A MULTI-USER PROCESS INTERFACE SYSTEM

FOR A

PROCESS CONTROL COMPUTER

by BARRY GRAHAM SHERLOCK

Submitted to the University of Cape Town in partial fulfilment of the requirements for the degree of Master of Science in Engineering.

September 1983

ACKNOWLEDGEMENTS

My sincere appreciation is extended to:

Professor H.S. Bradlow, for his guidance, encouragement and patience while supervising this project.

Bill Randall, who supplied the air-column apparatus used in the student project, and was always ready to assist in all matters relating to the Chemical Engineering department.

Tony Eva, for introducing me to the use of the PDP-11, and for modification of the plotting terminal line from current loop to RS-232.

Alan Day, for valuable technical assistance including construction of the Media front panel.

Bruce Ingram of SANS for advice and documentation on using the Media hardware.

My brother Derek who assisted with the printing and copying of this thesis.

The CSIR, for their financial assistance during 1982.

Any others whom I may unwittingly have failed to mention here.

ABSTRACT

This thesis describes a system to implement a distributed multi-user process interface to allow the PDP-11/23 computer in the Electrical Engineering department at UCT to be used for process control. The use of this system is to be shared between postgraduate students for research and undergraduates for doing real-time control projects. The interface may be used concurrently by several users, and access is controlled in such a way as to prevent users' programs from interfering with one another.

The process interface hardware used was a GEC Micro-Media system, which is a stand-alone process interface system communicating with a host (the PDP-11/23) via a serial line. Hardware to drive a 600 metre serial link at 9600 baud between the PDP-11/23 and the Media interface was designed and built.

The software system on the host, written in RTL/2, holds all data from the interface in a resident common data-base and continually updates it. Access to the interface by applications programs is done indirectly by reading and writing to the data-base, for which purpose a library of user interface routines is provided.

To allow future expansion and modification of the Media interface, software (also written in RTL/2) for an LSI-11 minicomputer interfaced to the Media bus was developed which emulates the operation of the GEC proprietary Micro-Media software. A program to download this software into the LSI-11 was written.

A suite of diagnostic programs enable testing of the system hardware and software at various levels.

To ease testing, teaching and applications programming, a

general-purpose simulation package for the simulation of analogue systems was developed, as well as graphics routines for use with a Tektronix 4010 plotting terminal.

A real-time computing project for a class of undergraduates was run in 1983. This project made extensive use of the system and demonstrated its viability.

TABLE OF CONTENTS

CHAPTER 1

INTRODUCTION

1.1 Requirements

This project arose out of the need of the University of Cape Town's Electrical and Chemical Engineering departments for an interface system to enable them to use the PDP-11/23 minicomputer that is shared between the two departments, for process control. The interface system had to satisfy the following requirements:

1. Since the PDP-11 is used for various purposes, such as departmental administration, teaching and research, the use of the process interface must not load the computer unduly; i.e. its use must coexist with the other tasks performed by the computer.

2. The interface system should be suitable for use both for postgraduate research and for undergraduate teaching.

3. Multi-user access to the system should be possible, so that it can be used concurrently for postgraduate

research and undergraduate teaching. Typically, at any given time, the interface may be in use by one postgraduate and three or four out of a class of about fifty final-year undergraduates.

4. The system should be commissioned as quickly as possible, with as little effort as possible from University staff, since the University is badly short-staffed in this area.

5. Software access to the interface system must be carefully controlled, so as to ensure that no two users can accidentally or deliberately interfere with each other's software. In particular, the use of the system by undergraduate students must not in any way interfere with the research use by postgraduates.

6. Geographic considerations, viz. the fact that the PDP-11/23 is situated in the Electrical Engineering building and the processes to which it must interface are in the Chemical Engineering building 600 metres away, dictate that the sytem must be distributed.

1.2 The Process Interface System

1.2.1 Commercial System

A Media system [1] was chosen as the process interface hardware (see chapter 2 for a description of Media). This choice was based on the following considerations:

1. Media is available in various sizes, ranging from very small systems, such as the one used in this project, to very large industrial systems involving several thousands of inputs and outputs. From the teaching point of view, therefore, the students would be using a system which, although small and relatively inexpensive, is similar in architecture to large systems used in the industrial environment.

2. Media is essentially a modular system, since it consists of sets of card-cages or "bins" into which the various Media circuit cards (such as analogue or digital inputs and outputs) are plugged. This means that Media can be easily expanded by the addition of further Media bins or by replacing cards or inserting additional cards within a bin.

3. Media is widely used in industrial process control in the Western Cape, by such companies as AECI and SA Nylon Spinners (SANS). Since contact is maintained between the University and (particularly) SANS, the advantage would be gained of a productive interchange of knowledge between the University and industry.

4. Media provides fast access to data anywhere in the system, since the Media cards are mapped to word addresses on the Media bus or "highway".

General Electric Corporation (GEC) supply a small system, called the GEC Micro-Media system [2], which is a stand-alone Media process interface system which communicates with the outside world via a serial line, using a simple link-level protocol. The system may therefore be used as a remote stand-alone "outstation" controlled, via the serial line, by a host computer (in this case a PDP-11/23).

Stand-alone operation in Micro-Media is achieved by including three special Media cards: the 8085 CPU card, Media interface card and serial line interface card. The Media interface card causes the Media cards to be addressable by the 8085 on the CPU card, and the serial line interface card enables the 8085 to communicate via the serial line to the host. The 8085 CPU card has two ROMs containing a program which continually monitors the serial line, receives command frames from the host, decodes them, acts on them (for example, read a value from a particular analogue input), and encodes and sends the reply frames. Use of the GEC Micro-Media system with this built-in program enables the system to be commissioned very quickly because it is ready to run and only the host software to drive the serial link need be written.

Because of the simplicity of the serial link protocol used by the GEC Micro-Media system it is possible to write this host software without modifying the operating system device drivers, i.e. a normal serial port driver can be used provided that it supports a transparent mode which passes all characters (the ports of the PDP-11/23 can be configured to do this).

It was therefore decided to implement a GEC Micro-Media system. The configuration chosen was one with two Media bins containing the following Media cards:

1. A 10-bit analogue-to-digital converter card plus a 16-way multiplexer card, thus providing 16 multiplexed analogue inputs.

2. Two 16-line opto-isolated digital input cards.

3. A 16-line digital output card.

4. A 4-channel 8-bit digital-to-analogue converter card, thus providing 4 analogue outputs.

5. The 8085 CPU, Media interface and serial line interface

cards.

6. LSI-11-to-Media interface cards.

These cards provide sufficiently many inputs and outputs to support the applications envisaged for the system.

1.2.2 The Modified System

In addition to being interfaced to the 8085 as explained above, the Media highway may be interfaced to the LSI-11 Q-bus by means of the LSI-11-to-Media interface cards mentioned above. The use of these cards to interface an LSI-11 microcomputer to the Media highway enables the LSI to access all of the Media cards at memory speeds. This interface can coexist with the 8085 subsystem, i.e. it is not necessary to remove the 8085 CPU, Media interface or line interface cards if the LSI-11 interface is to be used.

A major aspect of this thesis is the development of an alternative software system [3] to enable an LSI-11 microcomputer to control Media as an alternative to the GEC 8085-based system. This system, which will henceforth be referred to as the "LSI-11 Media system", is software compatible from the host point of view with the GEC Media system and was developed because of the following considerations:

1. The documentation available on the GEC Media system was not sufficient to enable it to be easily modified and extended. The LSI-11 Media system, on the other hand, having been developed as part of this project, is fully documented and understood and can be modified to allow for future developments, such as the addition of further Media cards.

2. Although the GEC Media system is in theory immediately usable, there were in fact several practical difficulties in getting it to operate correctly. Difficulties encountered included a hardware problem whereby the system would re-initialise itself unexpectedly every few minutes thus destroying data held in RAM, and a software bug which made the analogue input data inaccessible.

As an alternative to developing an LSI-11 system which emulates the GEC Media system, we could have designed and developed an LSI-11 system without ensuring compatibility with the GEC system. This approach has the advantages that it could be more closely tailored to the needs of the application in mind, and that one would not be forced to live with the several deficiencies of the link-level protocol used by the GEC system (see chapter 2). However, it was felt that these disadvantages were outweighed by the fact that compatibility would enable the GEC Media system to be used as a back-up system in the event of a hardware failure in the LSI-11 Media system.

The LSI-11 Media system software emulating the operation of the GEC system was written in the high-level structured real-time language RTL/2 in the form of two tasks running under the operating system SMT [4]. This combination was chosen because:

1. The software could be developed on the host PDP-11/23 computer using its editing, RTL/2 compiling and linking utilities.

2. RTL/2 as a real-time language offers several attractive features including efficient code generation, legibility and ease of writing, debugging and modification.

3. SMT is a small (6K words) multitasking operating system ideally suited to downloading and running multi-task real-time applications on a small LSI-11 micromputer such

as the one used. It provides support for up to sixteen independent tasks written in RTL/2.

The LSI-11 Media system software, named SMT.TSK (after the operating system used), must be downloaded from the host computer using a program called ODT (see chapter 3). This program enables the operator to load a bootstrap loader into the LSI, and then, by starting the bootstrap loader running, download SMT.TSK and start it running. The necessity to download the program before use, although simple and quick, is a disadvantage of the LSI-11 Media system, since the GEC system program resides in ROM and does not need to be downloaded. This is however offset by the flexibility of being able to download specialised software systems if so desired.

1.3 Serial Data Link Hardware

Because of the relatively large distance of 600 metres between the Media interface and the host, an ordinary RS-232 link could not be used. The link is a 4-wire link installed by the GPO and is driven in differential mode using the 8820 and 8830 differential line driver and receiver integrated circuits. Two of these 4-wire lines are used: one for the Media interface and one for a remote terminal to the PDP-11. The line-driver hardware is described in chapter 4. The system hardware is illustrated in figure 1-1.

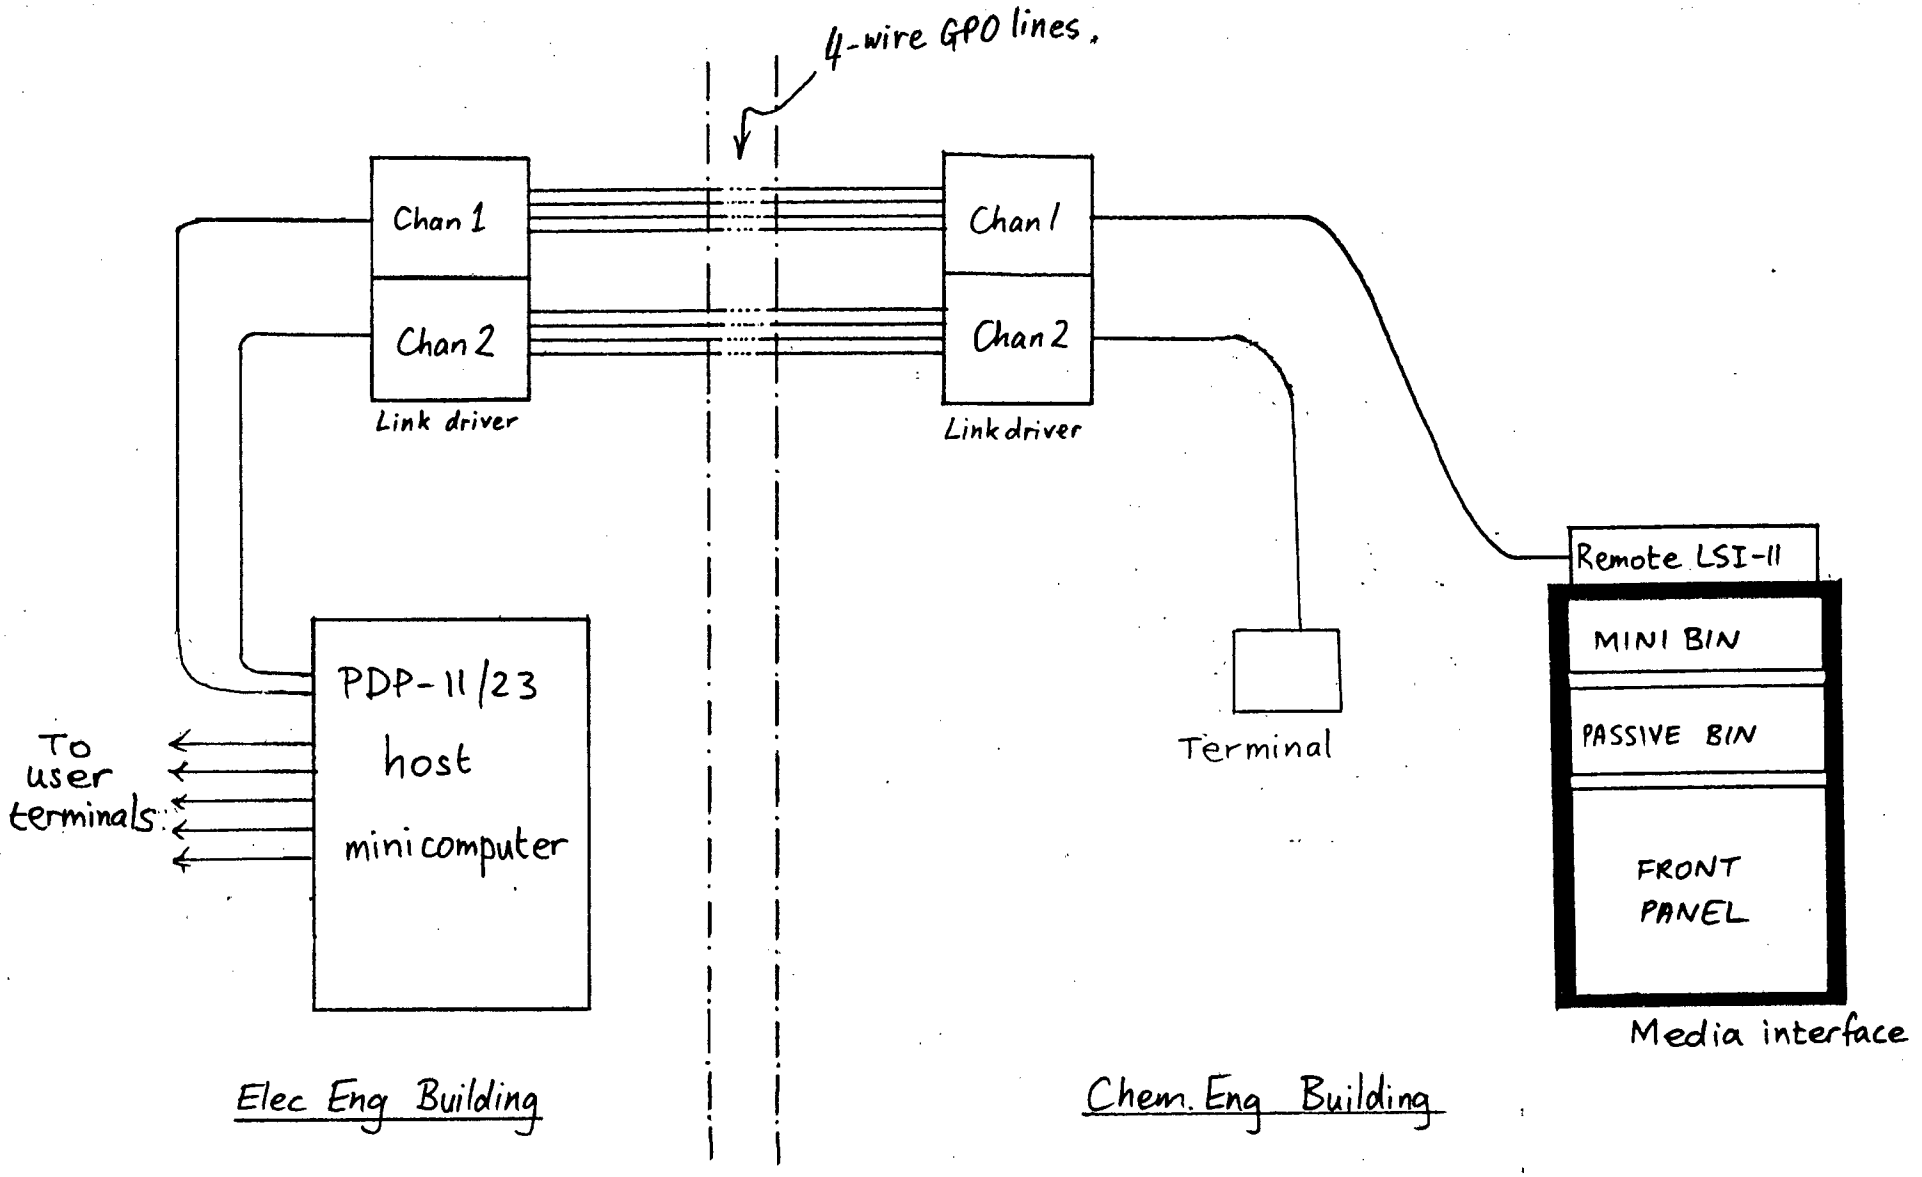

Fig 1-1: System hardware.

1.4 The Host Software System

1.4.1 Introduction

The PDP-11/23 host minicomputer runs the multi-user multi-tasking operating system RSX-11M [5] which provides the environment for the development and execution of multiple real-time tasks using a priority-structured, event driven task scheduler. Password log-in protection, memory protection and a heirarchical file structure make it suitable for use by many users (such as a class of students).

The host software system provides the necessary routines, libraries, diagnostics and tasks to enable user-friendly multi-user access to the Media interface. The host software, like the LSI-11 Media system software, is written in the language RTL/2 [6] , a structured high-level language for real-time systems. RTL/2 offers the advantages of compiling into efficient code, it has comprehensive error handling, it is easy to learn and can be used for both systems and applications programming. It was therefore felt that RTL/2 was a good choice both for the host software system and for the applications programs to be run using the system. Its use in industry (e.g. at AECI and SANS) means that students using RTL/2 will be gaining useful programming experience.

The RTL/2 compiler for the PDP-11 was written by SPL International, who also supplied a run-time support package to interface between RTL/2 and RSX-11M. [7] The SPL interface has several shortcomings [8], such as poor naming of the interface procedures, insecure use of system traps, inadequate error reporting and large memory overhead on file I/O.

Therefore, it was decided to use an alternative run-time support package called MTSLIB [9] which was developed at AECI and corrects most of the deficiencies of the SPL interface.

1.4.2 Multi-user Access to the Media Interface

1.4.2.1 The Media Data-base -

In order to keep careful control over access to the interface, user applications software is not given direct access to the serial line connected to the Media interface. Instead, a copy of all information relevant to Media is kept in a resident common data-base in the memory of the PDP-11 host computer. This data-base is called MEDCOM (for "Media common") and contains all the input and output data, times of last update, access control codes, setpoints, etc.

1.4.2.2 The Media Update Task -

A task called MEDUPDAT (for "Media update task") runs continually and updates the database regularly with fresh information from Media and writes output data from the data-base to Media. The update task is the only task that communicates directly with the serial link to Media; all other tasks, including user application programs, read and write data from/to the data-base and rely on the updating task to ensure that the data in the data-base is up-to-date and that the output data is passed on to Media.

1.4.2.3 The Media User Interface Library -

In addition to being denied direct access to the serial link, applications software is not given direct access to the data-base MEDCOM itself, but must access it in a controlled fashion, to ensure that application tasks cannot interfere with one another. To this end, a library of routines (called MEDUSER, for "Media user routines") provides easy read and write access to the data-base, and hence via the updating task to the Media interface itself. From the user point of view, accessing Media is a simple and direct operation, because the routines in MEDUSER make all of the following transparent:

1. Securing and releasing of the data-base for indivisible operations (see chapter 6)

2. The operation of the Media update task, and

3. Encoding and decoding of frames in the Micro-Media protocol and the sending and receiving of data link frames.

For example, to write the data OUTDATA to analogue output number 2, the user would simply write

```
WRMEDOUT( ANALOG, 2, OUTDATA);
```

and would not have to worry about securing, releasing, protocols, etc. The disadvantage is obviously the time uncertainty in controlling Media; i.e. one cannot know exactly when the data written to MEDCOM will reach Media because a variable amount of time may elapse before MEDUPDAT performs the transaction with Media.

1.4.2.4 Exclusive access to Media outputs -

Access to MEDCOM via the MEDUSER interface has been controlled in such a way that any user is permitted to read data from any part of the data-base, since this will not interfere with other users' activities, but a user can only write to those parts of the data-base to which he has "attached" before running his tasks. Before running any task which writes information to MEDCOM, the user must attach to the outputs involved by running a task called ATTACH, after which he has exclusive access to the outputs to which he has attached. The user may if he wishes specify to the ATTACH task which outputs to which he wishes to attach, or may allow ATTACH to give him whichever happen to be free.

A procedure is supplied in the MEDUSER interface which enables a user-written task to determine which outputs it is attached to. This approach allows user programs to be independent of which particular outputs are used, obviously a desirable feature since the availability of different outputs will clearly vary from time to time due to the muti-user teaching and research use. The ATTACH task is described in detail in chapter 7.

1.4.2.5 The Data-base Manager -

A task called MEDRMD (for "Media RMDEMO") provides a dynamically updated display of the activity of the data-base. This display is updated every second and gives details of which user is attached to each output, how much time has elapsed since the last update and which task is currently securing the data-base. This task is similar in spirit to the RSX-11 RMDEMO task [10] which gives a dynamic display of the use of the computer system resources such as memory, pool, task lists and disc space. Use of MEDRMD enables a system manager to monitor the activity of the data-base, and correct any complications that occur (such as users attaching to outputs and failing to detach afterwards). It also enables a user

to quickly and easily see whether MEDUPDAT is in fact updating the data base, and see to which outputs he is attached.

One of the accounts (account number [300,1]) is designated the data-base manager's account : a user with [300,1] as his protection UIC has more privileged access to the data-base than do the other users. By using the information from MEDRMD, he can keep control over the data-base: for example, he can forcibly detach from outputs users who fail to do so themselves.

1.4.3 The Necessity for Simulation

Although the primary function of this system for the purposes of teaching is to give the students hands-on experience of the control of a real process, practical factors dictate that much of the time the students will not in fact be controlling a real process, but instead a software simulation of the process. For example, there may be only one set of apparatus, or the apparatus may be delicate and easily damaged by a program which is not fully debugged. The data-base MEDCOM, therefore, contains not only all the data needed for the Media interface itself, but also an additional part which is used for simulation. This part of MEDCOM is not updated by MEDUPDAT, but instead by a simulation task which simulates the effect of the Media update task plus the Media interface and the process apparatus. From ther users' point of view, however, it is exactly as if he were controlling a real system. The only difference to the user is that when he attaches to outputs using ATTACH, he specifies that he wishes to use a simulated system.

To enable the easy simulation of analogue systems, a simulation package (see chapter 9) has been written which enables easy implementation on the digital computer of almost any analogue block diagram.

1.4.4 Graphics Interface

A library of routines simplifying the use of the Tektronix 4010 plotting terminal is provided. This library is not intended to be a complete graphics interface, but merely provides sufficiently many software building blocks to enable users to easily build up their own routines such as graph-plotting routines. This allows users to plot graphs of the parameters of the processes that they are controlling - for example the value of one of the analogue inputs against time. Hard copies of the graphs plotted may be obtained using the hard-copy unit attached to the plotting terminal.

1.4.5 System Management and Diagnostic Tools

Various diagnostic programs have been written which can be used to test the Media interface and the various software modules and libraries. These are described in chapter 8.

1.5 Typical Applications

1.5.1 Teaching

The system was used during the 1983 academic year to teach the fundamentals of real-time software and multitasking to final-year Electrical Engineering undergraduates at UCT. The project, which is described in detail in chapter 10, involved controlling the

temperature of air emerging from a 60 cm vertical column, as in figure 1-2:

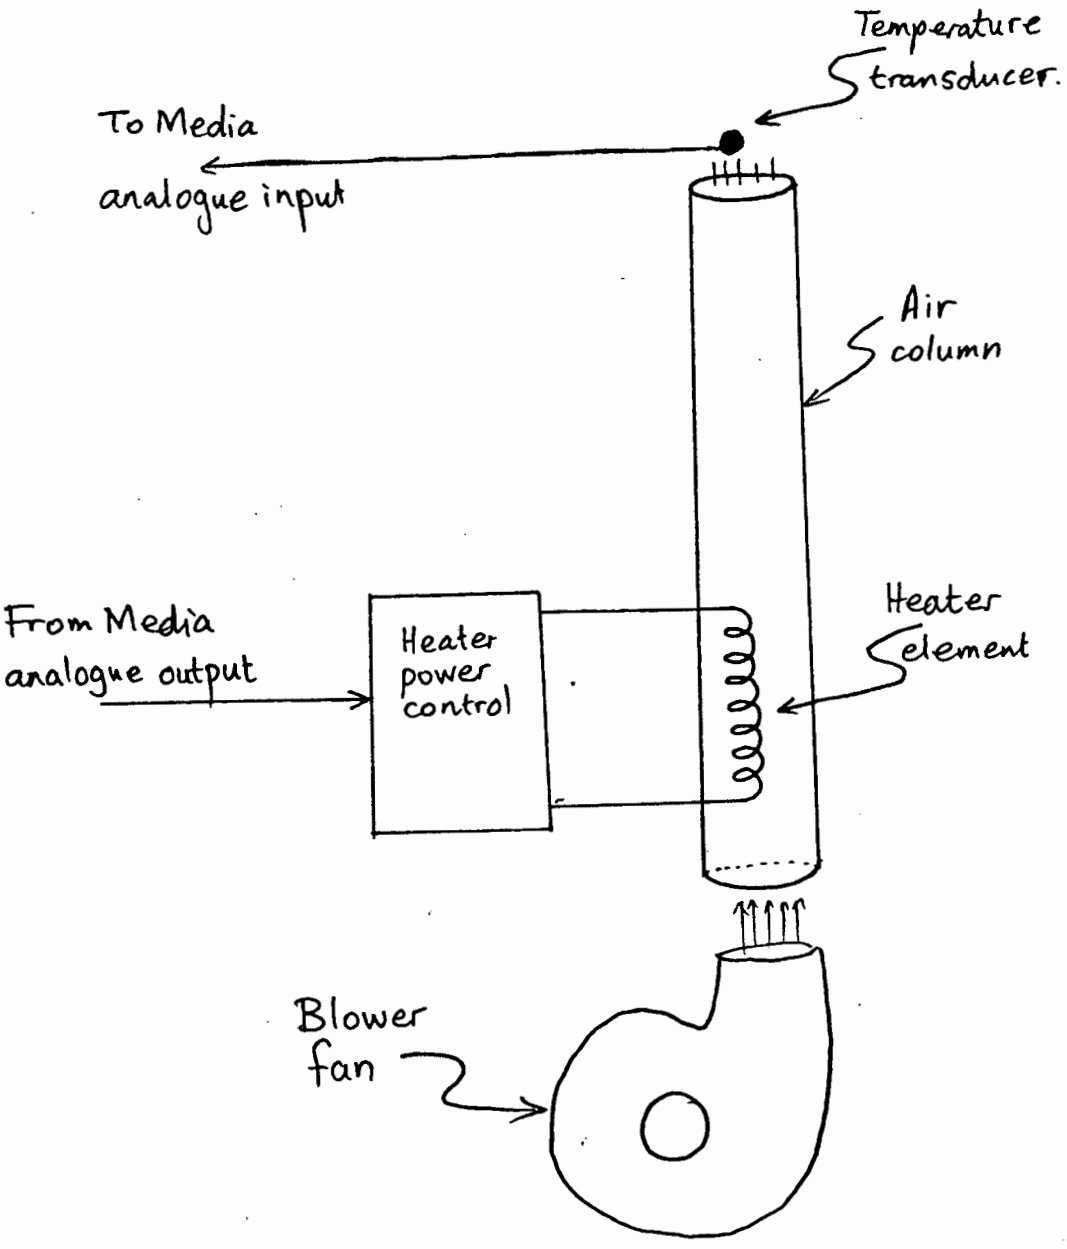

Figure 1-2: Air-column apparatus

Air is blown upwards at a constant rate by the blower fan and the temperature read by the thermistor is read in via one of the analogue inputs of the Media interface. The power output to the heater is controlled via one of the analogue outputs.

In addition, a simulation task could be run which simulated the operation of four such columns using the simulation portion of MEDCOM. The students' software, which accessed the data-base using the MEDUSER library, could be debugged and tested on the simulation system and then run on the real system - thus allowing up to five students to run their software simultaneously.

1.5.2 Research

A good example of a research project that could be undertaken using Media is the determination, using adaptive control techniques, of the characteristics of a variable reflux-ratio fractional distillation tower, illustrated in figure 1-3. Two analogue inputs would be used to measure the temperature at two points in the column, and another would give a measure of the purity of the emerging distillate. One analogue output would vary the power to the heater, and another would vary the reflux ratio.

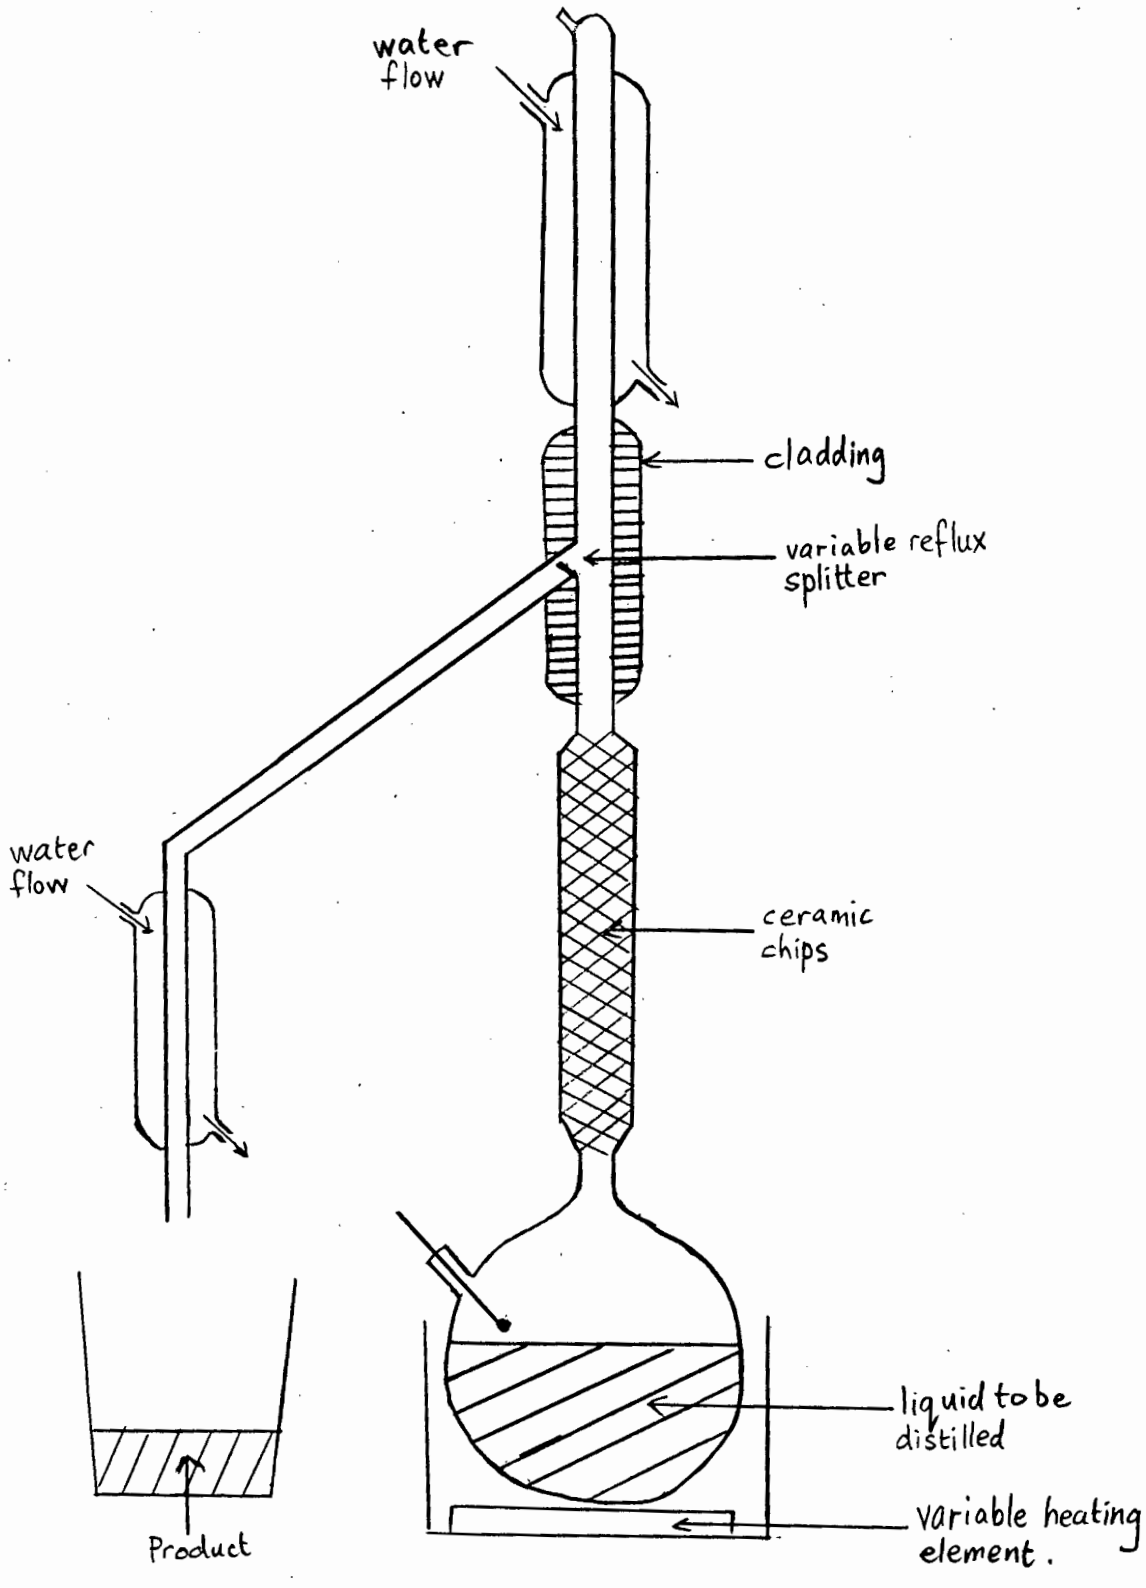

Fig 1-3: Variable Reflux-ratio distillation tower

CHAPTER 2

MEDIA

2.1 HARDWARE

2.1.1 Introduction

Media, or Modular Electronic Digital Instrumentation Assemblies [1], is a family of process control interfaces designed by Imperial Chemical Industries (ICI). The use of Media offers the following advantages:

1. Media provides "data highways" which give read, write and control access at memory speeds to any part of the system. It is therefore particularly suited to the control of more complex systems.

2. The highways provide random access to data.

3. Media is modular, since it is divided into groups of 19-inch card racks into which a wide variety of available

Media cards may be plugged. Because of this modularity, Media offers flexibility in configuration and capabilities.

4. Media can safely be used in a hostile electrical environment, since isolation is provided on all inputs and outputs.

Media systems come in three basic models:

1. Media Major.

   This is the largest of the family and is used to control large industrial plants involving several thousand plant signals.

2. Media Minor.

   This model is of intermediate size and fills the gap between Media Major and Micro-Media.

3. Micro-Media.

   Micro-Media is used to control small systems, typically consisting of up to 32 control loops.

The process data is transferred on the Media highways, of which there are two types:

1. Active highway. This contains those Media cards which can take charge of the highway as master.

2. Passive highway. The passive highway is controlled by the active highway and contains those Media cards which respond to commands but do not take control of the highway, e.g. digital inputs and outputs.

Up to 16 Media cards can be plugged into each 19-inch rack-mounting "Media bin". These bins can be of three types:

1. Active bins: These contain cards which are situated on the active highway.

2. Passive bins: These contain cards which are situated on the passive highway.

3. Mini-bins: Mini-bins have both an active and a passive part, and are only used in small Media systems.

2.1.2 The UCT Micro-Media installation

The UCT Media system [11], which is a Micro-Media system supplied by GEC, has a mini-bin and a passive bin housed in a welded open-frame chassis. The analogue and digital input and output lines from the Media cards are connected to three connector rails at the back of the Media chassis. A diagram of the connector rails is given in Appendix A.

The mini-bin has the following cards installed:

1. M7100 8085 CPU card

2. M7101 CPU-to-Media interface card

3. M6310 serial I/O card

4. M0410 minibin control card

5. M7000 PDP-11 interface (data)

6. M7001 PDP-11 interface (control)

7. M7002 LSI/Media bus interface with M7022 LSI-to Media cableform.

8. M0601 Highway terminator

The passive bin has the following cards installed:

1. Two M2001 16-line digital input cards. These 32 digital lines are intended to be driven by switch contacts, but have been brought out to the front panel (see appendix A) in such a way as to enable them also to be driven by TTL logic levels.

2. One M3302 16-line digital output card. These 16 lines emerge from the card with logic high being 24 volts, but have been brought to the panel (see appendix A) in such a way as to allow a choice between 24 volts and TTL logic levels.

3. One M3004 4-channel analogue output card. The outputs have 8-bit precision, with 00H being equivalent to -4mA, and FFH to -20mA. They have been brought to the panel in such a way as that they are also available as -1V to -5V voltage outputs (see appendix A).

4. One M1601 16-way analogue multiplexer card. Selection of a particular channel is described in Appendix B.

5. One M1000 10-bit analogue-to-digital converter card. The analogue input to this card is the one selected by the multiplexer card. The input voltage range is -1V (for 000H) to -5V (for 3FFH). The format of the data read is described in Appendix B.

6. M0003 passive highway terminator card.

A serious problem with the system is that the ground reference level for the digital cards is 15 volts below that of the analogue

cards. This means that there must be two ground levels (analogue ground and digital ground), which leads to unnecessarily complicated circuitry when interfacing Media to the circuit being controlled.

Specific details of the programming of each individual Media card are given in appendix B.

2.2 SOFTWARE

2.2.1 Outline

As was menioned in the introduction, the heart of the Micro-Media system consists of three boards: an 8085 CPU board,a Media interface board and a serial I/O board. These boards are plugged into the active section of the mini-bin. Two ROM chips on the CPU board contain a program, written in Coral-66, allowing Micro-Media to be used as a remote data input/output station, connected to the host computer via a serial data link. A simple half-duplex link-level protocol [12], described below, is implemented whereby the host sends command frames, and receives reply frames from Micro-Media.

The Micro-Media software continually scans the Multiplexed analogue inputs and stores the values read into an area of RAM called the "analogue list". The data items stored in the analogue list are called "list items".

The 32 bits in the two "digital change words" stored in RAM correspond to up to 32 16-line digital input cards. Whenever the state of any of the input lines to one of the digital input cards changes, the Media program sets the bit in the digital change

words corresponding to this card. The digital change words are cleared by the Media program after the host reads them. The philosophy behind the use of the digital change words is to allow the host to determine whether or not any of the digital input lines have changed state, without having to access each digital input card. In the present system, however, which has only two digital input cards, only two bits of the digital change words are used and no real advantage is gained over simply accessing both digital input cards.

Each Media card is identified by its "Media address", i.e. its address on the Media highway, and each item in the analogue list has a "list address". Media and list addresses are 10-bit addresses. In the LSI-11 Media system, the Media addresses correspond to successive locations in the I/O space of the LSI, as explained in appendix B.

The Micro-Media protocol is a half-duplex link-level protocol. All transactions between Media and the host are initiated by the host. The host sends a frame in which is encoded a command field to indicate to Media which of sixteen possible operations it must perform, and Media replies with a reply frame including a status field indicating whether or not the operation was successful, and if not, what went wrong. Frame data integrity is checked using a block check character. Error correction is not performed - the host is expected to take corrective action, such as retransmitting a frame, if the reply from Media indicated that the received frame was faulty. A timeout is implemented by Media whereby the time interval between any two successive bytes within a frame may not exceed a certain amount, or else the frame is rejected.

2.2.2 Media protocol frame format

Each frame consists of a number of bytes into which the various frame fields are encoded. The first and last byte of each frame

has bit 6 set (regarding the least significant bit as bit 0, and the most significant bit as bit 7). No other byte within a frame has bit 6 set. After the first byte of a frame is detected, all further bytes are included in the frame until another byte with bit 6 set is detected. This byte is then taken as the last byte in the frame.

This scheme has the disadvantage that the same method (setting bit 6) is used to indicate the start and the end of the frame, and therefore, should a start or end byte be lost, all start bytes will be identified as stop bytes (and vice-versa) and so no further frames will be transmitted correctly.

The following fields are present in all frames:

1. The command code. The command code informs the Media program which of sixteen possible operations (such as read digital change words or write to Media address) it should perform. The command code consists of bits 0 to 3 of the first byte in the frame. All possible command codes are listed in Table 2-1 and described below.

2. The terminal address. Bits 4 and 5 of the first two bytes contain a 4-bit terminal address, used to identify a particular terminal if a multidrop line is used. In the LSI-11 Media system, these bits are ignored.

3. The block check character (BCC). Bits 0 to 5 of the final byte in the frame form a BCC, which is formed as the logical exclusive-OR (vertical parity) of all previous bytes in the frame.

4. Parity. Bit 7 of each byte may be used as a parity bit. The LSI-11 Media system does not use the parity bit, but instead puts zero into these fields.

5. Reply status. In the case of Media-to-host reply frames, bits 0 to 3 of the second byte give status information as listed in Table 2-2. The status information informs the

2.2.3 Media operations

The operations which Media can perform in response to a command frame from the host are summarised in Table 2-1.

When data is written to Media, this is done in a two-stage process, so as to ensure integrity. A frame with a command field indicating a write (code C or D) is sent to Media, containing an item of data to be written to a specified Media or list address. Before taking any action, Media reflects the entire frame back to the host. If the host is satisfied with this reply, it then sends a confirmatory frame with a command field indicating "go" (code E) causing the data to be written, and Media replies with a 3-byte frame containing the status field. Should a confirmatory "go" frame not be received from the host, Media will not write the data, but will simply perform whatever operation is specified by the command field of the next frame received (i.e. the initial "write" frame will have had no effect).

The following list describes all the operations which may be specified by a frame from the host:

1. Single read from Media address (code 1). Media returns the value read from the specified Media address.

2. Single read from list address (code 2). Media returns the value read from the specified list address.

3. Block read from Media addresses (code 3). The frame from the host indicates how many items must be read, and the Media address of the first item. The items are read from consecutive Media addresses and returned inside the reply frame.

4. Block read from list addresses (code 4). Same as for (3), except that list addresses are used.

5. Read digital change words (code 7). The reply frame from

Media contains the digital change words.

6. Read the printer status word (code 8). The reply from Media contains the printer status word, which indicates the status of the printer local to the Media interface. Since our system does not have a local printer, this function is not implemented in the LSI-11 Media system.

7. Write to a single Media address (code C). The frame from the host contains the Media address and the data to be written to that address. Media does not actually execute the write until it receives a confirmatory "go" frame, but instead reflects the entire frame back to the host for checking.

8. Write to a single list address (code D). As for writing to a Media address except that a list address is used.

9. Go (code E). This is the confirmatory command used in the second stage of a write operation and informs Media that it may now execute the write specified in the previous host command frame.

10. Write text to printer (code 0). The frame received by Media contains text which must be printed on the printer local to the Media interface. Since our system does not have such a printer, this command was not implemented in the LSI-11 Media software.

CHAPTER 3

THE LSI-11 MEDIA SYSTEM

3.1 THE LSI-11 MEDIA SOFTWARE

3.1.1 General

This software component emulates the operation of the GEC proprietary Micro-Media software. Since the target LSI-11 microcomputer consists only of CPU board, memory and serial I/O interface, the operating system used must be built together with the Micro-Media software into a single task (called SMT.TSK) before being downloaded into the LSI-11.

The operating system used is SMT (for "Standard Multi-Tasking") version 18 which is a small (about 6K words) multitasking operating system designed for use in real-time control applications [4]. Because of its small size, SMT is ideally suited to applications such as this one where the system can be

compiled on a minicomputer and downloaded into a microcomputer such as the LSI-11 used. SMT is written mostly in RTL/2, but has assembler code inserts where necessary. The use of a high-level language makes the operating system easier to understand and to update.

SMT provides the framework into which the user may insert up to 16 tasks written in RTL/2 for his particular application. Full RTL/2 system and stream I/O facilities are provided for the tasks, as well as 16 user events and 16 facilities. SMT allows 255 levels of priority for the tasks. Standard RTL/2 error handling mechanisms are provided.

3.1.2 SMT System Modules

The operating system itself consists of the following modules:

3.1.2.1 The SMTB1 and SMTB1X modules -

These contain all the machine-dependent system code, including interrupt handling, real-time clock handling, unrecoverable error handling and system start-up code. Both are supplied with SMT, but SMTB1X is the one that must be used with the RSX-11 macro-assembler, since it contains certain .PSECT directives that the assembler requires.

Because SMT was originally written to run on the old pre-LSI PDP minicomputers, it does not exploit the larger instruction set of the LSI-11 to the full. The LSI-11 has additional instructions for processor status word access which were not present in the instruction sets of the earlier PDPs. To enable these more efficient instructions to be used, SMTB1X must be edited to change

the old instructions to the new ones. All the necessary changes are included in a file called SMTB1X.EDT (not supplied with SMT). An edited file, SMTB1XUP.RTL, is produced by the DEC editor, as follows:

```
EDT SMTB1XUP.RTL=SMTB1X.RTL
*INC =X /FI:SMTB1X.EDT
*XEQ =X
*EX
```

SMTB1X is compiled using

```
RTL SMTB1X,SMTB1X=SMTB1XUP/CN:F/PE:SMTB1X/TI:SMTB1XUP
MAC SMTB1X=SMTB1X
```

The /CN:F switch is needed because SMTB1X contains code inserts, the /PE switch is used to generate a .PSECT directive at the beginning of the output macro-11 source and the /TI: switch specifies a title.

3.1.2.2 The SMTU1 and SMTU1X modules -

These contain the machine-dependent user task definitions and initialisation code, i.e. the details about all the user tasks that will be built into the system - what the names for the base procedures of the user tasks are, what the tasks' priorities are, whether they are to be initialised into the running or suspended states, etc. Therefore, SMTU1X must be edited to configure it to run the two user tasks SMTCOMS and SMTMULTI (these are described later). This module as supplied also includes the device driver routines for the console serial line of the LSI. However, in this application, these have been replaced by custom-written drivers in the SMTDEVDRV module (below), and so must be deleted from this module.

As for the SMTB1X module above, SMTU1X is the one that must be

used with the RSX-11 assembler. A file, SMTU1X.EDT, is provided which contains all the necessary commands for the DEC editor to edit SMTU1X.RTL to produce SMTU1XUP.RTL.

SMTU1X is compiled using

```
RTL SMTU1X,SMTU1X=SMTU1XUP/CN:F/PE:SMTU1X/TI:SMTU1X
MAC SMTU1X=SMTU1X
```

The meaning of the switches used was described in the section on SBTB1X.

3.1.2.3 The SMTB2 module -

This module contains the machine-independent system routines. Included amongst these are routines connected with event flags such as WAIT, DELAY, SET and RESET, the securing and releasing of facilities, the printing of error messages when unrecoverable errors occur and the standard RTL/2 stream I/O procedures such as IREAD and TWRT.

The only modification necessary is the suppressing of the output of the error-message printing routine ERPRIN (for reasons explained later). This is done by commenting out the bulk of the routine. Examination of the listing of the routine will show that an alternative method would have been to set the error count ECT to zero just before ERPRIN tests its value.

SMTB2 is compiled using

```
RTL SMTB2,SMTB2=SMTB2/TI:SMTB2
MAC SMTB2=SMTB2
```

3.1.2.4 The RTLCTL module -

This module contains the control routines for RTL/2 tasks running under SMT. These include the trap handlers, array bound checking routines, stack unwind routines, type conversion and all arithmetic routines such as compare, add, subtract, multiply, divide and arithmetic shift.

The module is written in macro-11 and does not need to be modified. It is assembled using

```
MAC RTLCTL=RTLCTL
```

3.1.2.5 The SMTB3 module -

This contains the system data tables and the stacks for the tasks which form part of the SMT operating system itself (e.g. the real-time clock task). The contents of the system data tables is not of any relevance from the user point of view.

No modifications are needed to SMTB3, and it is compiled using

```
RTL SMTB3,SMTB3=SMTB3/TI:SMTB3
MAC SMTB3=SMTB3
```

3.1.3 User modules

3.1.3.1 The SMT device driver SMTDEVDRV -

The device drivers supplied with SMT as part of the SMTU1X module are not suitable for use as drivers of the Media serial line, which must transmit and receive 8-bit binary data without special significance to any of the characters.

The supplied drivers were deleted and a module SMTDEVDRV was written to replace them. The module consists of the hardware input and output console line interrupt servicing routines as well as byte input and output procedures intended to be assigned to the standard RTL/2 stream input and output procedure variables IN and OUT in the SVC data brick

```
SVC DATA RRSIO;
  PROC () BYTE IN;
  PROC (BYTE) OUT;
ENDDATA;
```

The description below of these four procedures should be read in conjunction with the listing of SMTDEVDRV:

1. PROC INSERIAL ().

   This is the hardware serial input interrupt service routine and is vectored to via location 000060. It is executed whenever a byte has been received on the line and is ready for processing by the Media software.

   Inspection of the listing will show that INSERIAL takes this byte and puts it into a buffer (INAREA.INBUFF) and increments the buffer pointer (INAREA.INPT). It then queues the console input event INEVENT and returns.

2. PROC OUTSERIAL ();

   This is the hardware serial output interrupt service routine and is vectored to via location 000064. It is

executed on completion of the transmission of a serial output byte.

All it does is to queue the printer event flag PREV to indicate to the software that transmission of the character is complete.

3. ENT PROC INBYTE () BYTE;

This procedure, together with INSERIAL, replaces the SMT-supplied console input procedure INTTY. It is assigned to the standard RTL/2 byte input procedure variable IN by the Micro-Media communications task SMTCOMS. All 8 bits of all input bytes are passed, none of them being given any special treatment.

Its operation is as follows. If there are bytes left in the input buffer, the output pointer INAREA.OUTPT is incremented and the byte pointed to is temporarily saved in the variable CHAR. A test is then done to see if the byte is the last one left in the buffer. If it is, then the buffer pointers INAREA.INPT and INAREA.OUTPT are reset to zero. A suspension of interrupts using HLOCK takes place during this critical test-and-reset operation. The procedure then returns the byte saved in CHAR.

4. ENT PROC OUTBYTE (BYTE B);

This procedure is used to output bytes to the console line. It is assigned to the standard RTL/2 byte output procedure variable OUT by the Micro-Media communications task SMTCOMS. All 8 bits of all bytes are passed, and no special significance is attached to any of the characters.

SMTDEVDRV is compiled using

```
RTL SMTDEVDRV,SMTDEVDRV=SMTDEVDRV/CN:F/PS:DEVDRV/TI:SMTDEVDRV
MAC SMTDEVDRV=SMTDEVDRV
```

3.1.3.2 The SMTCOMS user task -

3.1.3.2.1 General description -

SMTCOMS is the serial I/O communications task. It performs the following operations:

1. Receiving and transmitting of all data link frames.

2. Decoding the Micro-Media protocol serial link command frames received from the host, and detecting any errors in these frames (such as faulty block check character).

3. Constructing the Micro-Media reply frames which it will send to the host.

4. Performing all operations (such as Media read or write) that are specified by the command frames received from the host.

3.1.3.2.2 Detailed description -

This description should be read in conjunction with the program listing.

SMTCOMS is activated every time an input byte from the host arrives down the serial link. It waits for the event flag INEVENT which is set by the input interrupt servicing routine INSERIAL.

The input bytes are built up into complete frames (a frame being a complete command from the host in the Media protocol format). This is done by the procedure BUILD() which is called for each input byte.

Checking of the input characters is only done once the input frame is complete. The successive bytes of an input frame must arrive within two seconds of each other, otherwise the frame is rejected.

The start and end bytes of each frame are detected by testing bit 6 of each incoming byte - a byte in a Media frame has bit 6 set if and only if it is a start or end byte.

When the BUILD() routine indicates that the frame is complete, PROCESS() is called to process the frame. It checks that the block check character (BCC) is correct, decodes the frame, takes appropriate action according to the Media code, builds up a reply frame and outputs the reply down the console line.

The fundamental procedures for accessing Media highway addresses are WMEDIA and RMEDIA. These are also called by the SMTMULTI task when it accesses Media.

1. ENT PROC RMEDIA (INT AD) INT. The returned integer contains the data read from the card at Media address AD. AD is multiplied by 2 and added to the base address 176400 to convert it to an LSI address.

2. ENT PROC WMEDIA (INT ADDR, VALUE). The data VALUE is written to the Media address ADDR.

Should a Media access error cause a bus time-out unrecoverable error, control is passed to the unrecoverable error processing label UNRECOV. Unrecoverable error processing is discussed in section 3.1.4.

Procedure GETADD extracts the Media or list address from the address field of input frame, and DECODE similarly extracts the data from the data field.

3.1.3.2.3 Error conditions recognised -

The SMTCOMS task recognises several error conditions :

1. LENERR : Length of input frame is inconsistent with the Media code used.

2. TOOMANY : Too many bytes in input frame - input buffer overflow.

3. TIMEERR : Timeout error while waiting for input.

4. BADCODE : Invalid Media code received.

5. BLOCKERR : BCC of received message incorrect.

6. MEDIAERR : Media access error.

7. UNEXPGO : GO code received which was not preceded by a write message.

The Micro-Media protocol, however, only allows five types of error status to be returned :

1. Parity, framing or overrun error in input frame. This is returned for LENERR and TOOMANY.

2. Timeout on character input. This is returned for TIMEERR.

3. Invalid Media code. This is returned for BADCODE and UNEXPGO.

4. BCC faulty. This is returned for BLOCKERR.

5. Media error. This is returned for MEDIAERR.

3.1.3.2.4 Compiling SMTCOMS -

SMTCOMS is compiled using

```
RTL SMTCOMS,SMTCOMS=SMTCOMS/CN:F/TI:SMTCOMS
MAC SMTCOMS=SMTCOMS
```

3.1.3.3 The SMTMULTI user task. -

SMTMULTI is the analogue multiplexer scan task. Its function is twofold:

1. It must continually read the digital input cards and update the digital change words in RAM accordingly.

2. It must continually read the multiplexed analogue input data and store this in the analogue list in RAM.

Every 60 milliseconds it reads in the digital inputs, compares them with the values read the previous time, and stores the digital change words accordingly. It then writes to the multiplexer to select the next analogue input to be read, waits 40 to 60 milliseconds to allow the multiplexer to settle, and reads in the data from the ADC card. Only one analogue input is read each time. It therefore takes 16 times as long, i.e. about one second, to scan all 16 inputs.

Any Media access which causes a bus timeout on access is regarded as a Media error, and causes error processing to pass to the unrecoverable error label. The unrecoverable error processing then puts the card responsible for the error out of scan.

A list of cards which are out of scan is maintained, as well as a pointer to this list. Each time round the loop, one of the out-of-scan cards (if there are any) is accessed to see whether it has come back into scan, and if so, its element is removed from the out-of-scan list. If however, the card is still out of scan, an unrecoverable bus time-out error will again occur. It is for this reason that only one of the out-of-scan cards can be tested at a time.

SMTMULTI is compiled using

```
RTL SMTMULTI,SMTMULTI=SMTMULTI/CN:F/TI:SMTMULTI
MAC SMTMULTI=SMTMULTI
```

```
SVC DATA RRERR;
  LABEL ERL;
  INT ERN;
  PROC (INT) ERP;
ENDDATA;
```

3.1.5 Building SMT.TSK

Once all the modules have been compiled as described already, they may be task-built to form SMT.TSK using the following command

```
TKB @TKBSMT
```

where TKBSMT.CMD is

```
SMT/-HD/-MM,SMT/-SP/MA/CR=LOWCR,SMTB1X,SMTB2,SMTB3
RTLCTL,SMTU1X,SMTDEVDRV,SMTMULTI,SMTCOMS
/
STACK=0
UNITS=0
PAR=EXEPAR:0:160000
/
```

LOWCR.MAC reserves space for the bottom area of LSI memory which will contain the interrupt vectors. It consists simply of

```
.PSECT
.BLKW   128.      ; Reserve 256. bytes for int. vectors
.END
```

3.1.6 Note on debugging the user SMT modules.

In the SMTCOMS, SMTMULTI and SMTDEVDRV modules, certain RTL/2 lines have been commented out using triple percent signs ("%%%"). These lines were originally present while the software was being

debugged, and cause messages to be printed down the console line describing what the programs are doing. If it is ever necessary to debug or extend these routines, the abovementioned debugging lines can be temporarily put back by changing all occurrences of "%%%" to "%%". Once debugging is complete, changing "%%" to "%%%" will cause the debugging lines to be commented out again.

3.2 REMOTE SYSTEM DOWNLOADING AND STARTUP

3.2.1 The ODT program

3.2.1.1 General -

The remote system start-up procedure is structured around the use of a program called ODT, so called because it interacts with the microcoded ODT (Octal Debugging Technique) program [13] which runs on the LSI-11 when it is halted.

ODT, which is run on the host and provides semi-transparent access to the console line of the remote LSI-11, enables the operator to perform any of the operations that are supported by the LSI-11's console ODT. ODT can therefore be used to examine and change any of the LSI's memory and register locations. As was mentioned in the introductory chapter, ODT (together with the bootstrap loader SMTLOAD) also provides the means whereby the LSI-11 Micro-Media software SMT.TSK can be downloaded into the remote LSI-11 and started running.

Ideally, ODT should provide full transparency between the

operator's terminal on the host and the LSI-11's console line, so that from the operator's point of view it would seem that his terminal was directly plugged into the LSI. Such transparency can be achieved using RSX-11M's asynchronous system traps (ASTs) [14] to deal with the incoming characters from the two ports, but the simpler approach of using standard QIO calls was used which allowed the program to be made operational sooner and with less effort.

Unfortunately, use of the RSX-11M QIO$S [15] I/O directive only allows one to achieve partial transparency. The operator types in a complete ODT command followed by a carriage return. This command is scanned and checked by the program, and if it is a satisfactory ODT command, is sent down the line to the LSI. The program then waits for a reply from the LSI, in most cases with a one-second time-out. The reply received is then sent to the user's terminal.

This approach requires the program to calculate the number of characters expected in the reply from the LSI, and in order to do this, a record is kept of what "state" the LSI is currently in. The four states used are :

1. START : The LSI is waiting for a command and has output an '@' prompt.

2. MEMORY : An LSI memory location is currently open.

3. REGISTER : An LSI register location is open.

4. PSW : The LSI processor status word location is open.

If the user types in a command which is inappropriate for the current state of the LSI, it is rejected and an error message is displayed.

3.2.1.2 The flush (F) command -

The flush ('F') command, which is recognised in all states, is provided so that the user can flush the input type-ahead buffer of the host serial port to get rid of any unwanted input characters. The program issues an I/O directive to read all characters without echoing them, with a one-second time-out (a QIO$S #IO.RAL!TF.RNE directive). Any input in the buffer, plus any that arrives in the next second, is discarded after being output to the user's screen. It is recommended that the flush operation be done on program startup and also whenever replies from the LSI appear not to be properly aligned with the commands sent out. The flush command also returns the program to the START state.

3.2.1.3 Commands recognised in START mode -

In addition to the flush command, the following are recognised in START mode :

1. Open memory location
   <octaldigitlist><'/'> (e.g. '700000/')

   Memory location 'octaldigitlist' is opened and the contents displayed. 'Octaldigitlist' must consint of one to six octal characters. The program is put into MEMORY mode.

2. Open register location
   <'$'|'R'><octaldigit><'/'> (e.g. 'R6/')

   Register number 'octaldigit' is opened and the contents displayed. the program enters REGISTER mode.

3. Open PSW location
   <'$'|'R'><'S/'> (i.e. '$S/' or 'RS/')

   The PSW is opened and the contents displayed. the program enters PSW mode.

4. Go
   <octaldigitlist><'G'> (e.g. '1070G')

   Processing is started from the location specified by 'octaldigitlist'. No timeout is put into effect and the program will wait until the LSI has output 11 characters (normally caused by the LSI halting again). The program remains in START mode.

5. Proceed
   <'P'> (i.e. 'P')

   Causes processing of the LSI to continue from the location pointed to by the value of register 7. As for the Go command, no timeout is imposed and the program remains in the START state.

6. Help
   <'H'|'HELP'>

   Sends to the terminal a short summary of the operation of the ODT program.

7. Exit
   < control-Z>

   Stops execution of the program and returns control to MCR.

8. Load
   <'L'> (i.e. 'L')

   This command is described in the section on downloading SMT (below).

3.2.2 Commands recognised in MEMORY and REGISTER state

1. Next location
   [<octaldigitlist>]<'N'> (e.g. '1000N')

   The contents of the current location are replaced by 'digitlist' if this field is present. Then the next location is opened and its contents displayed. The state remains unchanged.

2. Close location
   [<octaldigitlist'>]<'C'> (e.g. '34C')

   The contents of the current location are replaced by 'octaldigitlist' if this field is present. Then the location is closed and the program enters START state.

3.2.2.1 Commands recognised in PSW mode -

In PSW mode, only the Close location command is recognised. Its syntax and operation is the same as for MEMORY/REGISTER mode.

3.2.2.2 Downloading the LSI-11 Media software -

The 'L' command, which can be invoked in START state, is used to download a bootstrap loader into the LSI, cause this downloaded loader to run and download the file 'SMT.TSK' into the LSI.

On typing 'L' the user is asked

DOWNLOAD THE ABSOLUTE LOADER (Y/N) ?

If the answer is Y, the absolute loader, stored in an octal dump format in the file SMTLOAD.ABS, is loaded, word by word, into the LSI, using the standard ODT commands, as if a person had typed it all in by hand. All the information loaded is also displayed on the terminal screen. When this is complete, the program asks,

LOAD SMT (Y/N) ?

If Y is typed, then the file SMT.TSK is loaded in 512-byte blocks down the line. After each block, the LSI returns a checksum byte, which the ODT program compares to the checksum it calculated. If a checksum error occurs, it is necessary to restart the LSI, flush the input buffer ('F' command) and start loading again. On the other hand, if SMT is successfully loaded, the message 'LOADING COMPLETE' is displayed and the program asks

START SMT RUNNING (Y/N) ?

If Y is typed, execution of the SMT program is started, and the LSI-11 Media system is functional. The user will normally then type control-Z to exit to MCR.

If N is typed, then the ODT commands can be used to examine and modify the downloaded SMT program.

Step-by-step instructions for Media system startup are given in appendix M.

3.2.2.3 Terminal settings -

The PDP port currently being used as the Media serial link is TT10:. For the program to download correctly, it is essential that this terminal be set to read-pass-all, as follows :

```
SET /RPA=TT10:
```

It is also recommended that the port be set to SLAVE, so that it ignores unsolicited input, and to NOECHO so that if a spurious character occurs, it will not be echoed back and forth across the link :

```
SET /SLAVE=TT10:
SET /NOECHO=TT10:
```

The link speed is 9600 baud :

```
SET /SPEED=TT10:9600:9600
```

These four commands are included in DL0:[1,2]STARTUP.CMD and are executed as part of the host system start-up.

3.2.3 SMTLOAD - a bootstrap loader for the LSI-11

3.2.3.1 Description -

SMTLOAD is a 160-byte-long bootstrap loader for the LSI-11, which is put into the LSI memory by the ODT task using the 'L' command as explained above, and which loads the LSI-11 Media program SMT.TSK into the LSI memory.

SMTLOAD itself occupies the 160 bytes from address 157000 to 157240. It is loaded by the ODT program while the LSI is halted and in console-ODT mode. The file SMTLOAD.ABS, which is an octal dump of SMTLOAD, is sent down the serial line byte-for-byte as if a user had typed it all in by hand.

The ODT program then sets the PSW of the LSI to 000340 (priority 7) so that it cannot be interrupted, and starts the LSI running from location 157000.

The first two bytes received by STMLOAD are interpreted as the length in bytes of the file to follow. A running checksum is also maintained. After every 512 bytes received, the checksum byte is output down the console line for checking by the ODT program. Once all the bytes have been received, SMTLOAD halts.

SMT.TSK is then ready to be run by a "0G" command from ODT.

3.2.3.2 Constructing SMTLOAD.ABS -

SMTLOAD is assembled and taskbuilt as follows:

```
MAC SMTLOAD=SMTLOAD
TKB @TKBSMTLD
```

where TKBSMTLD.CMD is

```
SMTLOAD/-MM/-HD,SMTLOAD/-SP=SMTLOAD
/
STACK=0
PAR=EXEPAR:157000:1000
//
```

The resultant task is a binary file SMTLOAD.TSK which has to be translated into an octal dump format by the DMP utility :

```
RUN $DMP
DMP>SMTLOAD.ABS=SMTLOAD.TSK/BL:3
```

Then SMTLOAD.ABS must be edited (using EDT) as follows :

1. Delete the first two lines. These contain page heading information.

2. Delete all line-feed characters, by typing

   ```
   S/<LF>// %BE:%E
   ```

   where <LF> is the line-feed character on the terminal keyboard.

3. The last several lines will contain only zero data. Delete these lines.

CHAPTER 4

THE SERIAL LINK INTERFACE HARDWARE

4.1 The serial lines

There are three 4-wire links running between the computer rooms of the Electrical Engineering and Chemical Engineering buildings, a distance of some 600 metres. These lines were installed by the Post Office.

Two of these are currently in use - one as the line connecting the LSI-11 (in Chem Eng) to the host PDP-11/23 (in Elec Eng), and the other as a general-purpose terminal link to the PDP. Both run at 9600 baud and use the balanced-line interface units described below.

4.2 The serial interface units

Each unit contains the circuitry necessary to interface two independent RS-232C channels to two balanced 4-wire lines (i.e. the GPO lines).

A full cicuit diagram of the unit is given in Appendix D.

The chips used are the DS8820 dual differential line-driver and the DS8830 dual differential line receivers [16].

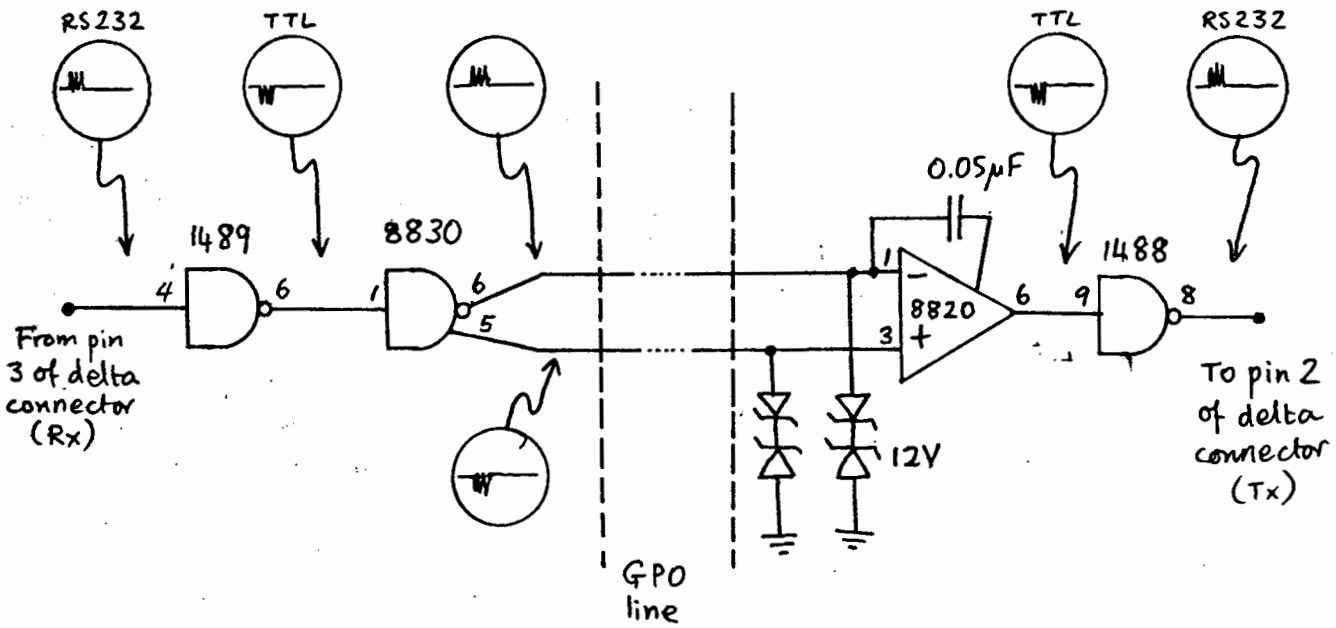

Figure 4-1.

Figure 4-1 shows the system circuit diagram for one of the two channels.

4.2.1 Circuit operation

Let us suppose that a terminal is plugged into the RS-232 connector for channel 1 of the unit. When a character is typed, the RS-232 level signal appears at pin 4 of the 1489. The 1489 converts this signal to an inverted TTL-level signal at pin 6, which drives pin 1 of the 8830. The 8830 converts this to a differential signal (the two levels being about +1V and +4V) between its AND and NAND outputs (pins 6 and 5). The AND output signal is inverted relative to the original input from the terminal, whereas the NAND output signal is not.

These outputs go via two of the wires in the GPO link to pins 1 and 3 of the 8820 in the interface unit on the other side of the link. These signals are limited between -12V and +12V by the protection zener diodes shown.

The line is terminated with a capacitor of 0,05 microfarads between pins 1 and 2 of the 8820. The capacitor is chosen such that the time-constant RC formed with the 170 ohm termination resistance R internal to the 8820 chip is three times [17] the line signal-propagation time. This time was measured as being about 3,6 microseconds.
Hence RC = 3 *3,6 microseconds, where R = 170 ohms, and from this we calculate C = 0,05 microfarads.

The 8820 converts the differential signal to a TTL-level signal inverted with respect to the original signal. This is converted to an RS-232 signal via the 1488 chip and appears on pin 8 of the chip, from where it is connected to the RS-232 delta connector.

CHAPTER 5

MEDCOM - THE DATA-BASE

5.1 Description

All the information obtained from Media is stored in a data-base called MEDCOM, which is continually being updated by the Media update task. MEDCOM is an RSX-11M resident common which is permanently in memory, and is linked to at task-build time by tasks that must access Media. User tasks wishing to access Media do this indirectly by reading or writing to MEDCOM using the user interface routines in the MEDUSER library (see chapter 7).

In addition to containing all information relevant to Media, MEDCOM also contains information which is used, as described in the introduction, to enable real-time simulation of systems. MEDCOM contains sufficient extra space to allow for the simulation of four analogue outputs, four analogue inputs, 16 digital output lines and 32 digital input lines. The simulation part of MEDCOM is not updated by the Media update task, but instead by a simulation task which simulates the effect of the Media update

task communicating with a Media interface connected to a process. The reason why simulation is necessary is given in the introductory chapter, and an example of a simulation task is described in the concluding chapter.

The basic structural item of MEDCOM is the MEDCARD (for "Media card") record, which is defined as

```
MODE MEDCARD (INT STAT, MEDDAT, ADDR, REAL SCANTIME);
```

where

1. STAT is a status word, the bits defined as follows:

```
Bit 0:  1 = card is in scan
        0 = card is out of scan
Bit 1:  1 = 'ADDR' field is a Media address
        0 = 'ADDR' field is a list address
Bit 2:  1 = output card
        0 = input card
Bit 3:  1 = analogue card
        0 = digital card
Others: Reserved
```

2. MEDDAT . For an input, MEDDAT is the data as read from Media by the the update task. For an output, MEDDAT is the data that the update task must write to Media.

3. ADDR is the Media or list address of the card (or item).

4. SCANTIME is the time (in seconds past midnight) of the most recent successful transaction between Media and the data-base for the item. (i.e. when last it was updated).

In the case of the digital inputs and outputs, the MEDCARD record corresponds to an actual card physically plugged into the Media

highway. The MEDDAT field then contains the state of sixteen digital lines.

However, a MEDCARD record does not directly represent a card on the Media highway in the following cases:

1. The analogue inputs are represented in MEDCOM by an array of 16 MEDCARDs, corresponding to the 16 analogue list items in RAM inside Media.

2. MEDCOM has four MEDCARDs to represent the four analogue output channels, even though the four outputs are physically situated on the same Media card.

3. The digital change words and the Media status word (see appendix E) are also represented by MEDCARDS.

4. Parts of MEDCOM which are used for simulation clearly do not correspond to physical Media cards.

The record used for describing an analogue output is the AOREC record, defined as follows:

```
MODE AOREC( INT UIC, USERINT, REF MEDCARD ANIN, REAL
 SETP);
```

where

1. UIC is the protection user identification code of the user attached to the output. This is used by the MEDUSER library routines to determine whether or not the calling program should be permitted to write to the corresponding output.

2. USERINT is an integer which is intended to be used for inter-task communication by the user attached to the corresponding analogue output.

3. ANIN is a pointer to the MEDCARD record representing the analogue input being controlled by this output.

4. SETP is the setpoint of this analogue input. The ANIN and SETP fields are provided to simplify the programming of single-input single-output (SISO) control loops since these are the most frequently encountered. If the system is not a SISO control loop, the ANIN and SETP fields are not used.

MEDCOM consists of two ENT data bricks:

```
ENT DATA INAREA;
  ARRAY(20) MEDCARD ANINP;       % 20 analogue inputs     %
                                 % (16 real, 4 simulated)%
  ARRAY(4)  MEDCARD DIGINP;      % 4 digital input cards  %
                                 % (2 real, 2 simulated)  %
  MEDCARD   MEDSTAT;             % Media status word      %
  ARRAY(2)  MEDCARD DIGCHAN;     % digital change words   %
ENDDATA;

ENT DATA OUTAREA;
  ARRAY(8)  MEDCARD ANOUTP;      % 8 analogue outputs     %
                                 % (4 real, 4 simulated)  %
  ARRAY(2)  MEDCARD DIGOUT;      % 2 dig. output cards    %
                                 % (1 real, 1 simulated)  %
  ARRAY(8)  AOREC   AODESC;      % descriptions of a.o.'s%
  ARRAY(2,16) INT DIGUICS;       % UIC's for each d.o.    %
ENDDATA;
```

We see that the MEDCARDs used for simulation are stored in the same arrays as those used for access to the real Media system. The real inputs and outputs always are the lowest-numbered elements in these arrays, and the simulation inputs and outputs are the higher-numbered elements. For example, the 16 real

analogue inputs are represented by elements 1 to 16 of the array ANINP above; and the 4 simulation analogue inputs are represented by ANINP(17) to ANINP(20).

INAREA holds all information that is read in from Media: a MEDCARD record for each of the 16 analogue inputs and the two digital input cards, MEDCARD records for the digital change words and the Media status word. For simulation, there are 4 MEDCARDs for the analogue inputs and 2 for the digital inputs.

OUTAREA holds all information about Media outputs: a MEDCARD record for each of the 4 analogue outputs and the digital output card, an AOREC record to describe each analogue output, and a UIC to control write access to each digital output line. For simulation, there are four MEDCARDs and four AORECS for the analogue outputs, one MEDCARD for the digital outputs, and a UIC for each digital output line.

5.2 Modifications needed for future changes

The numbers of real and simulation inputs and outputs of each type (analogue or digital) are given in LET statements in the RTL/2 source for MEDCOM and the other modules which refer directly to the data bricks INAREA and OUTAREA. Should it be decided to include further Media or simulation inputs or outputs at a later stage, it will be necessary to change these LET statements to reflect these additions to the system. This also applies, of course, should cards be removed instead of added. No further changes to the software should be necessary, except that MEDRMD (see chapter 7) would have to be rewritten because the layout of its screen display obviously depends on the number of inputs and outputs in the system.

5.3 Building MEDCOM as a resident common

This is described in appendix H.

CHAPTER 6

THE SOFTWARE INTERFACE BETWEEN MEDIA AND THE DATA-BASE

6.1 THE MEDIA UPDATE TASK

This task, called MEDUPDAT, runs continually and executes all the transactions between MEDCOM and Media. As explained in the introductory chapter, user tasks access Media indirectly by writing to and reading from MEDCOM, and rely upon MEDUPDAT to do the following at frequent intervals:

1. Write to Media the output data put into MEDCOM by the user tasks.

2. Read data from all Media inputs and put this data into MEDCOM for access by the user tasks.

Whenever an item of data is successfully transferred between Media and MEDCOM, the time of day is written into the relevant MEDCARD.SCANTIME field. This field allows user tasks to determine how much time has elapsed since the most recent update of the

corresponding input or output.

Each update of the data-base is done in the following order (the MEDLNK routines referred to are described in the section on MEDLNK below):

1. Analogue inputs 1 to 8 and then 9 to 16 are read from Media using the MEDLNK routine BLOCKIN to read in a block of list items. This read is done in two blocks because the 36-byte type-ahead buffer used by the RSX-11M full-duplex terminal driver is not large enough to receive the size of reply frame that results from a 16-item block read.

2. The first and then the second 16-line digital input card are read from Media, using the MEDLNK routine SINGLIN to do a single Media read.

3. The digital change words are read, using the MEDLNK routine GETDCW (get digital change words).

4. The four analogue outputs are written to in sequence, using the MEDLNK routine WRITE to write the data from MEDCOM to the Media address of the analogue output card.

5. The 16-line digital output card is written to, using the MEDLNK routine WRITE to write the data from MEDCOM to the Media address of the card.

If any transaction with Media results in Media indicating that a "Media error" has occurred, then the Media card in question is put out of scan (in/out of scan is indicated by one of the bits of the STAT field of a MEDCARD record). A card which is out of scan ceases to be written to or read from by MEDUPDAT, because a Media error usually means that the card is not present on the Media highway. However, after every ten complete updates of MEDCOM, the

update task tries to access those cards which are out of scan. If a further Media error does not occur, then the card in question is put back into scan.

The speed at which MEDUPDAT runs is not dependent on the frequency of access to MEDCOM by users, since it continually updates all data-base information. Rather, it is dependent largely on the overall load on the PDP-11, the serial link data transmission rate and the priority at which MEDUPDAT is running. MEDUPDAT pauses for 0.1 seconds after each complete scan of the data-base.

Each update involves the transfer of 189 bytes on the serial link, which amounts to a total time of about 0.2 seconds per update at 9600 baud. This figure constitutes the limit to the speed of MEDUPDAT when the PDP-11 is not loaded, but under normal loads the processing time limits the update rate to about once per second. It was found that with a priority of 80, MEDUPDAT was capable of updating at least every two seconds, even when the system was heavily loaded.

Thus, the interface can only be used to control systems which have time constants in excess of about four seconds. This constitutes a fairly serious limitation on the range of applications for which it may be used. Fortunately, the applications envisaged use systems with time-constants of the order of minutes rather than seconds.

6.2 PROCEDURES INTERFACING BETWEEN THE DATA LINK AND MEDCOM

The Media update task is the only task which accesses the serial link directly (with the exception of the diagnostics described in chapter 8). It does this by calling procedures within a library MEDLNK of routines which transfer data between Media and MEDCOM.

These routines in turn call a routine MESSANS, inside the module LINKLB, which controls the link itself.

6.2.1 The Serial Link Control Software

The link-control software is contained in the module LINKLB. This module contains only one ENT procedure,

```
ENT PROC MESSANS( REF ARRAY BYTE OUTBUF, INT OUTLEN,
                  REF ARRAY BYTE INBUF , INT INLEN  ) INT;
```

whose function is to output a frame of OUTLEN characters from the buffer OUTBUF down the serial link, and receive a reply frame consisting of INLEN characters into the buffer INBUF, giving error status information in the integer returned.

This procedure is the lowest-level procedure used on the host side of the link. All frames to Media are transmitted via a call to MESSANS.

The write is done using the RSX-11M QIOW directive [15]. The directive queues the buffer OUTBUF to the full-duplex terminal driver, which is instructed to write all characters (QIOW$S #IO.WAL), and a one-second timeout on output is imposed. This method enables the standard RSX-11M full-duplex terminal drivers to be used, and therefore avoids the necessity of writing a device driver for the host to handle the Media link.

Reading the reply is complicated by the fact that one ideally would want to read until the second occurrence of a character with bit 6 set, and this cannot be done directly in RSX-11M unless a special device driver to implement this is written. Therefore the number of characters expected in the reply (i.e. INLEN) is passed to MESSANS so that it knows how many characters to read. A

problem with this is that, should an error reply be received, its length will be three rather than the expected INLEN characters. If one were to issue a QIOW directive to the driver with (say) a three-second time-out to read all INLEN characters, one would discover that whenever any sort of error occurred, the time-out would occur, thus disabling all activity on the link for the full three-second time-out period.

Since this is not acceptable, what is done is to read the first three characters of the reply, to determine whether they form a complete reply (by checking whether bit 6 of the third byte is set), and if not, to read the remaining (INLEN - 3) characters, also using a QIOW directive. A 1-second timeout is imposed on the first read, and a 3-second time-out on the second read. The QIOW directives used instruct the terminal driver to read the input characters, without echoing them, and put them into the buffer INBUF (QIOW$S #IO.RAL!TF.RNE).

This method only works because all error replies are 3 characters long. Using the above method, time-outs on input should never occur, irrespective of the error encountered (short of failure of the line), and so maximum link bandwidth can be utilised.

Errors reported in the returned integer are:

1. Timeout error on input or output

2. QIO directive failure on input or output

3. INLEN or OUTLEN <= 0

6.2.2 MEDLNK: Procedures interfacing MEDCOM to the data link

The module MEDLNK consists of the procedures which are used (by the Media update task) to transfer data between MEDCOM and the link to the remote Media system.

MEDLNK is the module that does all the encoding into, and decoding from, the Media protocol. All error checking on reply messages from Media is also done here. MEDLNK has procedures enabling single or block read from a Media or list address, single write to a Media or list address, and read of the Media status word or the digital change words.

During critical activities, the data-base is secured using the secure and release procedures described later in this chapter. The period during which MEDCOM is secured has been made as short as possible.

If any access to Media fails for any reason other than a Media error, a second attempt is made. Should this fail too, the standard RTL/2 error recovery procedure ERP is called, causing an error message to be sent to the system console. This message gives an error number (see appendix L) as well as recording the time at which the error occurred.

Occurrence of a Media error causes the access to be aborted and the "out of scan" bit of the .STAT field of the relevant MEDCARD record is set, so that the Media update task can put the card out of scan.

The ENT procedures in the module MEDLNK are described below. In all cases, the SCANTIME element of each MEDCARD record involved is updated if and only if the transaction with Media was successful. The integer returned is the error status, which may indicate successful operation, Media error or one of several other errors (see appendix L for details). The Media code MCODE which

indicates to Media which operation must be performed (see Table 2-1) is not checked for validity.

1. ENT PROC SINGLIN (INT MCODE, REF MEDCARD INP) INT;

   This procedure does a single read from the Media or list address INP.ADDR, and the data, which is a 16-bit integer, is written into INP.MEDDAT.

2. ENT PROC BLOCKIN (INT MCODE, FIRST, LAST,
   REF ARRAY MEDCARD MBLOCK) INT;

   This procedure does a block read (Media or list depending on MCODE). The number of items read is LAST minus FIRST, and the Media/list addresses are MBLOCK(FIRST).ADDR to MBLOCK(LAST).ADDR. The values read are written into the MEDDAT fields of elements FIRST to LAST of the array MBLOCK. LAST must be greater than FIRST, but the procedure does not check this. However, it does check that the .ADDR fields in the array MBLOCK are suitably ordered.

3. ENT PROC WRITE(INT MCODE, REF MEDCARD OUTDAT) INT;

   This procedure writes the data OUTDAT.MEDDAT into Media or list address OUTDAT.ADDR.

4. ENT PROC GETDCW(REF ARRAY MEDCARD DIGCN) INT;

   This procedure gets the digital change words, using a block Media read, and puts them into the MEDDAT fields of DIGCN(1) and DIGCN(2).

6.3 SECURING AND RELEASING DEVICES AND FACILITIES

Two secure/release mechanisms are used - one for the serial data link and one for the data-base MEDCOM.

6.3.1 Securing and releasing the serial link

This is easily done because the MTSLIB RTL/2 interface provides procedures SECDEV (LUN) and RELDEV (LUN), where LUN = logical unit number of the device to be secured/released. These procedures are used in MESSANS to control access to the link.

Strictly speaking it is not necessary to secure and release the link because under normal circumstances only one task, namely MEDUPDAT, accesses the link. However, it is done because it is good programming practice to do so, and because it enables the Media link diagnostic tasks (see chapter 8) to be run while MEDUPDAT is active.

6.3.2 Securing and releasing the data-base

An altogether more thorny problem is that of securing and releasing the data-base MEDCOM, to ensure that indivisible operations such as the updating of a MEDCARD record cannot be interrupted by other tasks.

Securing of facilities is usually done using a "test-and-set lock". This involves performing an indivisible operation which sets a flag or location to a state representing "device secured" while at the same time determining whether or not the flag was set

before the operation. Using this mechanism, to secure a facility a program sets the flag to the "device secured" state, and if the flag was not in the "device secured" state before the operation, then the task knows that it has secured the facility. On the other hand, if the flag was already in the "device secured" state then some other task has secured the facility and the task must try again until such time as it succeeds.

Releasing the facility is done simply by setting the flag to some state other than "device secured".

The MTSLIB interface provides secure and release procedures [18] which use the group-global event flags as a test-and-set lock to secure and release facilities. The radix-50 name of the task currently securing each facility is stored in a data-brick inside RSXBA2, which must be installed in a common partition of memory, and hence any tasks using the secure and release must be linked to this partition at task-build time.

These MTSLIB procedures have certain disadvantages :

1. It turns out to be necessary, because of limitations on the operating system directives available, to have a secured device represented by a flag in the reset state, and a non-secured device represented by a flag in the set state. The problem with this is that at system start-up, all flags "wake up" in the reset state, thus representing all facilities secured. It is thus necessary at system start-up time, or at any rate before any securing or releasing is done, to explicitly set any event flags that will be used for facility locking.

2. An attempt to remedy the above complication led to the author of MTSLIB partially relaxing the test-and-set mechanism by allowing a task to secure the facility regardless of the state of the event flag, provided that the field in RSXBA2 containing the name of the task

currently securing the facility was filled with zeros, as it would be on system start-up.

Unfortunately, this made it possible for two tasks to be simultaneously secured to the same facility. The circumstances under which this occurs are the following. The release procedure first clears the task-name field in RSXBA2 to indicate that no task is currently secured to the facility and then releases the facility by setting the relevant event flag. If a second task attempts to secure the facility between these two operations, it succeeds because the task-name field is zero, and therefore both tasks are simultaneously secured to the facility. Worse still, the first task then almost immediately releases the facility by setting the event flag, leaving the the facility free to be secured by a third task!

Because of this, the secure/release procedures could not be trusted to work reliably.

3. If a task is aborted (by using the ABO command or signing off) while it is securing a facility, the facility is never released and so no other task can access the facility, which therefore "hangs". The facility is not automatically released on task abortion because the facility secure/release mechanism is not part of the RSX-11M operating system, which consequently cannot be expected to tidy up on behalf of a mechanism of which it has no knowledge.

4. SECURE and RELEASE use group-global event flags. This means that all users of the facility would have to be in the same UIC group or else the mechanism would have no value.

It was felt necessary to use global event flags, so as to make it possible for users of all UICs to use Media. This is especially the case because the system is designed to support different categories of user, viz. students and researchers, whose accounts will be assigned different UIC group codes. It was also necessary to correct the bug mentioned in (2) above. This was done by restoring the strict test-and-set lock mechanism and providing a task, MCOMINIT, which initialises the relevant event flags by setting them and is run automatically on system start-up by the system start-up file LB:[1,2]STARTUP.CMD.

A partial solution was also found to problem (3) above, which was to write a task specifically designed for aborting tasks using the Media data-base (see appendix F).

A description of all the procedures relating to securing and releasing as well as the modifications necessary to RSXBA2 are given in appendix G. Forming a common partition RTLLIB containing RSXBA2 and linking user programs to this partition are described in appendix H.

CHAPTER 7

USE AND MANAGEMENT OF THE MEDIA SYSTEM

7.1 USE OF THE SYSTEM

7.1.1 Control of an individual user's access to the system

7.1.1.1 Introduction -

Since one of the fundamental requirements of the system is that it must allow multi-user access in such a way that no users are permitted to interfere with one another, it is of primary importance that access to the data in MEDCOM be carefully controlled.

It was decided to allow each user read access to all of the data in MEDCOM, since this could not compromise the security of other

users' tasks. However, it is clear that a user must not be permitted to write data to parts of MEDCOM (such as outputs) that are in use by another user, since this would destructively interfere with his system. No harm is caused, however, by another user reading from any part of the data-base.

A user may wish to write to MEDCOM under the following circumstances (see the chapter on MEDCOM for a description of the data records referred to):

1. Writing data to a Media output. The data will have to be put into the MEDDAT field of the MEDCARD record corresponding to the required Media output.

2. Writing to the AODESC.USERINT integer associated with one of the analogue outputs (this integer being intended for a user's inter-task communication).

3. Assigning an analogue input as the one being controlled by a particular analogue output. This is used in controlling SISO systems and involves writing to the AODESC.ANIN field of the output in question.

4. Setting the setpoint of an analogue input when controlling a SISO system, by writing to the AODESC.SETP field associated with the corresponding analogue output.

Therefore we see that all write operations to MEDCOM involve writing to a MEDCARD or AODESC record which is associated with a particular output. Consequently, the need to control write access to MEDCOM reduces to controlling write access to the (analogue and digital) outputs.

7.1.1.2 The ATTACH task -

This control is effected by requiring that a user "attach" to the outputs he needs, using a task called ATTACH, before running his tasks, and detach from these outputs (also using ATTACH) after his work is completed so that the outputs are free for use by other users.

Since there are several users of Media, however, a user may not have the same output every time he uses Media - another user may be busy with the one that he had on the previous occasion. On the other hand, he may for some reason wish to use the same output every time (the ATTACH task allows a user to specify the particular output required if he wishes). In either case it would clearly not be satisfactory for him to have to modify his software to suit the particular outputs he happens to attach to. Therefore a means is provided (the ATTACHED routine in the MEDUSER library described below) whereby a user progam can determine which outputs the user is attached to.

Corresponding to each analogue and digital output, the ATTACH task maintains an integer in MEDCOM containing the protection UIC of the user who is attached to the output, and hence authorised to write to it. If no-one is attached to an output, then the integer is zero. Any attempt by a user of the MEDUSER procedures to write to a part of MEDCOM not corresponding to an output to which he is attached, will be aborted and the standard RTL/2 error recovery procedure ERP called. For the digital outputs, the corresponding attached-UIC integers are stored in the array DIGUICS in the brick OUTAREA of MEDCOM. For analogue output number I, the attached UIC is kept in AODESC(I).UIC.

The security of this mechanism is dependent upon all users accessing MEDCOM only via the "official" interface, namely MEDUSER. Therefore, users should not be given specifics of the exact layout of MEDCOM.

7.1.1.3 Using the ATTACH task -

Attaching to outputs is done by the user prior to running his control (user applications) task. The user runs the task ATTACH, and is asked whether he wishes to attach or detach. If the reply is attach, then he is given the following menu of choices:

1. Any digital output (Real Media)
2. Any digital output (Simulation)
3. Specific digital output
4. Any analogue output (Real Media)
5. Any analogue output (Simulation)
6. Specific analogue output

Note that it is during the attaching process that the user determines whether he will be using the real Media system or the simulation system.

Digital outputs 1 to 16 and analogue outputs 1 to 4 are the real Media outputs. Digital outputs 17 to 32 and analogue outputs 5 to 8 are the simulation outputs.

Choice (1), (2), (4) and (5) imply that the user wishes to attach to an output, but does not mind which one it is. The program will find the lowest-numbered output channel that is not yet attached to, attach the user to it and print out an appropriate message. If none are available, the program will inform him of this.

Choices (3) and (6) imply that the user wishes to attach to a particular output. If the output required is not already attached to, then the program attaches the user to it; otherwise it informs him that the output is not available.

In all cases, if the required output is out of scan, then the program will inform the user and not allow him to attach to it.

Once the user has finished using the output, he must detach himself from it so that it becomes available for use by other users. To do this, he runs ATTACH and requests the Detach menu, which is as follows:

1. Detach from digital output
2. Detach from analogue output
3. Detach from all outputs

If the choice is (1) or (2) the user is asked which output number is to be detached. The program will only allow a user to detach from those outputs to which he is attached. Choice (3) detaches the user from all outputs (analogue and digital) to which he is attached.

The ATTACH task secures and releases the data-base in such a way as to ensure a test-and-set lock mechanism on attach (this mechanism is described in chapter 6), which makes it impossible for two users both to be attached to the same output at the same time, even if they simultaneously request to attach.

7.1.2 Applications-user access to Media

7.1.2.1 Introduction -

Applications-user access to Media is done by calls to a library, called MEDUSER, of routines the aim of which is not only to ensure strict control over the data-base MEDCOM, but also to provide a simple and easy-to-use interface which makes it seem from the user point of view as if he is accessing Media directly. In reality, of course, all Media data passes via MEDCOM and the Media update task, but this occurs transparently to the user software.

The global event-flag secure and release procedures described in chapter 6 are used inside the MEDUSER routines to secure the data-base and thus prevent other tasks accessing the data-base during critical sections of the code when it is necessary to write or read data in an indivisible manner. The user never secures or releases MEDCOM explicitly. This minimises the chance of MEDCOM becoming "hung" by a user securing and not subsequently releasing it. This possibility is further discussed in the section below on aborting Media tasks.

The MEDUSER procedures allow the user to perform the following operations:

1. Determine which outputs the user is attached to (proc ATTACHED).

2. Write data to an analogue or digital output (proc WRMEDOUT).

3. Read data from an analogue or digital input or output (proc RDMEDIA). Reading from an output is done in a multi-tasking application when one task wishes to see what value another task has written to an output.

4. Read or write to one of the AODESC.USERINT integers which are intended for inter-task communication use (procs WRCOMMINT and RDCOMMINT).

5. Read the time that an input or output was last scanned by the Media update task or the simulation task (proc RDSCANTIME).

6. For a SISO system, create a logical association between an analogue output and an analogue input indicating that the input is being controlled by the output; or determine which input is being controlled by a given output (procs SETANINP and GETANINP).

7. For a SISO system, to set or read the setpoint of an analogue input being controlled by a given analogue output (procs SETSETPT and GETSETPT).

7.1.2.2 Using the routines in the MEDUSER library -

The user should include the following LET statements in his source program :

```
LET ANALOG  = 0;
LET DIGITAL = 1;

LET INPUT   = 0;
LET OUTPUT  = 1;
```

These values are passed in the ADSWITCH and IOSWITCH parameters of the procedure calls. (e.g. X := RDMEDIA(ANALOG, INPUT, 3) would read analogue input number 3 and put the value into X).

All errors that occur are reported via ERP or RRGEL. A list of error numbers is given in appendix L.

In the description of the procedures in MEDUSER, CHANNUM represents the channel number of the digital or analogue input or output channel in question. The following channel numbers are valid:

1. Digital inputs. Numbers 1..32 are the real Media digital input; numbers 33..64 are the simulation digital inputs.

2. Digital outputs. Numbers 1..16 are the real Media digital outputs; numbers 17..32 are the simulation digital outputs.

3. Analogue inputs. Numbers 1..16 are the real Media analogue inputs; numbers 17..20 are the simulation analogue inputs.

4. Analogue outputs. Numbers 1..4 are the real Media analogue outputs; numbers 5..8 are the simulation analogue outputs.

The following is a description of the procedures in the MEDUSER library.

1. ENT PROC ATTACHED (INT ADSWITCH, REF ARRAY INT OUTARRAY);

   This procedure examines the AODESC.UIC or DIGUICS fields in MEDCOM, and puts into the array OUTARRAY the channel numbers of those outputs to which the user is attached. The rest of OUTARRAY is filled with zeros. For example, if ADSWITCH = DIGITAL and the user is attached to digital outputs 1, 5 and 7 then the procedure will set OUTARRAY(1) to 1, OUTARRAY(2) to 5, OUTARRAY(3) to 7 and the other elements of OUTARRAY to zero. The length of OUTARRAY must be greater than or equal to the number of outputs attached to.

2. ENT PROC WRMEDOUT(INT ADSWITCH, MDATA, CHANNUM);

   This procedure writes the data MDATA to the analogue or digital output number CHANNUM. CHANNUM must be in the correct range. For an analogue output, only the least significant eight bits of MDATA are used because the DAC is 8-bit. The digital output value is 0 if MDATA is zero, or 1 if MDATA is not zero. In order for the write to succeed, the user must be attached to the output and the output must be in scan.

3. ENT PROC RDMEDIA(INT ADSWITCH, IOSWITCH, CHANNUM) INT;

This procedure reads the analogue or digital input or output number CHANNUM from MEDCOM and returns the value read. CHANNUM must be in the correct range. Digital inputs and outputs will be returned as 0 or 1. Analogue inputs (outputs) will be returned as a 10-bit (8-bit) number in the ten (eight) least significant bits of the returned integer and the other bits zero.

4. ENT PROC WRCOMMINT(INT CHANNUM, VALUE);

This procedure writes VALUE into AODESC(CHANNUM).USERINT which is an integer used for inter-task communication. CHANNUM must be in range 1..20 and analogue output number CHANNUM must be attached to.

5. ENT PROC RDCOMMINT(INT CHANNUM) INT;

This procedure reads the value of the inter-task communication integer corresponding to analogue output number CHANNUM and returns the value read. CHANNUM must be in the range 1..20.

6. ENT PROC SETANINP (INT ANOUTPNUM,ANINNUM);

This procedure causes analogue input number ANINNUM to be logically associated with analogue output number ANOUTNUM by setting AODESC(ANOUTNUM).ANIN to point to analogue input ANINNUM. This would then mean that analogue input ANINNUM is the one which is being controlled by analogue output ANOUTNUM. ANOUTNUM and ANINNUM must be in the correct ranges and analogue output number ANOUTPNUM must be attached to.

7. ENT PROC GETANINP (INT ANOUTPNUM) INT;

This procedure returns the channel number of the analogue input logically associated with analogue output ANOUTPNUM

should not be a problem.

Under conditions (1) or (2) above, the chance of MEDCOM "hanging" is relatively small because it is only secured for short periods of time. Nonetheless, it was felt that an alternative aborting task to the RSX-11M ABO command, which does not ensure that the task releases MEDCOM before it exits, should be written. This task is called ABM (for "abort Media").

ABM is a non-privileged task which should be installed as ...ABM and uses the same command-line format as ABO, i.e.

```
ABM TASKNAME
```

or,

```
ABM
```

where the taskname is assumed to be the default taskname for the terminal, e.g. "TT7" if invoved from terminal TT7:.

ABM should be installed at a high priority (say 150.) to ensure that it operates quickly even when the system is very heavily loaded.

ABM works by securing MEDCOM, issuing an abort directive to abort the task and then releasing MEDCOM. In this way it is assured that the task being aborted is not securing MEDCOM. A detailed description of ABM is given in appendix F.

7.2 MANAGEMENT OF THE MEDIA SYSTEM

7.2.1 Introduction

One of the accounts (account number [300,1]) is designated the "data base manager's account". The data-base manager is the user who has logged on under this account and has [300,1] as his protection UIC. The software system allows the data-base manager to perform certain operations that other users may not - he is able to "unhang" MEDCOM should it "hang" for any of the reasons given in the above section, and he can forcibly detach any user from any output should that user fail to do so himself.

7.2.2 The MEDRMD display of data-base activity

The RSX-11M RMDEMO task [10] gives a dynamic display of the use of the computer resources such as memory, pool, task lists and free disc space. Since it is updated every second, the RMDEMO display gives the viewer a good idea of what is happening in the system from moment to moment, and whether or not any of the critical system resources, such as system pool, are dropping below acceptable limits.

A task called MEDRMD (for "Media RMDEMO") was written which is intended to give the data-base manager a similar display, except that the activity of MEDCOM rather than the RSX-11M system is displayed.

MEDRMD displays information relating to the parts of MEDCOM associated either with the real Media interface or with the simulation system. When MEDRMD is running, typing an 'S' displays information about the simulation portion of MEDCOM, typing control-C or control-Z causes MEDRMD to terminate and typing any other character displays information about the real Media interface.

MEDRMD displays the following information :

1. The protection UIC of the user attached to each analogue and digital output.

2. The date and time.

3. The name of the task that is currently securing MEDCOM.

4. The time (in seconds) that has elapsed since MEDCOM was last updated by MEDUPDAT. This is split into five subfields :

   a. Digital inputs 1

   b. Digital inputs 2

   c. Digital outputs

   d. Analogue inputs

   e. Analogue outputs

   Should any of the cards be out of scan, the text "*OUT OF SCAN*" is displayed in the relevant field instead of the time since last update.

Although MEDRMD is intended primarily for use by the data-base manager, the display may be viewed by any user. Uses for the display are the following:

1. To see which output channels are attached to, and which are free.

2. To check that the update task is running properly - if it

is not, then the time since last update will continually increase.

3. To see which task is currently securing MEDCOM - for example, if the data-base manager [300,1] sees that the "Task currently securing MEDCOM" field does not change, he can run UNHANG (see below) to remedy the situation where a task has exited while secured to MEDCOM.

The display is terminated and the screen cleared, as in RMD, when the control-C or control-Z character is typed at the keyboard. MEDRMD achieves this by using the AST-routines in the module AST (see Appendix I).

7.2.3 Detachment by the data-base manager

The ATTACH task allows the data-base manager to detach any or all of the users who are attached to outputs. By examining the MEDRMD display, the manager can see which users have failed to detach from outputs after completing their work on Media, and then run ATTACH to forcibly detach such users so that the outputs are free for others to use.

7.2.4 The UNHANG task

If the data-base manager sees by examining the MEDRMD display that MEDCOM is secured by a task which has exited without releasing it (the symptom for this is that the "Task currently securing MEDCOM" field in the display does not change, he can "unhang" the data-base by running the UNHANG task.

UNHANG first checks the protection UIC of the invoking user to ensure that he is indeed the data-base manager, and then releases MEDCOM by calling FREEMEDCOM (see appendix G) and exits.

CHAPTER 8

SYSTEM DIAGNOSTICS

Diagnostics have been written to test the operation of various parts of the system:

1. The micro-Media data link protocol

2. The Media input and output hardware.

3. The software interfacing between Media and the data-base (i.e. MEDLNK)

4. The data-base MEDCOM.

5. The user interface library MEDUSER.

8.1 A diagnostic for the Media data-link protocol.

This task is called MEDFRAME and may be used to generate Media data-link protocol frames, send them down the serial link to

Media, receive the reply frame from Media and then display in octal on the operator's screen each byte of both frames. This enables the operator to determine whether the frame format of the responses from Media is correct.

MEDFRAME gives the operator a menu allowing him to generate frames corresponding to any of the following commands to Media:

1. Single Media or list read.

   MEDFRAME prompts the operator for which Media or list address is to be read.

2. Block Media or list read.

   MEDFRAME prompts the operator for the starting address and length of a contiguous block of Media or list items to be read.

3. Read digital change words.

4. Read Media status word (the Media status word is described in appendix D)

5. Write to Media or list address.

   This implements the first stage of a two-stage write. MEDFRAME prompts the operator for the data to be written and the Media or list address to which it must be written.

6. Go.

   This implements the second, or confirmatory, stage of a two-stage write.

7. Synchronise.

This causes a single byte with bit 6 set to be output to Media. It is included because the protocol cannot distinguish between the first and last byte in a frame because both are indicated by having bit 6 set. Should Media lose synchronism, this operation will restore it.

8.2 Diagnostics to test the Media input/output hardware.

8.2.1 The simulation package.

It will be explained in chapter 9 how the simulation package could be used as a diagnostic for the Media hardware, by simulating a SISO system in software and then controlling it via two pairs of Media analogue inputs and outputs.

8.2.2 The diagnostic MEDTEST.

MEDTEST can be used to test or exercise either the analogue or digital Media inputs and outputs. The description below presupposes familiarity with the Media front panel described in appendix A.

Two categories of digital tests can be performed:

1. Monitor switches.

   This provides a quick visual indication of whether the

digital inputs and outputs are functioning correctly. The operator chooses digital inputs 1-16 or 17-32 and wires these to the correspondingly numbered switches on the Media front panel. MEDTEST continually reads the digital inputs and writes the same data to the digital output lines, which are displayed on the LEDs on the panel. Altering the state of any of the switches will alter the state of the corresponding LEDs. The test is terminated by typing control-C at the keyboard.

2. Cyclic test.

The operator connects digital output lines 1-16 to the digital input lines, in one of the following formats:

1. Output lines 1-16 to input lines 1-16 (respectively).

2. Output lines 1-16 to input lines 17-32 (respectively).

3. Output line 1 to input lines 1 and 17, output line 2 to input lines 2 and 18, etc.

MEDTEST generates a series of constantly changing bit patterns in a 16-bit word. For each change, MEDTEST writes the 16 bits out to the digital outputs and then reads in the state of the digital input lines which the operator connected to the outputs. If the values read fail to match those written, a message to the operator's screen informs him of the error, giving the data value written and the incorrect value read back. After every sixteen write-read pairs, a '+' character is sent to the operator's screen. Typing control-C terminates the test.

For the analogue test, MEDTEST prompts for the numbers of four analogue inputs that it will associate with analogue outputs 1 to 4. In a continual loop, MEDTEST reads from these four analogue inputs and writes the data (scaled down from the 10-bit value read to an 8-bit value) to the analogue outputs. The four outputs thus will follow the voltages applied to the corresponding four analogue inputs. If this is not the case with one of the input-output pairs, then this pair is faulty. Typing control-C terminates the test.

8.3 A diagnostic for the Media-MEDCOM interface routines

The task MEDLNKTST provides a test for the routines in MEDLNK which interface between the serial link and MEDCOM.

MEDLNKTST is similar to the Media protocol diagnostic MEDFRAME, but works at a higher level. It uses the subroutines in MEDLNK to communicate with Media, and can be used to test any of the routines in MEDLNK (i.e. SINGLIN, BLOCKIN, WRITE, GETMED and GETDCW).

MEDLNKTST gives the operator a menu allowing the following choices:

1. Single Media or list read.

   The operator specifies the Media or list address of the item to be read. SINGLIN is then called to perform the read. The data read, and the error status returned by the call, is displayed.

2. Block Media or list read.

The operator specifies the starting address and number of items for a contiguous block of Media or list items to be read. BLOCKIN is then called to perform the read. The data read, and the error status returned by the call, is displayed.

3. Read digital change words.

The digital change words are read from Media by a call to GETDCW and displayed on the screen together with the error status returned by the call.

4. Read Media status word.

The Media status word (see appendix E) is read by calling GETMED and displayed on the screen together with the error status returned by the call.

5. Write to Media or list address.

The operator specifies the data and the Media or list address to which the data is to be written. A call to WRITE performs the write. The error status returned by the call is displayed.

8.4 Diagnostics for MEDCOM.

The task MEDRMD described earlier can also be used as a diagnostic for MEDCOM since it gives a running display of activity on MEDCOM.

8.5 Diagnostics for the user interface library.

8.5.1 The MEDUSER-testing task MUTEST

This task, called MUTEST, enables the testing of all of the subroutines in the MEDUSER library.

The operator is prompted with a menu consisting of the names of the routines in the library. After choosing one of these he is prompted for the values of each of the parameters that must be passed to the routine, e.g. channel number, data, etc. The appropriate MEDUSER routine is then called and any data returned by the routine is displayed on the screen. If an error occurs then an appropriate message is printed.

This task could also be used to inspect and change the data in MEDCOM (and hence Media) in an interactive way. For example, if a device controlled by one of the digital outputs for some reason must be turned off in a hurry, the quickest and simplest way to do this would be to write zero to the appropriate output using MUTEST.

8.5.2 The procedure READMEDCARD.

READMEDCARD is a procedure which was included in the user interface library MEDUSER to allow an indivisible read of a MEDCARD record in MEDCOM. It was written to assist in the debugging of MEDUSER.

```
ENT PROC READMEDCARD ( INT ADSWITCH, IOSWITCH, CARDNUM,
                       REF MEDCARD CARD);
```

This procedure reads the MEDCARD record determined by ADSWITCH, IOSWITCH and CARDNUM from MEDCOM and puts it into CARD. CARDNUM must be in the correct range (1..2 for digital output, 1..4 for digital input, 1..8 for analogue output and 1..20 for analogue input).

CHAPTER 9

A GENERAL-PURPOSE ANALOG SIMULATION PACKAGE

9.1 INTRODUCTION

The analogue simulation package was written with the following applications in mind:

1. It would facilitate the writing of simulation tasks which could simulate real processes interfaced to Media. Student tasks to control these processes could then be developed and debugged using the simulation part of MEDCOM and the simulation task, and when ready used on the real system.

2. It can be used within the student or research tasks which control the processes. For example, any analogue controller (a simple example is a proportional-plus-integral controller) could be implemented using the simulation package.

3. It can be used to test the operation of the Media interface hardware, without having to connect a process to Media.

   Consider, for example, the case where a control task has been developed to control a given SISO process. Suppose that it writes it outputs its control signal to analogue output number 1 and reads the process output from analogue input number 1.

   A second task is written using the simulation package to simulate the SISO process itself, reading its input from analogue input number 2 (say) and writing its output to analogue output number 2.

   If output 1 is connected to input 2, output 2 connected to input 1 and the control and simulation tasks executed, then the control task should control the simulated process. Failure to control correctly would indicate that one of the Media outputs or inputs used is not functioning correctly.

4. It can also be used for any other real-time or off-line simulation of analogue systems, possibly totally unrelated to Media.

In addition, a library of plotting subroutines is provided simplifying the use of the Tektronix 4010 plotting terminal. The description of this is included here because the plotting interface is intended chiefly to be used in conjunction with the simulation software.

Analog simulation languages, such as SIMC, MIMIC, and CSMP, are special-purpose computer languages enabling the user to simulate on the digital computer any system that can be represented on an analog computer. The digital computer has the advantage of a far

greater range and accuracy of real number representation, thereby avoiding the necessity for the tiresome process of scaling the inputs to integrators and amplifiers. In addition, the digital computer can easily perform any non-linear operation that may be required, which is not readily achievable on the analog computer.

During somewhat frustrating attempts to use the analog simulation languages SIMC and MIMIC on the Varian and Univac 1100/86 respectively, it occurred to the author that there would be several advantages in using a general-purpose high-level language such as RTL/2 rather than one of the dedicated analog simulation languages. A digital computer is, after all, capable of easily and accurately performing any of the operations of an analog computer, with the possible exception of integration. The main advantage of such an approach would be that one would not be constrained by the (usually rather narrow) restrictions placed on the user by simulation languages. Instead, one would be able to do anything permissible within the general-purpose language used, such as file manipulation or (in this application) calling the Media access routines in the module MEDUSER.

The main difficulty in developing the present package was to find a way of performing an accurate running integration on a variable, knowing only the present value f and past values $f_n, f_{n-1}, f_{n-2}, \ldots$ of the input variable f(t), and the past values $y_n, y_{n-1}, y_{n-2}, \ldots$ of the output variable y(t). Examples satisfying this requirement are the trapezoidal rule

$$y_{n+1} \equiv y_n + \int_{t_{n-1}}^{t_n} f\,dt = y_n + \tfrac{1}{2}\left(f_{n+1} + f_n\right)\Delta t$$

and the Simpson formula

$$y_{n+1} = y_n + \tfrac{1}{6}\left(f_{n+1} + 4f_n + f_{n-1}\right)\Delta t$$

where $\Delta t = t_{n+1} - t_n$.

However, these methods are not nearly as accurate as another

method, called the fourth-order Adams' method [19]:

$$y_{n+1} = y_n + \frac{1}{24}\left(9f_{n+1} + 19f_n - 5f_{n-1} + f_{n-2}\right)\Delta t$$

The advantage of this method is that the error is of the order of the time-step to the fifth power, being equal to

$$-\frac{19}{720}(\Delta t)^5 f^{(IV)}(\xi) \quad , \text{where } \xi \in (t_n, t_{n+1})$$

which is very small indeed.

The package implements an initialisation section, a main loop (each time round representing an increment of time DT) and a finishing-off or "tidying-up" section. The package can implement either real-time or offline simulation.

The functioning of the package is summarised in figure 9-1. The main procedure (RRJOB) is situated inside the package and is not written by the user. The user must supply the three routines SIMINIT(), SIMJOB() and SIMTIDYUP() shown in the figure. These are described in the next section.

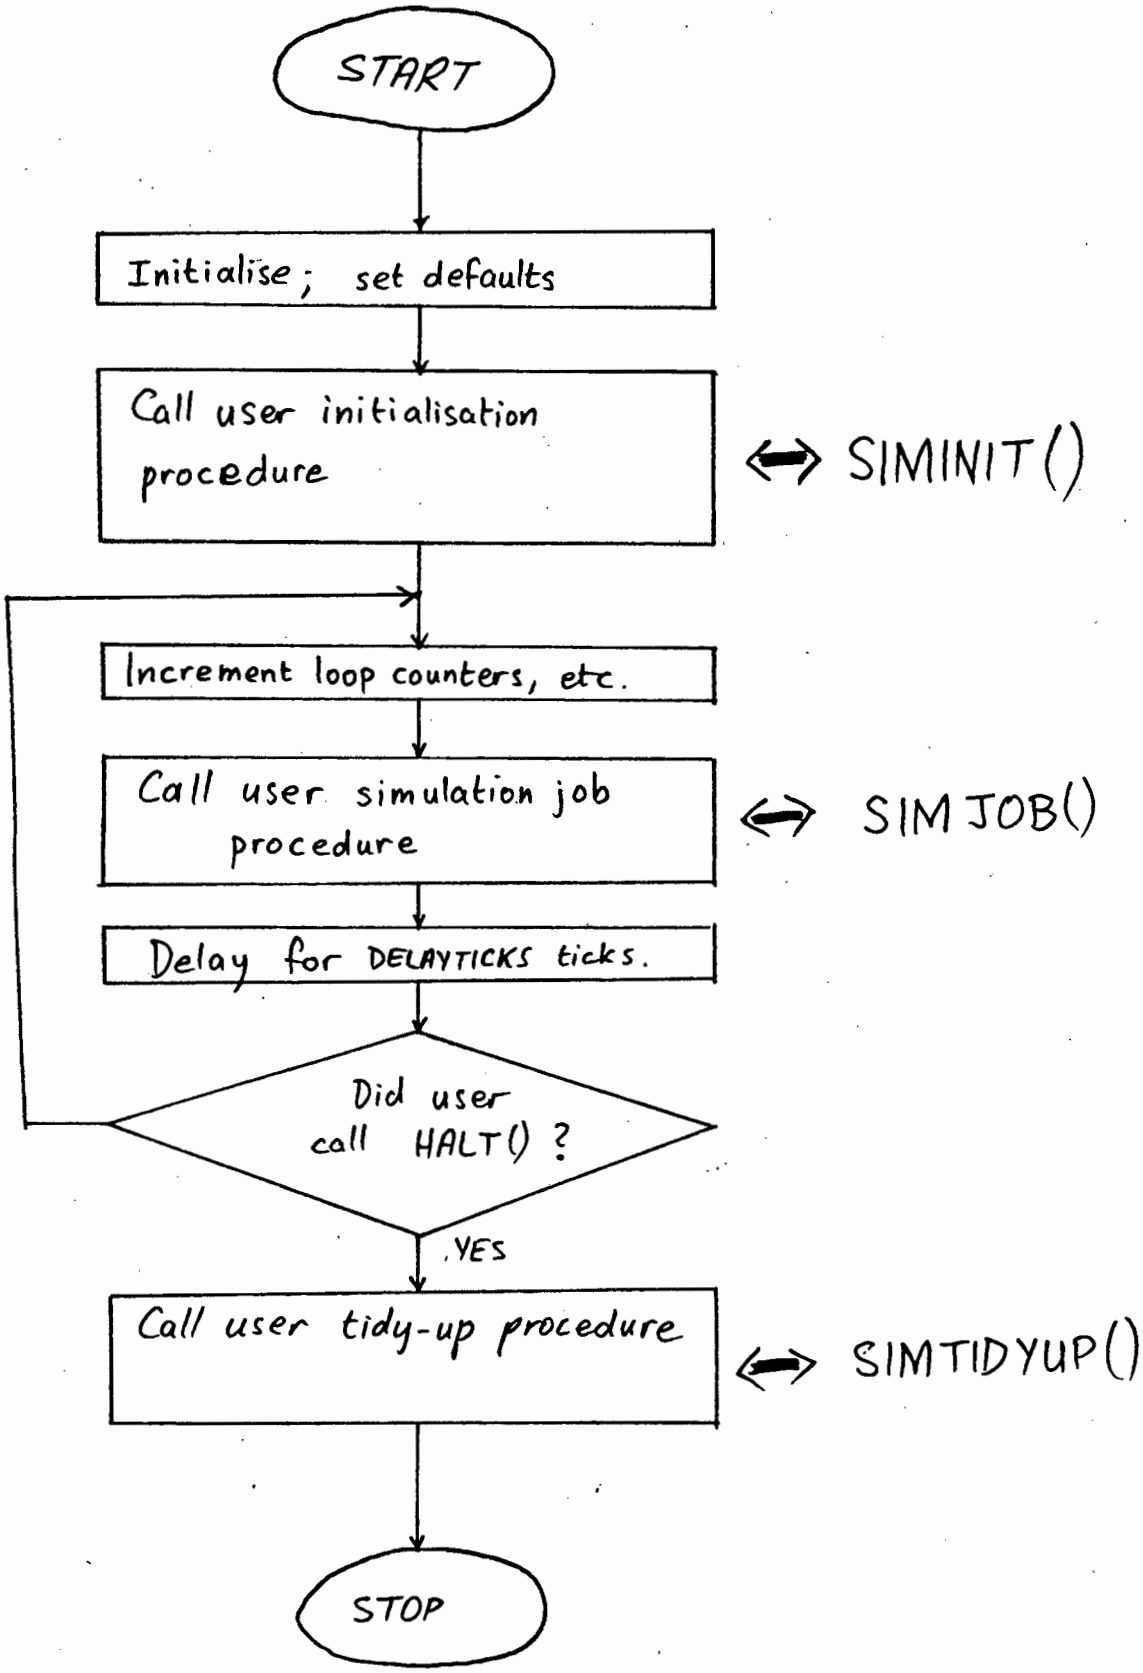

Figure 9-1 : Operation of the simulation package.

9.2 Using the simulation package

The user is required to do little more than draw the system block diagram and write down the system equations from this.

Three RTL/2 subroutines must be provided by the user:

a) ENT PROC SIMINIT()

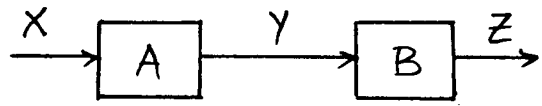
This procedure is called before the main loop and consists of any initialisation or change of default options (the defaults are real-time rather than off-line control, a delay of one second each time round the main control loop, and no AST processing). that the user may desire.

This routine may, for example, be used to read in the system constants of the analogue block diagram being simulated (such as time constants or gains, etc.) For this purpose, standard RTL/2 stream terminal I/O is initialised by the package before SIMINIT() is called.

Any other initialisation of any nature that must be performed before simulation is started (e.g. opening files) must be done in SIMINIT.

b) ENT PROC SIMJOB()

This procedure is called each time round the main loop and must contain the equations of the block diagram. The user must, however, be careful to get the equations in the right order. For example, if one were to simulate the following system



one could write

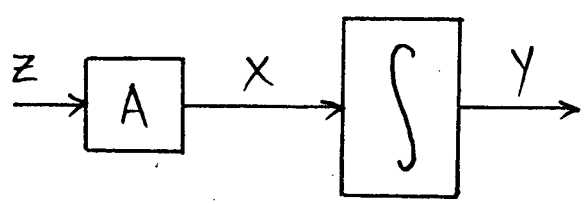
```
Y := X*A;
Z := Y*B;
```
(1)

or

```
Z := Y*B;
Y := X*A;
```
(2)

Obviously (1) is better than (2) because in (2) Z is calculated using the value of Y left over from the previous time round the loop, whereas in (1) the value of Y is first updated, then used.

All variables should be of type REAL except for inputs to integrators, which should be ARRAY(4) REAL for reasons given in the description of the INTEGRATE subroutine below. Elements 2 to 4 of this array can be ignored by the user because they are only used by the integration routine. The user should regard element 1 of the array as the actual variable. For example:



Here X is an ARRAY(4) REAL, Y is REAL and Z is REAL. The user writes

```
X(1) := A*Z;
INTEGRATE(X,Y,INITIALCOND);
```

The user can, of course, write to the screen or disc any information he chooses.

c) ENT PROC SIMTIDYUP()

This procedure is called after the main loop, and could be used to do any tidying-up needed, e.g. sending to the Tektronix screen information stored during the main loop, or closing files, etc.

The user has access to the following data brick used by the package:

```
ENT DATA SIMDATA;
  INT N,
      DELAYTICKS;
  REAL DT;
  ARRAY(4) REAL TIME;
ENDDATA;
```

These items are:

a) N:

The number of times round the main loop so far.

b) DELAYTICKS:

If simulation is real-time, this is the number of ticks (fiftieths of a second) of delay that will occur after each time round the loop. If some value other than the default value of 50 is required, this should be set up in SIMINIT(). If simulation is offline, DELAYTICKS is set to zero by the call to OFFLINE() (see below).

c) DT:

The time-step. For offline simulation, DT must be set up by the user in SIMINIT(). If simulation is real-time, DT is determined by the package as a running average over the past four sampling times - this is optimal for the integration method used. DT will then be equal to the execution time of

SIMJOB() plus DELAYTICKS ticks.

d) TIME:

If simulation is real-time, then this array will contain the actual real time (in seconds past midnight) of the present and past sampling instants.

The user can call the following procedures in the package:

a) ENT PROC() HALT

This procedure halts the simulation when called from SIMJOB(). The main loop is terminated on return from SIMJOB() and simulation falls through to SIMTIDYUP();

b) ENT PROC() OFFLINE

The package defaults to real-time simulation. If offline simulation is wanted, then OFFLINE() should be called from within SIMINIT(), in which case DT must also be set up by the user. A call to OFFLINE() sets DELAYTICKS to zero.

c) ENT PROC () NOAST

The package defaults to a mode whereby during the main loop processing may be interrupted at any time by typing control-C, causing an AST (Asynchronous System Trap) and the appearance on the screen of a menu of choices, e.g. whether to continue, restart, or abort. If this feature is not required, NOAST() should be called from within SIMINIT().

d) ENT PROC INTEGRATE (REF ARRAY REAL XDOT, REF REAL X,
REAL X0)

This procedure is the heart of the package and performs the integration. The input variable XDOT must be an array of

four reals. This is because the integration algorithm must be able to access past values of the input variable XDOT. For each integrator used, an array of four reals to represent the input variable must be declared by the user.

These past values of the input variable are stored as a stack consisting of XDOT(2), XDOT(3), and XDOT(4). This stack is maintained by the subroutine and the user need only consider XDOT(1) as the input variable. Each time INTEGRATE is called it updates the past values in this stack by "bumping" them down by one:

```
XDOT(4) := XDOT(3); % update oldest past value.,   %
XDOT(3) := XDOT(2);
XDOT(2) := XDOT(1); % update newest past value     %
                    % with present value of XDOT. %
```

The output variable X must be a real variable and NOT an expression.

X0 is the "initial condition" value for the integrator. Although it is only needed on the first call to the subroutine, it is passed every time. This approach, which leads to a user program layout similar to that used in most simulation languages, avoids the need to write another routine whose sole function is to initialise integrators.

9.3 Linking to the package

The user module containing the three user-written routines is linked to the package by setting up a taskbuild command file (say SIMTKB.CMD) containing the following:

```
USERMODULENAME=USERMODULENAME
SIMBGS,SCREEN,AST
@COMINTFCE
/
STACK=300
ASG=TI:1:2
LIBR=RTLLIB:RW
COMMON=MEDCOM:RW
//
```

The user then types TKB @SIMTKB and runs the resultant task.

9.4 PLOTTING LIBRARY FOR THE TEKTRONIX 4010 TERMINAL

The module PLOTLIB contains subroutines simplifying the use of the Tektronix 4010-1 plotting terminal for graphics output. This library is not intended to be a complete graphics interface, but merely provides sufficiently many software building blocks to enable users to easily build up their own routines such as graph-plotting routines. This allows users to plot graphs of the parameters of the processes that they are controlling - for example the value of one of the analogue inputs against time. Hard copies of the graphs plotted may be obtained using the hard-copy unit attached to the plotting terminal.

The Tektronix terminal was previously used with the Electrical Engineering department's Varian minicomputer, and was connected

via a current-loop serial line. The line-driver hardware of the terminal was converted to produce RS-232/C levels at 9600 baud so that it could be plugged into a serial port of the PDP-11/23.

The Tektronix screen has a resolution of 1024 points (horizontal) by 781 points (vertical). All graphics is done by means of escape-sequences as described in [20].

PLOTLIB contains the following ENT data brick:

```
ENT DATA PLOTDATA;
    REAL XOFFSET, XFACTOR, YOFFSET, YFACTOR;
    REAL XMIN := -1.0, XMAX := 1.0,
         YMIN := -1.0, YMAX := 1.0;
    ARRAY (20) BYTE REPLYBUF;
ENDDATA;
```

where

1. XMIN, XMAX, YMIN and YMAX are the X and Y values of the edges of the screen in the units used by the user.

2. XFACTOR and YFACTOR are scaling factors to convert real numbers in the ranges XMIN to XMAX and YMIN to YMAX respectively to integers in the ranges 0 to 1024 and 0 to 781 respectively.

3. XOFFSET and YOFFSET are offsets used in the above conversion.

The following ENT procedures may be used :

1. ENT PROC SCALE (REAL XMN, XMX, YMN, YMX);

   This procedure defines the limits of the screen as

called. Both axes will then range from -1.0 to 1.0.

3. ENT PROC GRAPHMODE ();

The terminal is put into graphics mode, so that it will be ready for graphics commands like MOVE and DRAW.

4. ENT PROC ALPHAMODE ();

The terminal is put into alphanumeric mode, so that it is ready to output or input alphanumeric characters.

5. ENT PROC DRAW (REAL XPOS, YPOS);

If the terminal is in graphics mode, a line is drawn from the current position on the screen to the point at (XPOS, YPOS). If the point is off the edge of the screen, ERP is called and the offending coordinate is truncated to the appropriate limit (XMAX, XMIN, YMAX or YMIN).

6. ENT PROC MOVE (REAL XPOS, YPOS);

If the terminal is in graphics mode, the current screen position moves to (XPOS, YPOS) but no line is drawn. Points off the edge of the screen are treated as in DRAW.

7. ENT PROC CLEARSCREEN ();

The entire screen is cleared of all alphanumerics and graphics. A delay of one second is executed to wait for the terminal to complete the screen-clearing process.

8. ENT PROC CROSSHAIRS ();

In graphics mode, this procedure causes a pair of crosshairs to appear on the screen. The position of the crosshairs is adjusted using the two potentiometers

alongside the keyboard.

9. ENT PROC GETCROSSHAIRS (REF REAL XPOS,YPOS);

   The current position on the screen of the intersection point of the crosshairs is written into XPOS and YPOS.

An example of the use of these routines is the program STAR.TSK which plots a pattern of lines on the screen. The task expects the Tektronix to be connected to TT12:.

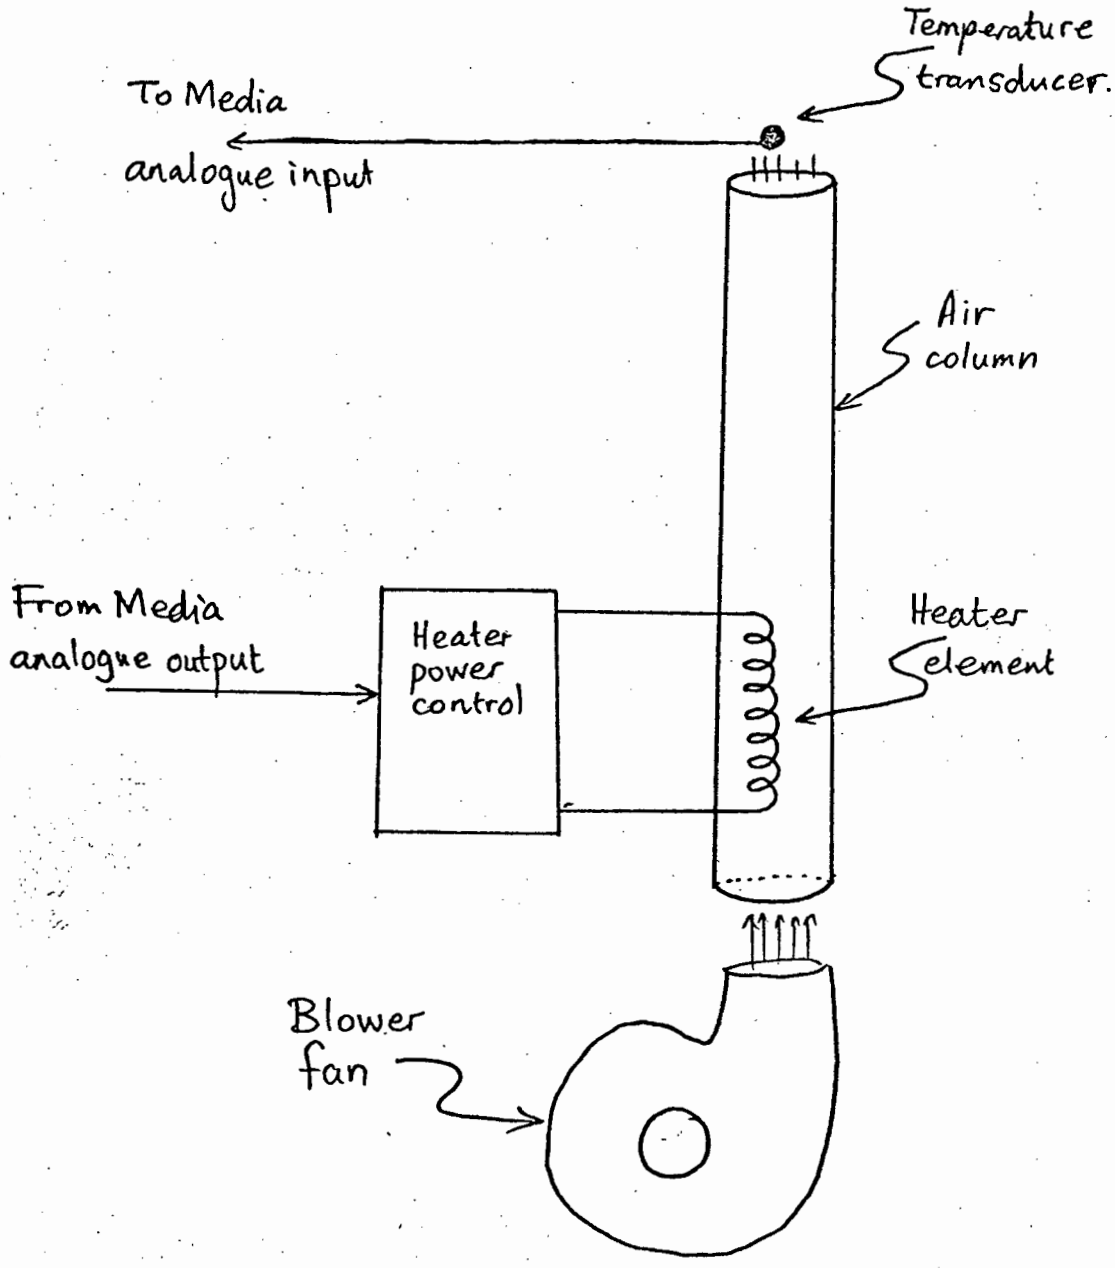
CHAPTER 10

CONCLUSION

A fitting conclusion to this thesis is to give an example of how the system has been used in practice. To this end, a description is given of the real-time project given to Electrical Engineering final-year students at UCT during the second trimester of 1983; this project having involved extensive use of all aspects of the Media system and the associated software.

The class consisted of about 40 students and the project was done in groups of two students each. The project instruction sheet is included as appendix K.

The apparatus used , developed in the Chemical Engineering department, is an 18-inch vertical thermally insulated column of air as illustrated below. The blower fan shown blows air up the column at a constant rate, and the temperature of the air emerging from the top of the column is measured by the thermistor whose output signal is connected to one of the Media analogue inputs. A heater element inside the column heats the air as it travels up the column. The heater can supply 0 to 1000 watts of power. The circuitry controlling the heater is connected to one of the Media analogue outputs.



This apparatus was used because it had the advantage that it was already built, operational and easily connected to Media with minimal further hardware construction. The disadvantage of the apparatus is that changes caused by the students' control tasks are not visually apparent - a system to control the level of water in a tank, for example, would have been far better in this respect.

The students' project involved the development of software to control the temperature of the air emerging from the column, using a simple proportional- plus-integral control algorithm. This

software had to be divided into three concurrently executing tasks:

1. The Operator Control Panel (OCP) task.

   This task allows the operator at any time to change the setpoint temperature or display on the screen information about the column (time, setpoint, temperature and power output).

2. The control task.

   This task performs the actual control. It reads in from the analogue input the value representing the temperature of the air and then converts it to temperature in degrees Centigrade using a calibration function to compensate for the non-linearity of the thermistor. The difference between this actual temperature and the desired (setpoint) temperature as set up by the OCP task is computed. This temperature error value is fed into the proportional-plus-integral control algorithm which calculates the amount of power which the heater must generate. The power is then written to the analogue output.

3. The logging task.

   This task logs all relevant information about the column (time, setpoint, temperature and power) to a disc file at regular intervals. This file may be examined later or printed out.

Inter-task communication is done using the WRCOMMINT and RDCOMMINT procedures from the user interface MEDUSER - for example, one of the bits in the common integer may represent an instruction from the OCP task to stop logging.

10.1 Simulation.

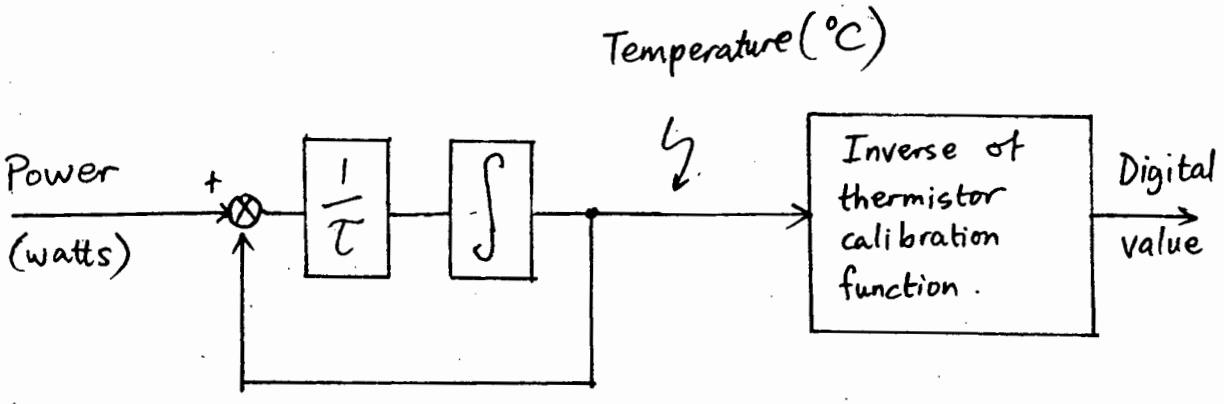
The existence of only one set of apparatus meant that only one student could use the real system at a time. Therefore, simulation software was written which uses the simulation package to simulate the operation of four other sets of apparatus (four sets because there are four simulation analogue outputs in the data-base). Thus, the system could be used by up to five students simultaneously.

The algorithm simulating the column operation is a simple first-order one:

$$\frac{\text{Temp out}}{\text{Power in}} = H(s) = \frac{A}{1+s\tau}$$

where it was assumed that the time constant τ may be different during heating and cooling of the column. The values of A, $\tau_{heating}$ and $\tau_{cooling}$ were determined empirically by taking readings of temperature against time for known values of heater power.

Thus the simulation of the column could be done using the following analogue block diagram:



The simulation task reads the power written by the user to the simulation analogue output and uses it as input to the simulation block above. The temperature, before being written to the simulation analogue input for the user program to read, must first be converted to the same digital value that would be produced by the thermistor in the real system. This is done using a look-up table to representing the inverse of the thermistor's calibration function.

The simulation of all four columns is done in parallel, and data is read from and written to the simulation portion of MEDCOM every second.

10.2 Results

The use of the computer by up to five students simultaneously for program editing, compilation and running, together with the simultaneous execution of the Media update task and the simulation task caused the computer to be very heavily loaded at times,

slowing it down considerably. This proved to be the major problem encountered. The only apparent solution to this is to reduce the number of students or to obtain a faster computer, the latter solution being a more practicable one.

No problems were experienced with the securing and releasing mechanism for MEDCOM because all students used the special Media abort task ABM to abort their tasks. As a result, it was never necessary to "unhang" MEDCOM using the data-base manager task UNHANG.

However, the students were less well disciplined regarding detaching from outputs after use. It was occasionally necessary to free outputs by detaching users who had left without detaching. In this regard, MEDRMD proved itself to be an invaluable management tool.

This student project involved heavy use of all software and hardware components of the system over a period of some seven weeks. During this time, the system was also being used for a final-year research project by a chemical engineering student, and it is therefore felt that the fact that the system ran successfully during the entire period of the projects demonstrates the viability and practicality of the multi-user process interface developed in this thesis.

APPENDIX A

MEDIA FRONT PANEL

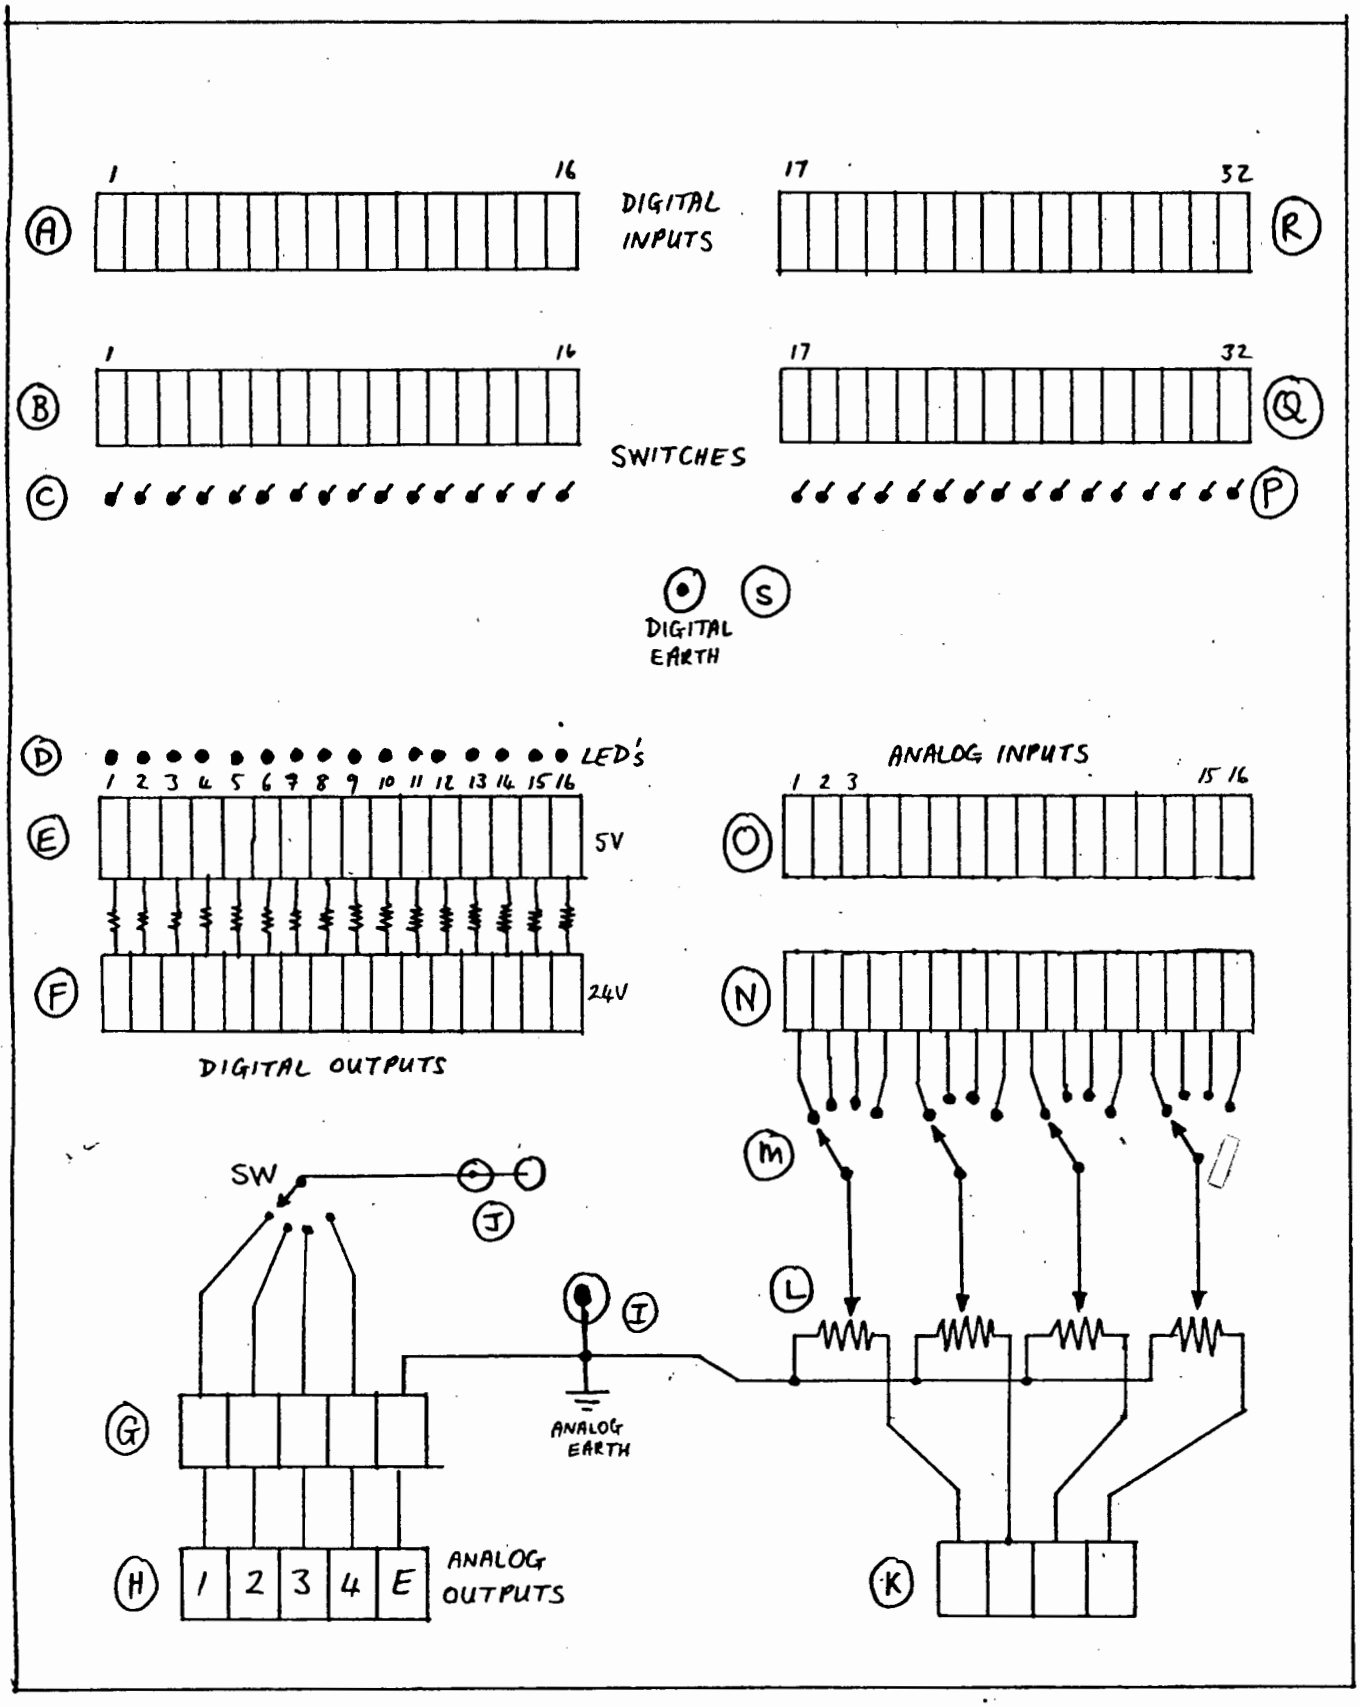

Figure A-1 : Media Front Panel.

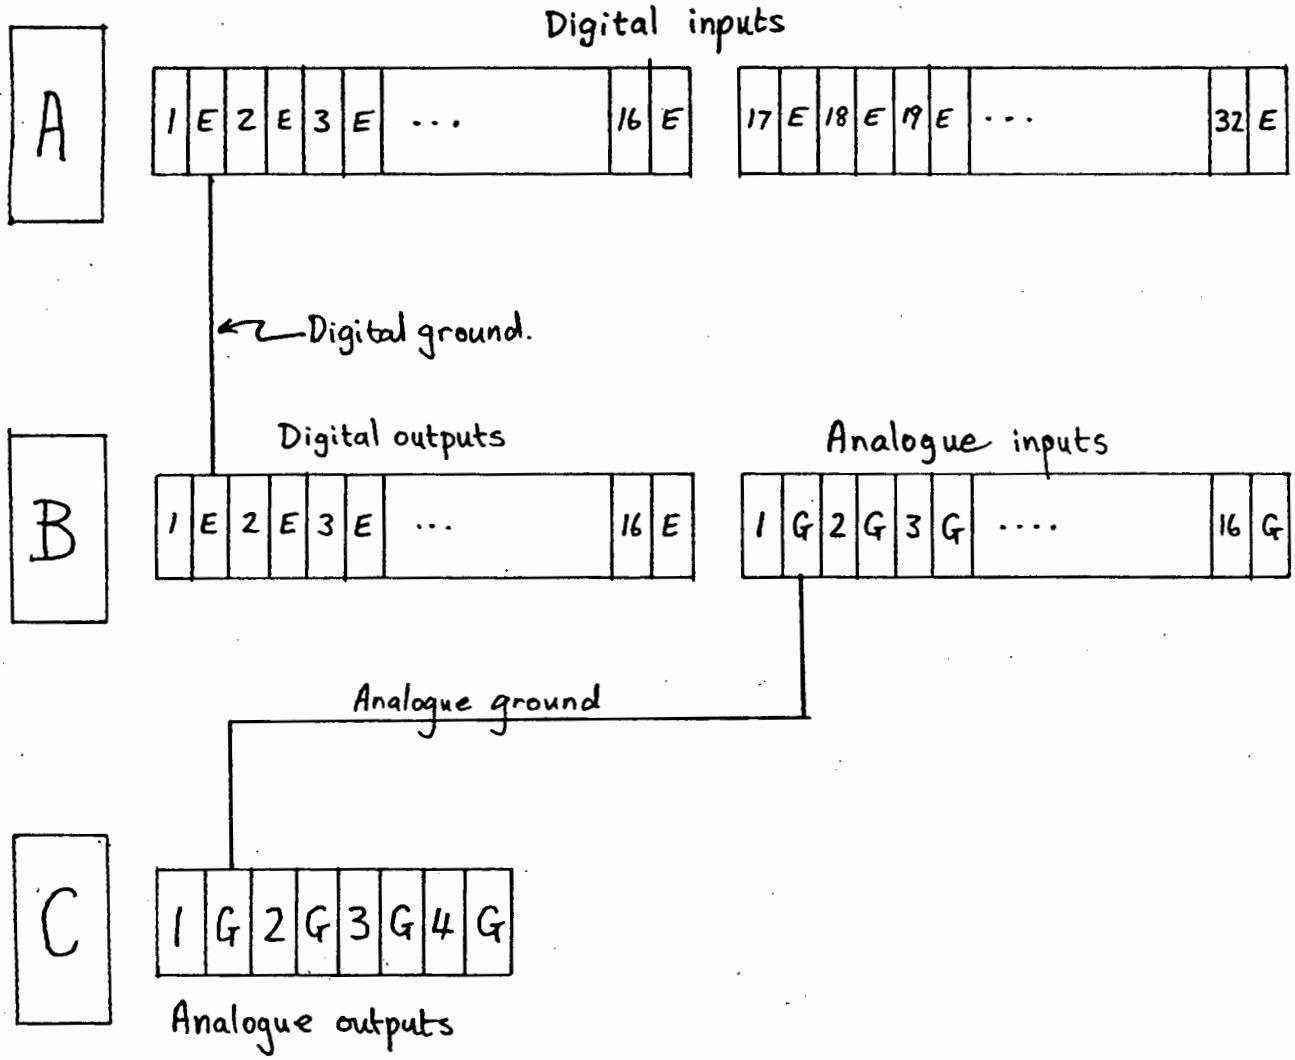

Figure A-2 : Media connection rails

The layout for the front panel of the Media system is shown in Figure A-1. This panel was designed in the Electrical Engineering digital laboratory and brings the analogue and digital output and input lines from the connection rails at the back of the Media housing (see figure A-2) to more easily-used connection blocks at the front of the housing. The Media lines are also level-shifted where this was felt desirable.

NOTE

Because of the way the Media cards have been designed, the analogue and digital Media cards use different earth reference levels. In fact,

Digital ground = Analogue ground - 15 volts.

Care must therefore be taken to ensure that one is referencing signals to the correct ground.

A.1 Digital Outputs

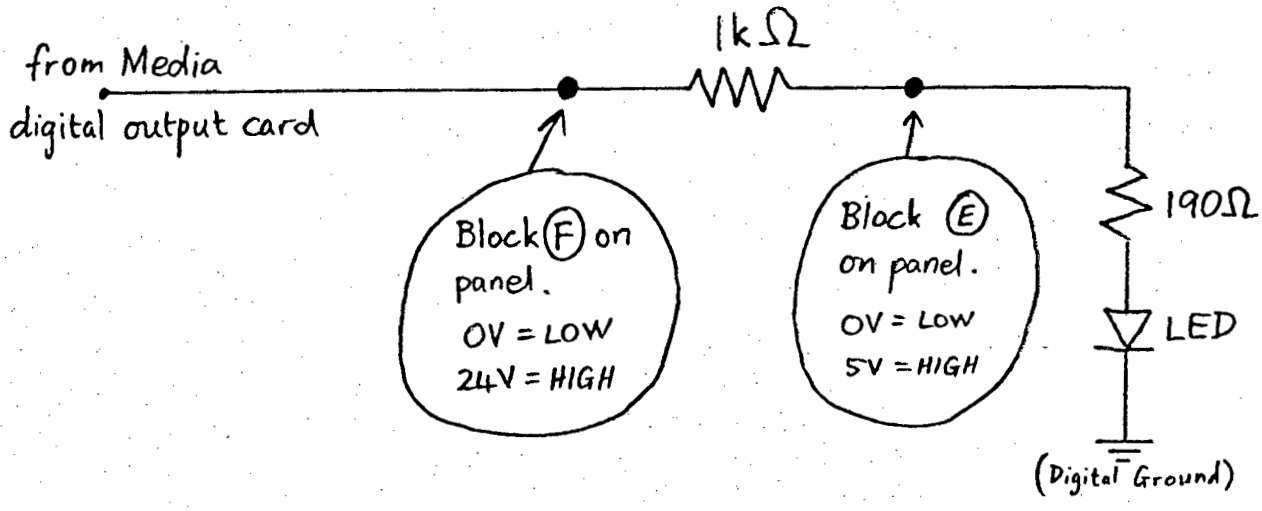

Figure A-3.

Each of the sixteen digital output lines is wired as in figure A-3. Thus all digital outputs are always displayed on the LEDs at (D) on the panel, and two levels are available - one at 24V and one TTL-compatible.

A.2 Digital Inputs

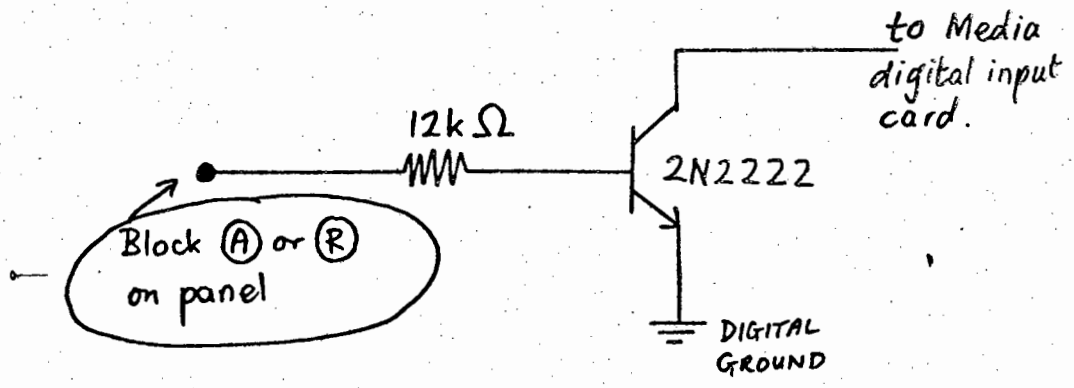

Figure A-4.

Blocks (A) and (R) on the panel are connection blocks enabling TTL-level signals to drive the digital inputs. In fact, any level

from about 3 volts to 24 volts will drive the inputs. The wiring of the inputs is shown in figure A-4. This circuitry was necessary because the inputs on the Media cards are intended to be operated by switches, not voltages.

Note that the circuit above is an inverting circuit : the inversion thus caused is undone in the software (procedure RDDIGINP in MEDUPDAT).

A.3 Switches

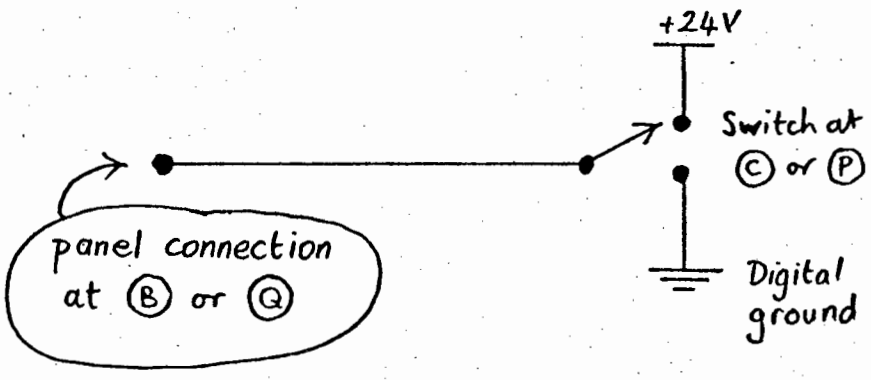

Figure A-5.

32 switches, wired as in figure A-5, are provided. These can be connected directly to the 32 digital inputs, as sense switches or for testing purposes. Switch up corresponds to logical 1 (or +24 volts) and switch down corresponds to logical 0 (or 0 volts).

A.4 Analogue Outputs

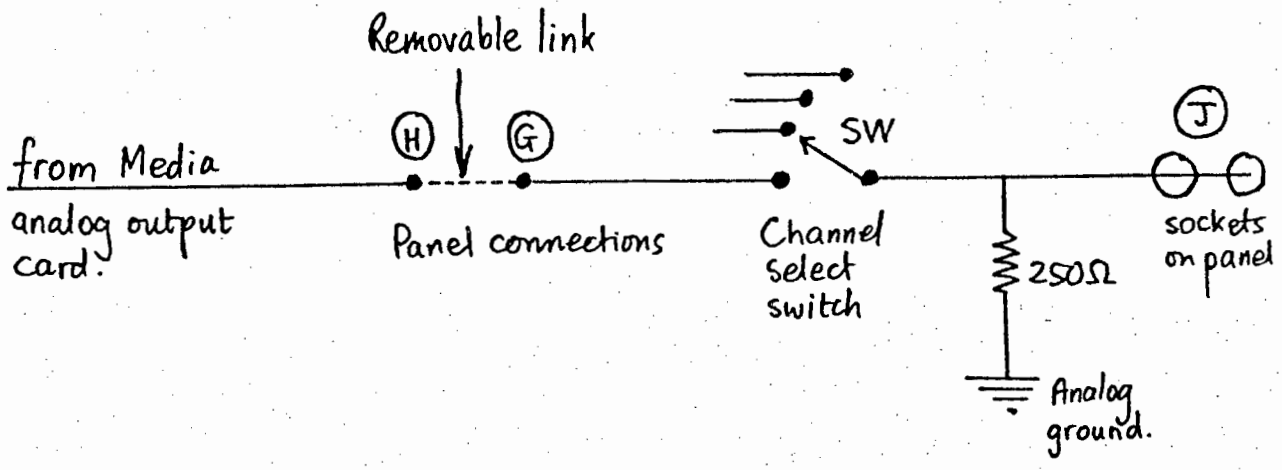

Figure A-6.

Each of the four analogue outputs is brought to a connection on block (H) on the panel. In addition, analogue earth is the rightmost connection on block (H).

-4 mA to -20 mA outputs are available from block (G) if the wire links between blocks (G) and (H) in the appropriate places are removed. Otherwise, the 4-way switch can be used to select one of the analogue outputs, which is then available as a -1 to -5 volt output at (J). The current-to-voltage conversion is done by a 250 ohm resistor, as shown in figure A-6.

A.5 Analogue Inputs

The 16 analogue input lines to the multiplexer card are connected to block (G) of the panel. -1V corresponds to an ADC output of zero, and -5V to an ADC output of HEX 3FF.

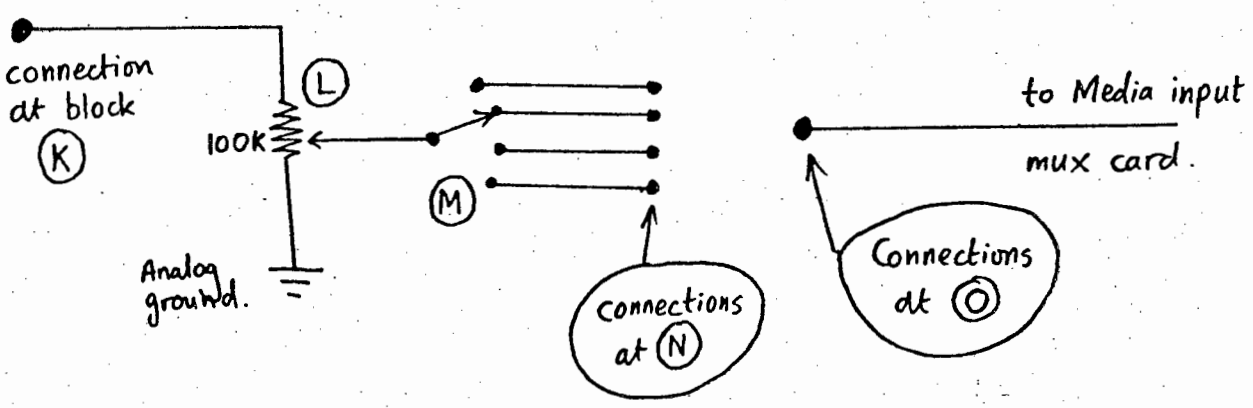

Figure A-7.

In addition, analogue signals can be connected to block (K), pass via attenuators (L) and switches (M) to block (N), and hence to block (O) via wire links. This is shown in figure A-7.

A.6 Connections to the Media connection blocks

The connections to the connection blocks at the back of Media are shown in figure A-2. The input/output lines from the Media cards are brought directly to the terminal points shown.

Digital ground is obtained by connecting the earth lines (from the Media cards) of the digital inputs and outputs together. Analogue ground is produced similarly.

APPENDIX B

ADDRESSING THE MEDIA CARDS

This section describes how the systems programmer interacts with the Media cards using the LSI-11.

B.1 Converting between Media and LSI-11 addresses.

A Media address is a ten-bit address of a card on the Media highway. When the PDP-11 to Media interface cards are present in the minibin, successive Media addresses are available to the LSI-11 as successive memory-mapped words in the I/O space of the LSI, starting from address octal 764000.

The formula for converting Media addresses to LSI-11 addresses is

LSI address = 764000 + (2 * Media address)

and to convert LSI addresses to Media addresses,

Media address = (LSI address - 764000) / 2.

B.2 Addresses of the Media cards

Media Card	Media address	LSI address
16-way dig. inp. card 1	Ø	764ØØØ
16-way dig. inp. card 2	1	764ØØ2
16-way digital output card	4 (octal)	764Ø1Ø
16-way analogue mux card	1Ø	764Ø2Ø
A/D converter card	14	764Ø22
4-way D/A converter card	14	764Ø3Ø

Table B-2: Addresses of the Media cards

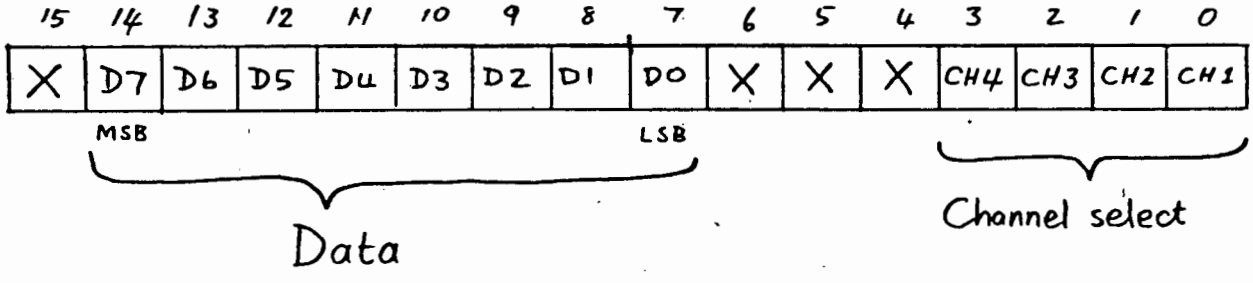
The Media and LSI addresses of the Media cards are given in Table B-1. In addition, the Media status word is available at LSI address 767776 (Media address 1777) and can be interpreted as :

000000 = last transaction successful
010000 = device missing error

B.3 Accessing the cards

B.3.1 The digital-to-analogue converter card

This card is a four-channel 8-bit digital-to-analogue converter. The word at Media address OCT 14 is organised as follows :

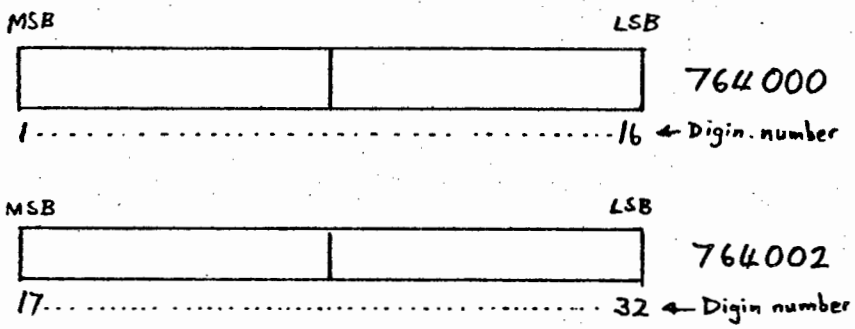


Any of the four channel-select bits can be used; so that the same data can be written to more than one output simultaneously if required. However, Micro-Media does not use this feature.

Each analogue output is a current signal in the range -4mA (for digital 0) to -20mA (for digital HEX FF).

B.3.2 The digital input cards

These are read as two consecutive words at Media addresses 0 and 1 for digital inputs 1-16 and 17-32 respectively.



Digital input number 1 the the most significant bit of the first word, and input number 32 is the least significant bit of the second word, as shown in the diagram.

The digital input cards require switch inputs, but have been wired to the front panel in such a way that either switches or TTL logic levels can be used.

B.3.3 The digital output card

These may be written to at LSI address 764010. Digital output 1 is the most significant bit and output 16 is the least significant bit.

The Media card provides 24V = logical 1 and 0V = logical 0. The outputs are also available on the front panel as TTL compatible levels.

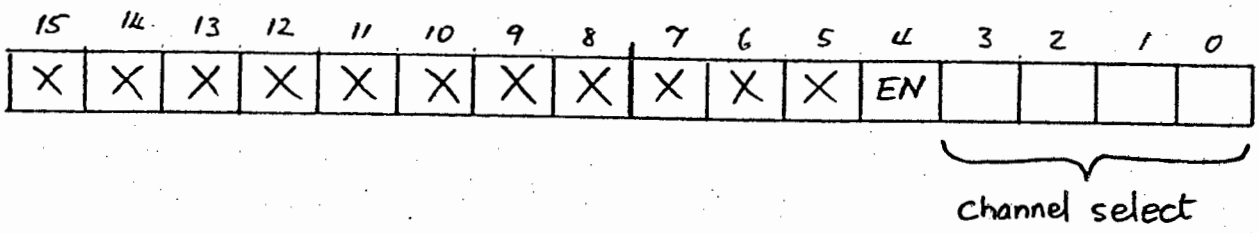
B.3.4 The analogue inputs

These 16 inputs are organised as a 16-channel multiplexer card at LSI address 764020 and an ADC card at address 764022.

To read an analogue input, the following procedure is followed :

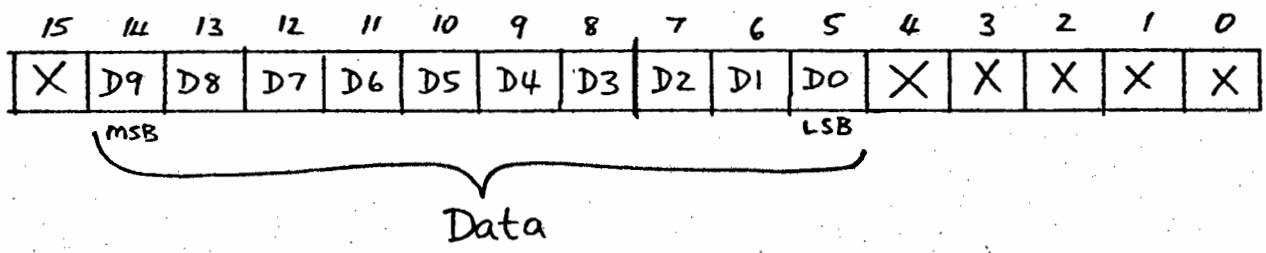
1. Select the required input by writing to the multiplexer.
2. Wait for the multiplexer to settle (this takes about 50 milliseconds).
3. Read the digital value from the ADC card.

B.3.4.1 The multiplexer card - The multiplexer card word at LSI address 764020 is organised thus:



To select analogue input n, a word must be written to the multiplexer with the enable bit (bit 4) set, and bits 0 to 3 must contain the number n-1. For example, to select channel 4, one must write OCT 000023 to the multiplexer.

B.3.4.2 The ADC card - The ADC card word at LSI address 764022 is organised as follows :



The data is read as the 10 bits from bit 5 to 14 (inclusive) of the word. -1V corresponds to digital zero, and -5V to digital HEX 7FE0.

APPENDIX C

DETAILED DESCRIPTION OF MEDIA LINK FRAME STRUCTURE

This appendix describes in detail the format of the Media data link frames introduced in chapter 2.

C.1 Symbols used

The descriptions below use the following symbols:

1. TA1 to TA4 are the 4-bit terminal address
2. P is the parity bit
3. A0 to A9 is the 10-bit Media address
4. D0 to D15 is the 16-bit data field
5. BCC is the block check character
6. X represents a don't-care bit

C.2 Single read (Codes 1,2,8)

The host-to-Media frame is as follows :

MSB LSB

P	1	TA3	TA2	CODE			
P	0	TA1	TA0	A3	A2	A1	A0
P	0	A9	A8	A7	A6	A5	A4
P	1	BCC					

The Media-to-host reply is as follows :

P	1	TA3	TA2	CODE			
P	0	TA1	TA0	STATUS			
P	0	D5	D4	D3	D2	D1	D0
P	0	X	D10	D9	D8	D7	D6
P	0	X	D15	D14	D13	D12	D11
P	1	BCC					

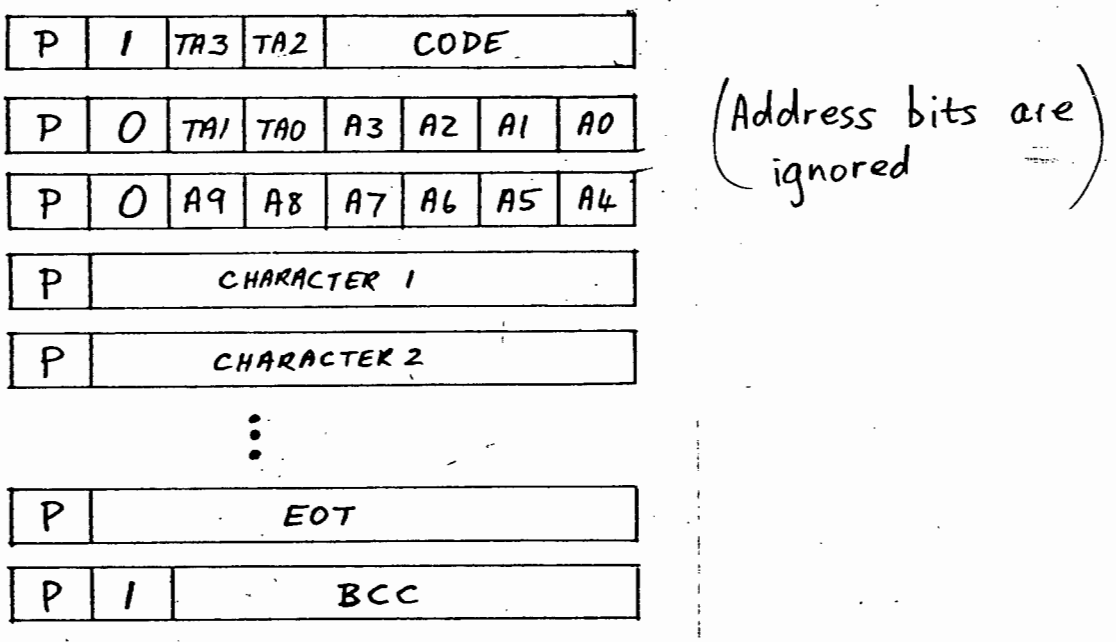
Thus the returned data is encoded into bytes 3 to 5 of the reply frame.

C.3 Printer output (Code 0)

This command causes the supplied text (CHAR1 to CHARn) to be printed at the terminal local to the Media. This is not implemented in the LSI-11 Media system as there is no local

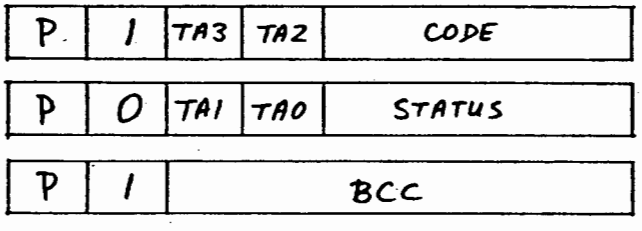
printer.

The host-to-Media frame is :



where EOT = control-D = binary 0000100.

The Media-to-host reply is :



C.4 Block read (Codes 3 and 4)

The Media or list address of the start address of the block is encoded into bytes 2 and 3 of the host-to-Media frame. The number of items required is put into byte 4. The frame is :

P	1	TA3	TA2	CODE			
P	0	TA1	TA0	A3	A2	A1	A0
P	0	A9	A8	A7	A6	A5	A4
P	0	NUMBER OF ITEMS TO READ					
P	1	BCC					

The Media-to-host reply is :

P	1	TA3	TA2	CODE			
P	0	TA1	TA0	STATUS			
P	0	D5	D4	D3	D2	D1	D0
P	0	X	D10	D9	D8	D7	D6
P	0	X	D15	D14	D13	D12	D11
P	0	D5	D4	D3	D2	D1	D0
P	0	X	D10	D9	D8	D7	D6
P	1	X	D15	D14	D13	D12	D11
P	1	BCC					

First word

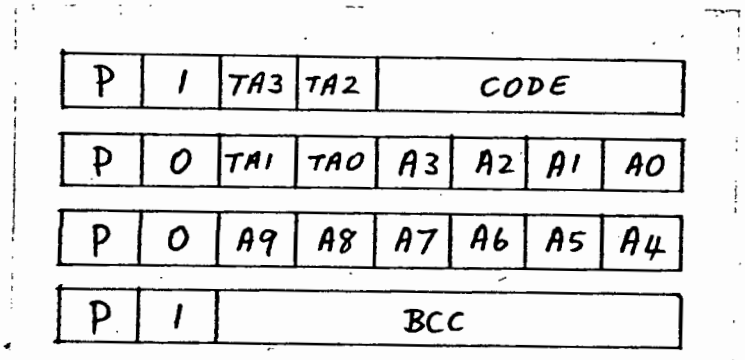
Second word

The k'th data item read is encoded into bytes 3k to 3k + 2 of the reply frame, as shown.

C.5 Keyboard input (Code 9)

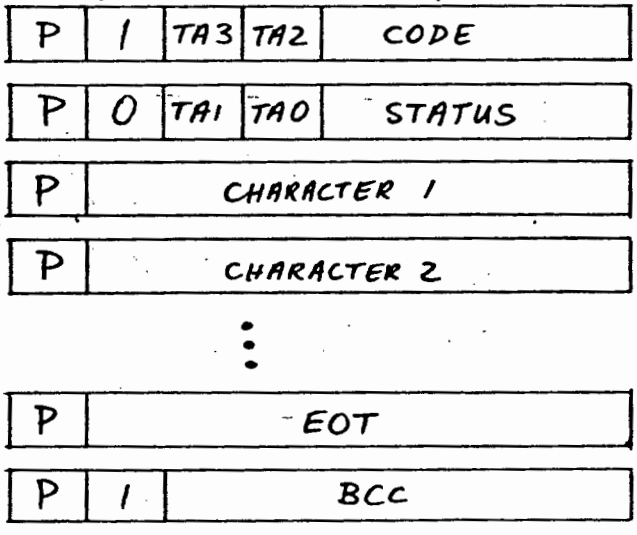
This is used for the host to read in the keyboard buffer of the terminal local to the Media. This is not implemented in the LSI-11 Media system.

The host-to-Media frame is :



(Address bits are ignored)

The Media-to-host reply is :



C.6 Single write (Codes C, D and E)

The write is implemented as a two-stage process. First the host issues a Media/list write frame (code C or D), as follows :

P	1	TA3	TA2	CODE			
P	0	TA1	TA0	A3	A2	A1	A0
P	0	A9	A8	A7	A6	A5	A4
P	0	D5	D4	D3	D2	D1	D0
P	0	X	D10	D9	D8	D7	D6
P	0	X	D15	D14	D13	D12	D11
P	1	BCC					

Media then does nothing except to echo this frame, in its entirety, back to the host for checking. If the host is satisfied with this reply, it sends a confirmatory 'Go' frame (code E), as follows :

P	1	TA3	TA2	CODE			
P	0	TA1	TA0	A3	A2	A1	A0
P	0	A9	A8	A7	A6	A5	A4
P	1	BCC					

←

The Media then performs the write and sends the following reply :

P	1	TA3	TA2	CODE
P	0	TA1	TA0	STATUS
P	1	BCC		

C.7 Read digital change words (Code 7)

The host-to-Media frame is :

P	1	TA3	TA2	CODE			
P	0	TA1	TA0	A3	A2	A1	A0
P	0	A9	A8	A7	A6	A5	A4
P	1	BCC					

where the address field is ignored by Media.

The Media-to-host reply is :

P	1	TA3	TA2	CODE				
P	0	TA1	TA0	STATUS				
P	0	D5	D4	D3	D2	D1	D0	First change word.
P	0	X	D10	D9	D8	D7	D6	
P	0	X	D15	D14	D13	D12	D11	
P	0	D5	D4	D3	D2	D1	D0	Second change word.
P	0	X	D10	D9	D8	D7	D6	
P	0	X	D15	D14	D13	D12	D11	
P	1	BCC						

C.8 Media frame lengths

Table C-1 shows the lengths of all the Media frames in bytes.

Code	Meaning	Length (bytes) Command	Reply
Ø	Printer output	variable	3
1	Read Media address	4	6
2	Read list address	4	6
3	Read block Media addresses	5	3(n+1)
4	Read block list addresses	5	3(n+1)
5	Spare	-	-
6	Spare	-	-
7	Read digital change words	4	9
8	Read printer status word	4	6
9	Read keyboard input	4	variable
A	Spare	-	-
B	Spare	-	-
C	Write to Media address	7	7
D	Write to list address	7	7
E	Go (2nd stage of write)	4	3

Table C-1: Media link frame lengths

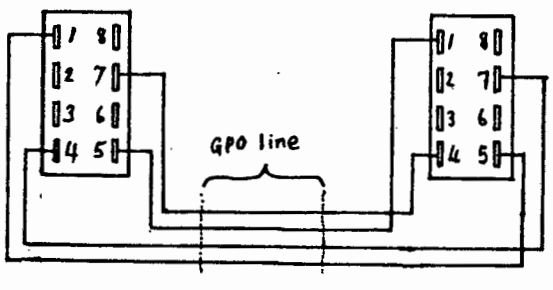
APPENDIX D

SERIAL LINK HARDWARE CIRCUIT DIAGRAMS

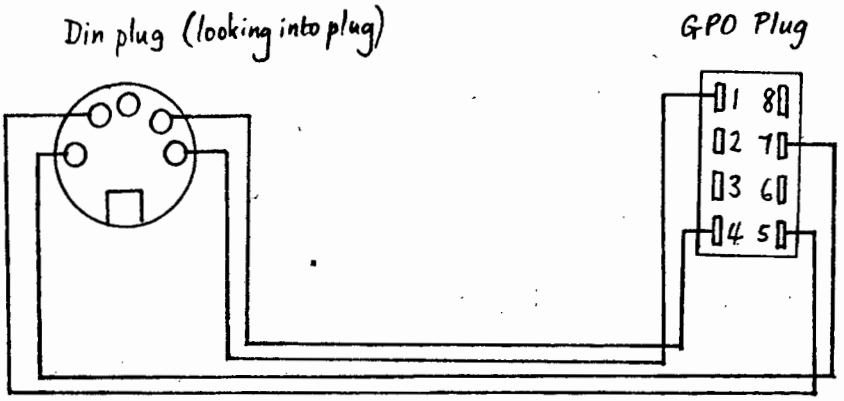
D.1 The serial lines

The wires of each 4-wire serial link between the Electrical and Chemical Engineering buildings are connected as follows:

Elec Eng wall socket pin number	Chem Eng wall socket pin number
1	5
4	7
5	1
7	4



The lead connecting the wall GPO socket to the DIN socket on the interface unit is wired thus:



D.2 The link driver circuitry

Two 5-pin panel-mounting DIN sockets

```
ENT PROC GETMED (REF MEDCARD MSTAT) INT;
```

which puts the Media status word into MSTAT.MEDDAT, updates MSTAT.SCANTIME and returns an integer indicating error status (as for the other procedures in MEDLNK).

APPENDIX F

THE ABM AND ABOM ABORTING TASKS

The two tasks ABM and ABOM are provided for use instead of the RSX-11M abort command ABO, and are intended for aborting applications tasks which access MEDCOM. ABO cannot be used for aborting such tasks because it does not ensure that the task releases MEDCOM before it exits.

ABM is a non-privileged task which should be installed as ...ABM and uses the same command-line format as ABO. ABM calls GETMCR() to get the command-line typed in, and from this, gets the name of the task to be aborted. It converts the task-name into radix-50 task name format. If the user did not specify a task name, then the usual default name is used (i.e. name "TT1" if invoked from terminal TT1:, etc.)

Once the task name is obtained, ABM secures MEDCOM using SECMEDCOM(), the task is aborted using the RSX-11M ABRT$S directive [21], and then MEDCOM is released. This ensures that the task being aborted will not be secured to MEDCOM on exit.

Two checks are necessary before the ABRT$S can be issued:

1. The task to be aborted must not be "MCR...". If a user

ABOM because privileged tasks cannot be installed from non-privileged terminals.

The above method of having two abort-MEDIA tasks is intended only as a temporary measure until a way is found around the difficulty mentioned above. There definitely is a solution, since the RSX-11M TAL command, given a task name, prints out information which includes the terminal from which the task was run.

APPENDIX G

THE SECURE/RELEASE MODULE GSECREL

G.1 Procedures provided in GSECREL

In addition to the procedures relating to the securing and releasing of facilities, three other procedures (the final three in the list below) are included in this module because they are often used by the same tasks that use the secure/release procedures.

1. ENT PROC GSECURE (INT FA);

   This proc secures the facility represented by event flag FA. It is similar to the MTSLIB SECURE, but uses the global event flags 33 to 56.

2. ENT PROC GRELEASE (INT FA);

   This proc releases the facility represented by the global event flag FA.

3. ENT PROC FORCEDRELEASE (INT FA);

   This is the same as RELEASE except that it releases the facility irrespective of who has secured it. It is intended for use by a system manager to free a facility that has become "hung" (as explained earlier).

4. ENT PROC SECMEDCOM ();

   Secures the data-base, using GSECURE with the event flag MEDCOMEF (= 33 at present).

5. ENT PROC RELMEDCOM ();

   Releases the data-base, using GRELEASE with the event flag MEDCOMEF.

6. ENT PROC MCOMINIT ();

   Sets the flag MEDCOMEF. This is meant to be called once only, as part of the RSX-11M system startup, and corrects for the problem mentioned in section 6.3.2 whereby the flags "wake up" in the reset state when the system is started up.

7. ENT PROC FREEMEDCOM ();

   This proc calls FORCEDRELEASE (MEDCOMEF) to free MEDCOM should it "hang". It is intended for use only by the data-base manager [300,1] and is called only by the task UNHANG.

8. ENT PROC MCOMTASK (REF R50NAME TASK);

   This proc returns the radix-50 name of the task which is currently securing MEDCOM. If no task is securing, TASK is zeroed. It is called by MEDUPDAT.

9. ENT PROC PRIVILEGED () INT;

   This proc returns 1 if the calling task was run from a privileged terminal, otherwise it returns 0. The calling task must have logical unit 1 assigned to TI:.

10. ENT PROC TASKINFO (REF TASKBUF TB);

    This is the same as the SPL interface proc RSXGTS except that it RRGELs if the GTSK$S directive fails.

G.1.1 Modifications to RSXBA2

As mentioned in chapter 6, the MTSLIB-supplied version of RSXBA2 stores the names of the tasks securing facilities. To do this, it uses a section of code equivalent to

```
MODE R50NAME ( INT R50N1, R50N2);
ENT DATA RRFACS;
    ARRAY(32) R50NAME FACS;
ENDDATA;
```

Element i of FACS contains the radix-50 name of the task securing the facility represented by event flag 64 + i.

To enable the secure/release mechanism using the global event flags (33 to 56), two extensions to RSXBA2 have been made :

1. code equivalent to

```
MAC RSXBA2=LB:[1,1]EXEMC/ML,SY:[100,6]RSXBA2
```

RTLLIB is then built using

```
TKB @RTLLIBTKB
```

where RTLLIBTKB.CMD is

```
RTLLIB/-HD,RTLLIB/-SP,RTLLIB=LB:[1,1]RTLCTL
SY:[100,6]RSXBA2,RRGEL
SY:[100,6]TTOUT,DEVIO,TWRT,IWRT,IWRTF,NLS,SPS
SY:[100,6]IREAD,TREAD,RWRTX,RWRTU,RREADU
/
STACK=0
PAR=RTLLIB:120000:14000
//
```

The details of forming the RTLLIB partition during system VMR are given in appendix H.

APPENDIX H

CONSTRUCTION OF MEDCOM AS A RESIDENT COMMON

H.1 Compilation and building of the data-base

Medcom is built using the following commands:

```
RTL MEDCOM,MEDCOM=MEDCOM
MAC MEDCOM=MEDCOM
TKB @TKBMEDCOM
```

where TKBMEDCOM.CMD consists of:

```
MEDCOM/-HD,MEDCOM/-SP,MEDCOM=MEDCOM
/
STACK=0
PAR=MEDCOM:140000:1100
//
```

The line PAR=MEDCOM:140000:1100 tells the taskbuilder that the

output file will be installed in a partition called MEDCOM, of size 1100 (octal) bytes starting at virtual address 140000 octal.

H.2 Creating partitions for MEDCOM and RTLLIB

RTLLIB, which is a library of RTL/2 procedures and contains the extended version of the RSXBA2 procedure which is needed by the global event-flag secure/release procedures, is introduced in appendix G, where it is also explained why RSXBA2 must reside inside a common area of memory.

This section deals with the procedure which must be followed when building the partitions RTLLIB and MEDCOM. This is done at VMR time during Phase two of RSX-11M system generation [22].

The file DL0:[1,54]SYSVMR.CMD must be edited to insert the lines

```
SET /MAIN=MEDCOM:*:11:COM
SET /MAIN=RTLLIB:*:147:COM
```

just before the line

```
SET /MAIN=GEN:*:*:SYS
```

to inform VMR that MEDCOM and RTLLIB will be common partitions of size 11 (octal) and 147 (octal) 64-byte blocks respectively.

VMR is then performed as follows:

```
SET /UIC=[1,54]
PIP DL2:RSX11M.SYS/NV/CO/BL:258.=DL0:RSX11M.TSK
PIP DL2:=DL0:*.STB
ASN DL2:=SY:
ASN DL2:=LB:
INS $VMR
VMR @DL0:SYSVMR
ASN DL0:=SY:
ASN DL0:=LB:
PIP =DL2:RSX11M.SYS
```

The new system is then booted using

```
BOO RSX11M
```

The files MEDCOM.TSK, MEDCOM.STB, MEDCOM.MAP, RTLLIB.TSK, RTLLIB.STB and RTLLIB.MAP must then be copied to LB:[1,1], and the startup file dl0:[1,2]STARTUP.CMD edited to include the lines

```
INS LB:[1,1]MEDCOM
INS LB:[1,1]RTLLIB
```

H.3 Linking tasks to MEDCOM

Tasks which access MEDCOM have to be taskbuilt as follows:

```
TKB @USERTKB
```

where USERTKB.CMD includes:

```
USERTASK,USERTASK/-SP=USERTASK
@LB:[1,54]COMINTFCE
/
LIBR=RTLLIB:RW
COMMON=MEDCOM:RW
//
```

It is not good programming practice to run AST service routines in an RTL/2 environment because this can compromise the system security [23]. A module called AST, has therefore been written which provides RTL/2-callable subroutines which enable the processing of ASTs in a simple fashion which does not involve the buffering up of incoming characters, and can only supply the task with the most recent unsolicited character.

I.2 Module description

The following description should be read in conjunction with the listing of the AST module.

Logical unit number 2 must be assigned to the terminal from which the asynchronous input is expected. Asynchronous input handling is initialised by attaching to logical unit number 2 using

```
QIO$S  #IO.ATA,...,<#ASTIO,#AST2>
```

where ASTIO is the address of the AST service routine ASTIOPROC() for characters other than control-C, control-S, control-O, control-Q, and control-X ; and AST2 is the address of the AST service routine AST2PROC() for input control-C characters. The control-S, control-Q, control-O, and control-X characters do not cause ASTs, but instead have the usual effect in controlling output to the terminal.

Processing of ASTs is terminated by issuing to logical unit number 2 a

```
QIO$S  #IO.DET,...
```

to detach from the terminal.

A local data brick contains the following two integers :

1. ASTFLAG. This takes one of three values :

   CTLC : Indicates that an unsolicited control-C character was input since the last input character dealt with by the user.

   AST : Indicates that an unsolicited character other than control-C, control-S, control-Q, control-O or control-X was input since the last character dealt with.

   NOTYET : Indicates that no unsolicited characters have been input since the last input character dealt with.

2.

   CHAR : An integer containing the unsolicited input character.

The AST service routines ASTIOPROC and AST2PROC should never be called explicitly. A call to RRGEL aborts any attempt to do so.

ASTIOPROC services non-control-C ASTs. It moves the value #AST to ASTFLAG to indicate the type of AST that has occurred, pops the character off the stack and stores it in CHAR. It then sets event flag ASTEF (event flag 4 at present), declares a significant event and exits via the RSX-11M AST-exit directive ASTX$S [24]. Failure of the ASTX$S would mean a serious system fault and is dealt with by calling RRGEL.

AST2PROC, the control-C AST service routine, is the same as ASTPROC except that it sets ASTFLAG to #CTLC and sets event flag AST2EF (event flag 3 at present).

ASTFLAG is reset to NOTYET whenever a character is actually dealt

with by any of the procedures WAITAST, WAITCTLC, WAITNCTLC, WTCCCZ, ASTYET, CTLCYET and NCTLCYET. For example, ASTFLAG is reset by WAITCTLC if a control-C occurred, otherwise not.

I.3 Procedures in the module

The user may call the following ENT procedures :

1. ENT PROC STARTAST();

   This procedure initialises for AST processing by issuing a QIO$S #IO.ATA directive to attach to logical unit number 2.

2. ENT PROC WAITAST(INT NTIX) INT;

   Puts the calling task into a wait state until an AST of either type occurs. A timeout of NTIX ticks is imposed. The integer returned is 1 if an AST occurred and 0 if the wait timed out.

3. ENT PROC WAITCTLC (INT NTIX) INT;

   As for WAITAST except that the wait is for ASTs of the control-C type only.

4. ENT PROC WAITNCTLC (INT NTIX) INT;

   As for WAITAST except that the wait is for non-control-C ASTs only.

5. ENT PROC WAITCCCZ (INT NTIX) INT;

   This procedure waits until control-C or control-Z is

typed, timing out after NTIX ticks. The returned integer is 1 if control-C or control-Z was typed, zero if timeout occurred.

6. ENT PROC ASTYET () INT;

   If an AST of either type has occurred since the last character dealt with, 1 is returned; otherwise zero is returned.

7. ENT PROC CTLCYET () INT;

   Returns one if a control-C AST has occurred since the last character dealt with; otherwise returns zero.

8. ENT PROC NCTLCYET () INT;

   Returns one if a non-control-C AST has occurred since the last character dealt with; otherwise returns zero.

9. ENT PROC ASTCHAR () BYTE;

   This procedure returns the most recently received input byte. A call to ASTCHAR would be preceded by a call to one of the routines which indicates whether an AST has occurred. For example,

```
IF WAITAST(50) = 1 THEN
   INPUTBYTE := ASTCHAR ();
END;
```

   would wait for up to a second for a character, and if one was typed, put it into the variable INPUTBYTE. This technique is used in MEDRMD to allow it to respond to the pressing of any key.

10. ENT PROC STOPAST ();

This procedure issues a QIOW$S #IO.DET to detach from logical unit number 2. The effect is to stop processing of ASTs and to return the terminal to its usual state.

APPENDIX J

SCREEN CURSOR ADDRESSING ROUTINES

The module SCREEN provides easy-to-use subroutines for screen cursor position control for a VT52 terminal. It is used by several of the software modules such as MEDRMD and ATTACH, and may also be used by applications tasks to present neatly-formatted data on the screen.

The RTL/2 byte-output procedure variable OUT should ideally be assigned to HSOUT, because binary escape-sequences are output to the screen. However, in practice no problems were encountered using TTOUT.

The following cursor-routines are in the module :

1. ENT PROC GOTOLC (INT LINE, COL);

   This procedure positions the cursor on line LINE and column COL of the screen. LINE must be in the range 1..24 and COL in the range 1..80, or ERP is called.

2. ENT PROC HOME ();

   This procedure positions the cursor at the top of the

screen, by outputting "<esc> H". It has the same effect as GOTOLC (1,1).

3. ENT PROC CLEOS ();

   Clears the screen from the current cursor position to the end of the screen, by outputting "<esc> J".

4. ENT PROC CLSCREEN ();

   Clears the entire screen by calling HOME() and then CLEOS().

5. ENT PROC CLEOL ();

   Clears from the current cursor position to the end of the line, by outputting "<esc> K".

6. ENT PROC FORCEBUFFEROUTPUT ();

   This procedure calls OUT(ETX) to force the output of OUTCL.BFR to the screen. It must be called if there is any danger of OUTCL.BFR becoming full, i.e. if more than 80 characters are output between successive newline or ETX characters.

7. ENT PROC PRINTTIME ();

   This is not a screen cursor routine. It calls TIMDAT(-1), and is only present in this module for historical reasons.

APPENDIX K

STUDENT PROJECT INSTRUCTION SHEET

It will be noticed that the project sheet on the next few pages refers to two data bases: the data-base MEDCOM and a simulation data-base. This is because when this project was set, the simulation part of MEDCOM was kept in a separate resident common called MEDSIM. The simulation data in MEDSIM was later included inside MEDCOM, enabling choice between simulation and real system to be done at attach time rather than taskbuild time.

UNIVERSITY OF CAPE TOWN

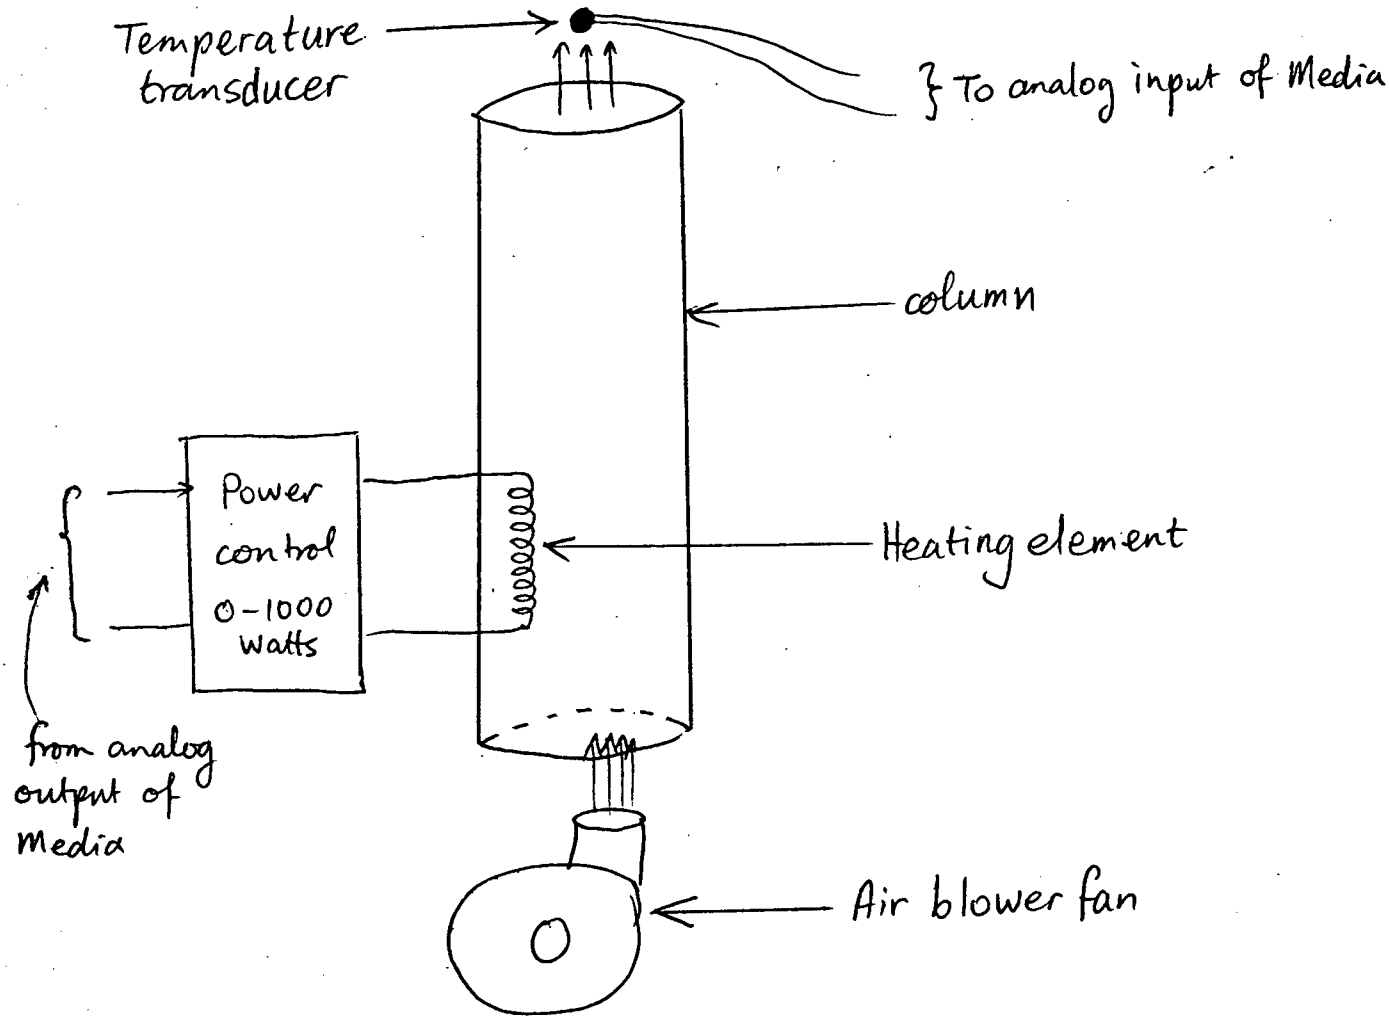
DEPARTMENT OF ELECTRICAL ENGINEERING

EE 476 REAL-TIME COMPUTER SYSTEMS PROJECT

INTRODUCTION

The project is aimed to give the student practical experience of real-time computer systems. The requirement of the project is for the student to design a software system to control the temperature of the air in a vertical column. Since the purpose of this course is to develop computer techniques rather than control techniques, a simple control algorithm (which is discussed below) is quite adequate.

The air column system is shown in the diagram below



The air is blown up the column by a blower fan, and, during its passage up the column, is heated by an electrical heating element. The temperture of the air emerging from the top of the column is measured by a temperature transducer (discussed below). The rate of flow of air is constant and cannot be varied.

The power to the heating element can be varied between 0 and 1000 Watts.

The temperature of the air emerging from the column must not be allowed to exceed 100°C.

Controlling the air-column system

The software system to control the temperature must allow the operator to change the desired temperature at any time, must provide a control algorithm for the temperature control and facilities to log the temperature on disc. Obviously all these activities must occur asynchronously and independently of each other so three tasks are required:

1. A task to control the temperature by adjusting the power to the heater.
2. A task to enable the operator to change the setpoint temperature, and to display the values relating to the column on his VDU.
3. A task to log the activity of the column onto disc.

The 3 tasks are concurrent in real-time and must all access the Media data-base.

A task, called the Media update task, performs a measurement scan of the MEDIA system at a regular interval and obtains data from the column (i.e. its temperature). The interval between measurements is known as the SAMPLING INTERVAL. Sampling is inherent in any computer control system. The results of the measurement scan are stored in a data base in the computer which is common to all tasks, i.e. all tasks can read and write to this data base (which is called MEDCOM meaning Media Common.) Tasks which need this data, such as a control task, then read MEDCOM and process the data they obtain from it. The control task would then output a value to the Media interface which would set the power to the heating element. The control task would do this at a regular interval known as the CONTROL INTERVAL.

Now four (or more) tasks are going to be accessing and manipulating the common data base (the media updating task, the control task, the OCP task and the logging task.) These tasks are running concurrently and the possibility exists that 2 tasks or more will try to use the data base simultaneously. This could lead to errors (e.g. say that the updating task updates the temperature and is then interrupted by the logging task which logs the temperature and the time, the latter having not yet been updated.) In order to avoid this a task must 'secure' the data base for uninterrupted working and then 'release' it when it is finished. If this is going to work all tasks must secure the data base before they work with it. If another task has already secured the data base the second task must wait until it has released it before continuing.

The control task and logging task must service the data base at regular intervals. After they have serviced the data base they must wait a period of real time before repeating. To do this the application program makes use of a "system directive" (i.e. a routine which interfaces to the operating system).

Simulating the system

Because there is only one set of air-column apparatus, and also because applications programs must be properly debugged before being used on a real-life system, a task has been supplied which simulates the behaviour of the column. Tasks running using the simulated system access a different data-base. This data base is updated by the simulation task instead of the media update task. The idea is that the software system will be developed and debugged using the simulation data-base, and then run using the real apparatus and data base.

As far as the software design for the project is concerned there is no difference between the actual and the simulated system. The simulation is a calculated real-time replica of the behaviour of the real column.

In order to provide a simulated real-time replica of the column behaviour the computer calculates the value of the temperature that would have been read in at each sampling interval. It does this at the same frequency as the sampling interval, so the update of the simulation common data base occurs in the same way as for the real system. Obviously the calculated result depends on the value of the setpoint temperature which is set by the OCP task. The OCP task does this by updating a memory location in the common data base. Another location stores the real time of latest update.

The Media system

The Media process control system, and the air column apparatus, is located in the University Chemical Engineering building and is connected to the PDP 11/23 computer in the Electrical Engineering building via a serial 9600 baud data line. All the link communication is performed by the Media update task described earlier.

The Media system has the following inputs and outputs:

1. 16 lines of digital output
2. 32 lines of digital input
3. 4 analogue outputs (DAC)
4. 16 analogue inputs (ADC)

The present project uses only the analogue part of the system - in the real system input and output number 1, and in the simulated system any one of input and output pairs 1, 2, 3 or 4.
The power to the heater is set by the analogue output, and the value of temperature is read via the analogue input.

Attaching the Media Outputs

If user A were to be running a program which uses analogue output number 2, say, to output the value for the power to the heating element, he must be sure that no other user can write to output number 2 - otherwise the other user could destructively interfere with the task user A is trying to perform. To prevent such an eventuality, a task is provided which 'attaches' a user to a particular output and ensures that no other user can use that output. This task, called ATTACH, must be run before executing any of the tasks which access the common data-base. When he is finished running his control tasks, the user runs ATTACH again to 'detach' from the output he had attached to. This is explained more fully later.

2. PROGRAMMING SPECIFICS

(a) Common data base - Medcom

This contains all the information pertinent to the media inputs and outputs : data values, addresses, setpoints, most recent update times, UIC's of users attached, etc. However, the user need not know exactly how the data is laid out because a number of procedures (see part (c) below) have been provided to read and write to/from Medcom.

Note: As mentioned earlier, there are in fact two copies of the database - one used for the simulated system and one for the real media system. The correct database is automatically linked in at task build time if you use $RTLCMP. (see below)

(b) Attaching to and detaching from outputs

(i) To attach type >$ATTACH
You will be prompted with a menu of choices - e.g. whether you wish to specify which output to attach to, or wish to attach to the lowest numbered output that is free, etc.

(ii) To detach, type $ATTACH and respond to the menu appropriately.

YOU WILL NOT BE ABLE TO WRITE TO AN OUTPUT WITHOUT ATTACHING YOURSELF TO ONE FIRST.
YOU MUST ALWAYS DETACH WHEN YOU ARE FINISHED.

(c) Accessing data in the Medcom data-base

Access to the data-base is provided via a set of subroutines provided for the purpose. To use these routines (which must be declared as EXT PROC's), you must have the following lines in your program:

```
LET ANALOG  =  0;
LET DIGITAL =  1;
LET INPUT   =  0;
LET OUTPUT  =  1;
```

These parameters are passed in the ADSWITCH and IOSWITCH parameters of the procedure calls.

The following procedures may be used:

(i) ENT PROC ATTACHED (INT ADSWITCH, REF ARRAY INT OUTARRAY);

You cannot know which output you will be using when you are writing an application program. In order to write to the correct output, you must use the procedure ATTACHED to find out which outputs you are attached to.
This procedure puts into the array OUTARRAY the numbers of those outputs to which the user is attached. The rest of OUTARRAY is filled with zeros. For this application we are using only analog outputs and so the ADSWITCH parameter must be given as ANALOG. The length of OUTARRAY must be greater than or equal to the number of outputs attached to (e.g. if you know that you will only attach to one output, OUTARRAY can be an array of length 1).

(ii) ENT PROC WROUTPUT (INT ADSWITCH, MDATA, CHANNUM);
This procedure writes the data MDATA to output channel number CHANNUM. In this application, ADSWITCH = ANALOG, CHANNUM must be in range 1 .. 4 and only the least significant 8 bits of MDATA are used because the DAC is 8-bit.

(iii) ENT PROC READINPUT (INT ADSWITCH, CHANNUM) INT;
This procedure reads in analogue (if ADSWITCH = ANALOG) input number CHANNUM and returns the value read. CHANNUM must be in range 1 ... 16. Since the ADC is a 10-bit ADC, the value is put in the 10 least significant bits of the returned integer, the other bits being set to zero.

(iv) ENT PROC RDSCANTIME (INT ADSWITCH, IOSWITCH, CHANNUM) REAL;
This procedure returns the time (in seconds past midnight) that the specified input or output channel was last updated by the update task.
As before we let ADSWITCH = ANALOG and CHANNUM be the channel number. IOSWITCH must be INPUT for an input or OUTPUT for an output.

(v) ENT PROC SETSETPT (INT CHANNUM, FRAC VALUE);
This procedure sets the setpoint for the analogue input controlled by analogue output number CHANNUM to VALUE.

(vi) ENT PROC GETSETPT (INT CHANNUM) FRAC;
This procedure returns the setpoint (as set up in a call to SETSETPT) of the analog input controlled by analogue output number CHANNUM.

(d) Securing and releasing the data-base

This is done automatically in the interface procedures described in (c) above, and occurs transparently to the user program.

The purpose of these routines is to open and close I/O channels. An I/O channel can be a VDU output, keyboard input, or disk file input or output. More than 2 channels can be open at any time but only two channels (one for input, one for output - see section (k) below) can be in use at one time.

Thus after you have initialised the I/O channels at the beginning of your program by saying

```
INITIO ( )
```

you open the channels you want to use, e.g.

```
OPENOUTFILE ("LOGFIL.OUT");  This opens LOGFIL.OUT as an output file.
```

Note that the input and output channels to the VDU console are automatically opened by INITIO.

You specify which channels you want to use for input and output by saying:

```
SWITTIN()  % Input currently comes from terminal %
SWITTOUT() % Output currently goes  to terminal %
SWFILOUT() % Output currently goes  to the opened output file %
```

At any time during your program you can change your current input or output channel by calling one of the above routines.

The code given in RRJOB in [2,1] EE476.RTL will open the user's console for input and output and set them as the current channels.

The command to open an output channel to the disk file (for the logging task) is also provided although it is between % signs so will not be compiled unless these are removed. The reason for this is that for tasks that do not require disk output you do not wish to open a disk file since it actually enters the file in your directory and will clutter it with a whole lot of empty files.

It is important to close a disk output file properly by executing

```
CLOSEOUTFILE()
```

when you have finished outputting to the disk.

Be careful not to output data in an endless loop to the disk because you will fill the disk!

Note: Input from files can also be done - consult the demonstrator for further details.

(k) Stream I/O

RTL/2 as a language has no equivalent of the FORTRAN READ or WRITE statements. The user program has to provide procedures to output to the device (via the I/O Driver of the operating system) or input from it. In order to be able to use the same routines for different devices one writes to the output channel and reads from the input channel rather than to the particular device. To write the same thing to different devices you can use the same output procedure and merely switch channels (using SWTTIN, SWTTOUT, and SWFILOUT).
For this reason Standard Stream I/O routines for use by RTL/2 programs are defined. A description of these standard Stream I/O routines is provided. Again these form a library which is linked to your program when your task is being built so you must provide EXT references for any routine you use.

Note: When writing to the output channel, whether text or data, your output will only actually be sent to the device when the appropriate termination character is output. Valid termination characters are LF (line feed) if a new line is required or ETX(control-C) if you wish to stay on the same line. Also, the ENQ (enquire) character should be used to terminate any text that prompts for input from the terminal console.

LF, ETX and ENQ are defined via 'let' definitions in [2,1] EE476.RTL. You cannot include these characters in a character string unless enclosed between # signs e.g.

```
TWRT("go to new line next #LF#");
```

You normally use LF except if you are prompting for input on the same line e.g.

```
TWRT ("INPUT INTEGER VALUE #ENQ#")
I: = IREAD();
```

If ENQ were not included the prompt would not appear on the screen. If you used LF the value input would be echoed on the line below your prompt.

(ℓ) Error numbers:

The meaning of the compiler error numbers (as you will see in your .SRC files) is given in the accompanying table.

If you make a logical mistake which results in program failure your task will be terminated and a message output:

'TASK' - nnn

Where TASK is the name of your task and nnn is the error number summarised in the accompanying table of run-time errors.

(m) Running the programs

In order to start your software system you run each task in turn.

For example let TASK1 = CONTROL TASK
TASK2 = OCP TASK
TASK3 = LOGGING TASK

TASK1 requires K, TI (see part (o) below) to be input and then continues controlling without further operator contact.

```
>RUN TASKI/TASK = TASK1
 INPUT K, TI : 1.0,2.0
```

After you input your values the cursor moves back to the beginning of the line but does not line feed. The system is now running TASK1. To be able to communicate with MCR you press 'return' again and you get the MCR prompt. You can then run TASK 3, etc.
To stop a task running, use the ABM command. ABM is a special version of the operating system ABO command, and must be used when aborting any tasks which access the data-base.
The format is:

```
ABM 'taskname'
```

Note: DO NOT USE 'ABO' TO ABORT MEDIA TASKS. This is because ABO does not ensure that the task being aborted releases the data-base. and thus the data-base may "hang".

(n) Printout required

Your logging task must give for every sampling interval (= 1 sec) the information about the column, i.e. time, setpoint, power, temperature. You must also show the effect of changing the setpoint. About 3 minutes of printout is sufficient.
The printout is contained in LOGFIL.OUT. Check it on your screen using PIP before actually printing it.

(o) Control interval and algorithm

The sampling interval is one second.

For the purposes of this project use a PI control algorithm given by

$$\text{POWER} = K*\left\{ e_n + \sum_n \frac{\Delta t_c}{T_I} \frac{(9e_n + 19e_{n-1} - 5e_{n-2} + e_{n-3})}{24} \right\} ,$$

where n is the error at the present sampling interval (given by temperature minus setpoint) and n-j is the error at the sampling interval j previously.

Δtc is the control interval which is taken as 1.0 seconds for the pruposes of the marked report.

Note: 1. The heater element is capable of delivering up to 1000 Watts. Thus POWER must be limited so that it is positive and does not exceed 1000 Watts.

2. It is a good idea to limit the contribution of the integral term in the above algorithm to the range - 1000 to + 1000 Watts, so that it does not grow excessively.

(p) The value to write to the analogue DAC output to produce a heating power of POWER watts (where 0.0 < POWER < 1000.0) can be determined from the following

(1) Power produced is linearly related to digital value written to the DAC (i.e. the analogue output).

(2) Digital 00 H produces 0 Watts

(3) Digital FF H produces 1000 Watts

The value ADCVAL read in via the analogue input analog-to-digital converter is however not linearly related to the actual temperature. This is because the thermistor used has a non-linear calibration curve.
The temperature can be calculated using the following relation:

temperature in degrees Centigrade = $a_3X^3 + a_2X^2 + a_1X + a_0$

where $X = \frac{1}{4}$(ADCVAL)
$a_3 = 1.1635\ E-5$
$a_2 = -2.8494\ E-3$
$a_1 = 0.5916$
$a_0 = 17.367$

(q) The task MEDRMD

Typing RUN MEDRMD causes a display of the activity of the data-base to the screen. The information displayed includes which user is attached to which output, when last the data-base was updated and which task has currently secured the data-base.

APPENDIX L

ERROR NUMBERS

Error numbers for all the software modules are listed below.

A prefix of 'U' indicates an unrecoverable error (a call to RRGEL) and a prefix of 'R' indicates a recoverable error (a call to ERP).

L.1 Errors reported by MEDUSER

R715 : User attempted to write to a part of MEDCOM (an output) to which he was not attached.
R716 : ADSWITCH or IOSWITCH parameter was not Ø or 1.
R717 : Channel number requested does not exist.
R7Ø9 : Media input/output is out of scan.

L.2 Errors reported by MEDLNK

R5Ø1 : BCC error in frame received from Media.
R5Ø2 : Alignment error in frame received from Media
R5Ø3 : Media code in reply frame from Media does not correspond to the command code sent to Media.

L.4 Errors reported by PLOTLIB

U609 : XMIN > XMAX or YMIN > YMAX in call to SCALE.
R610 : Error in reading the position of the crosshairs.
R611 : Attempt to MOVE or DRAW to a point off the edge of the screen.

L.5 Errors reported by AST

U607 : ASTX$S directive failure.
U608 : Other directive failures.

L.6 Errors reported by GSECREL

R215 : During facility release, state of event flag not consistent with facility having been secured.
U14 : Illegal event flag number (not in range 33..56).
U15 : Attempt to release a facility which was not secured.
U16 : Attempt to secure a facility that the task has already secured.

L.7 Errors reported by ODT

R604 : Unexpected end-of-file while reading SMT.TSK from disk.
R605 : Failure to open, close or read from the files SMT.TSK or SMTLOAD.ABS.

APPENDIX M

MEDIA SYSTEM STARTUP PROCEDURE

This appendix describes the procedure to be followed when the Media system is started up.

M.1 Starting up the GEC Media system

1. Plug the serial lead from the terminal into its socket on the serial line interface unit and sign on to the PDP.

2. Plug the Micro-Media serial line into its socket on the interface unit. This line will have been set up at system startup to slave, no-echo, read-pass-all and 9600 baud.

3. Power up the Media bins.

4. Run the Media update task MEDUPDAT.

5. Run MEDRMD to check that all is well.

M.2 Starting up the LSI-11 Media system

1. Plug the serial lead from the terminal into its socket on the serial interface unit and sign on to the PDP.

2. Plug the LSI-11 console line lead into its socket on the interface unit. This line will have been set up at system startup to slave, no-echo, read-pass-all and 9600 baud.

3. Power up the LSI and the Media bins.

4. Restart the LSI by raising the 'reset' switch while the 'halt' switch is in the up position. Then drop the 'halt' switch and raise it again.

5. Run the ODT program from the terminal.

6. type 'F'<CR> to flush the buffer. and then type a few ODT commands to check that communications between the terminal, PDP and LSI are functional.

7. Use the 'L' command to load and run the SMT Micro-Media replacement program. (See the description of the ODT program in chapter 3).

8. Exit ODT by typing control-Z.

9. Run the Media update task MEDUPDAT. The entire system should now be functional and ready for user applications programs to run.

10. Run MEDRMD to check that all is well.

APPENDIX N

SOFTWARE LISTINGS: HOST SYSTEM

Listings of all the software modules which run on the PDP-11/23 host system are given here. Pages of the listing have a circled page number at the top right-hand side of the page. As an example, the 3rd page of the 2nd program in this appendix is numbered "N-2-3".

The following are the programs listed in this appendix (given in roughly the same order as their discussion in the main text):

```
OPTION (1) CM;
TITLE ODT;
```

N-1-1

```
%                                                                    %
% THIS ROUTINE IS USED TO COMMUNICATE WITH THE LSI 1123 ODT          %
% AND DOWNLOAD THE SMT.TSK MEDIA EMULATION SOFTWARE INTO THE LSI.    %
%                                                                    %

LET LF = OCT 012;                  % LINE FEED CHARACTER             %
LET CR = OCT 015;                  % CARIAGE RETURN CHARACTER        %
LET ETX = OCT 003;
LET ENQ = OCT 005;
LET EOS = OCT 200;                 % END OF STREAM CHARACTER         %
LET BEL= OCT 007;                  % BELL CHARACTER                  %
LET EOM = OCT 200;                 % END OF FILE CHARACTER           %
LET SP = OCT 040;                  % SPACE CHARACTER                 %
LET DOL = HEX 24;                  % DOLLAR CHARACTER                %
LET     RNE      =   OCT 1020;     % CODE FOR READ NO ECHO           %
LET     RAL      =   OCT 1010;     % CODE FOR READ ALL               %
LET     TMO      =   OCT 200;      % CODE FOR TIMEOUT                %
LET     WRTCODE  =   OCT 410;      % WRITE WITH WAL                  %
LET     KILCODE  =   OCT 0012;     % KILL ALL I/O                    %
LET     DETCODE  =   OCT 2000;     % DETACH DEVICE                   %
LET     ATTCODE  =   OCT 1400;     % ATTACH                          %
LET     SERIALWRITELUN  =   5;     % LU OF SERIAL WRITE              %

APPENDIX O

SOFTWARE LISTINGS: LSI-11 MEDIA SYSTEM

Listings of all the software modules which form part of the LSI-11 Media system are given here. The SMT system modules are listed as modified for use in this system. Pages of the listings have a circled page number at the top right-hand side of the page. For example, the 3rd page of the 2nd program in this appendix is numbered "O-2-3".

The following are the programs listed in this appendix:

```
