1 **Abstract**

2

3

4 *Background:* ANY-Maze and EthoVision XT are two commonly used automated animal
5 tracking systems employed to produce reliable and consistent results in behavioural
6 paradigms. Data obtained with both tracking systems have presented differences, particularly
7 when varying laboratory lighting conditions and contrasts of mice coat colour against the arena
8 background in both water maze and tunnel maze.

9 *Method:* In this study, two fluorescent lighting conditions (58 and 295 lux), local to our
10 laboratory, and different coat-coloured mouse lines (C57BL/6J - black; CD1 - agouti; C3H/HeN
11 - white) were used to compare reproducibility in measures of tracking systems (ANY-Maze
12 versus EthoVision) in the open field test.

13 *Results:* Differences between systems were reliant on the contrasts between coat and
14 background colours. Surprisingly, black animals presented the greatest differences in read-
15 outs between tracking systems, regardless of lighting conditions. Data from both video
16 observation tools differed mainly in exploration-related parameters (distance travelled), but
17 less in more static proxies (time in thigmotaxis zone). Overall, EthoVision XT return higher
18 values for most parameters analysed relative to ANY-Maze. More inconsistencies in recording
19 and analysis can be expected from other video recording systems.

20 *Conclusion:* Data analysis software provides an additional source of variation in need of
21 consideration when reproducibility in behavioural neuroscience is required.

27

28 **1. Introduction**

29 Automated tracking of freely moving animals in behavioural paradigms offers numerous
30 advantages to enhance efficiency, reliability, and consistency with minimal human interference
31 (Noldus et al., 2001; Spruijt et al., 2014). This is particularly advantageous in quantifying
32 complex behavioural responses (such as full or partial rotations of 360° completed by the
33 animal's body; the angle between two consecutive vector movements of the animal; grooming;
34 etc.) in addition to the typical parameters of distance travelled or time spent in specific zones.
35 ANY-Maze and EthoVision XT, the most widely used automated video observation systems
36 in academia and industry, track by contrasting the animal image against the background
37 (Bailoo et al., 2010; Spink et al., 2001). Either a digital camera is used (as in this study), or an
38 analogue image from the camera is first digitized by a frame grabber and examined as a series
39 of frames, each comprising of a grid of pixels analysed frame-by-frame to differentiate tracked
40 objects from the background. The contrast between animal and background can be influenced
41 by the user depending on the study paradigm and subjects. For example, ANY-Maze allows
42 the user to alter the sensitivity of animal detection against the arena background. EthoVision
43 XT additionally provides tracking options such as grey-scaling or dynamic subtraction and
44 detection sensitivity. Each video software, however, is based on its own algorithms,
45 idiosyncratic to the manufacturer, for quantifications of the animal's behaviour (Noldus et al.,
46 2001; Spink et al., 2001).

47 The threshold for contrast differences can be set manually by the user or automatically by the
48 programme but is still extremely dependent on the lighting conditions and animal coat colour.
49 Local lighting conditions are known to influence the contrast of coat colours with the arena
50 background during tracking affecting the obtained results (Bailoo et al., 2010). In the case of
51 low animal and background contrast, the intensity and type of illumination will impact the
52 tracking systems. Uneven or dispersed illumination as well as reflections from surfaces of the
53 apparatus generally cause tracking of shadows or noise in tracks, resulting in inaccurate path
54 length measurements (Bailoo et al., 2010; Spink et al., 2001). The deviations in path lengths
55 obtained by the tracking systems from the actual path taken have been obtained using
56 inanimate and motor-driven such as discs (Bailoo et al., 2010; Lind et al., 2005). Under low
57 contrast fluorescent lighting at 563 lux, the path lengths of motor-driven rotating inanimate
58 disks were overestimated in ANY-Maze / underestimated in EthoVision XT for both water
59 maze and open field tests, but otherwise presented relatively similar results for discs of other
60 contrasts (Bailoo et al., 2010). Animals, however, often demonstrate unpredictable
61 movements which cannot be represented accurately by inanimate objects. Lighting and
62 contrast conditions may exacerbate the inaccuracy of recording unpredictable/non-systematic
63 movements and sharp turns of displacement in animals.

64 The reliability of ANY-Maze and EthoVision XT will be assessed using mice in the open field
65 test in this study. The open field test remains to be a popular sensorimotor paradigm which
66 provides a simple and rapid method of assessing different motor activity levels, exploration
67 habits, and anxiety traits in rodents (Denenberg, 1969; Robinson et al., 2018; Spruijt et al.,
68 2014; Wahlsten et al., 2006). The simplicity of the apparatus in the open field test makes
69 testing cost-effective and requires minimum to no experimenter expertise for the
70 administration of the test, nor training of the test subject. As the open field test produces
71 sufficiently reliable and repeatable measures on a range of independent variables, animal
72 behaviour is generally observed first in the open field test before other behavioural assays.
73 Clearly defined behaviours affected by genetic, physiological, and pharmacological
74 manipulations are likely to be related to locomotion and/or motor activities which the open field
75 test is sensitive to background of the animal (Robinson et al., 2018; Spruijt et al., 2014).

76 In this exploratory study, we used the open field at two different fluorescent light conditions
77 (58 versus 295 lux) and fed the recorded videos into i) ANY-Maze 6.3 and ii) EthoVision XT
78 11.5 and analysed the animal's behaviour with a focus on activity and anxiety-related
79 parameters. We compared three different mouse lines with black (C57BL/6J), agouti
80 (C3H/HeN) and white (CD1) coat colour. Our data show that despite identical tracks from the
81 two video systems, EthoVision XT appears to overestimate the distance parameters
82 particularly at 58 lux relative to ANY-Maze (or that Any-Maze appears to underestimate
83 relative to EthoVision XT). No differences in time in zone and ratios were observed.

84 2. Materials and Methods

85

86 2.1 Animals

87

88 Animals in this study were well handled and previously used in other non-invasive behavioural
89 paradigms (not open field) and were approximately 15 weeks old at the start of testing in the
90 open field. Ten C57BL/6J males (termed C57 from here on; registered in-house under the
91 study plan 2019_004 in relation to a Home Office Project Licence), 10 Crl:CD1 (ICR), and 10
92 C3H/HeNCrl all females (registered in-house under the study plan R0165; and annotated as
93 C3H and CD1 respectively from here on) from Charles River Laboratories (Margate, Kent, UK)
94 were used in this experiment. They were chosen to determine the effect of different coat colour
95 on video recording outcomes as they have black, agouti and white furs respectively.
96 Comparisons between sexes and strains of animals and large sample sizes of animals per
97 group were deemed of less importance for any comparisons between the analysis software,
98 but animals in this study were of similar weight and sizes for outcomes to be comparable.

99 The animals were group-housed (approximately 6-8 per group) in stock cages (Techniplast
100 1292N), measuring 45 x 38 x 13 cm under a 12:12 hours light:dark cycle (lights on at 0700),
101 with an average ambient temperature of $21 \pm 2^\circ\text{C}$ and humidity of $50 \pm 5\%$. Animals had free
102 access to standard rodent food chow and water *ad-libitum* and were provided with clean
103 bedding (corn cob and wood shavings) once per week. All animals were acclimatized to the
104 facility environment for approximately 5 weeks prior to open field testing. Test subjects were
105 handled by tail and scooping methods during the removal from their home cage and transfer
106 to the open field arena. All housing and handling of animals were in accordance with
107 international standards on animal welfare regulated by European Communities Council
108 Directive 63/2010/EU and the UK Animals Scientific Procedures Act (1986). The experiments
109 followed the study design, analysis and reporting methods recommended in the ARRIVE 2.0
110 guidelines and are detailed in the relevant segments below.

111 2.2 Apparatus, lighting conditions and testing procedures

112

113 Evaluation of general locomotor activity was conducted in a non-blinded manner due to the
114 nature of the coat colours of the subjects and only one experimenter was involved throughout
115 the tests and offline analysis. Animals of the same strain were allocated random identification
116 numbers and the test sequence of subjects was randomized using the Williams Square Design
117 (Wang et al., 2009). All animals within each strain were randomly assigned to an illumination
118 group (5-6 within each genotype per illumination group).

119 The apparatus comprised of a square box (made up of white reflective Perspex material),
120 measuring at 50 x 50 x 40 (height) cm. The arena floor was modified with black non-reflective
121 material during testing with CD1 mice to contrast between the white coat colour of CD1 and
122 the normally white floor of the arena. For comparison, bright (295 lux) and dim (58 lux) lighting
123 conditions as frequently used in our laboratory were selected. Overhead fluorescent lights
124 were used producing 58 lux in the arena; overhead fluorescent lights and 2 white wall LED
125 lights facing upwards from the arena were used for brighter lighting conditions at 295 lux.

126 The open field tests were conducted in a dedicated sound-attenuated room, with the
127 temperature and humidity maintained at $22 \pm 2^\circ\text{C}$ and $50 \pm 5\%$ respectively. Animals were
128 allowed to habituate to the room for approximately 30 minutes prior to testing. All animals were
129 tested in the open field in a single day, within 8 hours from the start of the light phase. Each
130 trial lasted 10 minutes. The mouse was placed in the centre of the arena to initiate the start of
131 the test. Only one mouse was tested at any one time and the apparatus was thoroughly
132 cleaned with odourless and alcohol-free wet wipes between each trial/animal.

133 **2.3 Methods of automated tracking**

134

135 An overhead camera (Imaging Source, DMK22AUCO3) was positioned 125 cm from the floor
136 of the arena and all tests were recorded as MPEG4/h.264 (producing 30 frames per second)
137 files on an adjacent computer. For calibration of arena alignments in both video recording
138 programmes, images were taken from a test video and divided with zone boundaries (Figure
139 1) used prior to re-tracking for both tracking systems. All videos were tracked on EthoVision
140 XT (Version 11.5, Noldus Information Technology, Wageningen, The Netherlands) and ANY-
141 Maze (Version 6.3, Stoelting Co.) but were analysed offline (EthoVision XT (Version 14, ANY-
142 Maze Version 6.3). Track-plots of the centre of gravity for each mouse line and illumination
143 were obtained from both video software to reveal the exploration paths in the arena (Figure
144 2).

145 The automatic tracking option was defaulted in ANY-Maze, which is without means to
146 manually adjust for animal size but for animal coat and apparatus background colours,
147 allowing for the program to adjust tracking parameters between the environment and
148 illumination. Detection settings for EthoVision XT were manually adjusted according to arena
149 floor contrast, animal coat colour and animal size. Percentages of samples in which subjects
150 were not found and the percentage of samples rejected, met an acceptable criterion of no
151 more than 5%, according to the EthoVision XT manual. Sampling rates for re-tracking were
152 maintained at 30 frames per second (fps) in both systems.

153 Initially, all parameters offered from each recording system were analysed and compared
154 between study cohorts and converted into heatmaps. These heatmaps compared categories
155 of parameters related to i) apparatus, ii) thigmotaxis and iii) centre point listing a total of 85
156 parameters for ANY-Maze and 161 for EthoVision XT. The most frequently reported proxies
157 were then selected and used for (i) a comparison between mouse lines and (ii) a comparison
158 between video analysis systems within each mouse line. Included in these proxies were: total
159 distance travelled in the arena (cm); frequency of total rotations; thigmotaxic response (outer
160 perimeter of 5cm width: time, distance, ratio), and average distance from the centre point (cm).
161 The periphery measured the outer edge of the arena with 5 cm away from its walls.

162 ---

163 Insert Figure 1 here

164 ---

165

166 **2.4 Statistical analysis**

167

168 Exploratory data analysis using heat-maps was applied to reveal all differences between
169 mouse line for all parameters that can be reasonably obtained in both ANY-Maze and
170 EthoVision XT. Data presented in heat-maps denote p-values with a threshold of 0.05 (dark
171 blue representing $p_{\text{threshold}} < 0.01$) obtained from Kolmogorov-Smirnov two-sample
172 comparisons. Parameters in the heat-maps were first clustered for within-system (Figure 3)
173 and between-system (Figure 3) comparisons for clarity (Gehlenborg & Wong, 2012; Timotius
174 et al., 2019). Apparatus measures concerning total distance and other additional information
175 regarding activity for the entirety of the test were categorized at the top of the map. Centre
176 point and thigmotaxic zone measures which are generally used as standard parameters were
177 clustered next. Heat-maps represent global read-outs over 10 minutes; time-dependent
178 differences and scoring by segment of test were omitted. For simplicity, parameters from head
179 and tail tracking were not considered.

180 For all comparisons between mouse lines and illumination recorded with different observation
181 software, estimation analysis was conducted using R (Dabestr package, v. 0.3.0, Ho et al.,
182 2018). Re-sampling at 10000 replacements and seed starting at 123456 was applied for
183 estimation analysis. Data were visualized as Cummings estimation plots– the mean and
184 standard deviation of each group is plotted as a gapped line next to the swarmplots. The mean
185 of the null is the difference-axis origin (aligned with the mean of the test group), and unpaired
186 mean differences were plotted with a shaded curve indicating the distribution of sampling error

187 for the difference between the means. Error bars on the difference axis depict the
188 bootstrapped 95% confidence interval for differences between means. C57Bl6/J mice and
189 ANY-Maze were selected in this study as the reference groups used to calculate mean
190 differences in the within-system and between-system analyses, respectively.

191 For conventional statistical analysis, data were pooled and tested for normality which revealed
192 the data to be skewed. This is not surprising given the small sample sizes (n=5-6/group – no
193 power calculation performed a priori). Hence all differences between tracking sensitivity for
194 each mouse line were averaged and contrasted using Kruskal-Wallis H tests for strain
195 comparisons. These differences were further analysed with Bonferroni-corrected Mann-
196 Whitney tests for comparisons against the reference group (C57Bl6/J in this study) where
197 significant findings were observed in Kruskal-Wallis H tests. Mann-Whitney U tests were used
198 in between-software comparisons for each strain. All conventional analyses were performed
199 with statistical differences set at 95% confidence levels and are reported in detail in figures
200 only. No outliers (with residuals more than two standard deviations away from the mean
201 defined a priori) were detected. Correlations between tracking software, independent of coat
202 colour and illumination, were performed with parametric Pearson's correlations (variables
203 presented normality in Kolmogorov-Smirnov tests).

204 Estimation statistics, heatmaps and graphs were performed in R (v.1.2.5033, R Core Team
205 (2021). R: A Language and Environment for Statistical Computing. R Foundation for Statistical
206 Computing, Vienna, Austria). All tests of normality and conventional statistics were performed
207 in SPSS (IBM SPSS Statistics v.25.0. Armonk, NY: IBM Corp).

208 3. Results

209 3.1 Heatmap comparisons differ between Any-Maze and EthoVision despite 210 identical track plots 211

212 Representative exploration paths for each mouse line with different coat colour (black, agouti,
213 white) and light intensity (58 lux and 295 lux) were obtained via each tracking system and are
214 presented in Figure 2. Differences in locomotor activity and spatial distribution occurred
215 between mouse strains and light intensities despite feeding the same video input into both
216 video tracking systems.

217 Differential comparison of proxies between CD1 (white) and C3H (agouti) against C57BL6/J
218 (black) mice for each lighting condition was converted in a colour-coded heatmap. An initial
219 total of 85 and 161 parameters were obtained for ANY-Maze and EthoVision XT respectively
220 (Figure 3). A direct comparison of 28 parameters compatible in both recording programmes
221 was performed and is depicted in Figure 3 and corresponding values are provided in Table 1.
222 Regardless of lighting conditions, C57BL6/J mice consistently presented with the greatest
223 number of differences (58 lux: 13 parameters and 295 lux: 12 parameters), followed by CD1
224 (58 lux: 9 parameters and 295 lux: 7 parameters) and C3H mice (58 lux: 5 parameters and
225 295 lux: 6 parameters). Amongst these parameters, differences ($p < 0.05$) common to all
226 experimental groups were found in measures related to the thigmotaxic zone (Table 1;
227 highlighted in blue): *absolute turn angle*, *thigmotaxic zone: maximum speed*, *thigmotaxic zone:*
228 *minimum distance from*, and *thigmotaxic zone: absolute turn angle*. These differences in
229 thigmotaxis are important parameters in the evaluation of the subject's emotionality and
230 anxiety states.

231 ---

232 Figures 2 & 4 and Table 1 here

233 ---

234 3.2 Differences between mouse strains and lighting intensities affect tracking 235 endpoints 236

237 A complete statistical summary of findings (visualised in Figure 5, 6) within each video analysis
238 system can be found in Table 1. Mouse strain and lighting intensity affected tracking read-outs
239 in both video analysis systems. Under dim light (58 lux), C3H mice presented with a lower
240 *total distance travelled* relative to C57BL6/J mice in both tracking systems (Figure 5A); yet
241 data were only significant for EthoVision XT recordings. The same profile was observed for

242 the distance moved in the thigmotaxic zone (Figure 5C). By contrast, ambulation was analysed
243 differentially for CD1 mice with ANY-Maze returning higher values compared with C57BL6/J
244 mice while EthoVision XT reported lower distances moved (Figure 5A). These differences
245 appeared despite seemingly identical tracks extracted from the video files. In terms of overall
246 activity, ANY-Maze reported a grading from highest to lowest of CD1 > C57BL6/J > C3H,
247 whereas EthoVision XT reported C57BL6 > CD1 > C3H.

248 *Average distance from the centre point* (Figure 5B), *time in the thigmotaxic zone* (Figure 6A)
249 and the derived *thigmotaxic ratios* (Figure 6B) were equal between C57BL6/J and C3H strains
250 but lower for CD1 mice. This was similarly observed in both video-analysis tools. As for the
251 total number of *rotations*, again there was no difference between C57BL6/J and C3H mice,
252 but CD1 showed heightened number of rotations in both observation tools (Figure 6C;
253 significantly different from C57BL6/J only in ANY-Maze). Overall, group-wise statistical
254 comparison was more sensitive for data derived from ANY-Maze (Figure 5C, 6C).

255 Higher consistency was obtained when the illumination was increased to 295 lux. For both
256 *total distance* and *distance in the thigmotaxis zone*, ANY-Maze and EthoVision XT reported
257 greatest values for CD1 (Figure 5A, C). For the parameters of *distance from the centre*, both
258 video tools returned significantly higher values for C3H mice relative to C57BL6/J but a smaller
259 difference for the CD1 relative to C57BL6/J were obtained (Figure 5B). When compared with
260 C57BL6/J, similar outcomes were observed for *thigmotaxis ratio* (Figure 6B) with slightly
261 elevated ratios in C3H mice, but little difference was reported for the CD1 strain. *Time spent*
262 *in the thigmotaxis zone* was significantly lower in C57BL6/J mice compared to C3H or CD1
263 mice in both tracking software, but patterns and outcomes of thigmotaxis time were similar for
264 both software. Intriguingly, the *number of rotations* differed between video analysis tools, but
265 demonstrate similar patterns. While ANY-Maze reported higher levels for C3H and CD1 strains
266 relative to C57BL6/J, EthoVision XT reported slight elevations. All these variations did not
267 reach significance.

268 ---

269 Figures 5 & 6 and Table 2 here

270 ---

271 **3.3 Differences between video recording and analysis software for each mouse** 272 **strain/coat colour**

273

274 A reorganization of the data was undertaken to enable a direct comparison between video-
275 observation systems for each mouse coat colour (depicted in Figures 7, 8 and Table 3). On

276 the same proxies, numerous software-related differences were identified, for which EthoVision
277 XT typically provided higher readouts than ANY-Maze. At both light intensities, these
278 differences were exclusive to measures of path length (*total distance moved*, Figure 7A, and
279 *distance moved in thigmotaxis zone*, Figure 7C) and while observed for all mouse strain/coat
280 colour, significances were observed for black coat colour in C57BL6/J mice only. Again, this
281 overestimation of EthoVision XT / underestimation of ANY-Maze is surprising given that the
282 tracks detected by both software systems were similar.

283 Identical values, however, were reported for the following parameters: *distance from centre*
284 (Figure 7B); *time in thigmotaxis zone* (Figure 8A) and *thigmotaxis ratio* (Figure 8C). There
285 was no effect of recording software on these data for any mouse strain/coat colour and were
286 independent of light intensity. Finally, EthoVision XT presented a smaller *number of rotations*
287 in all mouse strain/coat colour when recordings were conducted at 295 lux (Figure 8C), but
288 similar number of rotations (except in CD1 mice) at 58 lux.

289 To address the issue of precision of tracking between the two video observation software
290 packages measures of distance (*total distance travelled*, Figure 9A; *distance from centre point*,
291 Figure 9B; *distance in thigmotaxis*, Figure 9C) were further analysed by Pearson correlations
292 comparing the data for all subjects between both video systems at high and low intensity
293 illumination. All correlations were positive and significant. Overall, correlations were close to
294 R=1 for 295 lux, but R-coefficient was lower for 58 lux, particularly, in *total distance moved*
295 and *distance moved in the thigmotaxis zone* (Figure 9A, C). For the latter, values for data from
296 EthoVision XT were much higher than from ANY-Maze (see also Figure 7 and Table 3).
297 Reasons for these light-intensity dependent differences remain elusive and data strongly
298 suggest that work under brighter light intensities may achieve comparable values for both
299 video software packages independent of coat colour.

302 ---

303

304 4. Discussion

305 Here, two commercial video observation systems i.e., ANY-Maze and EthoVision XT, were
306 used for tracking rodent movement patterns. They allow the elimination of subjective and
307 labour-intensive manual scoring. The tracking systems require contrast between the subject,
308 arena background and adequate lighting for comparable and reliable tracking of the subjects.
309 ANY-Maze appeared to consistently present smaller read-outs (or EthoVision XT presented
310 larger read-outs) for all measures of distance, and this difference between systems is
311 exacerbated in low illuminations. Brighter light intensities of 295 lux, however, improved
312 robustness of findings, presenting near identical values in both video recording systems, but
313 it must be noted that higher illumination will affect certain behaviours, particularly anxiety, in
314 animals. At low light intensities, differences in primary read-outs of activity (distance travelled)
315 may be explained by increased dispersion of shadows observed, and the resultant low
316 contrast between subjects and background. Tracking inaccuracies may be further
317 exacerbated when this is coupled with sharper turns of angle displacement (particularly in the
318 thigmotaxic zone) and non-systematic movements. The use of infrared backlight as a solution
319 (such as in Bailoo and colleagues' work, 2010) would provide a high contrast and minimise
320 the effects of light intensities and complexities of the arena on the tracking precision in future
321 studies.

322 It is however, it was not in the remit of this work to determine which recording software
323 presents the most precise measurements with the data presented here. The true path length
324 could be determined by manually entering the position of the mouse in a frame-wise analysis
325 and summing up the distances with subsequent calculations and independent statistics.
326 Independent of this ground truth, we assume that testing of additional video systems including
327 for instance VideoMot (TSE systems: [https://tinateb.com/wp-](https://tinateb.com/wp-content/uploads/2016/06/tse_videomot2.pdf)
328 [content/uploads/2016/06/tse_videomot2.pdf](https://tinateb.com/wp-content/uploads/2016/06/tse_videomot2.pdf)), Smart video tracking (Panlab:
329 <http://www.panlab.com/en/products/smart-video-tracking-software-panlab>), VideoTrack
330 (Viewpoint, <https://www.viewpoint.fr/en/p/software/videotrack>), or open source video tracking
331 systems (Zhang et al, 2020; Krynitsky et al., 2020) may increase variability and incoherence.
332 If video tracking systems apply different algorithms for data input, one would expect deviations
333 in raw values for all parameters under scrutiny and for all lighting intensities. Given that only
334 some parameters differed significantly between EthoVision XT and ANY-Maze, and that
335 brighter arena conditions increased similarity between data, makes differences at the front
336 end unlikely. It rather suggests variation in algorithms for extraction and analysis of the
337 different parameters, particularly those impinging on measurements of movement and
338 exploration. These include *meandering* as an automatic endpoint in EthoVision XT, but it
339 needs to be manually calculated for ANY-Maze (*absolute turn angle* against *total distance*

340 *travelled*) or *rotation frequency* and vertical activity as noticed in our heat-map analysis. It is
341 consequently not surprising that differences between mouse strains occurred between
342 tracking software, and this is not only due to the greater number of parameters analysed by
343 EthoVision XT, or by the variation in activity between mouse lines.

344 With relevance to coat colours, black coat mice presented significant differences in distance
345 moved between software comparisons, in contrast to the agouti and white coat colours. This
346 could potentially be the result of light that may have reflected off the walls resulting in indirect
347 and diffused lighting. This will in turn cause more prominent shadows which may not be
348 distinguished from black coated mice, hence resulting in minute tracking errors. This would
349 not be an issue with lighter fur, for example mice with white coat, as the shadow of a lighter
350 coated mouse will not be confused with the mouse. Mice of the same strains may also have
351 different coat colours: A^{vy}/a mice display variable expressivity ranging from yellow to agouti,
352 with some mice having both yellow and agouti patches (Ounpraseuth et al., 2009). This
353 provides an opportunity for future work to evaluate differences in detection settings between
354 recording systems.

355 Strain and sex differences are known to also result in differences in animal size. Male mice for
356 most genotypes are generally larger than female sizes, and in this study, the C3H female mice
357 were noticeably the smallest and CD1 female mice were the largest. Hence animal strain and
358 sex differences, and thereby animal size, could influence the tracking, for example, larger
359 dispersion of shadows when tracking animals of a larger size. EthoVision can address this by
360 allowing the user to manually define the maximum and minimum size of the animal. This option
361 is, however, not available in ANY-Maze. The usability and type of detection settings therefore
362 differ between tracking systems, and it is recommended that the user considers the genotype
363 of mice and type of behavioural assay and apparatus prior to selecting the most optimal
364 recording and tracking system. Within experiments, we do not recommend alternating
365 between recording systems with different manufacturers and between different versions and
366 particularly different detection methods within the same recording software. Under
367 circumstances that this is inevitable, detection and recording methods should be factored in
368 the analysis and reported in the study.

369 As a corollary, the reproducibility of experiments between laboratories may be low when
370 different tracking software is applied. Towards this end, (Richter et al., 2011), used either ANY-
371 Maze, Ethovision 3.0/3.1 or Ethovision XT software in an inter-laboratory comparison of 6
372 European laboratories for several tests of anxiety-like and exploratory behaviours, including
373 the open field. Significant differences in distance travelled were obtained between
374 laboratories. While the authors discuss environmental and experimental differences as

375 reasons for this variability, no mention is made to the differences in tracking software; they
376 seemingly assume equivalence between tracking applications. While offering a great number
377 of analytic features and versatility, details of the implemented algorithms for commercial video
378 observation tools are not transparent to the user; this information, however, is readily available
379 for freely distributed software applications for animal tracking. Twenty-eight of such freeware
380 was investigated by Panadeira and coworkers (2021) for their features and strength and
381 weaknesses. They report that only 3 programmes included calibration algorithms for the
382 reduction of image distortion, which may substantially affect tracking accuracy and the
383 analysis of activity-related parameters. Many other limitations (lack for export function of
384 analysis metrics, lack for multiple animal recording, lack of updates and bug fixes in the last
385 three years) were identified. Clearly, algorithms idiosyncratic to each system, were optimised
386 for different video input/output types, type of animal/species being tracked, and calibration
387 methods, making differences in animal phenotyping/profiling highly likely (Panadeiro et al.,
388 2021). Taking this into consideration, a further comparison using more recording and tracking
389 systems, as well as using a larger sample size to address the heteroscedasticity of the data
390 in this study, could be performed to provide a more comprehensive understanding of the
391 variation between tracking systems.

392 Fortunately, the heterogeneity in the data output between the video tracking and analysis
393 systems utilised here has affected only few endpoints. Yet, these are the most frequently
394 reported primary outcome measures on which decision about impairment/enhancement are
395 typically based. It is of little conciliation that most parameters measured in this study returned
396 similar and robust data independent of mouse strain (coat colour), light intensity or tracking
397 software or hardware installation. Our unconventional approach of estimation statistics for
398 data comparison provides direct visual information of the degree of differences/similarities
399 between mouse strains on one hand, but also between the tracking applications.

400 5. Conclusion

401 Between-laboratory standardization and validation of read-outs is compromised by the use of
402 different tracking software, calibration methods and lighting systems amongst others.
403 Protocols for these factors are commonly kept idiosyncratic to each laboratory, to each
404 experimenter and/or to each paradigm. This contributes to undeliberate systematic errors
405 (Richter et al., 2009) and leads to seemingly irreproducible experimental results. Apart from
406 generic factors of animal holding and maintenance, or specific experimental factors like water
407 temperature or noise levels, we here provide compelling evidence that careful and detailed
408 knowledge about the automated tracking software in use and the experimental environment
409 is instrumental in ensuring that the same behaviour is indeed being probed. Finally, the
410 differences in outcome may be intrinsic to the tracking application and given the great number
411 of software tools that are available from vendors and as free ware, the reproducibility issue is
412 difficult to resolve.

413 Acknowledgement:

414

415 This project included funding from the Innovative Medicines Initiative 2/EFPIA, European
416 Quality in Preclinical Data (EQIPD) consortium under grant agreement number 777364. We
417 would also like to acknowledge the staff of the Medical Research Facility for their support
418 with animal care, handling and behavioural experiments.

419 Author Contributions

420 This research project was conceptualised by CL, SKJ and GR. The manuscript forms part of
421 the PhD thesis of CL, who performed experiments and statistical analyses. CL and GR wrote
422 the manuscript and all authors contributed to the final text and approved it for publication.

423 Data availability statement

424 All data are provided within the manuscript.

425

426 Conflict of interest:

427 The authors have no conflict of interest to report.

479 **Table legends**

480

481 **Table 1. Statistical summary of differences between tracking systems for each mouse strain and**
482 **light intensity in parameters which can be reasonably compared in both programs.**

483 Parameters with statistical significance at $p < 0.05$ revealed in all comparisons to C57BL6/J are
484 highlighted in bold; parameters marked with an asterisk are of interest and further visualised in the
485 figures. Differences were calculated using Kolmogorov-Smirnov tests using IBM SPSS Statistics 25
486 with statistical differences set at 95% confidence levels. *Ctrpt*, centre point; *Thig*, thigmotaxis; ηp^2 ,
487 partial eta-squared.

488

489 **Table 1. Statistical summary of comparisons within tracking systems.**

490 Data show estimated mean differences and confidence intervals, resampled 10000 times, with seed
491 starting at 123456 using R (v.1.2.5033, RStudio, Inc.). Conventional statistics were performed using
492 Kruskal Wallis H tests in IBM SPSS Statistics 25 and further analysed with Bonferroni-corrected Mann-
493 Whitney tests (significant associations in bold) where significant findings were observed in Kruskal-
494 Wallis H tests. Statistical differences were set at 95% confidence levels. ηp^2 , partial eta-squared (effect
495 size).

496

497 **Table 2. Statistical summary of comparisons between tracking systems.**

498 Data show estimated mean differences and confidence intervals, resampled 10000 times, with seed
499 starting at 123456 using R (v.1.2.5033, RStudio, Inc.). Conventional statistics were performed using
500 Mann-Whitney U tests using IBM SPSS Statistics 25 with statistical differences set at 95% confidence
501 levels. ηp^2 , partial eta-squared (effect size).

502 Figure legends

503

504 Figure 1. Calibrated images used for retracking in ANY-Maze and EthoVision XT.

505 Both images were taken at 58 lux light intensity with a white (left) or black (right) arena of identical
506 dimensions (see Methods). The boundaries of the arena, thigmotaxic zone and the centre point were
507 identically defined in both *ANY-Maze* and EthoVision XT.

508

**509 Figure 2. Representative track-plots obtained for each experimental group in ANY-Maze and
510 EthoVision XT at different illuminations.**

511 Blue lines demarcate the borders of the thigmotaxic zone (*inner line*) and arena (*outer line*); the center-
512 point is represented by a '+' sign.

513

**514 Figure 3. Heat-map demonstrating all differences observed in the open field between three
515 mouse strains.**

516 A total of 85 and 161 parameters were extracted from ANY-Maze (left) and EthoVision XT (right)
517 respectively. C3H and CD1 were contrasted to C57 mice for both tracking systems and differences
518 were analysed using p-values from Kolmogorov-Smirnov tests. Parameters were clustered according
519 to measures pertaining to the apparatus (ANY-Maze, #1-20, and EthoVision XT #1-69), centre point
520 (ANY-Maze, #21-36, and EthoVision XT #70-74) and thigmotaxis zone (ANY-Maze, #37-85, and
521 EthoVision XT #75-161). Blue fields represent p-values with the threshold of 0.05 (dark blue = $p_{\text{threshold}} < 0.01$). The heat-map was visualized using R (v.1.2.5033, RStudio, Inc.).

523

**524 Figure 3. Heat-map depicting differences in 28 parameters commonly reported by ANY-Maze and
525 EthoVision XT.**

526 The parameters were clustered according to measures related to apparatus (#1-8), centre point (#9-
527 12) and thigmotaxic zone (#13-28). Mouse strains are presented individually, and blue fields represent
528 p-values at a threshold of 0.05 (dark blue = $p_{\text{threshold}} < 0.01$) between tracking software. The heat-map
529 was visualized using R (v.1.2.5033, RStudio, Inc.).

530

**531 Figure 4. Comparison of ambulation of three mouse strains in the open field using two tracking
532 systems and two light intensities**

533 Parameters of ambulation are displayed for different mouse strains at 58 and 295 lux illumination for
534 comparisons within ANY-Maze and EthoVision XT (EthoVision) The parameters of activity are as

535 follows: *total distance travelled* (A); *average distance from the centre point* (B); *thigmotaxic distance*
536 (C). Single data points represent individuals for each strain. Cummings estimation plots represent
537 means (gap) \pm standard deviation (vertical lines) in the raw (top axis). The shaded curve and the error
538 bar in the bottom axis show the distribution of sampling error and its respective 95% confidence interval
539 for the difference between the means. Performance of C57BL6/J mice is represented by 0 line. Analysis
540 and visualisation of estimated mean difference plots were performed using R (v.1.2.5033, RStudio, Inc.)
541 with bootstrapping at 10000 samples, seed set at 123456, to estimate 95% confidence intervals. Post-
542 hoc Bonferroni-corrected Mann-Whitney tests were performed for all pairwise comparisons between
543 strains, where Kruskal Wallis H tests were significant, and are indicated as text in figure. Conventional
544 statistics present significance values with alpha set to 5% ($p < 0.05$). *Black* = C57 (N=5/6); *Green* = C3H
545 (N=5); *Blue* = CD1 (N=5) mouse strains.

546

547 **Figure 6. Comparison of thigmotaxis and stereotypic behaviour of three mouse strains in the**
548 **open field using two tracking systems and two light intensities.**

549 For three mouse strains at 58 and 295 lux illumination comparisons within ANY-Maze and EthoVision
550 XT (EthoVision), we analysed parameters for thigmotaxis: time in thigmotaxis zone (A); thigmotaxis
551 ratio (B) and number of rotations (C) for stereotypic behaviour. Single data points represent individuals
552 for each strain. Cummings estimation plots represent means (gap) \pm standard deviation (vertical lines)
553 in the top axis. The shaded curve and the error bar in the bottom axis show the distribution of sampling
554 error and its respective 95% confidence interval for the difference between the means. Performance
555 of C57BL6/J mice is represented by 0 line. Analysis and visualisation of estimated mean difference
556 plots were performed using R (v.1.2.5033, RStudio, Inc.). Post-hoc Bonferroni-corrected Mann-Whitney
557 tests were performed for all pairwise comparisons between strains, where Kruskal Wallis H tests were
558 significant, and are indicated as text in figure. Conventional statistics present significance values with
559 alpha set to 5% ($p < 0.05$). *Black* = C57 (N=5/6); *Green* = C3H (N=5); *Blue* = CD1 (N=5) mouse strains.

560

561 **Figure 7. Direct comparison between tracking software for activity parameters extracted from**
562 **behaviour in open field.**

563 Three different mouse lines and two illumination intensities are presented. Parameters of activity (total
564 distance travelled (A); mean distance from the centre point (B); thigmotaxic distance (C)), are compared
565 between the 2 tracking systems ANY-Maze (ANY) and EthoVision (Etho). Single data points represent
566 individuals for each strain. Cummings estimation plots represent means (gap) \pm standard deviation
567 (vertical lines) in the top axis. The shaded curve and the error bar in the bottom axis show the distribution
568 of sampling error and its respective 95% confidence interval for the difference between the means. Data
569 from ANY-Maze are represented by 0 line. Analysis and visualisation of estimated mean difference
570 plots were performed using R (see legend Figure 5). Conventional statistics (Mann-Whitney U tests

571 between groups) present significance values with alpha set to 5% ($p < 0.05$). *Black* = C57 (N=5/6); *Green*
572 = C3H (N=5); *Blue* = CD1 (N=5) mouse strains.

573

574 **Figure 8. Direct comparison between tracking software for thigmotaxis and stereotypy of mouse**
575 **behaviour in open field.**

576 For the different mouse strains and 58 and 295 lux illumination, parameters for thigmotaxis (time in
577 thigmotaxis zone (D); thigmotaxis ratio (E)) and number of rotations (F) for stereotypic behaviour are
578 compared between the 2 tracking systems ANY-Maze (ANY) and EthoVision (Etho). Single data points
579 represent individuals for each strain. Cummings estimation plots represent means (gap) \pm standard
580 deviation (vertical lines) in the top axis. The shaded curve and the error bar in the bottom axis show the
581 distribution of sampling error and its respective 95% confidence interval for the difference between the
582 means. Data from ANY-Maze are represented by 0 line. Analysis and visualisation of estimated mean
583 difference plots were performed using R (see Figure legend 5 for details). Conventional statistics (Mann-
584 Whitney U tests between tracking systems) at alpha set to 5% ($p < 0.05$) are indicated in the figure. *Black*
585 = C57 (N=5/6); *Green* = C3H (N=5); *Blue* = CD1 (N=5) mouse strains.

586

587 **Figure 9. Pearson correlations for measures of activity comparing between ANY-Maze and**
588 **EthoVision XT.**

589 Correlations of *total distance travelled* (A), *average distance from the centre point* (B) and *distance*
590 *travelled in the thigmotaxic zone* (C) are represented for 58 (left) and 295 lux (right). Note that higher
591 light intensities increase correlations (i.e. reproducibility) between the tracking applications. All graphs
592 and correlation analyses (R- and p-values on figures) were performed and plotted using R (v.1.2.5033,
593 RStudio, Inc.). *Black* = C57 (N=5/6); *Green* = C3H (N=5); *Blue* = CD1 (N=5) mouse strains.

Acknowledgement:

This project included funding from the Innovative Medicines Initiative 2/EFPIA, European Quality in Preclinical Data (EQIPD) consortium under grant agreement number 777364. We would also like to acknowledge the staff of the Medical Research Facility for their support with animal care, handling and behavioural experiments.

Author Contributions

This research project was conceptualised by CL, SKJ and GR. The manuscript forms part of the PhD thesis of CL, who performed experiments and statistical analyses. CL and GR wrote the manuscript and all authors contributed to the final text and approved it for publication.

Data availability statement

All data are provided within the manuscript.

Conflict of interest:

The authors have no conflict of interest to report.
