Abstract

High-purity powder specimens of $\text{AgCa}_2\text{Mn}_2\text{V}_3\text{O}_{12}$ and $\text{NaPb}_2\text{Mn}_2\text{V}_3\text{O}_{12}$ have been successfully synthesized by solid-state chemical reaction. The Rietveld refinements from X-ray powder diffraction data verified that these compounds have the garnet-type structure (space group $Ia-3d$, No. 230) with the lattice constant of $a = 12.596(2)$ Å for $\text{AgCa}_2\text{Mn}_2\text{V}_3\text{O}_{12}$ and $a = 12.876(2)$ Å for $\text{NaPb}_2\text{Mn}_2\text{V}_3\text{O}_{12}$. Calculation of the bond valence sum supported that Mn is divalent and V is pentavalent in these garnets. Estimation of the quadratic elongation and the bond angle variance showed that the distortions of the MnO_6 octahedra and the VO_4 tetrahedra are significantly suppressed. Our new results of $\text{AgCa}_2\text{Mn}_2\text{V}_3\text{O}_{12}$ and $\text{NaPb}_2\text{Mn}_2\text{V}_3\text{O}_{12}$ are compared to those of $\text{AgCa}_2\text{M}_2\text{V}_3\text{O}_{12}$ and $\text{NaPb}_2\text{M}_2\text{V}_3\text{O}_{12}$ ($M = \text{Mg}, \text{Co}, \text{Ni}, \text{Zn}$).

Fig. 1. Unit cell of garnet-type structure $\{C_3\}[A_2](D_3)O_{12}$ with space group $Ia\bar{3}d$ (No. 230). The crystal structures were drawn with a computer program VICS [25].

1. Introduction

The garnet-type compounds have been attracting great interests on the magnetic properties in the theory and experiments [1-8], in particular, ferrimagnetism of rare-earth iron garnets $R_3Fe_5O_{12}$ (R = rare-earth element) [1-3].

The garnet structure has cubic symmetry of the space group $Ia\bar{3}d$ (No. 230), as Fig. 1 depicts. The general structural formula for an oxide garnet can be represented as, $\{C_3\}[A_2](D_3)O_{12}$, with eight of these formula units per unit cell, where C-, A-, and D-sites are the cation sites. These cation sites are surrounded by oxygen ions O^{2-} at the vertices of a dodecahedron (C-site), octahedron (A-site), and tetrahedron (D-site), respectively. The structure is comprised of a three-dimensional framework by these polyhedrons sharing edges.

Generally, larger ions preferably occupy the larger sites, in the order of C-, A-, and D-sites. These cation sites are occupied by a wide variety of cations, for instance, alkali metal, alkaline earth metal, transition metal, and rare-earth ions can be appropriated by substituting either C- or A- or D-sites. A great number of garnet compounds with complex chemical compositions have been synthesized, in particular, non-iron garnet [1]. Oxide garnets with M ion at D-site are collectively dubbed 'M garnet', for instance, $\{AgCa_2\}[Mn_2](V_3)O_{12}$ and $\{NaPb_2\}[Mn_2](V_3)O_{12}$ so-called 'vanadium garnet'.

Recently, we have successfully synthesized high-purity powder specimens of AgCa₂Mn₂V₃O₁₂ and NaPb₂Mn₂V₃O₁₂ by solid-state chemical reactions. In these compounds, Ag⁺ and Ca²⁺ ions (or Na⁺ and Pb²⁺ ions) occupy the C-sites, Mn²⁺ ions occupy the A-sites and V⁵⁺ ions occupy the D-sites. In the garnet structure, the body-centered-cubic sublattice is build by octahedral A-sites. Thus, AgCa₂Mn₂V₃O₁₂ and NaPb₂Mn₂V₃O₁₂ have only one magnetic sublattice of the A-site, therefore, which provides a much simpler magnetic interaction. Prior to the magnetic studies of AgCa₂Mn₂V₃O₁₂ and NaPb₂Mn₂V₃O₁₂, we here focus and report on the synthesis and crystallographic studies of these vanadium garnets.

Nearly 30 years ago, many works on the vanadium garnets were reported [9-18]. The vanadium garnets, AgCa₂Mn₂V₃O₁₂ and NaPb₂Mn₂V₃O₁₂, were synthesized for the first time by Ronniger et al. [9], where only the lattice constants were given. Subsequently, the structure analysis of single crystal of AgCa₂Mn₂V₃O₁₂ was carried out by Rettich [10]. No crystal structure investigation of NaPb₂Mn₂V₃O₁₂ has been reported yet, as far as we know.

In this work, the detailed structure analysis of NaPb₂Mn₂V₃O₁₂ has been made for the first time by the Rietveld refinement using X-ray powder diffraction (XRD) data. To compare with the structure analysis of single crystal of AgCa₂Mn₂V₃O₁₂ [10], the crystallographic study for this compound has been re-investigated by the Rietveld refinement. The present work is an extension of our previous studies of AgCa₂Mn₂V₃O₁₂ (M = Co, Ni, Cu, Zn) and NaPb₂Mn₂V₃O₁₂ (M = Co, Ni) [15-18].

2. Experimental

Powder specimens of AgCa₂Mn₂V₃O₁₂ and NaPb₂Mn₂V₃O₁₂ were prepared by solid-state chemical reactions:

The starting materials, Ag (purity 99.99 %, melting point (mp) 1235 K), CaO (99.99 %, mp 2843 K), MnO₂ (99.9 %, decomposition point 808 K), V₂O₅ (99.9 %, mp 963 K), Na₂CO₃ (99.5 %, mp 1124

K), PbO (99 %, mp 1161 K), and V₂O₃ (99.9 %, mp 2243 K), were mixed in required amounts. Mixed powder materials were placed on an alumina boat in a muffle furnace whose temperature was elevated to 1073 K for AgCa₂Mn₂V₃O₁₂ and 1023 K for NaPb₂Mn₂V₃O₁₂ and was then held for 12 h in the ambient atmosphere. The resultant specimens were reground and pressed to rectangular bars at a pressure of 0.2 GPa. The same temperature program sequences were repeated once again, respectively.

XRD data were taken with Cu K α radiation at room temperature on a Bragg-Brentano-type powder diffractometer equipped with a curved graphite monochromator (graphite with a curvature radius of 224 mm). The radius of the goniometer was 185 mm. The open angle of the divergence and scattering slits were both 0.5 °, and the widths of the receiving slit and the monochromator-receiving slit were 0.15 mm and 0.6 mm, respectively. The specimen crushed sufficiently was charged into a flat glass holder. The XRD data were measured in a 2θ range from 10 ° to 120 ° with a step interval of 0.02 °. X-ray tube voltage and tube electric current were 30 kV and 100 mA for AgCa₂Mn₂V₃O₁₂ and 50 kV and 150 mA for NaPb₂Mn₂V₃O₁₂, respectively. The fixed counting times in the XRD measurements were 3 s for AgCa₂Mn₂V₃O₁₂ and 0.6 s for NaPb₂Mn₂V₃O₁₂. Details in the data collection are shown in Table 1.

The XRD data were analyzed by the Rietveld method with RIETAN-2000 [19]. We adapted the pseudo-Voigt profile function of Thompson et al. [20] made asymmetric with the procedure of Finger et al. [21], and the following reliable factors were used in the Rietveld refinements. The reliable factors of R -weighted pattern, R_{wp} , R -pattern, R_p , R -Bragg factor, R_B , and R -structure factor, R_F , are defined and expressed as [22],

$$R_{wp} = \left[\frac{\sum_i w_i (y_{i,obs} - y_{i,cal})^2}{\sum_i w_i (y_{i,obs})^2} \right]^{\frac{1}{2}}, \quad (3)$$

$$R_p = \frac{\sum_i |y_{i,obs} - y_{i,cal}|}{\sum_i y_{i,obs}}, \quad (4)$$

$$R_B = \frac{\sum_K |I_{K,"obs"} - I_{K,cal}|}{\sum_K I_{K,"obs"}}, \quad (5)$$

$$R_F = \frac{\sum_K \left| |F_{K,"obs"}| - |F_{K,cal}| \right|}{\sum_K |F_{K,"obs"}|}. \quad (6)$$

Here y_i is the intensity at the i th step, and $w_i = 1/y_{i,obs}$ the statistical weight. I_K is the integrated intensity assigned to the K th Bragg reflection at the end of the refinement cycles, and F_K is the crystal structure factor. The subscripts obs and cal with each notation are added to the meaning of the observed value and the calculated value. For the subscripts “obs”, I_K and F_K are not purely observed value except for the isolated reflections; thus it is estimated-observation-value obtained from programmatic allocation using the refinement parameters after the Rietveld analysis. R -expected, R_e , is the R_{wp} of the minimum expected statistically

$$R_e = \left[\frac{N - P}{\sum_i w_i (y_{i,obs})^2} \right]^{\frac{1}{2}}, \quad (7)$$

where N is the number of all the data and P the number of refined parameters.

Fig. 2. Observed (+), calculated (solid line), and difference ($\Delta I = I_{\text{obs}} - I_{\text{cal}}$) patterns for the Rietveld refinement from the X-ray powder diffraction data of $\text{AgCa}_2\text{Mn}_2\text{V}_3\text{O}_{12}$. The short vertical lines below the profiles mark the peak positions of all the possible Bragg reflections.

3. Results and discussion

Extremely high-purity specimen of $\text{AgCa}_2\text{Mn}_2\text{V}_3\text{O}_{12}$ has been prepared. On the other hand, a small amount of unknown impurity has been mixed in specimen of $\text{NaPb}_2\text{Mn}_2\text{V}_3\text{O}_{12}$. This unknown impurity could not be eliminated completely, although the reaction temperature was changed from 973 K to 1073 K, and the other solid-state chemical reactions using other starting materials were attempted.

Colors of both $\text{AgCa}_2\text{Mn}_2\text{V}_3\text{O}_{12}$ and $\text{NaPb}_2\text{Mn}_2\text{V}_3\text{O}_{12}$ powder specimens were brown. In the vanadium garnets $\text{AgCa}_2\text{M}_2\text{V}_3\text{O}_{12}$ and $\text{NaPb}_2\text{M}_2\text{V}_3\text{O}_{12}$, those colors have been known to change drastically due to M^{2+} ion at the A-site in octahedron [9, 15-17]. For example, colors of the vanadium garnets are reported to be dark green for $\text{AgCa}_2\text{Co}_2\text{V}_3\text{O}_{12}$ [16], yellow for $\text{AgCa}_2\text{Ni}_2\text{V}_3\text{O}_{12}$ [16], white for $\text{AgCa}_2\text{Mg}_2\text{V}_3\text{O}_{12}$ [9], dark brown for $\text{AgCa}_2\text{Cu}_2\text{V}_3\text{O}_{12}$ [15], yellowish-white for $\text{AgCa}_2\text{Zn}_2\text{V}_3\text{O}_{12}$ [15], dark green for $\text{NaPb}_2\text{Co}_2\text{V}_3\text{O}_{12}$ [17], and yellow for $\text{NaPb}_2\text{Ni}_2\text{V}_3\text{O}_{12}$ [17].

The diffraction peaks in the XRD patterns for both vanadium garnets were indexed on the basis of cubic symmetry with space group $Ia-3d$ except for one peak of unknown impurity in the specimen of $\text{NaPb}_2\text{Mn}_2\text{V}_3\text{O}_{12}$. The indices, the comparisons of d spacings between the calculated and the observed values, the observed peak intensities for $\text{AgCa}_2\text{Mn}_2\text{V}_3\text{O}_{12}$ and $\text{NaPb}_2\text{Mn}_2\text{V}_3\text{O}_{12}$ are listed in Tables 2 and 3.

The Rietveld refinements of the structures were carried out in the space group $Ia-3d$ with Ag^+ and Ca^{2+} (or Na^+ and Pb^{2+}) at the $24c$ -sites ($1/8, 0, 1/4$), Mn^{2+} at the $16a$ -sites ($0, 0, 0$), V^{5+} at the $24d$ -sites ($3/8, 0, 1/4$), and O^{2-} at the $96h$ -sites (x, y, z). The structure parameters reported for

Fig. 3. Observed, calculated, and difference patterns for the Rietveld refinement from the X-ray powder diffraction data of $\text{NaPb}_2\text{Mn}_2\text{V}_3\text{O}_{12}$.

$\text{AgCa}_2\text{M}_2\text{V}_3\text{O}_{12}$ ($M = \text{Mn, Co, Ni}$) [10, 16] were used as a starting model. The lattice constants used as starting values were determined by the least-squares method with data of Tables 2 and 3. In the refinement of $\text{NaPb}_2\text{Mn}_2\text{V}_3\text{O}_{12}$, the 2θ range from 29.7° to 30.0° was excluded because of the existence of unknown impurity.

In Table 1, the resulting R -factors reached $R_{\text{wp}} = 13.74\%$, $R_{\text{p}} = 9.83\%$, $R_{\text{B}} = 4.67\%$, and $R_{\text{F}} = 5.55\%$, with a fit indicator of $S = R_{\text{wp}}/R_{\text{e}} = 1.33$ for $\text{AgCa}_2\text{Mn}_2\text{V}_3\text{O}_{12}$ and $R_{\text{wp}} = 12.18\%$, $R_{\text{p}} = 9.21\%$, $R_{\text{B}} = 3.75\%$, and $R_{\text{F}} = 3.12\%$, with $S = 1.33$ for $\text{NaPb}_2\text{Mn}_2\text{V}_3\text{O}_{12}$. The lattice constants were $a = 12.596(2) \text{ \AA}$ for $\text{AgCa}_2\text{Mn}_2\text{V}_3\text{O}_{12}$ and $a = 12.876(2) \text{ \AA}$ for $\text{NaPb}_2\text{Mn}_2\text{V}_3\text{O}_{12}$. Figs. 2 and 3 show observed, calculated, and difference patterns for the Rietveld refinements from the XRD data of $\text{AgCa}_2\text{Mn}_2\text{V}_3\text{O}_{12}$ and $\text{NaPb}_2\text{Mn}_2\text{V}_3\text{O}_{12}$, and Tables 4 and 5 list the final structure parameters of these vanadium garnets.

The lattice constants reported by Ronniger et al. [9] where $a = 12.596(5) \text{ \AA}$ for $\text{AgCa}_2\text{Mn}_2\text{V}_3\text{O}_{12}$ and $a = 12.861(5) \text{ \AA}$ for $\text{NaPb}_2\text{Mn}_2\text{V}_3\text{O}_{12}$, and the lattice constant obtained from single-crystal data was reported to be $a = 12.6084(9) \text{ \AA}$ for $\text{AgCa}_2\text{Mn}_2\text{V}_3\text{O}_{12}$ [10]. These values are in good agreement with our results.

Table 6 presents selected the interatomic distances and bond angles calculated from the XRD data of $\text{AgCa}_2\text{Mn}_2\text{V}_3\text{O}_{12}$ and $\text{NaPb}_2\text{Mn}_2\text{V}_3\text{O}_{12}$. For comparison, Table 6 also lists the interatomic distances and bond angles estimated from the single-crystal data of $\text{AgCa}_2\text{Mn}_2\text{V}_3\text{O}_{12}$ in the previous report [10]. Our new results obtained from the XRD data of $\text{AgCa}_2\text{Mn}_2\text{V}_3\text{O}_{12}$ are fairly close to those calculated from the single-crystal data. The interatomic distances were determined to be $2.150(3) \text{ \AA}$ for Mn-O and $1.698(3) \text{ \AA}$ for V-O in $\text{AgCa}_2\text{Mn}_2\text{V}_3\text{O}_{12}$, and $2.224(4) \text{ \AA}$ for Mn-O and $1.680(4) \text{ \AA}$ for V-O in $\text{NaPb}_2\text{Mn}_2\text{V}_3\text{O}_{12}$, respectively. The sum of Shannon's ionic radii [23] can be calculated at

2.230 Å for Mn²⁺-O²⁻ (CN 6, HS) and 1.735 Å for V⁵⁺-O²⁻ (CN 4), which is reasonable agreement with the interatomic distances obtained by our Rietveld refinements. These results support that Mn has divalent and V has pentavalent.

To discuss oxidation state of Mn and V, the bond valence sum [24] was estimated with a computer program VICS [25]. The bond valence sum, V_i , can be considered as oxidation number of cation *i* located in the coordination polyhedron by oxygen ions *j* and is given by the empirical formula,

$$V_i = \sum_j S_{ij} = \sum_j \exp\left(\frac{l_0 - l_{ij}}{0.37}\right), \quad (8)$$

where S_{ij} is the bond valence, l_{ij} the interatomic distance, and l_0 the bond valence parameter ($l_0 = 1.790$ for Mn²⁺ and $l_0 = 1.803$ for V⁵⁺ [26]). The bond valence sum of Mn was calculated at 2.3 for AgCa₂Mn₂V₃O₁₂ and 1.9 for NaPb₂Mn₂V₃O₁₂, and that of V was estimated to be 5.3 for AgCa₂Mn₂V₃O₁₂ and 5.6 for NaPb₂Mn₂V₃O₁₂, respectively. Usually, the bond valence sums contain variations of about 10 % even in typical compounds, such as MnO and V₂O₅, which would be attributed to accuracy of the interatomic distances and feature of the empirical formula. Therefore, it can be considered that Mn is divalent and V is pentavalent. We are going to clarify the oxidation state of these ions from the study of their magnetism in the future works.

To investigate distortion of the MnO₆ octahedra and the VO₄ tetrahedra in both AgCa₂Mn₂V₃O₁₂ and NaPb₂Mn₂V₃O₁₂, their octahedral quadratic elongation, $\langle \lambda_{\text{oct}} \rangle$, tetrahedral quadratic elongation, $\langle \lambda_{\text{tet}} \rangle$, octahedral bond angle variance, σ_{oct}^2 , and tetrahedral bond angle variance, σ_{tet}^2 , [27] were also calculated with the VICS [25]. The quadratic elongation was evaluated using the formulae,

$$\langle \lambda_{\text{oct}} \rangle = \sum_{i=1}^6 \frac{(l_i/l)^2}{6}; \quad (9)$$

Table 6

Selected interatomic distances (Å) and bond angles (°) calculated from the X-ray powder diffraction data (this work) and the single crystal data (in Ref. [10]) of $\text{AgCa}_2\text{Mn}_2\text{V}_3\text{O}_{12}$ and $\text{NaPb}_2\text{Mn}_2\text{V}_3\text{O}_{12}$

Symmetry codes: (a) z, x, y ; (b) $1/2 + x, y, 1/2 - z$; (c) $x, -y, 1/2 - z$; (d) $1/4 - z, -1/4 + y, 1/4 + x$; (e) $1/4 - z, 1/4 - y, 1/4 - x$; (f) $1/4 - x, 1/4 - z, 1/4 - y$; (g) $z, -x, 1/2 - y$; (h) $-z, -x, -y$; (i) $1/2 + x, -y, z$; (j) $1/4 - x, -1/4 + z, 1/4 + y$.

$$\langle \lambda_{\text{tet}} \rangle = \frac{\sum_{i=1}^4 (l_i/l)^2}{4}, \quad (10)$$

where l_i is the distance from Mn or V to i th O, and l is the center-to-vertex distance of a regular octahedron or tetrahedron with the same volume. The bond angle variance for the octahedron and the tetrahedron was calculated with,

$$\sigma_{\text{oct}}^2 = \frac{\sum_{i=1}^{12} (\theta_i - 90^\circ)^2}{11}; \quad (11)$$

$$\sigma_{\text{tet}}^2 = \frac{\sum_{i=1}^6 (\theta_i - 109.47^\circ)^2}{5}, \quad (12)$$

where θ_i is the i th bond angle. From the crystal data obtained by the Rietveld refinements from the XRD data, these parameters were calculated at $\langle \lambda_{\text{oct}} \rangle = 1.00$, $\langle \lambda_{\text{tet}} \rangle = 1.01$, $\sigma_{\text{oct}}^2 = 1.00 \text{ degree}^2$, and $\sigma_{\text{tet}}^2 = 29.8 \text{ degree}^2$ for $\text{AgCa}_2\text{Mn}_2\text{V}_3\text{O}_{12}$ and $\langle \lambda_{\text{oct}} \rangle = 1.00$, $\langle \lambda_{\text{tet}} \rangle = 1.00$, $\sigma_{\text{oct}}^2 = 9.34 \text{ degree}^2$, and $\sigma_{\text{tet}}^2 = 17.4 \text{ degree}^2$ for $\text{NaPb}_2\text{Mn}_2\text{V}_3\text{O}_{12}$, respectively. The calculated values of $\langle \lambda_{\text{oct}} \rangle$ and $\langle \lambda_{\text{tet}} \rangle$ are

close to 1, and those of σ_{oct}^2 and σ_{tet}^2 are quite smaller than those of typical garnet-type compounds, e.g., $\sigma_{\text{oct}}^2 = 45.6 \text{ degree}^2$ and $\sigma_{\text{tet}}^2 = 66.8 \text{ degree}^2$ for $\text{Y}_3\text{Fe}_5\text{O}_{12}$ [28]. This finding shows that the MnO_6 octahedra and the VO_4 tetrahedra for both garnets are hardly distorted. For comparison, the quadratic elongation and the bond angle variance for the some garnets that same ions occupy both A- and D-sites, e.g., $\text{R}_3\text{Fe}_5\text{O}_{12}$, $\text{R}_3\text{Al}_5\text{O}_{12}$, and $\text{R}_3\text{Ga}_5\text{O}_{12}$ (R = rare earth element), were evaluated from the crystallographic data registered in the Inorganic Crystal Structure Database (ICSD) [29]. The values calculated for $\text{AgCa}_2\text{Mn}_2\text{V}_3\text{O}_{12}$ and $\text{NaPb}_2\text{Mn}_2\text{V}_3\text{O}_{12}$ were significantly lower than those for $\text{R}_3\text{M}_5\text{O}_{12}$ (M = Fe, Al, Ga). Thus, the distortions of the MnO_6 octahedra and the VO_4 tetrahedra in the vanadium garnets are significantly suppressed, comparing with those of the MO_6 octahedra and the MO_4 tetrahedra in $\text{R}_3\text{M}_5\text{O}_{12}$ (M = Fe, Al, Ga).

Finally, the lattice constants of $\text{AgCa}_2\text{Mn}_2\text{V}_3\text{O}_{12}$ and $\text{NaPb}_2\text{Mn}_2\text{V}_3\text{O}_{12}$ are compared with those obtained by the previous workers. When the combination of ions at the C-site in $\{\text{C}_3\}\text{Mn}_2\text{V}_3\text{O}_{12}$ changes from AgCa_2 to NaPb_2 , the increment in the lattice constant is 0.28 \AA ($= 12.876(2) - 12.596(2) \text{ \AA}$). Commensurable increments are also found between $\text{AgCa}_2\text{M}_2\text{V}_3\text{O}_{12}$ and $\text{NaPb}_2\text{M}_2\text{V}_3\text{O}_{12}$ (M = Mg, Co, Ni, Zn), for example, 0.27 \AA for M = Co and 0.26 \AA for M = Ni [9, 15-17]. On the other hand, the lattice constant strongly depends on the ionic radii of the A-site cations and linearly increased with increasing of the ionic radius when the same combination of cations locates in the C-site. In addition, the Ag/Ca-O and V-O distances in $\text{AgCa}_2\text{MV}_3\text{O}_{12}$ (M = Mn, Co, Ni) are independent of size of M cation at A-site. For instance, Ag/Ca-O distances are $2.471(3) \text{ \AA}$ and $2.597(4) \text{ \AA}$ for $\text{AgCa}_2\text{Mn}_2\text{V}_3\text{O}_{12}$, $2.457(3) \text{ \AA}$ and $2.574(3) \text{ \AA}$ for $\text{AgCa}_2\text{Co}_2\text{V}_3\text{O}_{12}$, and $2.444(2) \text{ \AA}$ and $2.570(2) \text{ \AA}$ for $\text{AgCa}_2\text{Ni}_2\text{V}_3\text{O}_{12}$, respectively [16].

Acknowledgments

The authors would like to thank Mr T. Yamagishi for his helpful experimental collaboration. This research was supported by the Research Fellowships of the Japan Society for the Promotion of Science for Young Scientists (18-1415).
