphological Characterizations

Scanning electron microscopy (SEM) images of the hierarchical NiMoO₄/MoS₂ nanostructure (Figure 1) show that the micro rods are vertically oriented and grown on a Nickel foam substrate. NiMoO₄ grown by optimizing the precursors and synthesis temperature produces well-aligned vertically grown smooth nanorods (Figure 1a). The deposition of MoS₂ via magnetron sputtering is performed for 30 min, with a rate of around 0.5 nm s⁻¹, calculated by combining the deposition duration, cross-sectional SEM, and RBS analyses, which were also characterized in our recent work.^[20] The morphology of MoS₂ deposited for 7 min (for comparison purposes, Figure S1a, I), displays a spot of nanoparticles, leaving most of the NiMoO₄ nanorods uncovered. However, for the 30 min MoS₂ deposition (Figure 1c,d), the as-synthesized NiMoO₄ rods are completely covered and interconnected nanosheets are visible.

The MoS₂ nanoflakes are grown homogeneously all over the nanorods, decorating the NiMoO₄ nanostructure. The construction of the hierarchical NiMoO₄/MoS₂ nanostructure can be

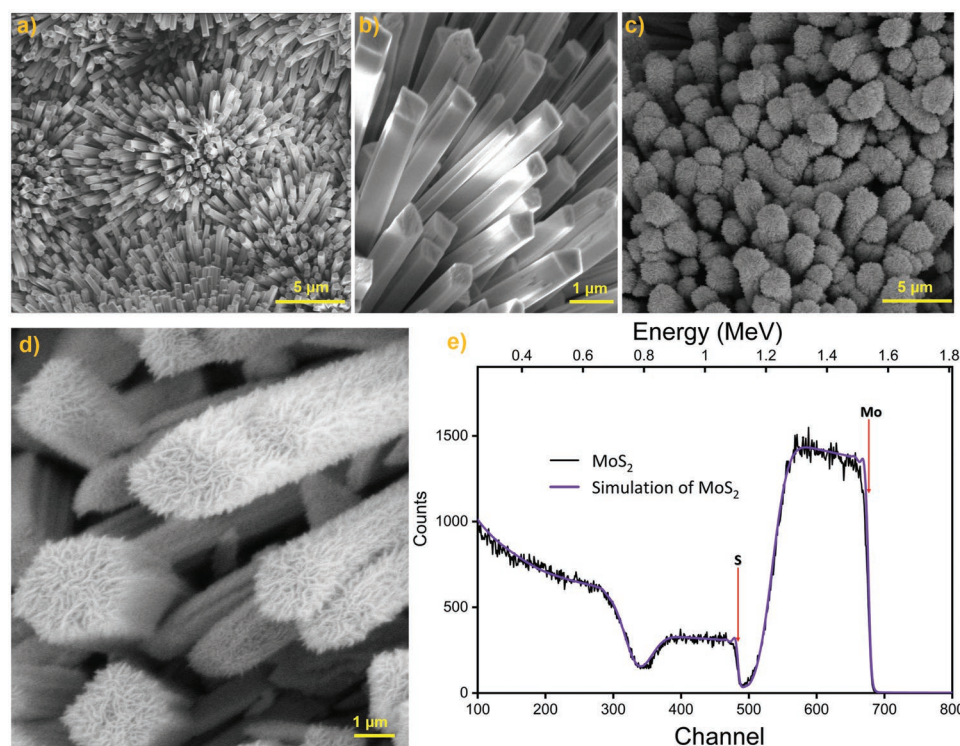

Figure 1. Morphological and structural characterization: SEM images for a,b) NiMoO₄, and c,d) MoS₂ wrapping NiMoO₄ micro-rods, e) RBS with corresponding x-RUMP code simulations spectra for MoS₂. The surface edges for Mo and S are indicated by the vertical arrows.

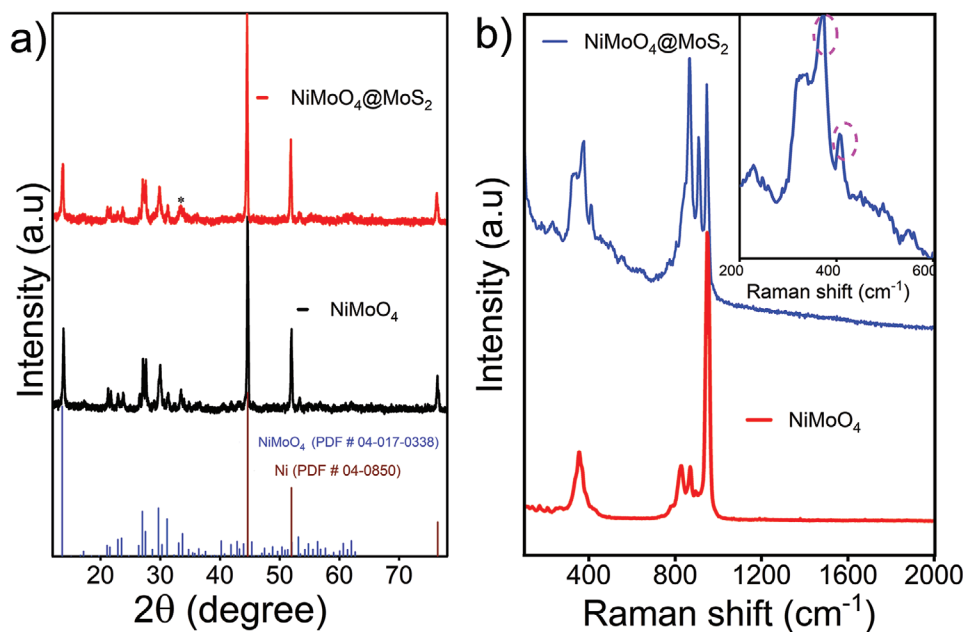

Figure 2. a) X-ray diffraction spectra of NiMoO₄/MoS₂ (red) and NiMoO₄ (black), Bottom line: expected reflections from NiMoO₄ (blue), nickel substrate (wine). b) Raman spectra of NiMoO₄ (red) and NiMoO₄/MoS₂ (blue), with an inset showing the resolution of the Raman peak for MoS₂ at 378 and 408 cm⁻¹ associated with E_{12g} and A_{1g} vibration modes of MoS₂.

easily recognized in the SEM images. Hierarchical nanostructure created due to the strong attachment of MoS₂ nanosheets can be beneficial for improving the catalysis process because it can easily provide an extra pathway for ions and electrons transport at the interface. (Figure 1e) shows the RBS spectra of MoS₂ with a uniform in-depth distribution of all the detected elements. The increased yield of the high-energy signal marked by the arrows confirms the presence of Mo and S. The atomic ratio for Mo:S is calculated as 1:1.5 with the help of RUMP code simulations (in agreement with our previous work^[20]).

The composition and phase structure of as-synthesized nanostructure were investigated by XRD and Raman spectra. XRD patterns of NiMoO₄ and NiMoO₄/MoS₂ (Figure 2a) confirm the presence of hydrated NiMoO₄. The intense peaks at 2θ = 44.4°, 51.8°, and 76.3° correspond to the nickel substrate, indexed by PDF# 04-0850. The remaining peak corresponds to the diffraction pattern of hydrated nickel molybdate (NiMoO₄·xH₂O), referenced by PDF# 04-017-0338.^[21] For simplicity, we named the NiMoO₄·xH₂O as NiMoO₄. The XRD pattern of NiMoO₄ is not affected by the addition of MoS₂. The reflection at 2θ = 33.4° (labeled asterisks), which is broad compared to the XRD peak of NiMoO₄, confirms the presence of MoS₂.^[17,22]

The weak XRD pattern of MoS₂ is overlapped with the strong peak of NiMoO₄, and some of the reflections pertaining to MoS₂ are not completely visible in the diffraction pattern. We observed a similarly broad and weak XRD peak for sputtered MoS₂.^[17,23] The Raman spectrum of NiMoO₄ (Figure 2b) displays an intense peak at 949 cm⁻¹ (due to a symmetric Mo=O bond), at 869 cm⁻¹ and at 826 cm⁻¹ (due to an asymmetric Mo=O bond), and a broad peak at 356 cm⁻¹ (due to Mo-O bending).^[21,24,25] The intensity of the Raman band associated with NiMoO₄ decreased due to the presence of MoS₂. The two characteristic bands at ≈378 and ≈408 cm⁻¹ associated

with E_{12g} and A_{1g} vibration modes of MoS₂, respectively (see inset of Figure 2b), clearly show the presence of 2H MoS₂ nanosheets.^[23]

MoS₂ sputtering deposition results in an anisotropic coating of pristine NiMoO₄, as highlighted by HR-TEM and low-magnification micrographs (Figure 3a). The nanowire coating degree depends on the relative nanowire orientation during the sputtering process and the portion of nanowire considered for the analysis, ranging from almost pristine NiMoO₄ nanowires to fully covered ones (Figure S1, Supporting Information). The hydrated NiMoO₄ nanowires crystal phase is confirmed by high magnification micrographs, as well as MoS₂ one (Figure 3b,c), whose crystallinity degree varies in different areas of the sample. The high-magnification micrographs display a lattice spacing of 0.63 nm, corresponding to the (002) plane of the hexagonal MoS₂, which is consistent with the interlayer spacing of hexagonal 2H-MoS₂.^[20] STEM-EDS mapping of a fully coated NW displays the selective concentration of Ni-Kα signal in the core of the nanowire, while Mo and S have homogeneously distributed over all the heterostructure, confirming the distribution of all elements across the hierarchical structures (Figure 3d,e and Figures S2 and S3, Supporting Information). The O-related signal is also located in the core of the heterostructure, but it is worth noticing a slight background signal on the shell area, suggesting the possible presence of surface oxide impurities, resulting from partial oxidation of the sulfide structures during the sputtering process.

XPS was used to characterize the elemental compositions and chemical valence of the NiMoO₄/MoS₂, and NiMoO₄ systems (Figure 4). The most intense core level lines in the overview spectrum of NiMoO₄/MoS₂ (Figure 4a) are attributed to C1s, Mo3d, and S2p and weaker features to O1s, S2s, Mo4s, and Mo4p. No Ni signal is detected due to the thickness of the MoS₂

Figure 3. a) Low magnification and HR-TEM micrograph for the MoS_2 decorated NiMoO_4 sample displaying the anisotropic deposition of MoS_2 . In the inset, high magnification detail of the MoS_2 coated side exhibits reflections compatible with (0, 0, 2) lattice planes. b,c) High-resolution micrograph of selected areas (edge color corresponding to the highlighted area) of the same nanowire displayed in (a) and corresponding FFT, representing the typical lattice observed on the nanowire core and the decorating nanoflakes, respectively. d) STEM-HAADF micrograph of MoS_2 decorated NiMoO_4 nanowire with e) relative distribution of EDS $K\alpha$ peaks for Ni, Mo, O, and S, confirming the core-shell structure.

layer covering the NiMoO_4 micro-rods and the Ni foam substrate. The O1s spectrum (Figure 4b) presents two components at 530.6 eV, ascribed to the presence of MoO_x , and at 531.8 eV, due to the presence of OH groups and adsorbed water. The Mo3d spectrum can be fitted with three doublets (the rightmost peak in Figure 4c is attributed to S2s emission).

The energy position of the $\text{Mo}3d_{5/2}$ peaks of the doublets is 229.5, 230.6, and 232.8 eV and corresponds to Mo^{4+} (in 2H- MoS_2), Mo^{5+} , and Mo^{6+} , respectively. The last component confirms the presence of Mo oxides on the surface of the

system (unreacted metallic Mo that oxidizes in contact with air). The other two components find their counterpart in the S2p spectrum (Figure 4d), which is well described by two doublets. The dominant component ($\text{S}2p_{3/2}$ at 162.4 eV) derives from S^{2-} in 2H- MoS_2 . The other component ($\text{S}2p_{3/2}$ at 163.7 eV) is connected to the presence of $\text{Mo}_3\text{-S}$ and Mo-S_3 clusters, in which Mo shows the Mo^{5+} oxidation state.^[26] As a reference, we report in the bottommost row of Figure 4 the O1s, Mo 3d, and Ni3p core levels of the hydrous NiMoO_4 micro-rods. The two components describe the O1s spectrum in Figure 4e: the

main peak at 531.0 eV is attributed to O in NiMoO₄, and the peak at 532.1 eV to OH groups and water. The Mo3d spectrum of Figure 4f is fitted with one doublet associated with Mo⁶⁺ (Mo3d_{5/2} at 232.6 eV) in NiMoO₄.^[27–29] The Ni3p spectrum of Figure 4g, shows only one doublet (Ni3p_{3/2} at 68.1 eV) and the related satellite feature (Ni3p_{3/2} at 72.3 eV). This Ni²⁺ is correlated to the presence of NiMoO₄.^[13,30]

2.2. Electrochemical Characterizations

The OER catalytic performances of the hierarchical structures (NiMoO₄/MoS₂) and bare NiMoO₄ are investigated using linear sweep voltammetry (LSV) by a three-electrode system.

Both NiMoO₄ and NiMoO₄/MoS₂ catalysts prove their catalytic activity, evidenced by the increase in current density after the onset potential (Figure 5a). Thanks to the presence of highly active MoS₂, the heterostructure (NiMoO₄/MoS₂) displays a dramatic shift of the onset potential to less positive values (lower overpotential). In particular, NiMoO₄/MoS₂ results in a current density of 10 mA cm⁻² at an overpotential of 90 mV, while NiMoO₄ needs 223 mV to reach a similar current density. The lowest overpotential (90 mV), evidenced by the fastest increase in the current density of NiMoO₄/MoS₂, demonstrates the importance of MoS₂ in modifying the catalyst surface/interface properties for better electrochemical activity.

The Tafel plot, derived from the polarization curve (Figure 5b), provides additional information on the kinetics of

Figure 5. OER performance of the catalyst. a) Polarization curves of NiMoO₄/MoS₂, NiMoO₄, and nickel foam. b) Corresponding Tafel plots of the catalysts (NiMoO₄/MoS₂, NiMoO₄). c) Overpotential at different current densities, d) stability (chronoamperometry measurement) for NiMoO₄/MoS₂ (the inset shows the LSV after the stability test), and e, f) Nyquist plot at 1.45 V, C_{dl} extracted from cyclic voltammetry for NiMoO₄/MoS₂ and NiMoO₄.

the OER process on the catalyst surfaces. NiMoO₄/MoS₂ possesses a Tafel slope of 76 mV dec⁻¹, which is lower compared to NiMoO₄ (103 mV dec⁻¹), suggesting a faster kinetics during the OER process of the NiMoO₄/MoS₂ catalyst. The overpotential at different current densities was also computed for both catalysts and displayed in Figure 5b. In addition to the overpotential value producing 10 mA cm⁻², NiMoO₄/MoS₂ current density of 50, 100, and 200 mA cm⁻² at overpotentials equal to 155, 255, and 430 mV, respectively. Similarly, the same current densities are produced by NiMoO₄ with 311, 409, and 730 mV overpotentials. Compared to our previous work,^[13] the bare NiMoO₄ in the present study shows a minor decrease in the overall performance due to the heat treatment in the PVD chambers. Moreover, an OER rate of 10 mA cm⁻² for the NiMoO₄/MoS₂ can be readily attained by applying a small-scale overpotential (90 mV), which is very low compared to recently published works.^[31–35] For comparison purposes, the substrate NF was also characterized in terms of LSV and overpotential (Figure 5a,c). We have also compared the electrochemical properties of the MoS₂ catalyst using our recently published work, for which MoS₂ requires an overpotential of 500 mV to produce a current density of 100 mA cm⁻².^[20] However, NiMoO₄/MoS₂ structure needs 250 mV to produce a similar current density, demonstrating the electrocatalytic phenomena behind the hierarchical structure of composites for improving OER catalyst.

Long-term stability tests were performed using chronoamperometry at a potential of 1.40 V versus RHE by producing a constant current density of 60 mA cm⁻². The hierarchical heterostructure shows a decrease in current density for the first few hrs (Figure 5d, inset), suggesting the detachment of loosely attached MoS₂ nanosheets from the NiMoO₄ nanorods. However, it is clear that the performance of hierarchical heterostructure improved after the incorporation of MoS₂ nanosheets. Besides, NiMoO₄ maintains its long-term stability at 1.53 V versus RHE to produce a current density of 50 mA cm⁻² for nearly 18 h, with negligible losses, as shown in Figure S3, Supporting Information. EIS is used to elucidate the charge transfer kinetics, as displayed in Figure 5e. The EIS spectra are collected at a DC potential of 1.45 V versus RHE, for which the charge transfer process is kinetically controlled. An associated fitting for the EIS data is displayed in Table S1, Supporting Information. Since the catalyst surface is rough and porous, the impedance analysis contains constant phase elements (CPE) rather than pure capacitors. The decrease in the charge-transfer resistance for NiMoO₄/MoS₂ (10.9 Ω) compared to pure NiMoO₄ (14.4 Ω) indicates that the hierarchical heterostructure has a much faster electron transfer during the electrochemical reaction, arising from the existence of NiMoO₄ and MoS₂ phases. It is also consistent with its lower Tafel slope, which corresponds with the improved electrocatalytic performance.

The electrochemical active surface area (ECSA) is evaluated by measuring the double-layer capacitance (C_{dl}) using CV recorded from 1.1–1.20 V (vs RHE) (Figure S5, Supporting Information). The double-layer capacitance derived from the CV provides an estimation of the ECSA of NiMoO₄/MoS₂ (1.9 mF cm⁻²) and NiMoO₄ (1.7 mF cm⁻²). These minor differences in C_{dl} suggest only a minor increase of ECSA for the heterostructure, suggesting that both catalysts provide nearly similar accessible and abundant reaction sites in non-faradic regions. The enhanced catalytic activity observed in the case of the hierarchical structure can, therefore, be attributed to the altered intrinsic activity rather than the geometrical factor. The electrochemical performance indicates that the hierarchical NiMoO₄/MoS₂ is an electrocatalyst material with superior OER activity and stability under alkaline conditions. It can be seen that after a long stability test, the morphology of the heterostructure preserves as observed in Figure S6, Supporting Information. The inherently high activity of the NiMoO₄ is believed to be responsible for the improvement of electrocatalytic performance. For instance, in our recent work^[13] we have shown that during the OER process, hydrous NiMoO₄ undergoes an in situ transformation into NiOOH, with the dissolution of Mo species. Especially, the leaching of Mo species creates voids that are active toward the OER, allowing to improve the electrochemical activity. In this work, the presence of thick MoS₂ protects the hydrated NiMoO₄ and makes it difficult to detect the dissolution of Mo from NiMoO₄ nanorods. In many works, catalysts containing Ni, Fe-doped nickel oxides, and hydroxides of Ni were very active as water oxidation catalysts in alkali electrolytes.^[34,36] This is because the Ni redox process on

the surface occurring at lower anodic potential activities alters the catalyst surface to become more active and rougher during the reaction. Therefore, it is reasonable to state that the presence of hydrated NiMoO₄ is also responsible for the outstanding performance of the catalyst. Also, the hierarchical nanostructure results in increased porosity of the electrode, which improves the contact area of the interface, facilitating electrolyte diffusion through the entire hierarchical nanostructure.

Very interestingly, the hierarchical NiMoO₄/MoS₂ nanostructure can be also used as a charge storage device. Thanks to the very active site densities created at the surface/interface of NiMoO₄ due to the presence of MoS₂ nanosheets, the heterostructure becomes an excellent candidate for supercapacitors. We measured the capacitance of the as-obtained NiMoO₄@MoS₂ composite using cyclic voltammetry and galvanostatic charge-discharge (GCD) in a three-electrode system, as shown in Figure 6a–d. The charge storage mechanisms in pseudocapacitive materials possess battery-like charge-discharge properties. Therefore, the specific charge capacity (C_s) of the prepared samples is calculated from the GCD curves using Equation (1).^[37–39]

$$C_s (\text{Ahg}^{-1}) = \frac{\int i(A) dt (s)}{3600 \times m (g)} \quad (1)$$

where i , t , and m are the applied current density (A), discharge time (s), and the active mass of material (g), respectively. The mass of the active sample was obtained by subtracting the substrate NF. Here the active mass is 1 mg cm⁻².

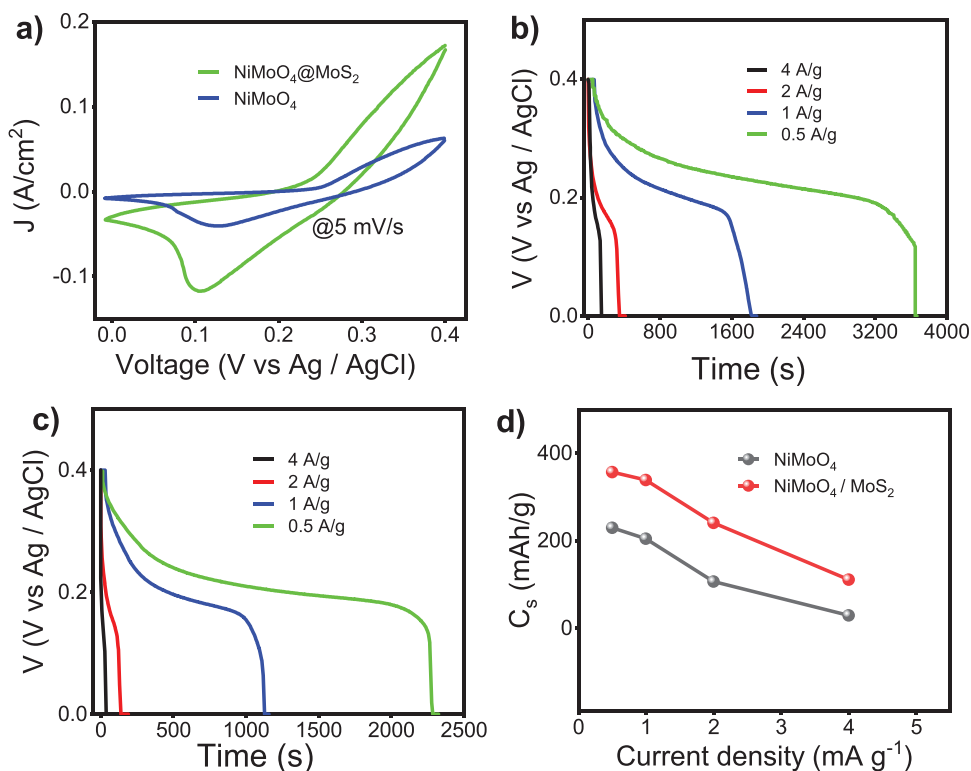

Figure 6. a) Cyclic voltammetry curves for hierarchical NiMoO₄/MoS₂ and NiMoO₄ at a scan rate of 5 mVs⁻¹. b, c) Galvanostatic discharge curves for NiMoO₄/MoS₂ and NiMoO₄ respectively. d) Specific charge capacities of NiMoO₄/MoS₂ and NiMoO₄ at various current density.

The CV curve for NiMoO₄/MoS₂ and NiMoO₄ (Figure 6a) displays a redox peak in the reverse scan (repeated CV measurement performed to produce a stable CV curve). By comparing the CV curves, we reveal that the capacity for NiMoO₄/MoS₂ is larger than that of pristine NiMoO₄, evidenced by the larger integrated area of the corresponding curve. The discharge capacity of the hierarchical NiMoO₄/MoS₂ and NiMoO₄ was measured at different currents (Figure 6b,c).

The specific charge capacity is calculated from each discharge curve using Equation (1) and displayed in Figure 6c. At discharge currents of 0.5, 1, 2, and 4 A g⁻¹, the NiMoO₄/MoS₂ and NiMoO₄ nanostructure can reach 358, 339, 241, 111 and 230, 205, 107, 28 mAh g⁻¹, respectively. Clearly, the hierarchical nanostructure exhibits an improvement in specific charge capacity due to the presence of MoS₂ nanosheets. The hierarchical NiMoO₄/MoS₂ nanostructure results in up to 1.8 times longer discharge rate compared to NiMoO₄, at 0.5 A g⁻¹. Besides, we evaluated the stability/reversibility of the nanostructures (Figure S7, Supporting Information), exhibiting good cycling durability, with 94% for NiMoO₄/MoS₂ and 85% for NiMoO₄ after 2000 charge-discharge cycles. The last 10 charge-discharge cycles of the 2000 cycle are also presented in Figure S7c, Supporting Information. Furthermore, the energy storage mechanism for NiMoO₄/MoS₂ and NiMoO₄ was analyzed with help of the relationship between peak potential and cathodic sweep rate.^[9,40,41] As shown in Figure S7e, Supporting Information. The calculated b value of the cathodic NiMoO₄/MoS₂ is 0.51, suggesting the charge storage principle is a battery-like characteristic.^[9,40,41] The higher performance of NiMoO₄/MoS₂ nanostructure is justified mainly due to the high conductivity of NiMoO₄, and the porous and interconnected MoS₂ nanosheets surrounding the nanorods which provide a path for ion transport between the interface and electrolyte. In addition, NiMoO₄ can create NiOOH in situ, which can offer further surface redox sites due to the conversion between nickel (II) and nickel (III) species. This redox activity at the surface accounts for the enhancement of the charge storage of hierarchical nanostructure, contributing to the higher specific charge capacity. Furthermore, the presence of MoS₂ nanoflakes is beneficial; because it promotes the electrochemical properties of active materials by providing an extra active site density, assisting the adsorption of oxygen intermediates, and accelerating the bubble release rate by providing additional surface areas.

3. Conclusion

We described a method to develop efficient hierarchical electrocatalysts for OER and charge storage applications through an easy and scalable method. A hierarchical structure is fabricated by modifying the NiMoO₄ nanosheets with MoS₂ nanosheets: MoS₂ nanosheets uniformly surrounding the nanorods improve the electrochemical properties of the hierarchical nanostructure. The interconnected porous network also helps to effectively store ions and charges that improve OER activity and the charge-storing capacity. Moreover, the NiMoO₄/MoS₂ displays a very low overpotential (90 mV) to produce a current density of 10 mA cm⁻², which is one of the minimum

overpotentials among the ones reported in the literature. Furthermore, at a discharge current of 0.5 A g⁻¹, the hierarchical nanostructure displays 358 mAh g⁻¹ charge storage capacity, up to 1.8 times a longer discharge rate than NiMoO₄. This work shows the benefit of hierarchical nanostructure in altering the charge transfer process and improving the performance of the catalyst.

4. Experimental Section

NiMoO₄ Synthesis: Hierarchical NiMoO₄/MoS₂ nanostructure was fabricated by first hydrothermally synthesizing NiMoO₄ followed by a subsequent magnetron sputtering process. First, commercial nickel foam (NF) was cleaned using an ultrasonic bath in 3 M HCl (to remove oxide) for 15 min followed by a 15 min wash with acetone, ethanol, and distilled water. Then, a piece of NF (4 × 6 cm²) was placed inside a 100 ml hydrothermal reaction vessel containing 1 g Ni(NO₃)₂·6H₂O, 0.5 g (NH₄)₆Mo₇O₂₄·4H₂O, and 75 ml of distilled water. Finally, the vessel was sealed and maintained at 140 °C for 6 h. The reaction product was washed with ethanol and distilled water and dried overnight at 60 °C. The obtained structure was a hydrated NiMoO₄, labeled as NiMoO₄. MoS₂ deposition was performed by magnetron sputtering as described in our previous work.^[20] The molybdenum sulfide target, MoS₂, 99.95% pure, 3.00" diameter, was used as a source for magnetron sputtering. The deposition was performed for 30 min, with a rate of around 0.5 nm s⁻¹, calculated by combining the deposition duration, cross-sectional SEM, and RBS analyses. During the deposition, the substrates were heated at 200 °C in an argon atmosphere. To avoid the difference that may arise due to the heating process in the PVD chamber during MoS₂ deposition, the bare NiMoO₄ nanorods were subjected to heating in a similar condition used for MoS₂ deposition.

Characterization: The morphology and composition of NiMoO₄/MoS₂ nanorods were characterized by Magellan 400 field emission scanning electron microscopy (FESEM), and transmission electron microscopy (TEM). Elemental analysis was conducted using energy-dispersive X-ray spectroscopy (EDX) in the FESEM. X-ray diffraction patterns (XRD) were recorded on the PANalytical Empyrean X-ray diffraction diffractometer with a Cu Kα source. Raman analysis was carried out using a Senterra Raman spectrometer from Bruker equipped with a 532 nm laser for excitation) in the ambient environment. Rutherford backscattering spectrometry (RBS) was carried out for analyzing the composition and thickness of the film. 1.8 MeV ⁴He⁺ beam in IBM geometry was used. The scattering angle was θ = 160°. Sampled was deposited on Silicon. The analysis was performed on samples deposited on silicon under a similar condition to MoS₂. The RBS spectrum was analyzed with the help of RUMP code simulation.

X-ray Photoelectron Spectroscopy (XPS) analysis was carried out at the VUV-Photoemission beamline of the synchrotron Elettra in Trieste (Italy). XPS spectra were collected using a Scienta R-4000 electron spectrometer with 700 and 690 eV photon energy for the NiMoO₄/MoS₂ and NiMoO₄ systems, respectively, and 250 meV total energy resolution. The data were analyzed using Voigt line shape peaks. The base pressure during the XPS experiments was below 5 × 10⁻¹⁰ mbar. The binding energy (BE) scale was calibrated by using adventitious carbon at 284.6 eV.

High-resolution transmission electron microscopy (HR-TEM) characterization was performed on FEI Tecnai F20 TEM, equipped with a Schottky emitter operating at 200 kV, Energy dispersive X-ray spectrometer (EDS), and high angle annular dark field for scanning TEM imaging (STEM-HAADF).

Electrochemical Measurements: The electrocatalytic performance test and electrochemical impedance spectroscopic (EIS) analysis of the as-synthesized catalysts was performed using a three-electrode system at room temperature in a multi-purpose electrochemical workstation potentiostat (Solartron Analytical, ModulabXM). Saturated calomel electrode (SCE) and platinum foil were used as the reference and

counter electrodes, respectively. Linear sweep voltammetry (LSV) was conducted in 1 M KOH, with a scan rate of 10 mV s⁻¹. The potential of the reference electrode was converted to a reversible hydrogen electrode (RHE) by the relation: E(RHE) = E(SCE) + 0.059*pH + 0.242 with pH = 14. EIS was measured over the frequency spectrum range from 100 kHz to 50 MHz at an Ac amplitude of 10 mV. The polarization curves were manually IR compensated. Chronoamperometry measurement was performed for stability tests.

Acknowledgements

The authors recognize the financial support from Knut & Alice Wallenberg foundation, the Swedish foundation consolidator fellowship, the European Union's Horizon 2020 research and innovation program under grant agreement No 654002, Luleå University of Technology Lab Fund program, and Kempe Foundation for partial funding. R.M. and V.M. acknowledge funding from the European Commission Graphene Flagship Core3. Grant Numbers: 881603. The research leading to this result has been supported by the project CALIPSOplus under Grant Agreement 730872 from the EU Framework Programme for Research and Innovation HORIZON 2020 (beamtime nr. 20205170, VUV-Photoemission beamline, Elettra, Trieste, Italy). This work has been carried out within the agreement "Convenzione operativa per collaborazione scientifica tra CNR ISM e Dipartimento di Scienze Molecolari e Nanosistemi Università Ca'Foscari Venezia (Prot.n. 709, 14/04/2021)". Partial support through the project EUROFEL-ROADMAP ESFRI is gratefully acknowledged.

Conflict of Interest

The authors declare no conflict of interest.

Data Availability Statement

The data that support the findings of this study are available in the supplementary material of this article.

Keywords

electrocatalysts, hierarchical nanostructures, hydrous catalysts, magnetron sputtering, oxygen evolution reaction, pseudo capacitors, water splitting
