Abstract

Allergic bronchopulmonary aspergillosis (ABPA) is a consequence of hypersensitivity reaction to *Aspergillus fumigatus* that can chronically colonize the airways of patients with abnormalities in their airway mucosal defenses, including mucociliary clearance and epithelial cell function, such as patients with bronchial asthma and cystic fibrosis. We present an interesting case of a 62-year-old woman who presented with purulent cough, subfebrile temperature and chest pain. She was ineffectively treated for a month with standard antibiotics and was finally diagnosed with ABPA.

Keywords: allergic aspergillosis; finger-in-glove sign; tubular opacities

A 62-year-old woman presented with purulent cough, subfebrile temperature and chest pain in the right side of thorax that all began a month earlier and did not respond to standard antibiotics. She had a history of nasal polypectomy, five operations of chronic sinusitis and right lung segmentectomy due to lung tumor (non-specific inflammatory changes in histopathologic examination) - all procedures were performed over ten years earlier. She also had a five-year history of allergic rhinitis and bronchial asthma with moderate obturation in spirometry.

Pulmonary auscultation revealed decreased breath sounds and single rhonchi over the right lower lung field. Vital signs were normal. Laboratory tests showed normal blood morphology with eosinophilia $1023/\mu\text{l}$ (13.8%) and total serum IgE level of 923 IU/mL. C-reactive protein level was elevated 7 times over normal range. Other laboratory parameters (creatinine, electrolytes, transaminases, urine analysis) were normal. Chest X-ray showed opacities over the middle and lower right lung field (Fig. 1 panel A), which was confirmed in computed tomography (panel B). CT additionally showed tubular opacities in the aboved-mentioned lung areas, described as the „finger in glove” sign (panel C, arrows). Sputum culture result was positive for *Aspergillus fumigatus*. Serum IgE antibodies specific for *Aspergillus* were positive (3rd class) and the patient had a positive result of skin prick test with *Aspergillus fumigatus* allergens, as well as positive test for precipitating antibody to *Aspergillus* antigen.

This clinical-radiological picture is consistent with allergic bronchopulmonary aspergillosis (ABPA). ABPA is a consequence of hypersensitivity reaction to *Aspergillus fumigatus*, an airborne saprophytic fungi species which is ubiquitous in the environment. *Aspergillus fumigatus* can chronically colonize the airways of patients with abnormalities in their airway mucosal defenses, including mucociliary clearance and epithelial cell function, such as patients with bronchial asthma and cystic fibrosis [1]. There are no epidemiological data concerning the prevalence of ABPA in Polish population but, taking into consideration its global prevalence, which is 2.5% of adult asthmatics, it seems that disease is underdiagnosed [2, 3]. The criteria for a diagnosis of ABPA are the following (there should be fulfilled at least six out of seven): (a) atopic bronchial asthma or cystic fibrosis, (b) peripheral blood eosinophilia $> 1000/\mu\text{l}$, (c) immediate *Aspergillus* species skin test reactivity, (d) positive test for precipitating antibody to *Aspergillus* antigen, (e) increased total serum IgE level or *Aspergillus* species-specific IgE antibodies, (f) chest radiographic infiltrates and (g) central bronchiectases [3].

Although our patient did not present central bronchiectases, she had mucoid impaction of the large airways that often manifests as tubular opacities known as the „finger-in-glove sign”, which might be observed in radiological examinations of patients with allergic bronchopulmonary aspergillosis [4].

Oral corticosteroids are the mainstay in treatment of ABPA. Their role is to reduce the inflammatory response triggered by *Aspergillus fumigatus*. Antifungals (itraconazole) are also administered in order to decrease the burden of fungal colonization [5].

After 6 months of antifungal treatment, the patient was asymptomatic, and chest radiography showed complete regression of previously described opacities (Fig. 1 panel D).

Fig. 1 Imaging findings revealed by chest x-ray and computed tomography: opacities over middle and lower right lung field (Fig. 1 panel A and B), tubular opacities - „finger in glove” sign (panel C, arrows) and complete regression of pathological changes after treatment (panel D).
