## 1 **ABSTRACT**

2 The Manual on Uniform Traffic Control Devices (MUTCD) specifies minimum retroreflectivity  
3 requirements that include an obligation for agencies to develop a strategy for maintaining  
4 compliance. States were given a deadline of January 1, 2012 for the implementation of an  
5 assessment or management plan, which led to an increased emphasis on sign asset management.  
6 However, a new rule was submitted to the federal register to extend and modify the deadlines.  
7 With budget considerations it is important that a transportation agency implement an assessment  
8 or management plan that is efficient and provides compliance with the standards required by the  
9 Manual on Uniform Traffic Control Devices (MUTCD). The development of an efficient plan  
10 requires knowledge of the overall condition of an agency's assets as well as unique  
11 considerations regarding their performance. Through a review of previous data collection  
12 efforts, this paper details the development of a data collection strategy for assessing the  
13 performance of traffic signs maintained by the Utah Department of Transportation (UDOT).  
14 Agency operations, site selection, and attribute collection were all considered while developing a  
15 collection plan for an agency where limited inventory and installation data was available.  
16 Retroreflectivity measurements were taken for 1,433 UDOT signs. This sample provided a  
17 snapshot of current compliance and assisted in the selection of an asset management plan for  
18 maintaining sign retroreflectivity. Results from the study showed that UDOT's signs were well  
19 over 90% compliant to the MUTCD standards and preliminary management strategies were  
20 presented to address vandalism and other damage.

## 21 22 **INTRODUCTION**

23 Establishing standards for minimum levels of retroreflectivity for traffic signs was first directed  
24 by the Congress to the Secretary of Transportation in 1992. This congressional mandate  
25 established the foundation for the adoption of new language into the second addition of the 2003  
26 Manual for Uniform Traffic Control Devices (MUTCD). The necessity for a sign management  
27 program comes from the necessity to comply with the MUTCD standards, as well as a need to  
28 efficiently allocate maintenance funds.

29 The MUTCD currently contains the mandate that by the year 2012 "Public agencies or  
30 officials having jurisdiction shall use an assessment or management method that is designed to  
31 maintain retroreflectivity" (*I*) at a level that is at or above the minimum retroreflectivity levels  
32 that are provided. However, a new rule has been proposed to modify the current retroreflectivity  
33 regulations. As guidance, the MUTCD provides six assessment and management methods for  
34 complying with this mandate. These methods are:

- 35 A. Visual Nighttime Inspection
- 36 B. Measured Sign Retroreflectivity
- 37 C. Expected Sign Life
- 38 D. Blanket Replacement
- 39 E. Control Signs

40  
41 Methods A and B are classified as assessment methods and methods C, D, and E are  
42 classified as management methods for complying with the minimum retroreflectivity level  
43 standards. Each assessment or management method is designed to maintain the minimum  
44 retroreflectivity levels shown in Table 1.

45 Agencies are required to ensure that all traffic signs in their jurisdiction that are not  
46 explicitly excluded in the MUTCD be in compliance with these standards. Currently the signs

1 must be compliant by the year 2015 for regulatory, warning, or post-mounted guide signs and the  
 2 year 2018 for street sign names and overhead guide signs although. At this time, it has been  
 3 proposed that the MUTCD be amended to remove these compliance dates, but the minimum  
 4 levels to be maintained are to remain for regulatory and warning signs. With budget  
 5 considerations and constraints, it is important that transportation agencies select a management  
 6 or assessment method that will best meet the agencies compliance needs, while doing so in the  
 7 most efficient manner possible. Each individual method requires varying types and degrees of  
 8 agency resources and carries their individual costs in ensuring an acceptable degree of overall  
 9 compliance.

10  
 11

**TABLE 1: Minimum Retroreflectivity Levels**

Sign Color	Sheeting Type (ASTM D4956-04)				Additional Criteria
	Beaded Sheeting			Prismatic Sheeting III, IV, VI, VII, VIII, IX, X	
	I	II	III		
White on Green	W*; G ≥ 7	W*; G ≥ 15	W*; G ≥ 25	W ≥ 250; G ≥ 25	Overhead
	W*; G ≥ 7	W ≥ 120; G ≥ 15			Post-mounted
Black on Yellow or Black on Orange	Y*; O*	Y ≥ 50; O ≥ 50			2
	Y*; O*	Y ≥ 75; O ≥ 75			3
White on Red	W ≥ 35; R ≥ 7				4
Black on White	W ≥ 50				–
<sup>1</sup> The minimum maintained retroreflectivity levels shown in this table are in units of cd/lx/m <sup>2</sup> measured at an observation angle of 0.2° and an entrance angle of -4.0°. <sup>2</sup> For text and fine symbol signs measuring at least 48 inches and for all sizes of bold symbol signs <sup>3</sup> For text and fine symbol signs measuring less than 48 inches <sup>4</sup> Minimum sign contrast ratio ≥ 3:1 (white retroreflectivity ÷ red retroreflectivity) * This sheeting type shall not be used for this color for this application.					
<b>Bold Symbol Signs</b>

<b>Fine Symbol Signs (symbol signs not listed as bold symbol signs)</b>					
<b>Special Cases</b>					
<ul style="list-style-type: none"> <li>• W3-1 – Stop Ahead: Red retroreflectivity ≥ 7</li> <li>• W3-2 – Yield Ahead: Red retroreflectivity ≥ 7; White retroreflectivity ≥ 35</li> <li>• W3-3 – Signal Ahead: Red retroreflectivity ≥ 7; Green retroreflectivity ≥ 7</li> <li>• W3-5 – Speed Reduction: White retroreflectivity ≥ 50</li> <li>• For non-diamond shaped signs, such as W14-3 (No Passing Zone), W4-4P (Cross Traffic Does Not Stop), or W13-1P,2,3,6,7 (Speed Advisory Plaques), use the largest sign dimension to determine the proper minimum retroreflectivity level.</li> </ul>					

12  
 13

14 Selecting an appropriate management or assessment method to efficiently maintain sign  
 15 retroreflectivity requires an understanding of the conditions and factors unique to a particular  
 16 agency. Additionally, it is important to understand the degree of current overall compliance with  
 17 minimum standards when establishing policy to manage any of an agency's assets. In order to  
 18 facilitate this, it is imperative that agencies collect information regarding the state and condition  
 19 of their assets.

20 The objective of this research is to provide a data collection and analysis procedure that  
 21 will assist in the development a sign asset management strategy to comply with the minimum  
 22 retroreflectivity levels stipulated in the MUTCD. The purpose of data collection is to provide a  
 23 quantitative assessment of overall compliance with minimum retroreflectivity levels, which will  
 24 give guidance in the selection of a management method to ensure future compliance. The data  
 25 collected is analyzed to provide insight regarding the current state, performance, and special

1 considerations relating to the Utah Department of Transportation's (UDOT) sign assets. This  
2 paper provides detail of the data collection effort, analysis of the collected data, and then shows  
3 how the data collected influenced the sign management strategy for UDOT.

## 4 5 **BACKGROUND**

6 Each assessment or management method requires some degree of understanding of an agencies  
7 sign assets and how they are performing over time. Beyond just meeting the minimum  
8 retroreflectivity conformance criteria, sheeting performance, damage rates, maintenance, and  
9 overall visibility should all be considered when developing a sign asset management program.

10 In the past, the majority of data collection efforts for the retroreflectivity of traffic signs  
11 have been focused upon understanding how the retroreflectivity of traffic signs deteriorates (2)  
12 (3) (4). For development of an asset management strategy to comply with the then proposed  
13 minimum levels of retroreflectivity of signs in North Carolina, a study was performed that  
14 reviewed various approaches to managing retroreflectivity (5). The work focused on the  
15 collection of retroreflectivity data and its use in the evaluation of the effectiveness of current  
16 inspection methods as well as the potentials of implementing various management strategies.  
17 The field data collection portion of the project was concerned with field inventories and  
18 compliance as well as the effectiveness of various methods of maintaining retroreflectivity.  
19 Collecting data with this focus provided a framework for which cost analyses and operational  
20 performance may be evaluated.

21 Research performed for the Louisiana Department of Transportation & Development  
22 evaluated data collection procedures with respect to the use of computer based technologies  
23 including GIS, GPS and inventory equipment. (6) Key attributes were collected in order to allow  
24 for assessment of the possibility of performing larger scale inventories. The collection area was  
25 selected for its widely varied functional road classification as well as a variation of in the  
26 commercialization of its regions. The data collection procedure was designed to provide a basis  
27 for future analyses and to assist in future decision making.

28 There have been various other data collection efforts where the data collection  
29 methodology was explicitly designed in order to achieve specific goals. These goals range from  
30 assisting with the management of retroreflectivity, to modeling the deterioration of  
31 retroreflectivity over time. Researchers at Purdue University collected retroreflectivity  
32 measurements for 800 Type I and Type III signs where sign age was known over a 20-year  
33 period. The data was collected for the development of survival curves for Type I and Type III  
34 sheeting. The resulting curves were to assist in determining replacement costs and assessment  
35 cycles when managing the retroreflectivity of traffic signs. The results were limited though, as  
36 not all Type I and Type III sheeting is alike and cannot be combined for failure prediction. (7)

37 In studying in-service Type III high intensity traffic signs in Texas, researchers  
38 developed a collection plan that included sampling procedures to account for sign densities and  
39 varying site conditions. (8) The collection focused on regional areas that displayed distinctive  
40 characteristics. This study did not provide a data collection procedure to assess overall  
41 conformance with minimum standards. However, such targeted attribute collection will provide a  
42 basis to evaluate special considerations relevant to an agency's assets.

43 Pierce County in Washington State found that a sign inventory that included  
44 retroreflectivity measurements proved useful in assisting with the selection of a sign  
45 management strategy. (9) The county found that the data collected was beneficial for managing  
46 their traffic signs. Additionally their inventory provided an approximation of the control group

1 size needed to maintain a desired degree of reliability in estimating the representation of the  
2 overall population. For other agencies retroreflectivity measurements have been found  
3 instrumental in assisting to evaluating compliance with required minimum standards. (10) Such  
4 an inventory provides significant assistance in identifying issues with the performance of assets  
5 currently in use.

6 The collection of field data is the first step in the development of an efficient  
7 management plan. Past experience has proven that the proper selection of samples, procedural  
8 methodology, and attribute collection is crucial when trying to identify performance and  
9 compliance issues within an agency's assets. Great care must be taken in the development of a  
10 data collection procedure to ensure that potential issues may easily be identified and that results  
11 of the collection may be utilized for planning and policy making.

## 12 13 **DATA COLLECTION METHODOLOGY**

14 The necessity for a sign management program comes from the need to comply with the MUTCD  
15 standards and by necessity. Increasingly limited budgets and resources provide challenges for  
16 state DOTs to allocate their maintenance funds efficiently. The allocation of limited resources  
17 must be based on the analysis of various options and tradeoffs and decisions must be made with  
18 quality information (11).

19 In order to develop a data collection plan that facilitates a transportation agency's need to  
20 efficiently manage assets, special consideration must be taken when developing a data collection  
21 strategy. The purpose of data collection is to provide a quantitative assessment of overall  
22 compliance with minimum retroreflectivity levels, which will give guidance in the selection of a  
23 management method to ensure future compliance. When developing the data collection  
24 procedure it is important to include considerations that can directly affect the selection,  
25 methodology, and procedure of a particular plan. These considerations include: agency  
26 operations, site selection, sign attribute selection, and procedural methodology.

### 27 28 **Agency Operations**

29 Understanding the operational procedures of an agency is instrumental for evaluating the  
30 feasibility of asset management options as well as providing a context for data collection. Using  
31 prior inventory efforts and understanding data management procedures within UDOT provided  
32 key information for developing a collection strategy. Recent efforts by UDOT in developing a  
33 central database for transportation assets proved beneficial. The database provided information  
34 including an inventory of sign retroreflectivity conducted between 1999 and 2001.

### 35 36 **Site Selection**

37 Collection sites were selected to be representative of signs within the state to provide an overall  
38 snapshot of compliance and conditions present within different geographic areas. It is critical  
39 that the sample provide the best representation possible of the overall population given the  
40 resources available. The structure of UDOT consists of four administrative regions.

41 Each region is subdivided into maintenance stations where maintenance is overseen at the  
42 local level. In Utah, maintenance strategies are directed and overseen at the region level. As  
43 noted in the Texas study (8), there can be difficulty in establishing a sample set that is truly  
44 representative of the overall condition of signs as sign densities vary greatly and costs must be  
45 considered when establishing a sample set. In the case of UDOT with maintenance efforts

1 varying greatly by region and individual maintenance sheds it was important to provide a  
2 representative sample.

3 To establish an overall sample, sign data was collected for locations that were  
4 representative of each region. From reviewing previous inventory efforts within the state,  
5 junction areas between state routes were identified as containing among the highest densities of  
6 traffic signs. For this reason routes were selected that had a high junction density. Along with  
7 the high sign density, junctions also contained a wide variety of sign color. To better represent  
8 the variation of maintenance and construction activities between stations and regions on highway  
9 segments, signs of every color were collected in intervals of five to fifteen miles. The survey  
10 team, who based the decision on sign density and geographic conditions present along the route,  
11 determined the intervals. Because canyon routes represent unique situations in Utah and  
12 contained high densities of signs, data was collected every five miles whereas data on rural roads  
13 were collected every fifteen miles. These intervals were used to provide an adequate  
14 representation of the overall sign population.

15

### 16 **Sign Attribute Selection**

17 To analyze and determine special considerations unique to Utah with regards to sign asset  
18 management, specific attribute data was collected for signs. All data was recorded with a hand  
19 held GPS unit that included a customized data dictionary to enter information. Attributes  
20 recorded in the hand held GPS unit included background color, sheeting type, retroreflectivity  
21 measurements, orientation, mount height, offset, installation date, and major and minor damage.  
22 Identification of sheeting types was accomplished by applying the Federal Highway  
23 Administrations identification guide (12). Retroreflectivity measurements were taken with the  
24 use of a Delta RetroSign Model 4500 retroreflectometer. The Model 4500 illuminates the sign at  
25 a  $-4^{\circ}$  angle with the angle of observation being  $0.2^{\circ}$ . In addition to recording information in the  
26 hand held GPS unit photographs were taken of every surveyed sign and linked to the data to  
27 further classify any damage or vandalism.

28 In order to classify damage issues of the signs and the associated effects on  
29 retroreflectivity five damage categories, shown in FIGURE 1, were used during the collection  
30 process. Damage categories included bending, peeling, vandalism, cracking, and other. These  
31 categories are defined as follows:

- 32 • *Bending damage* describes signs that had significant portions of the sheeting bent  
33 causing light to be reflected away from its origin.
- 34 • *Peeling damage* applies to the legend of a sign peeling off of the background  
35 sheeting.
- 36 • *Vandalism* is the most diverse category of damage and included damage caused by  
37 paintballs, bullet holes, beer bottle impacts, stickers, and graffiti.
- 38 • *Cracking damage* was only present upon Type I sheeting signs and consisted of the  
39 retroreflective background cracking and degrading over time.
- 40 • Other forms of damage recorded were fading, tree rubbing, and tree sap.

A. Bending Damage

B. Peeling Damage

C. Vandalism

D. Cracking Damage

E. Other Damage Types

---

**FIGURE 1** Damage Categories.

1  
2  
3

1 **Installation Data**

2 Because of the limited installation data, additional effort was taken to collect sign data where  
 3 installation information was known. Since 2008, UDOT has mandated that all signs placed into  
 4 the field have an installation sticker on both the front and back of the sign. Typically the sticker  
 5 on the front of the sign has a transparent background with a black legend for the year it was  
 6 installed, whereas the back contains the month and year of installation and the company that  
 7 constructed the sign. Although mandatory since 2008, compliance with this policy was not  
 8 consistently adopted by the stations and contractors installing signs for UDOT.

9  
 10 **Collection Procedure**

11 After a few preliminary trails it was determined that the data collection would be performed by a  
 12 three-man team to increase safety and efficiency of the data collection process. For increased  
 13 efficiency each man would have specific task to complete for the various sign attributes.  
 14 Researcher one was the driver of the vehicle and was in charge of loading and unloading the  
 15 ladder as well as taking retroreflectivity measurements. Researcher two was the front seat  
 16 passenger and was in charge of entering data into the hand held GPS unit. Researcher three was  
 17 in charge of taking photographs and sign measurements. The sign survey process was broken up  
 18 into three sequential stages: the (1) setup, (2) measurement, and (3) teardown.

19 As the member of the research team took the retroreflectivity measurements, the other  
 20 members of the team began to enter attributes of the sign into the GPS unit. Following this  
 21 survey process the research team was able to measure on average 15 signs per hour, which is  
 22 comparative to pervious collection projects (5). This average included the time spent traveling  
 23 between sign locations. In the case of a full sign inventory where sign densities were much  
 24 higher, this collection rate would likely prove much higher. It is also possible to increase this  
 25 rate by reducing the number of attribute measurements per sign.

26  
 27 **DATA ANALYSIS**

28 The research team measured a total of 1,433 signs, spanning UDOT’s four regions. The sample  
 29 size was approximately 1.5% of the 95,000 signs UDOT currently maintains. Expectedly, white  
 30 and yellow signs make up the majority of the surveyed signs. TABLE 2 displays a summary of  
 31 surveyed signs divided amongst UDOT’s four regions.

32  
 33 **TABLE 2 Surveyed Sign Summary**

Region	Signs by Color then Type																				Total			
	Red					White					Yellow					Green								
	III	III	HIP	IX	XI	I	III	III	HIP	IX	XI	I	III	III	HIP	IX	XI	I	III	III		HIP	IX	XI
One	4	2	2	0	44	107	17	23	0	17	91	3	23	0	4	96	5	5	0					443
Two	12	13	7	0	0	6	35	19	8	1	15	6	6	1	0	4	8	6	1					148
Three	7	4	1	3	20	73	3	4	10	11	50	4	12	14	4	46	21	13	7					307
Four	86	12	4	13	13	100	18	21	9	7	81	35	26	8	7	58	4	18	15					535
Total	109	31	14	16	77	286	73	67	27	36	237	48	67	23	15	204	38	42	23					1433

34  
 35  
 36 In accordance with ASTM E1709-09, four measurements for both the retroreflective  
 37 background and legend, if applicable, were taken for each sign. These four measurements were  
 38 averaged in order to determine the signs overall retroreflectivity per the ASTM standard. During  
 39 the measurement of each sign, special considerations were taken to ensure that the

1 retroreflectometer was held vertical and steady against the sheeting as well as taking  
 2 measurements at the same four areas regardless of sign damage. FIGURE 2 displays box-and-  
 3 whisker plots for each sign type collected across all four UDOT regions. The vertical lines that  
 4 traverse the plots are the minimum retroreflectivity levels for each sheeting background type and  
 5 color.

6

### 7 **MUTCD Compliance**

8 One goal of this research was to take UDOT's limited sign inventory and installation data and  
 9 assess the current compliance rate for the new MUTCDs minimum retroreflectivity levels. For  
 10 the compliance rates presented within this research signs were only rejected if the  
 11 retroreflectivity was below minimum retroreflectivity levels. Though damage was reported and  
 12 categorized, a sign was never rejected purely based on damage alone. TABLE 3 displays the  
 13 compliance rate for the surveyed signs by sheeting type and color.

14

15

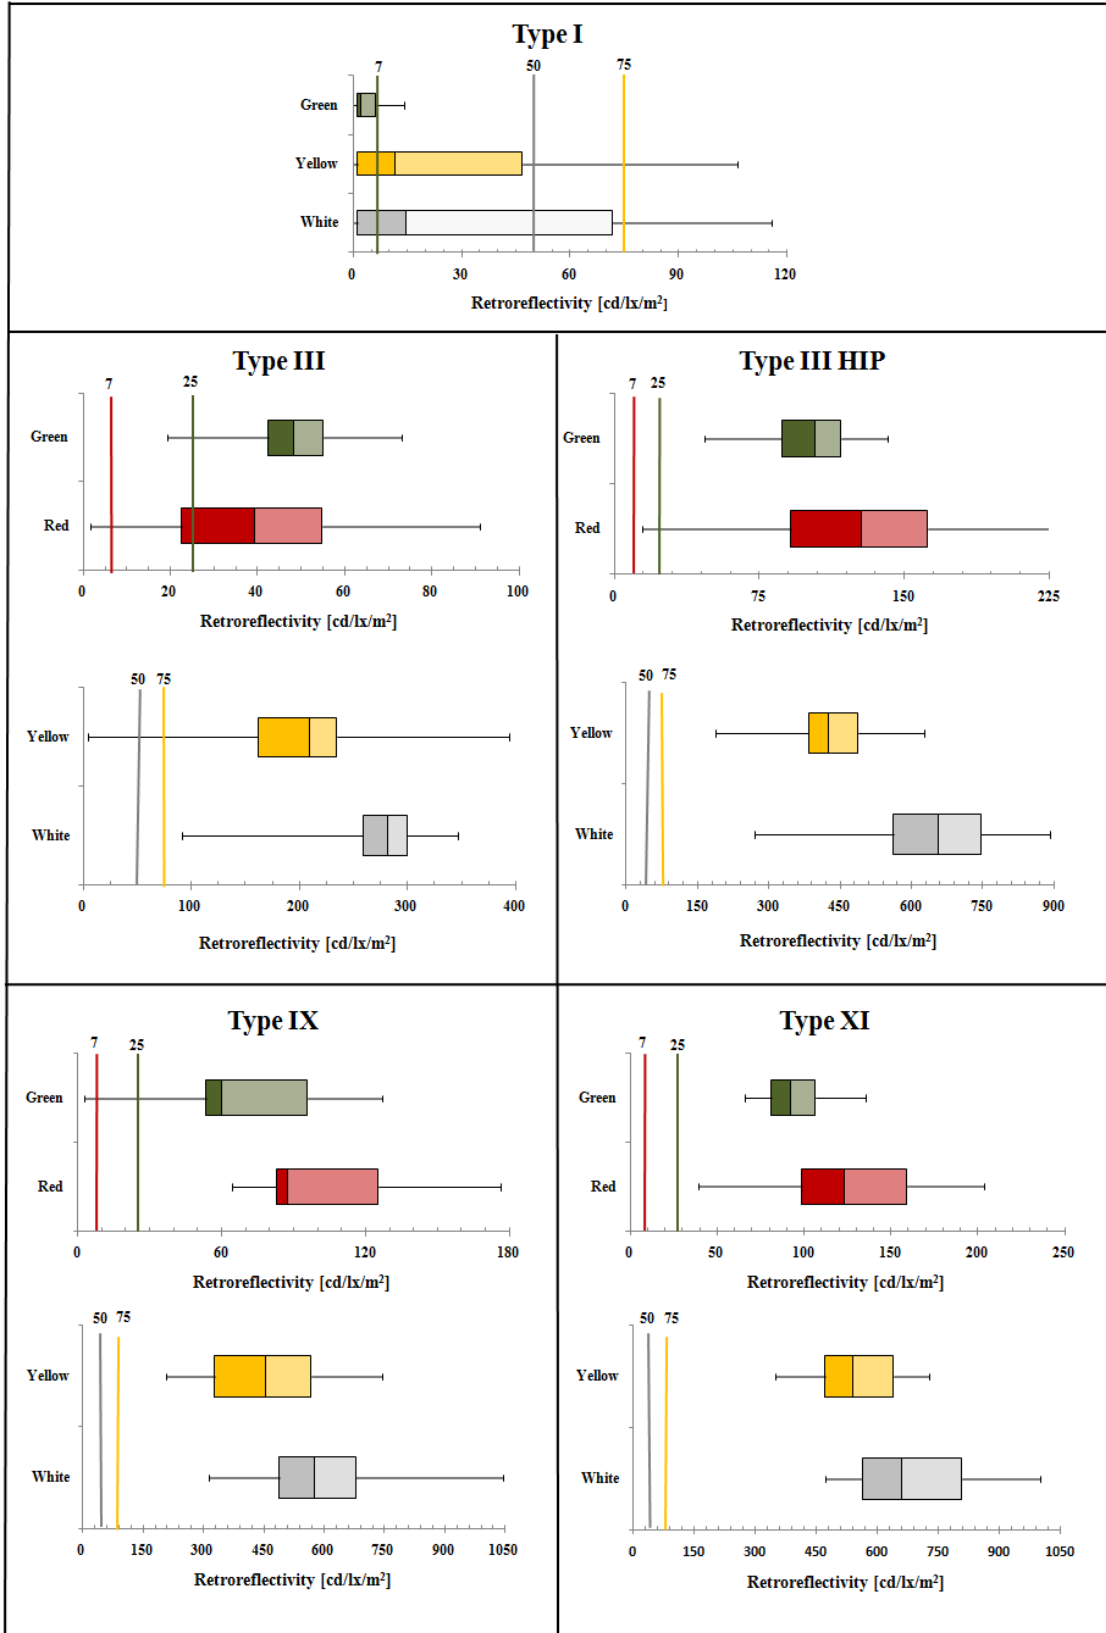

**TABLE 3 Compliance Summaries**

Color	Sheeting Type					Rejected
	I	III	III HIP	IX	XI	
Red	0	6	0	0	0	4%
White	46	0	0	0	0	9%
Yellow	33	20	0	0	0	13%
Green	9	3	2	5	0	6%
Rejected	69%	3%	1%	3%	0%	

16

17

18 The vast majority of all rejected signs were Type I and Type III. Although there were  
 19 seven rejections of Type IX sheeting, all of which were green, five were caused by legend  
 20 retroreflectivity and the remaining two were caused by special causes. For the six rejected red  
 21 signs, one was a stop sign and the remaining five were exclusion signs. For the overall sign  
 22 sample population the failure rate was 9 %

1

2

**FIGURE 2 – Retroreflectivity Box-and-Whisker Plots by Sheeting Type and Color**

### 1 *Type I Signs*

2 UDOT began phasing out the use of Type I sheeting due to its low levels of retroreflectance and  
3 corresponding short service life. At the completion of the survey period there was no Type I red  
4 sheeting signs surveyed. Comparing this to a retroreflectivity study conducted in 1999 where in  
5 Region 1 and Region 3 there were 177 red signs in service shows the concerted effort by UDOT  
6 to remove Type I signs.

7 The mean retroreflectivity level for Type I signs in the surveyed sample set was 36  
8 (cd/lx/m<sup>2</sup>) which is well below the minimum level of 50 (cd/lx/m<sup>2</sup>). Sixty percent of all Type I  
9 whites failed, which is triple the rate calculated from measurements taken in the 1999 study.  
10 White Type I signs had the high rate of cracking damage which is likely the root cause for the  
11 increase in failures. Although the majority of Type I white signs are most often non-compliant,  
12 there are a few examples that are still perform well. In the surveyed sample population Type I  
13 white were usually used for route identifications and speed limit signs.

14 Yellow Type I had the highest failure rate of any Type I sign color with 80% have  
15 retroreflective measurements below the minimum levels. This is an increase in the 77% failure  
16 determined from the 1999 retroreflectivity study. Yellow Type I had the high rate of vandalism  
17 and had mean retroreflective at a third of the minimum level.

18 Green backgrounds made up the smallest percentage of Type I sheeting with only 15  
19 being measured during the sign survey. Similar to the other Type I background colors, Green had  
20 a mean measurement, of 4 cd/lx/m<sup>2</sup>, that is below the minimum retroreflective level. Of the  
21 survey sample 75% of them measured below the minimum level.

### 22 23 *Type III Signs*

24 The UDOT Type III signs were performing rather well with only three percent failing. Values  
25 for Type III red ranged from a value of 12 to 91 cd/lx/m<sup>2</sup> with a mean of 38 and a standard  
26 deviation of 21. Of 111 signs collected there were only 6 failures. The failures were all old  
27 sheeting where visible damage and fading was present.

28 Of 204 Type III green measured only 2 signs were found to be failing. Values measured  
29 ranged from 19 to 73 cd/lx/m<sup>2</sup> with a mean of and standard deviation of 9 cd/lx/m<sup>2</sup>. Very few  
30 issues were found with the Type III green population where the only exceptions being signs that  
31 exhibited extreme fading and cracking.

32 The Type III yellow sample set contained the highest degree of variability with measured  
33 values ranging from 5 to 394 cd/lx/m<sup>2</sup>. The mean measurement of the Type III yellow signs was  
34 194 and the standard deviation 72. The majority of failed signs exhibited either extreme damage,  
35 weathering, or vandalism was present. Of all signs evaluated yellow sheeting was roughly three  
36 times more likely to display vandalism than any other sheeting. Damage was often visible from  
37 bullet holes, paintballs, and damage from projectiles thrown from vehicles such as glass bottles.

38 From the samples collected there were no Type III white sheeting failures. Observed  
39 values ranged from 91 to 394 cd/lx/m<sup>2</sup> with a mean 275 cd/lx/m<sup>2</sup> of and standard deviation of 36  
40 cd/lx/m<sup>2</sup>. The Type III population is performing extremely well with respect to compliance with  
41 the majority of signs well above the minimum required standards.

42 The Type III HIP population, though small, was performing very well within the state.  
43 Type III red values ranged from 15 to 225 cd/lx/m<sup>2</sup> with mean of 122 and a standard deviation of  
44 52.7. White values ranged between 270 to 890 cd/lx/m<sup>2</sup> with a mean of 646.8 and standard  
45 deviation of 142.4. Yellow values ranged between 189 to 627 cd/lx/m<sup>2</sup> with a mean of 434.6 and

1 standard deviation of 86. Green values ranged between 47 to 141 cd/lx/m<sup>2</sup> with a mean of  
2 101.2 and a standard deviation of 20.3.

3

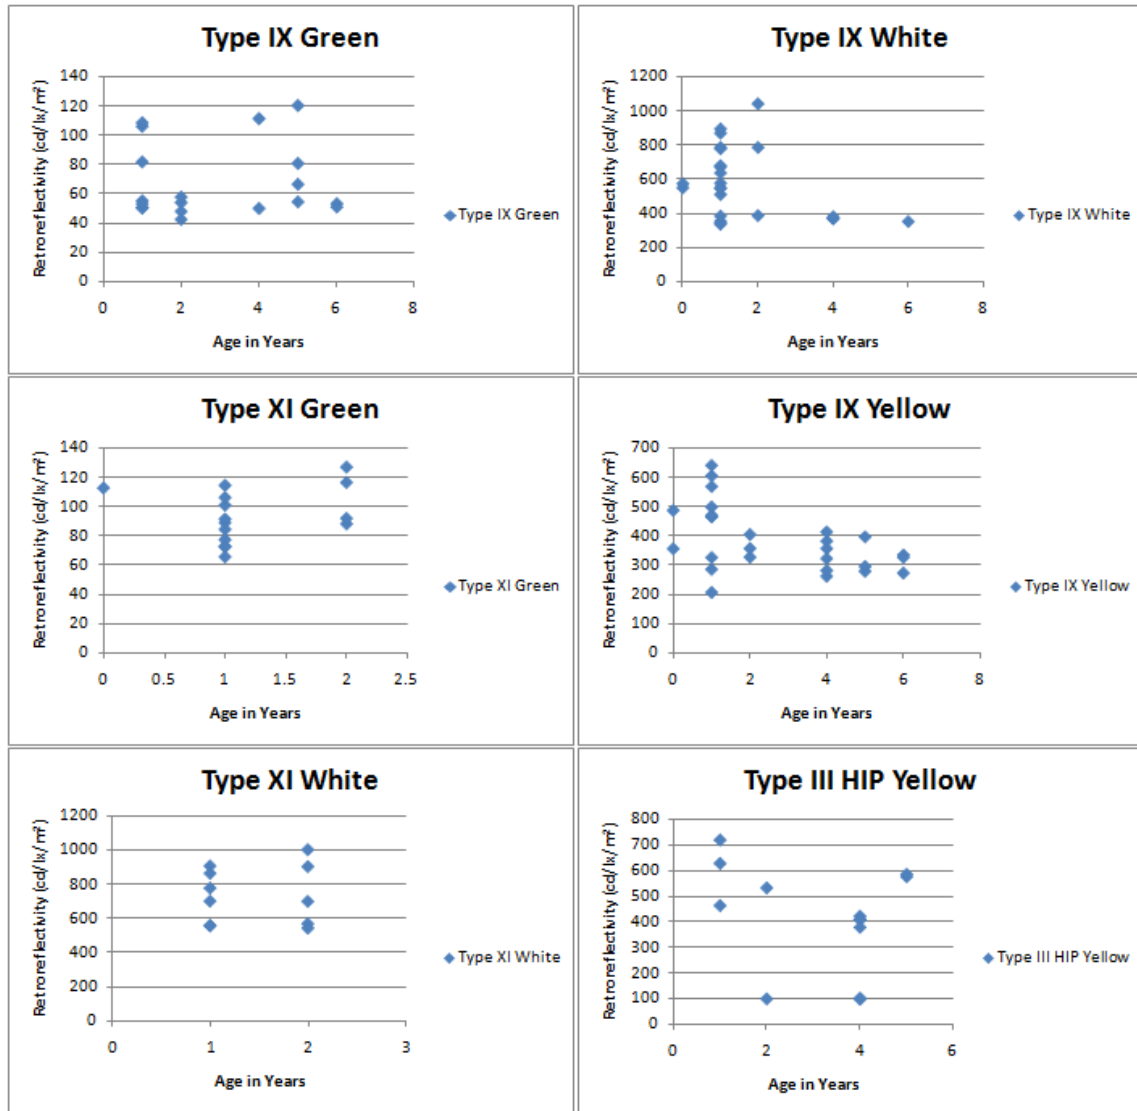

#### 4 *Type IX and XI Signs*

5 Type IX and Type XI are the newest sheeting in UDOT's overall sign population. Aside from a  
6 few exceptions with Type IX Green sheeting, the Type IX and Type XI sheeting were  
7 performing well beyond the minimum required levels. The mean and standard deviation for  
8 Type IX green was observed at 72.6 and 29.79 cd/lx/m<sup>2</sup> respectively. The green Type IX signs  
9 that exhibited low values were a result of a construction issue where Type IX green sheeting was  
10 overlaid upon Type IX white with the legend being cut from the green overlay. Signs with this  
11 construction exhibited extreme peeling problems and low retroreflectivity values in relatively  
12 new signs. There were no failures recorded for signs with red, white or yellow backgrounds for  
13 either Type IX or Type XI. The values for these sheeting types did vary greatly within sample  
14 populations.

15

#### 16 **Prismatic Sheeting Variance**

17 When collecting the sample sign data, inspectors noted a great degree in variation in the  
18 measurement of many recently placed traffic signs that utilized prismatic sheeting. This  
19 tremendous variation was evident when reviewing the plots for signs where installation dates  
20 where known. Because the tracking of sign installation data is a relatively new procedure for  
21 UDOT and has taken some time for implementation, the samples with known sign installation  
22 data was fairly low. Despite the small data set with known installation dates, an extreme degree  
23 of variation is clearly evident in signs that were recently placed as seen in FIGURE 3. These  
24 measurements were for signs that did not display signs of damage.

1  
2 **FIGURE 3 Retroreflectivity measurements of prismatic sheeting with installation dates.**

3 The greatest ranges of measurements were seen in Type IX, Type XI, and signs with  
4 white and yellow backgrounds. TABLE 4 provides an example of the range of values of  
5 measurements recorded by researchers for Type IX and Type XI signs that were placed within  
6 one year of inspection and had no visible damage or weathering.

7

1

**TABLE 4 Type IX and Type XI Placed Within 1 Year.**

Type	Retroreflective Measurements (cd/lx/m <sup>2</sup> )				
	Color	Mean	Standard Deviation	Low	High
IX	Green	78	23	51	109
IX	Yellow	455	141	208	643
IX	White	597	188	338	898
XI	Green	88	16	66	115
XI	White	725	149	554	904

Further evaluation of these signs identified a possible explanation to this variation regarding an issue of inefficiency with the construction of many of UDOT's newly placed traffic signs. The problem identified relates to the rotational sensitivity of the sheeting used for a large majority of signs placed within recent years. While the sheeting utilized by UDOT for many of their new signs is designed to be usable at any orientation, due to the utilization of cube corner retroreflection the sheeting is most effective when placed at a specific orientation. The range of values measured varies greatly depending on the orientation with which the sheeting was placed with much sheeting not being placed at the optimal orientation. This issue was discovered primarily for Type III HIP, Type IX, and Type XI Sheeting where signs throughout the state were discovered that the sheeting was oriented at varying degrees. This issue is further exaggerated when measurements are taken with a point retroreflectometer. FIGURE 4 shows an example of the range of values possible from sign construction with sheeting in varying conditions when sign sheeting is placed at varying orientations. The measurements were taken from three types of white sheeting currently being used by UDOT. FIGURE 4 also shows the signs at 0 and 90 degree orientations. With the sheeting on these signs it can be determined by orientation of the pattern seen in the white background.

21

22

**FIGURE 4 Rotational Sensitivity Example**

1 Similar distributions were found for other Type IX and Type XI sheeting currently being  
 2 utilized by UDOT. Sheeting placement in varying orientations was found for all background  
 3 color types. The majority of yellow signs constructed of any type of prismatic sheeting within  
 4 UDOT were discovered to be placed at an orientation less than optimal.

5 Damage and weathering are of particular concern in the development of an asset  
 6 management strategy to maintain compliant with minimum retroreflectivity requirements. Even  
 7 small amounts of damage that is visible during the daytime can have a large effect upon the signs  
 8 ability to convey messages under nighttime conditions. The overall percentage of damaged signs  
 9 varied greatly by region and environment. Damage was classified as either being major or minor  
 10 dependent upon the overall effect of the message of the sign. Major damage included any degree  
 11 of damage on the sign face that affected the legibility of the sign. TABLE 5 summarizes damage  
 12 rates throughout UDOT's regions.

13  
 14 **TABLE 5 Damage Rates by Region and Color**

Region	Damage By Region			
	% Damaged (All Types)		% Vandalized	
	Major	Minor	Major	Minor
One	30%	18%	12%	5%
Two	5%	14%	1%	5%
Three	26%	34%	12%	12%
Four	12%	22%	6%	9%

Region	Damage By Color			
	% Damaged (All Types)		% Vandalized	
	Major	Minor	Major	Minor
Red	13%	25%	5%	12%
White	18%	17%	6%	8%
Yellow	17%	27%	16%	10%
Green	14%	19%	5%	3%

15  
 16  
 17 **Conclusion**

18 With deadlines approaching for compliance with the MUTCD retroreflectivity requirements, this  
 19 research was intended to provide a data collection strategy to assist with state DOT planning and  
 20 policy development. With budgetary constraints it is imperative to utilize a strategy that will  
 21 provide both efficiency and compliance. In order to develop an efficient asset management  
 22 strategy there must be an understanding into how a particular agency's assets are performing and  
 23 what conditions are present that are affecting the overall performance and life of the assets. For  
 24 this reason particular emphasis is given on the procedure and methodology used when collecting  
 25 data for this purpose. It is important to gather the necessary information in a manner that  
 26 provides an overall representation of the agency's assets.

27 Previous experience informed the data collection strategy of this project and the  
 28 experiences of the research team helped inform the future data collection procedures as well as  
 29 the ability to highlight previously unknown issues to UDOT, such as the rotational sensitivity of  
 30 the signs. Many unique conditions and situations that directly affected traffic sign management

1 were found though the data collection procedure. As these considerations were identified and  
2 incorporated into the process the continuing insight provided for a better overall understanding  
3 of how the sign assets were performing.

4 Overall the sample sign survey provided a valuable assessment of overall compliance  
5 with the MUTCD minimum retroreflectivity requirements. Reviewing the data also identified  
6 issues with UDOT's sign construction and management that were previously unseen. Utilizing a  
7 methodology that included the collection of sign and sight condition attributes provided the  
8 information necessary to develop a retroreflectivity management plan that considers UDOT's  
9 own assets and the most economical and feasible steps to ensure compliance. Outside of Type I  
10 sheeting used by the state, the majority of UDOT's assets are currently in compliance with the  
11 new MUTCD standards (91%). With the complete removal of Type I signs the percentage of  
12 compliant signs would increase to 97%.

13 The data collected throughout the state, and the results from analysis of the data from this  
14 project, may now be used in the development of the plan. The high percentages of damaged  
15 signs found, as well as limited installation and service life performance data currently available  
16 to UDOT, indicate that an assessment method, either visually or through measurements, will best  
17 serve for maintaining retroreflectivity compliance until further information is available. The  
18 compliance rates of various sheeting types provided for quick assessments of alternatives for  
19 bringing the DOT's current assets up into compliance with MUTCD standards. Given the high  
20 failure rate of Type I signs within the state, an initial blanket replacement of all Type I signs and  
21 tracking the performance of the replacements would be very beneficial. The data collected also  
22 provides for operational changes that has potential of bringing greater efficiency and  
23 performance of UDOT's assets. By carefully planning the collection procedure, a better overall  
24 understanding of the materials and maintenance practices between maintenance stations and  
25 between regional oversight. Dividing collection proceedings in this manner allowed for better  
26 understanding and facilitated data collection that better represented the overall population. This  
27 information will be used to develop plans for the maintenance and coordinated replacement of  
28 signs for the state.
