ACKNOWLEDGMENTS

This research was supported by NOAA, National Marine Fisheries Service, Northwest and Alaska Fisheries Center (Contract 83-ABC-00102) and by NOAA, Office of Sea Grant (Grant No. NA81AA-D-00086; Project No. R/OPF-17).

We would also like to thank S. Lewis and others at the ODFW Marine Regional Office for supplying Floy tags and a marking gun and for forwarding recovery data for tagged fish; agency tag coordinators for supplying release data for coded-wire tag groups; J. Norton and others at the ODFW Clackamas laboratory for decoding CWT's; all the people who participated in the cruises either on board or as drivers; R. Brodeur and J. Trautman for processing samples and for helping prepare tables and figures for this report; J. Sharpe and M. Armbrust for typing the tables; and the captain and crew of the Pacific Warwind.

INTRODUCTION

The College of Oceanography, Oregon State University, conducted three cruises (May 16-27, June 9-27, and September 15-24) in 1983 to study the distribution, abundance, migration, growth and feeding habits of juvenile salmonids during their first summer in the ocean. This is the third year we have had a series of cruises during the summer months and the fifth year that we have sampled the Oregon and Washington coasts during June. The purpose of this report is to describe the sampling area and methods used for the 1983 cruises and to present some preliminary results.

METHODS

Vessel and Gear

The Pacific Warwind, a 28 m (92 ft) commercial drum purse seiner was chartered for these cruises. A herring purse seine of 32 mm (1.25 in) stretch measure mesh and approximately 495 m long was used to collect salmonids and associated nekton. All sets were round hauls, where the net was laid out in a circle by seiner and skiff. The direction of the opening of the seine when half set was noted. A depth gauge attached to the bottom of the net indicated that the seine fished to a depth of about 49 m. Each set sampled an area of approximately 19,000 square meters.

Sampling Area

Sets were made at stations generally 9.3 kilometers apart along transect lines extending from $48^{\circ}20'N$ to $44^{\circ}20'N$ in May, from $48^{\circ}20'N$ to $43^{\circ}00'N$ in June, and from $48^{\circ}20'N$ to $43^{\circ}28'N$ in September (Figs. 1 and 2). We generally sampled from the 37 m contour out to 37 kilometers offshore, or until juvenile salmonids were no longer caught.

Fifty-five good sets were made during May, 58 during June and 52 during September. Eight additional sets were attempted but were aborted because of gear problems, high winds or strong currents. Set positions were determined by Loran C except during most of the September cruise when radar was used because of a Loran C receiver malfunction. Locations and times of purse seine sets along with environmental data are given in Appendix A.

Environmental Data

Temperature of a surface-water bucket sample was taken at each station. Additional water samples were taken with an NIO bottle at 1 m and at 10 m from which chlorophyll-a and phaeophytin concentrations and salinity were determined.

Salinities of the water samples were measured at the Mark O. Hatfield Marine Science Center with a Guildline Autosalinometer (Model 8400). Chlorophyll-a and phaeophytin content of 140 ml water samples were determined by filtering the water through a 0.3 um (pore size) glass fiber filter (Gelman type A/E). The

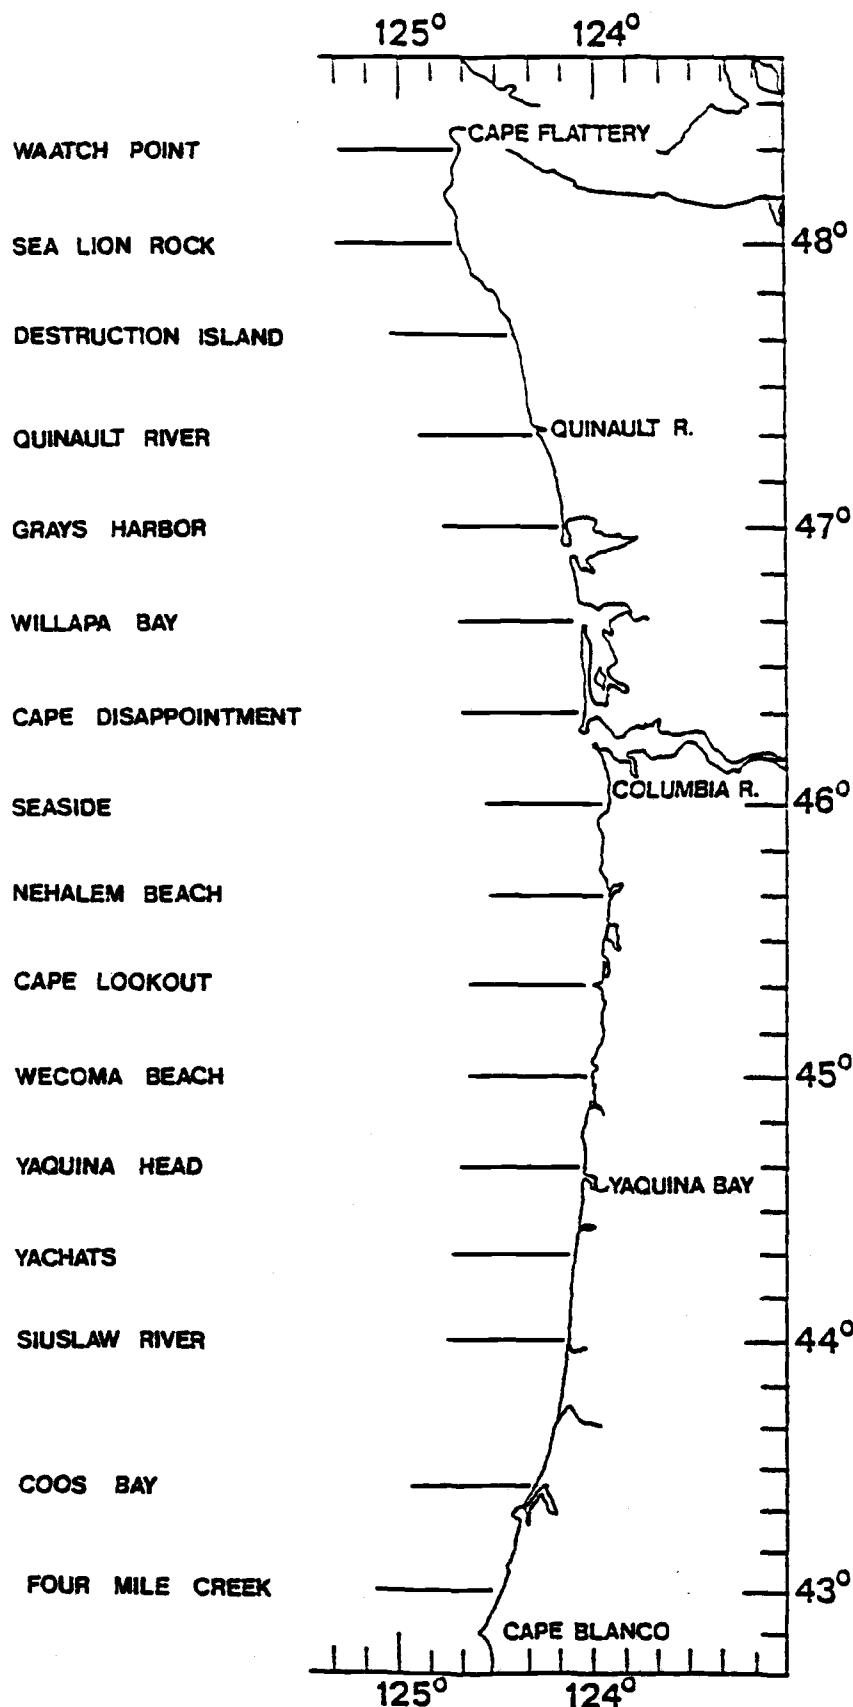

Figure 1. Transect lines sampled during the 1983 purse seine cruises.

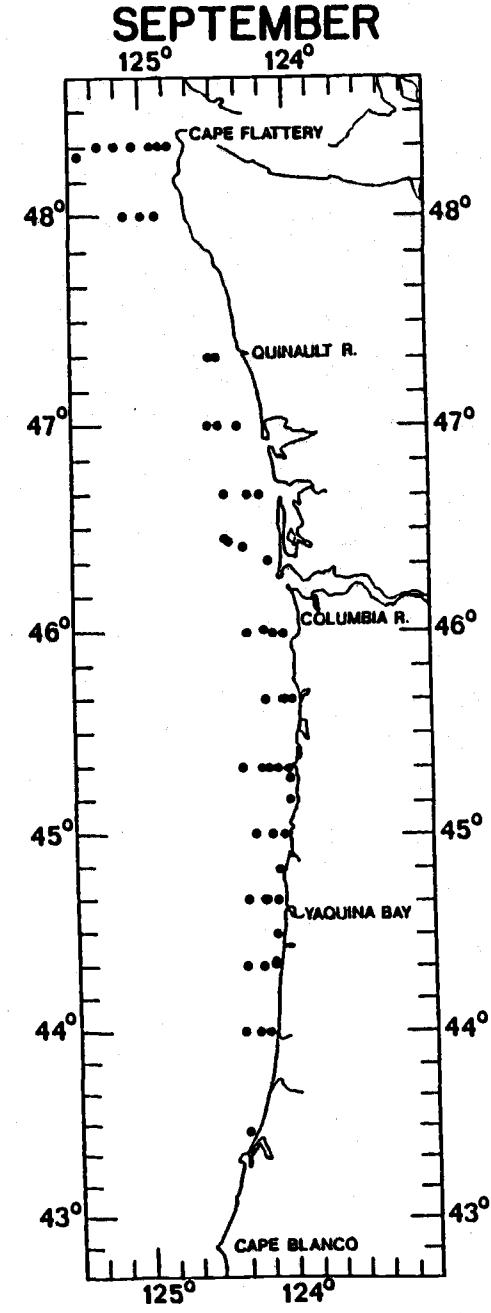

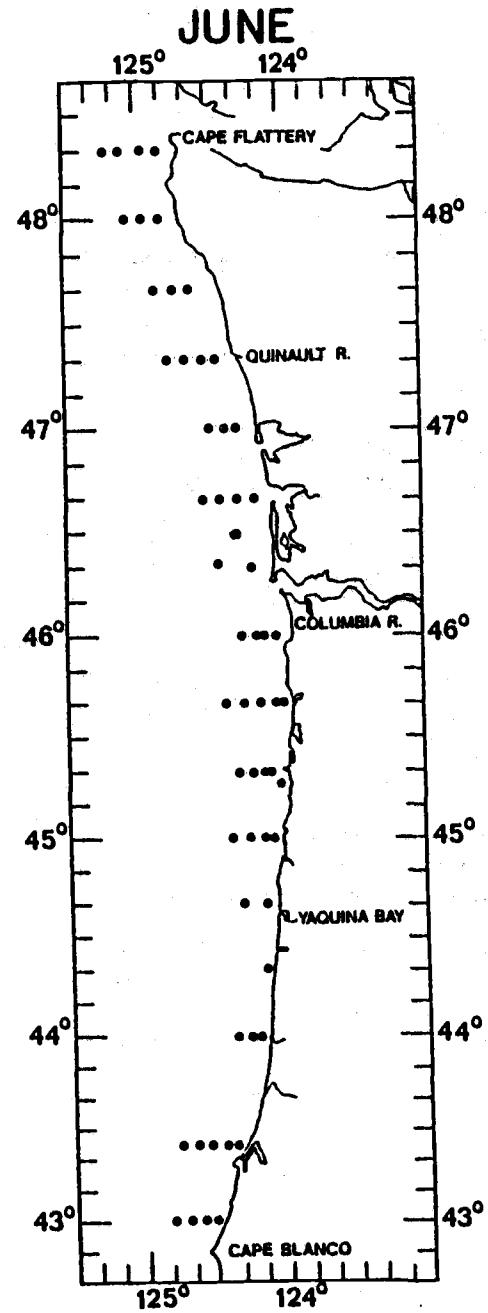

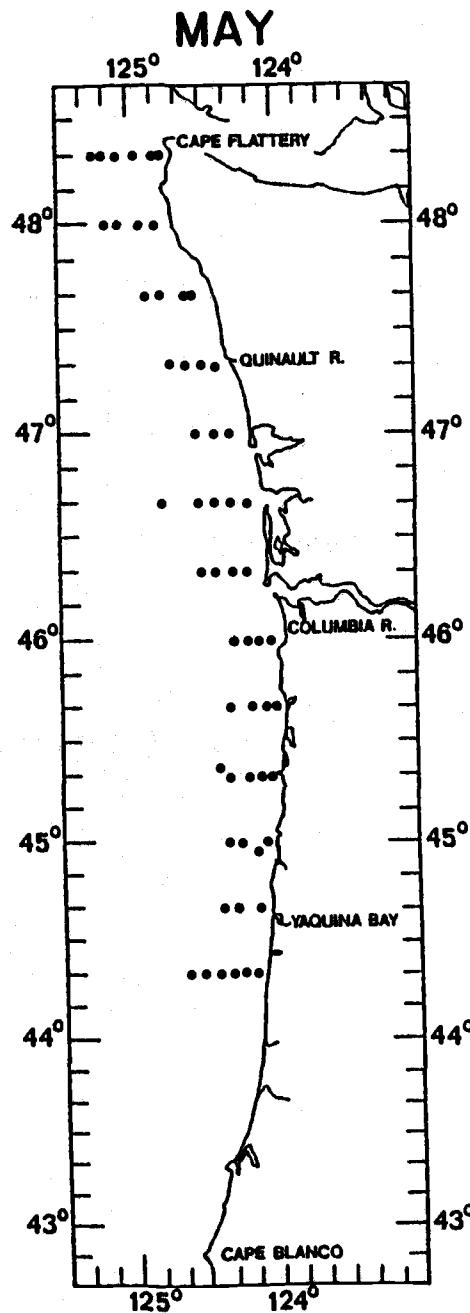

Figure 2. Set locations for May, June and September 1983.

pigment was extracted from the filtrate with a known volume of 90% acetone; and the fluorescence measured with a Model-10 Turner Designs Fluorometer.

Water clarity was measured with a 30 cm Secchi disk. Ambient light intensity was measured at deck level with a Spectra Lumicon light meter.

Processing the Catch at Sea

The purse seine catch was dip-netted from the seine bunt, lifted aboard in the bunt or brailed aboard. Large catches of medusae sometimes occurred and a rough estimate was made of their total volume in each set. Medusae were identified and counted and individual bell diameters were measured from a subsample of the total catch. Fishes and squids were also identified, counted and measured. Stomachs were removed from possible predators of juvenile salmonids and preserved in 10% formalin. Selected whole fishes and squids were also preserved.

Juvenile salmonids were anesthetized in a seawater solution of MS 222, identified, and measured to the nearest millimeter (F.L.). They were then checked for adipose clips, individually wrapped in plastic bags (along with a label identifying set number, species and length) and frozen.

Adult salmonids were anesthetized in a seawater solution of MS 222, identified, measured, sampled for scales, and examined for adipose clips and other marks. Heads from adipose clipped adults were removed, labeled and frozen for later recovery of coded wire tags.

Most adults were released after they were measured and scale samples removed. To trace movements of adult salmon in the ocean 142 coho, 5 chinook, and 1 steelhead were tagged with orange Floy tags below the dorsal fin using a Dennison Mark II tagging gun. The Floy tags were supplied by the ODFW Marine Regional Office, Newport, Oregon. Fish were released after they had recovered from the anaesthetic in a tank of circulating sea water. All fish were active when released to the ocean, although sometimes badly descaled. Three adult wolf-eels and 3 ocean sunfish were also tagged and released.

Kidney smears were taken from adult coho and adult chinook for a study of bacterial kidney disease (BKD) by Craig Banner, Department of Microbiology, O.S.U. Stomachs were removed and preserved from all adult salmon killed.

Laboratory Processing of Juvenile Salmonids

Each frozen juvenile salmon was given an identification number (collection year, seine set number and fish sequence number), weighed in a tared plastic bag, re-identified and re-examined for adipose fin clips and other marks. Scales from a subsample of 25 fish of each salmonid species from each set were removed from the preferred area (see Scarneccchia, 1979) and mounted on gum cards from which acetate impressions were made. Heads from individuals with adipose fin clips were removed and sent to the Oregon Department of Fish and Wildlife, Clackamas laboratory, for removal and decoding of coded wire tags. Stomach contents from 10 fish of each species from each set were

removed, weighed and preserved in 5% buffered formalin. Kidney smears from these fish were examined for BKD by personnel of the Department of Microbiology, O.S.U.

RESULTS

Ocean Conditions

Associated with the 1983 El Nino were higher than average sea-surface temperatures off Oregon and Washington in May and June. Sea surface temperatures during these two months averaged 1°C to 4°C higher than in 1982 (Table 1).

Catch of Salmonids

Seven species of salmonids occurred in the 1983 purse seine collections (Table 2, Appendix B). As in 1981 and 1982, chinook and coho were much more abundant than the other species. In 1983, however, the total catch of juvenile chinook was higher than that of juvenile coho. Almost 8 and 4 times as many juvenile coho as juvenile chinook were collected in 1981 and 1982, respectively. Chum and sockeye were the next most numerous salmonids, although almost all of these fish were collected in one set off Cape Disappointment in May.

Catch Per Set of Salmonids

Mean catch per set of juvenile coho and chinook salmon was

Table 1. Comparison of sea-surface temperatures for 1982 and 1983. Average of all stations. Repeat measurements at the same stations averaged and counted only once.

calculated for three areas for each of the three cruises in 1983 (Table 3). Mean catch per set of juvenile coho was lower in 1983 than in 1982 in all areas during June and September, and also lower from Cape Lookout south in May, (See Fisher *et al.*, 1983, p.14 for comparison). During September 1983, all but 2 of the 143 juvenile coho collected north of the Columbia River were from the Waatch Point transect; elsewhere off Washington the mean catch per set of juvenile coho was extremely low.

Catch per set of juvenile chinook, unlike coho, was higher in 1983 than in 1982 south of the Columbia River during September. The difference between the two years in catch of juvenile chinook salmon during September may be due partly to a change in coverage of our sampling. In 1983 we used a shallower net and were able to sample in closer to shore. Of 207 juvenile chinook collected south of the Columbia in September 1983, 204 were collected within 4.3 km of the coast. Twelve sets were made within 4.3 km of the coast south of the Columbia River during September 1983 but only two sets were made in September 1982.

Coho Length-Frequency Distributions

Coho length-frequency distributions showed two distinct modes during the summer: the smaller mode comprised of juvenile (.0 age) fish and the larger mode of maturing (.1 age) fish (Figure 3). The size of juvenile coho was similar in all areas

Table 3. Number of sets and catch per set of juvenile coho and chinook salmon.

SEPT 1983

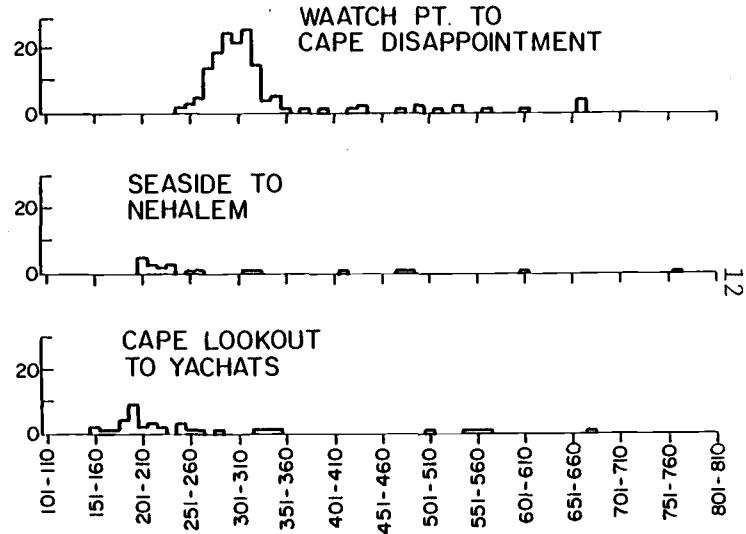

Figure 3. Length-frequency distributions of coho salmon, 1983.

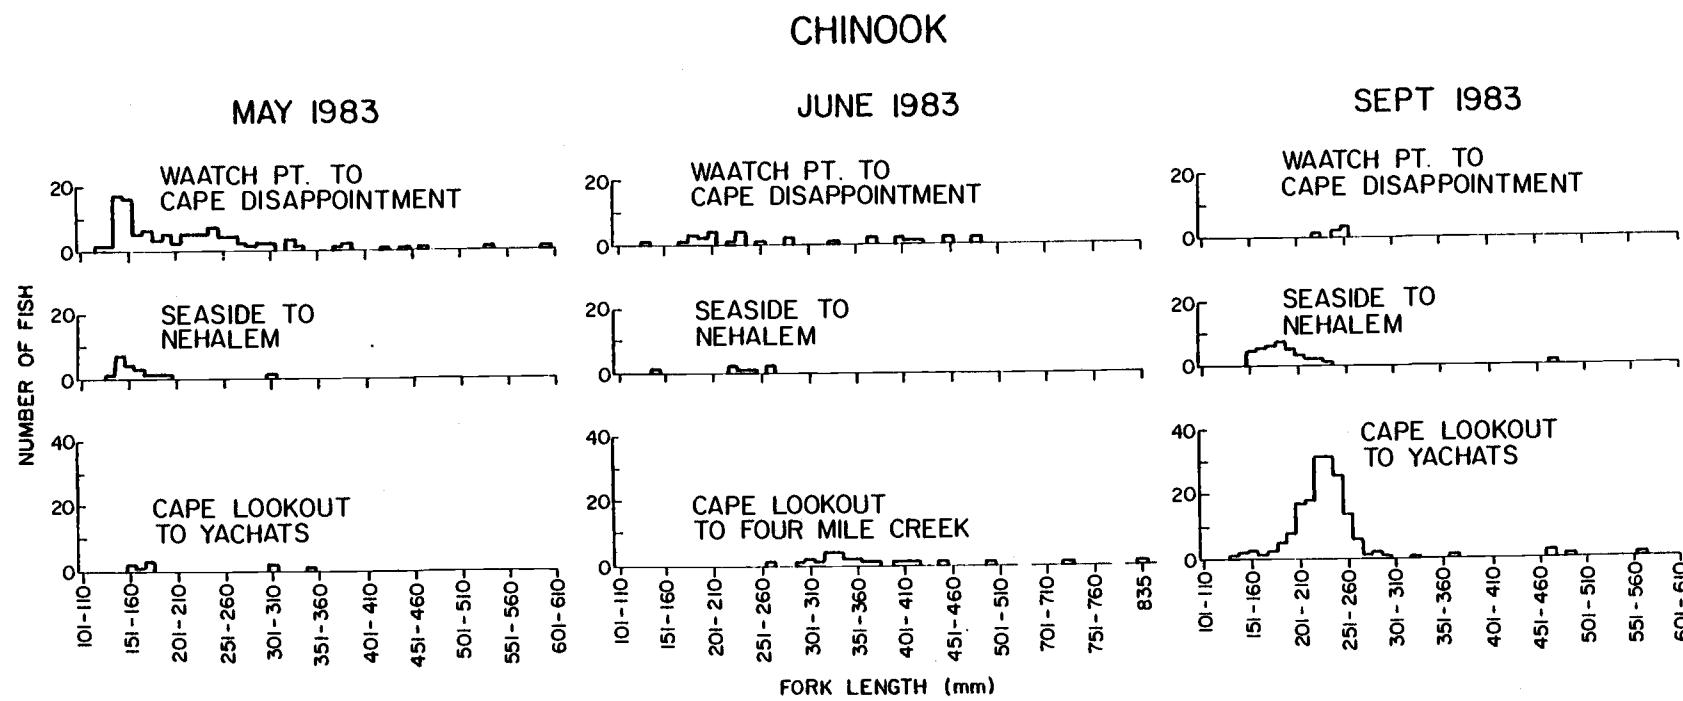

Figure 4. Length-frequency distributions of chinook salmon, 1983.

during May 1983 and also was similar to the size of juvenile coho collected in May 1981 and 1982. In all cases the modes were centered at about 151-170 mm F.L.

During June 1983 the juvenile coho were largest north of the Columbia River (the mode at approximately 195 mm F.L.) and smaller south of the Columbia River (the mode at 151 to 160 mm F.L.). This differs from June 1982 when juvenile coho were larger south of Cape Lookout, but is similar to June 1981 when the juveniles were larger between Tillamook Rock and Leadbetter point than they were to the south (Wakefield *et al.*, 1981; Fisher *et al.*, 1983).

During September 1983 (Figure 3) and 1982 and August 1981 juvenile coho were distinctly larger to the north than they were to the south.

Length-Frequency Distributions of other Salmonid Species

Length-frequency distributions of chinook appear in Figure 4. A broad range of sizes was represented in all three months with a distinct mode at 220-250 mm F.L. south of Cape Lookout in September. The lengths of other salmonid species are shown in Table 4.

Recoveries of CWT'd Juvenile Coho

During the summer 40 juvenile coho with CWT's were collected (Table 5, Appendix C). The CWT'd fish were divided

into four groups based on origin: 1) Columbia River 2) Coastal Oregon Public Hatchery, 3) Oregon Aqua-Foods Inc. (OAF) and 4) Anadromous Inc. All OAF and Anadromous coho and all but one coastal Oregon fish were found north of where they entered the ocean (Table 5, Figure 5). Columbia River fish were found both north and south of the Columbia River. No coastal Washington CWT'd coho were collected in 1983. That most CWT'd juvenile coho in June and September were collected north of where they entered the ocean together with the larger size of juveniles and greater catch per set to the north during these months suggest a general northward migration of juvenile coho during the summer of 1983.

Recoveries of CWT'd juvenile chinook

Most CWT'd juvenile chinook were collected north of the Columbia River in May (Table 6, Appendix C). None of the chinook collected in September 1983 had CWT's although total catch was greater than in May or June.

Recoveries of Floy Tagged Salmon

Through December 1983 18 of the 148 (12.2%) adult salmonids tagged with floy tags were recovered. Large movements both to the north and south occurred between release and recovery among many of the tagged salmon (Table 7).

Table 6. Catch of juvenile CWT'd chinook by month and area.
