

“Nascent Developments in Arctic Fisheries: Managing the Red King Crab in the Barents Sea”

Present and emerging Arctic fisheries

Distribution & Management Overview

- ✓ East Finnmark coast
- ✓ Purposeful Introduction at Kola, from N.Pacific
- ✓ 12% Barents coverage

History of Invasive Red King Crab

Scientific Commercial split management

RU had established unilateral quotas E26° REZ

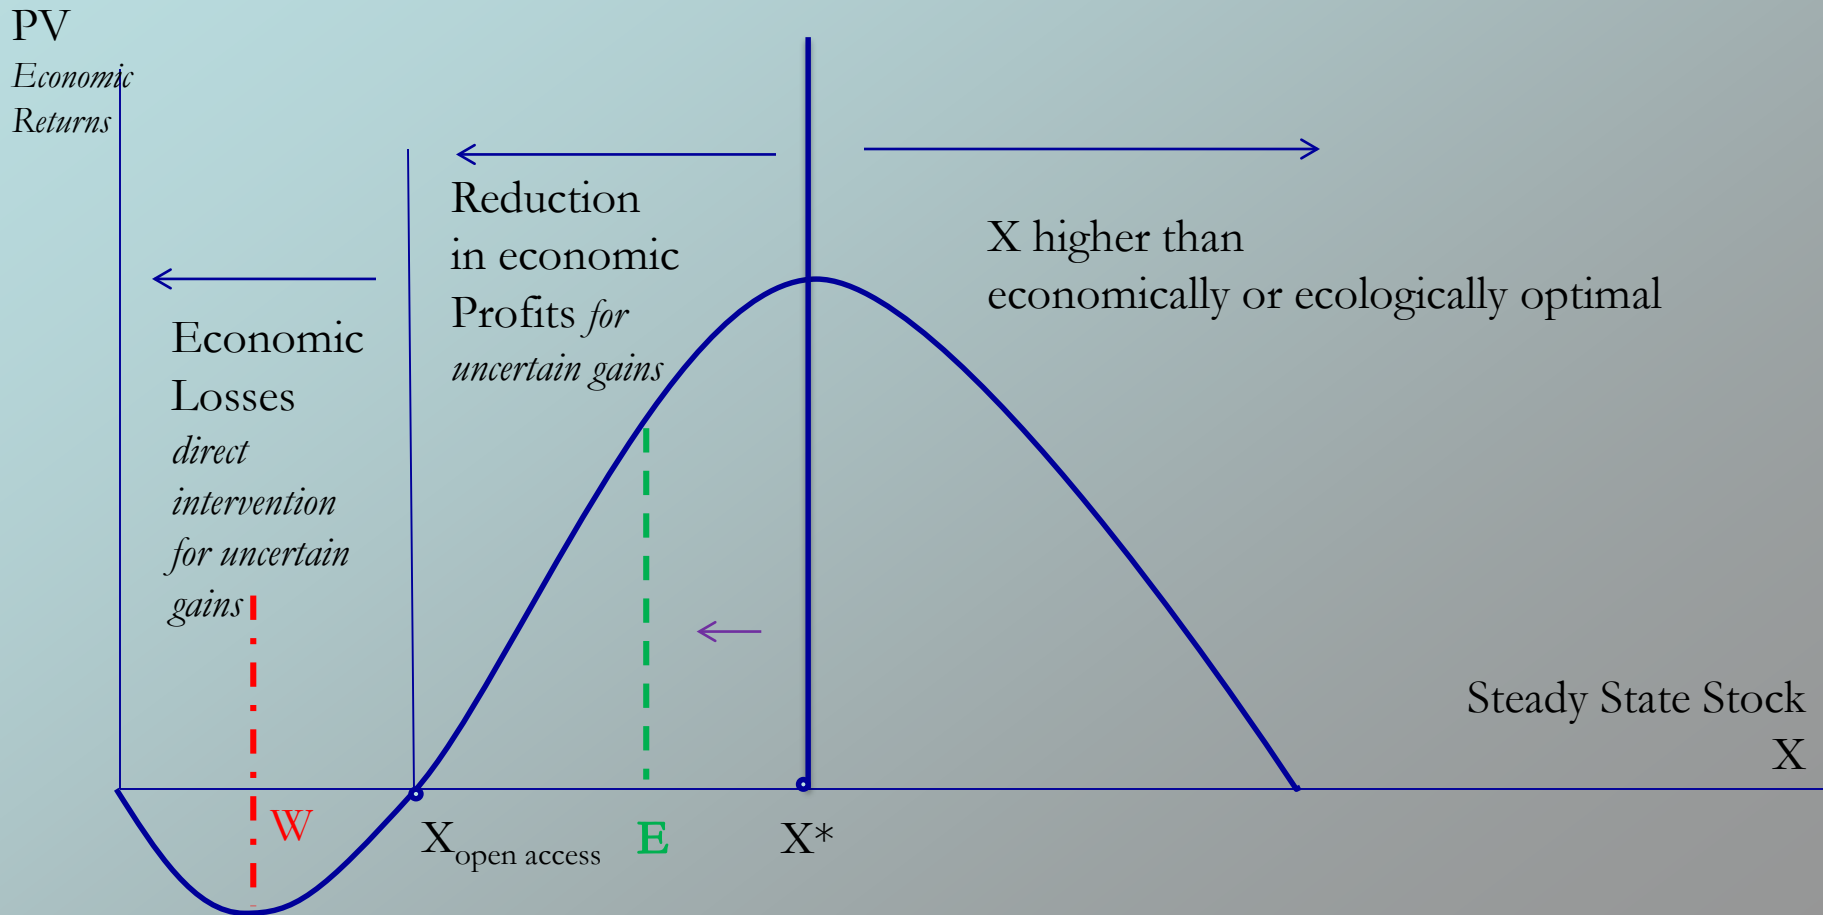

- ✓ Introduction (No consent)
- ~2000 female,
- ~1000 male,
- ~10,000+ juvenile,
- ~1.5 mil larvae E. Russia

✓ Agreement for joint management

- ✓ Migration noted
- ✓ Discussion NO-RU

- ✓ Joint management as 'protected species' to grow stock (Asset? Liability?)
- ✓ Experimental quota fishery
- ✓ NO high quotas to push down migration

Tradeoffs of a profitable invader

Scarce Empirical Observations

- Inevitable Uncertainties
 - Stock (X)
 - Growth F(X)
 - Damages DM(X)
 - Control Costs
- Trade off-Sign of λ
 - X or h source of future benefits ?
 - Value from investing in this asset or divesting in this liability

$$MaxV = \int_0^{\infty} e^{-\delta t} [Ph_t - C(X_t)h_t - DM(X_t)] dt$$

$$F'(X_t) - \left(\frac{DM'(X_t) + C'(X_t)F(X_t)}{P - C(X_t)} \right) = \delta$$

s.t.

$$\dot{X} = F(X_t) - h_t$$

$$0 \leq h_t \leq X_t$$

$$X_0 \leq X(0)$$

$$\lambda = \frac{\dot{\lambda} - DM'(X) - C'(X)h}{\delta - F'(X)}$$

Cost Function

- 2016 NO Registry & 2002-2007 dataset
- Individual effects: Variation in costs across vessels
- Regression Analysis: explanatory variables: annual X, Vessel Length (VL), harvest (monthly)
- **Overview of how output and X affect variable unit costs**

$$CPUE_{males} = 0.0085 X^{0.4482}$$

- Annual Operational Costs sorted by VL (S:8-9.9m, M: 10-14.9m, L: 15-20.9m)
- **Fixed Weighted Averaged Cost for every year**

$$\bar{C}_t = AC_t^S / \sum_S T_t + AC_t^M / \sum_M T_t + AC_t^L / \sum_L T_t$$

$$C(X) = \frac{\bar{C}_t * CQ_i / \sum_i PD}{0.0085 X^{0.4482}}$$

- %CQi fraction of crab quotas when compared to overall other quotas
- AC annual cost; weighted average of annual VL classes
- ΣPD is the sum of Pot days (for every individual trip) of every vessel i.

$$C_{2005}(X) = \frac{32}{X^{0.4482}}$$

$$C_{2002}(X) = \frac{178}{X^{0.4482}}$$

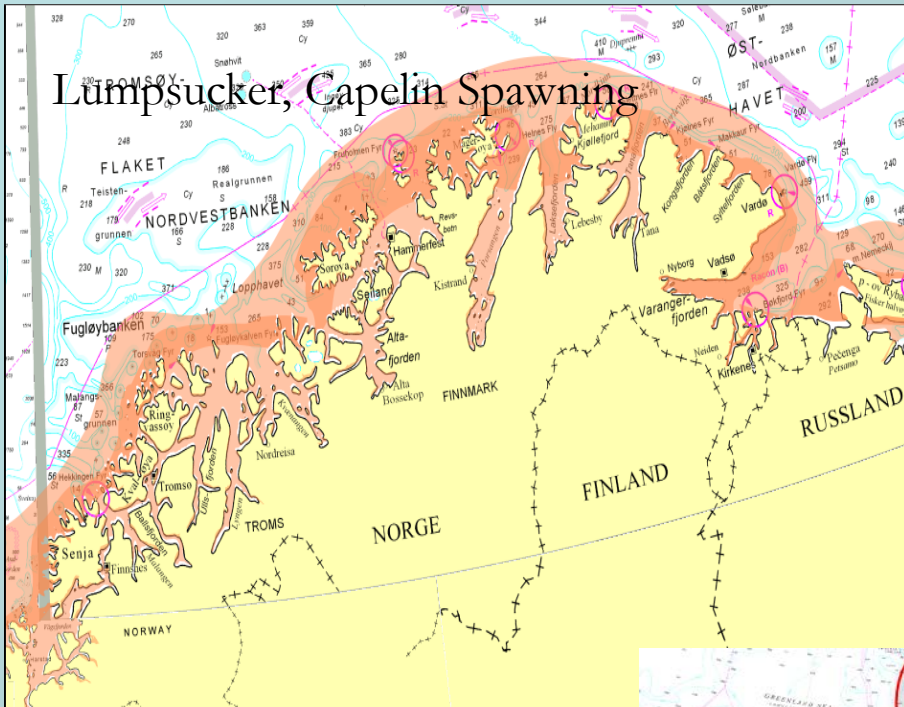

Broadening the Perspective

Multiple Fisheries managers (RU/NO) goals incomplete

Full Ecological Economic Story includes Damages and Externalities, and Unknowns

- Different Costs, Incentives
 - Bycatches
 - removing baits, losing target species, entangling & destroying nets
 - Predation upon commercial species
 - Capelin (*Mallotus villosus*)
 - Arctic lump sucker (*Cyclopteropsis macalpini*)
 - Icelandic Scallop (*Chlamys islandica*)
 - Ecosystem Damages
 - Benthos
 - Competition with native species
 - Parasites & Commensal

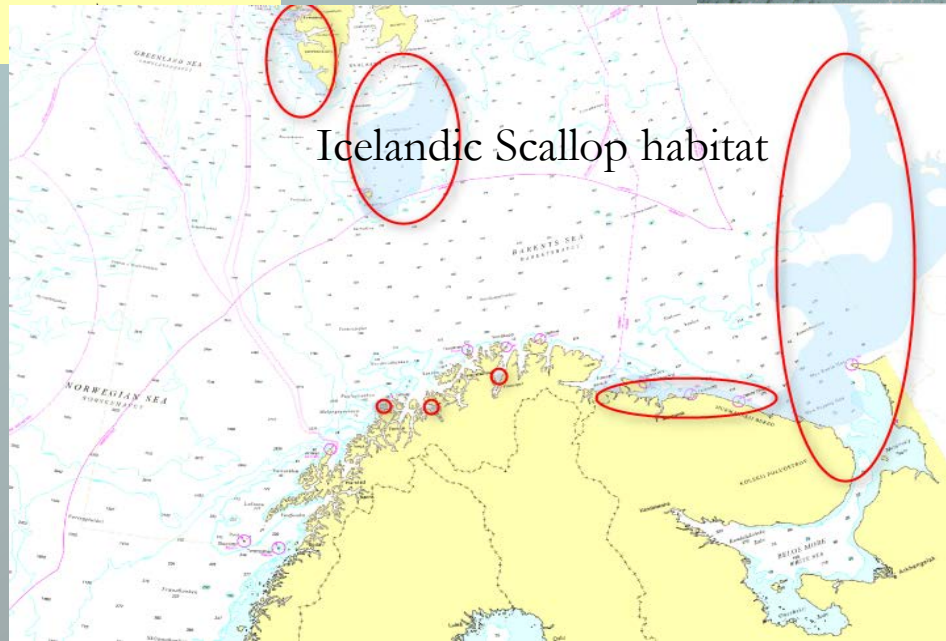

Lumpsucker, Capelin Spawning

epifaunal communities are impoverished

trawl catch at 110 m depth in non invaded nearby fjord

Pro's and Cons of Commercial harvesting as a means of control for ecological goals

- ✓ Quotas: Compensation for Damages
- ✓ Market Benefits grow larger as invasion develops
- ✓ Increasing economic dependence
- ✓ Additional pressure on Social Planner
- ✓ Myopic strategies may justify larger steady state X^*

- ✓ $RKC < 0.8\text{kg}$ not commercial
- ✓ Måsøy: Expand the border to give access to Quota Regulation!
- ✓ E/W Discard policy differs too
- ✓ Norwegian violations of international policy on invasive species?

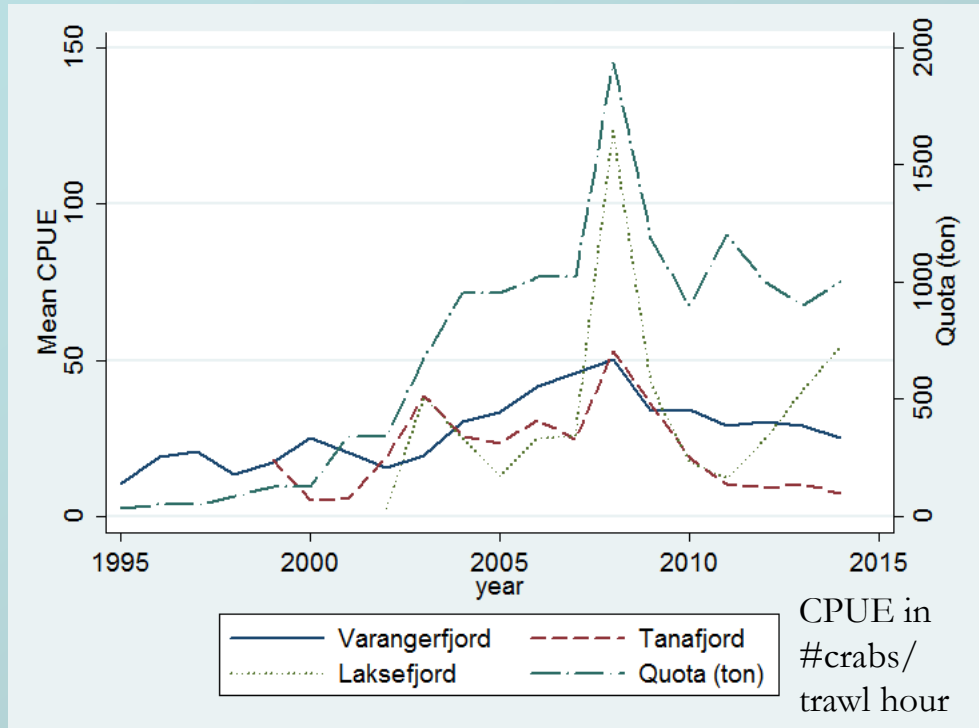

Thank you very much for your attention

mkour@sdu.dk, baka@sdu.dk, lmfernandez@vcu.edu

Blunt management tools: Need for refinement?

- ✓ RKC expanding spatially & in density
- ✓ Management pushing down X
- ✓ Laksefjord (close to 26°): unstable. Increased harvest maybe ?
- ✓ Posangerfjord & other fjords ?!

Spatially explicit concerns

✓ West

Reduce X (With Investment beyond OA outcome):

- own damages
- International Spatial spread/Mitigation?

✓ East

Reduce X (With Quota?) for

- own damages (*if any*)
- Within Norway Spatial spread/Mitigation?
