INTRODUCTION

During February, March and April 1974, the interdisciplinary Coastal Upwelling Ecosystems Analysis experiment known as JOINT-I took place over the continental shelf and slope near Cabo Corveiro in the NW African upwelling region. As part of the field program, Oregon State University made a series of repeated hydrographic surveys from R/V GILLISS along latitudes 21°20'N and 21°40'N (Fig. 1). The more northerly line was the site of the current meter mooring and meteorological buoy array maintained during the same period by Oregon State University in cooperation with the Deutsches Hydrographisches Institut, Hamburg. This report contains the complete set of contour plots of hydrographic section and anchor station data obtained by OSU. The low-pass filtered time series of current and wind measurements from each OSU mooring are also included.

A summary of the CTD and STD data and the calibration of the probes used during JOINT-I are reported by Barton, Stevenson and Gilbert (1975). From computer listings of the complete data set, vertical sections were contoured by hand. The depth interval between observations was always less than 5 meters and usually about 2 meters. Smooth contours were drawn to pass through the observed or interpolated depth of selected isosurfaces at each station. Numerous large inversions of salinity and temperature created a considerable problem in contouring. Although consistency in interpretation was the aim, there are undoubtedly other equally possible configurations of the isopleths in some cases. The contoured sections are subject to aliasing by internal waves and tides, but it is felt that the distributions have not been greatly distorted by short period fluctuations, at least on the shelf. The 24-hour anchor station in 100 m of

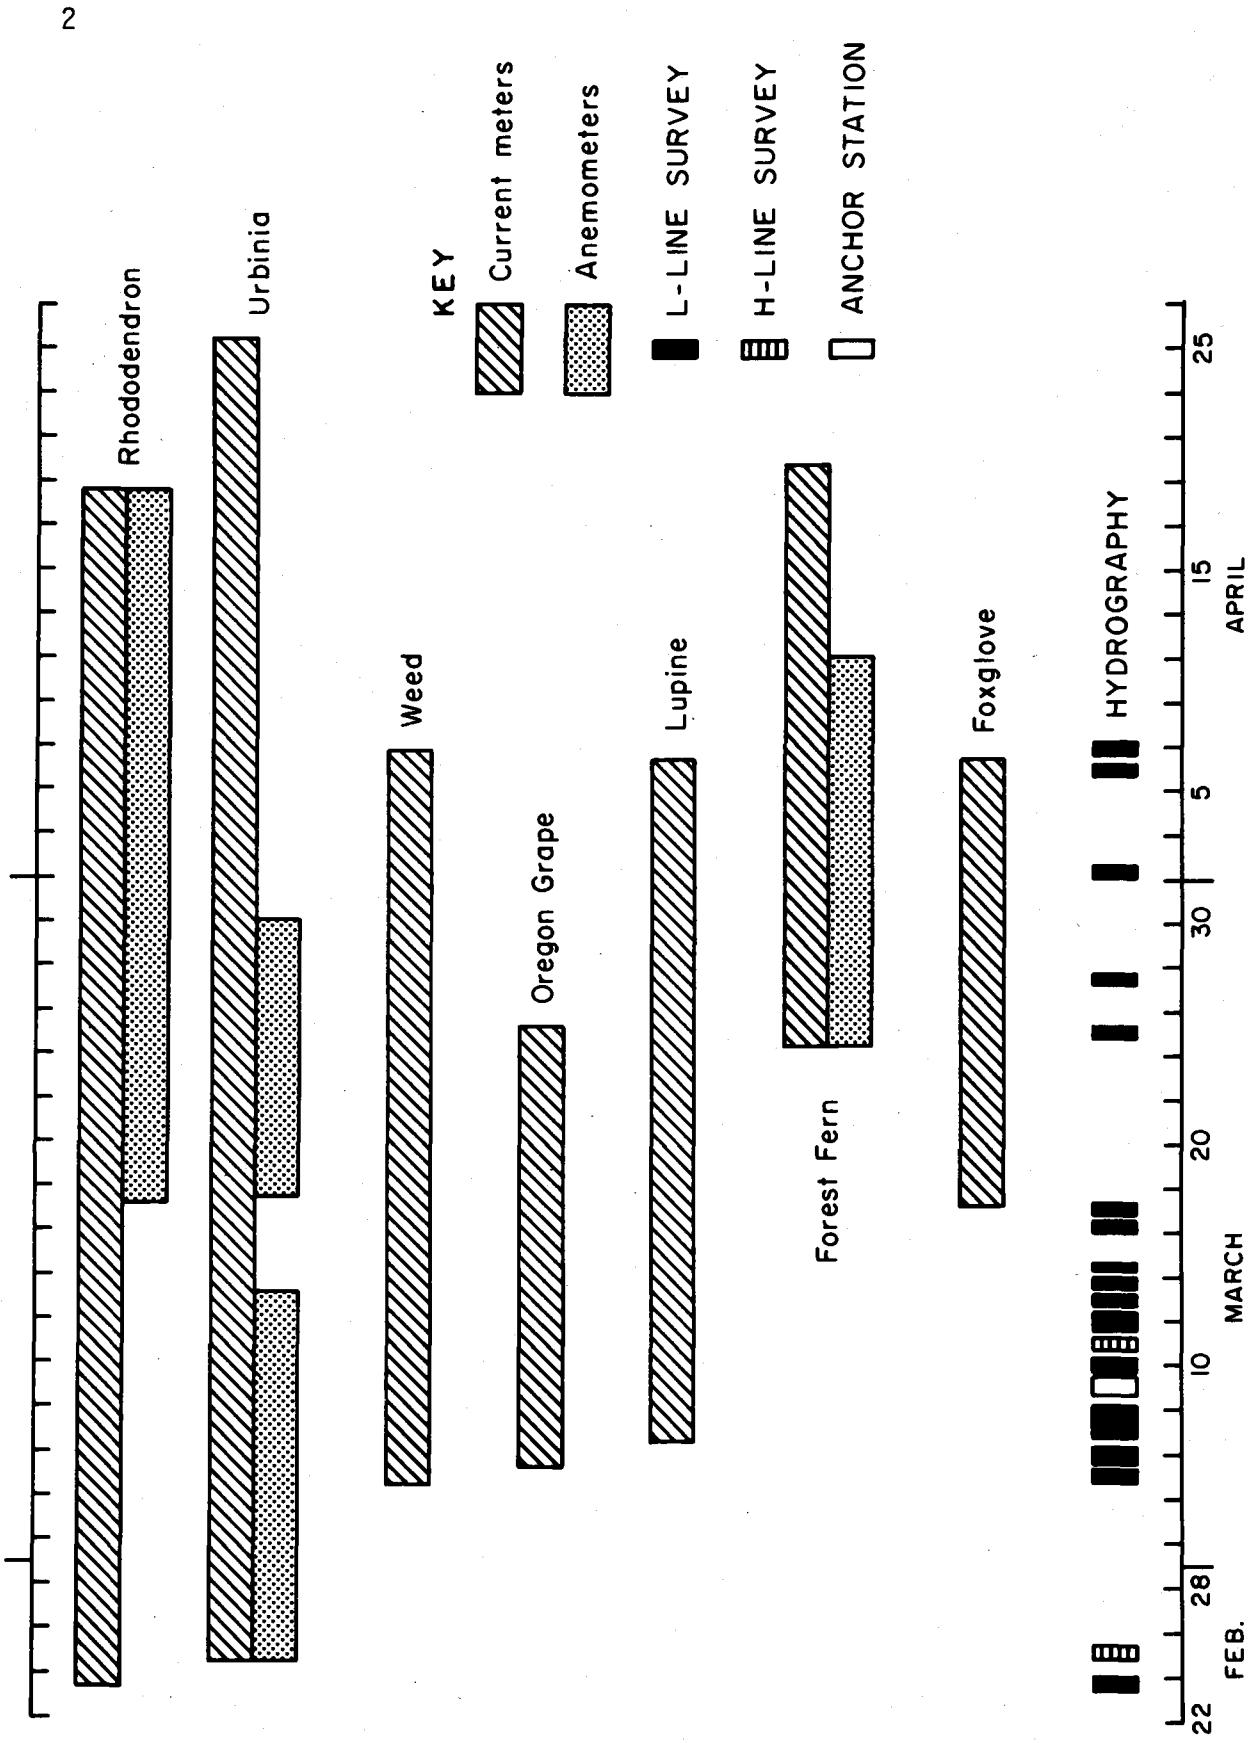

Fig. 2 Operating periods of the various moorings and times of hydrographic surveys during JOINT-I.

water tends to support this supposition (see page 15). A standard bottom profile was used for all sections resulting from repeated occupations of the same line.

In the displayed sections contours are drawn at regular intervals of 1°C in temperature, 0.1 o/oo in salinity, and 0.1 units of sigma-t. Occasionally, extra contours are indicated and labeled. A dashed portion of an otherwise solid contour indicates uncertainty in its positioning. Station numbers are indicated at the top of the sections and distance away from the shoreline is indicated at the bottom.

The position of the OSU current meter array is shown in Fig. 1. The operating periods of the various moorings are illustrated together with the times of the OSU hydrographic surveys in Fig. 2, and in Fig. 3 the vertical arrangement of current meters along 21°40'N is shown. The current meter and anemometer data were recorded at 5 or 10 minute intervals. The resultant time series were filtered to produce hourly series. In this form they are reported by Pillsbury, Bottero, Still and Mittelstaedt (1975). In the present report, the hourly series were further filtered with a symmetrical cosine filter spanning 121 hours with a half power point at 40 hours to suppress diurnal and higher frequency oscillations. Use of the low-pass filter shortens the time series by 2 1/2 days at each end.

Wind observations were recorded at Rhododendron, Urbinia and Forest Fern. A complete record for the whole length of the experiment was not obtained at any one site. For this reason, the two shelf wind series (Rhododendron and Urbinia) were joined at the end of the Urbinia record to provide one continuous series. Comparison of simultaneous measurements

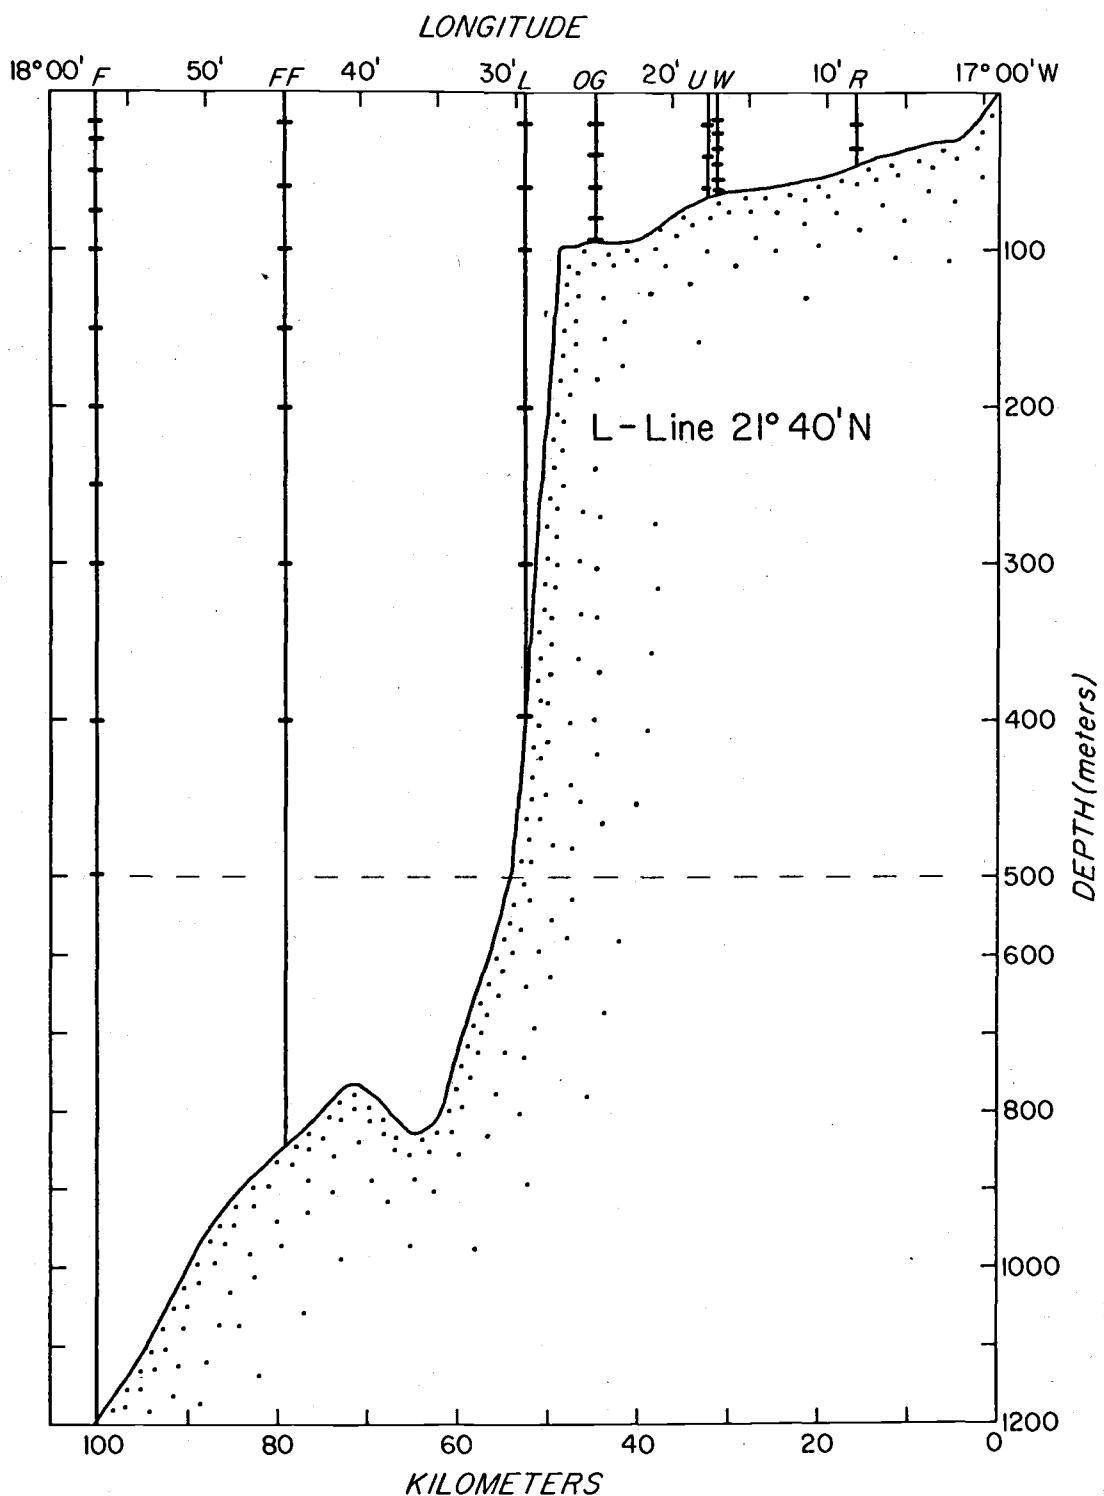

Fig. 3 The vertical distribution of current meters along the mooring line during JOINT-I. Each bar represents a current meter.

over 12 days of overlap between the two records showed no significant differences. A 5-day gap in the joined record existed because of a failure of the direction sensor in the Urbinia anemometer, which was corrected when the instrument was serviced on 17 March. The bad observations were replaced by wind data from the buoy Lisa, deployed by the NOAA Pacific Marine Environmental Laboratory. Lisa was situated within 1 km of Urbinia.

Data from each mooring are presented in order of distance from the coast. Mooring name, position, water depth, length of data series, and depths of the instruments are listed for each mooring. The vector series of low-passed measurements from all the current meters on the mooring are displayed on one page (except for Foxglove) at half day intervals beginning at midday or midnight GMT. The vector wind series is shown at the head of the page for the current record length. The vector series are followed by scalar series plots of the northward (v) component and the eastward (u) component of the current at all observation depths.

Also included in the report are sections of mean temperature, salinity and sigma-t along 21°40'N, based on mean profiles calculated from the repeated occupations of each standard station position, and sections of the mean northward (v) and eastward (u) components of velocity, based on the overall record mean from each current meter regardless of record length. The mean currents are additionally displayed as depth profiles for each mooring.

ACKNOWLEDGMENTS

Many people cooperated in the collection and processing of the data set contained in this volume. Mr. W. E. Gilbert processed the hydrographic data and drafted the figures. Mr. J. S. Bottero processed the wind and current meter data. Ms. Karie Tamura typed the manuscript. Dr. Ekki Mittelstaedt supervised the Deutsches Hydrographisches Institut participation in the current meter program. Dr. D. Halpern of the NOAA Pacific Marine Environmental Laboratory, Seattle, kindly provided wind data from buoy Lisa to make it possible to present a continuous time series.

Financial support was given by the International Decade of Ocean Exploration under National Science Foundation Grants IDO 72-06422 and IDO 71-04211.

THE OBSERVATIONS

H-line hydrographic sections ($21^{\circ}20'N$):

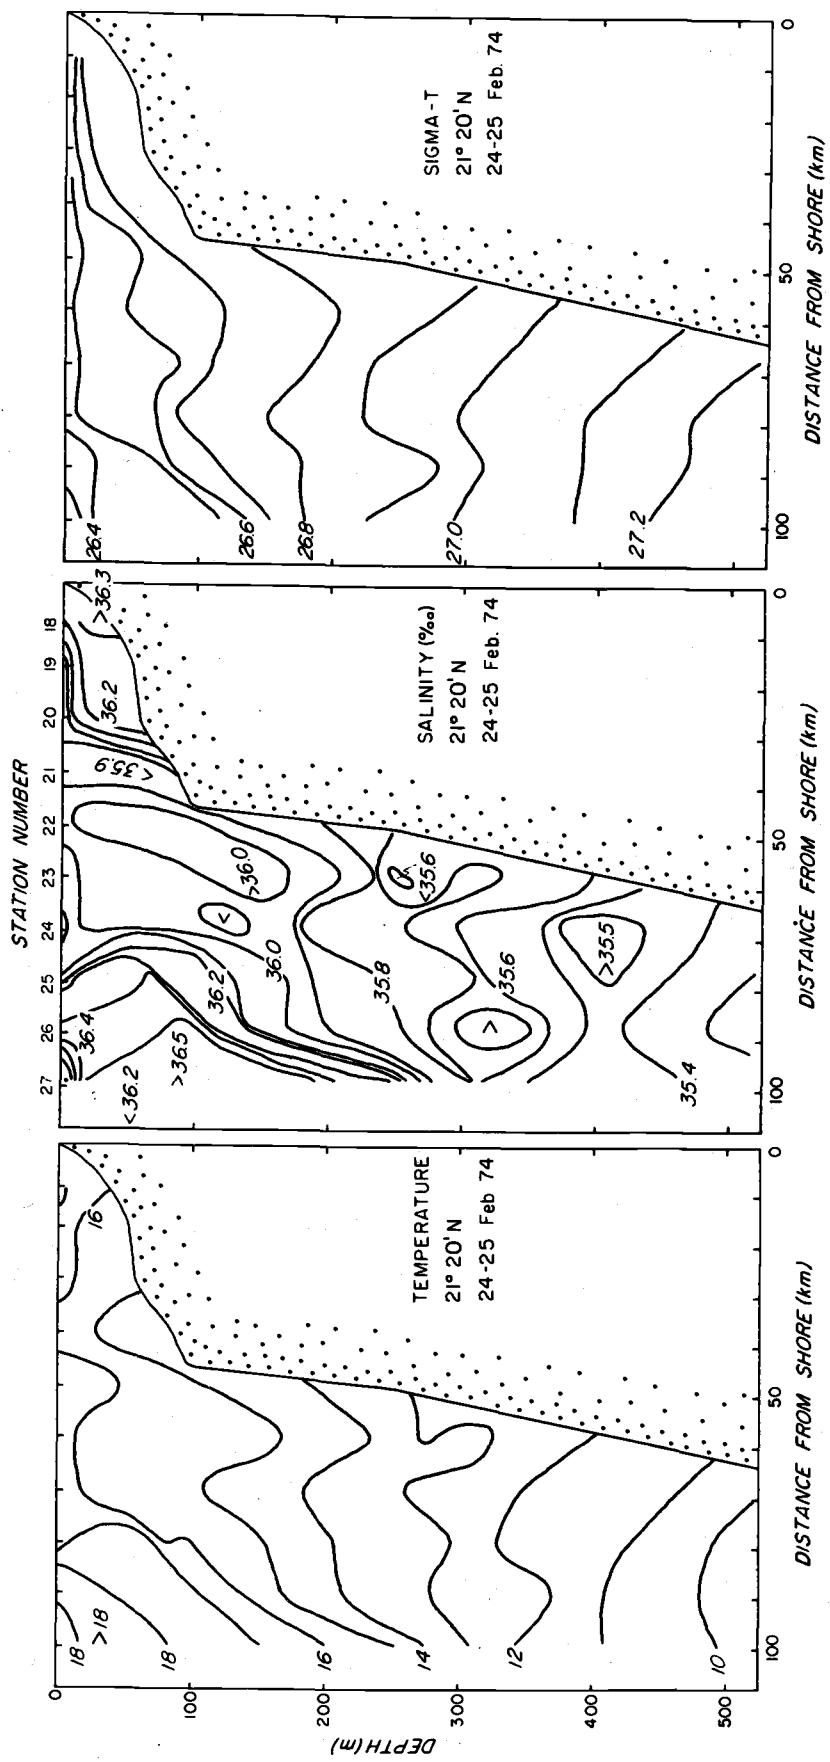

Stations 18-27, 24-25 February 1974	8
Stations 108-114, 10-11 March 1974	9

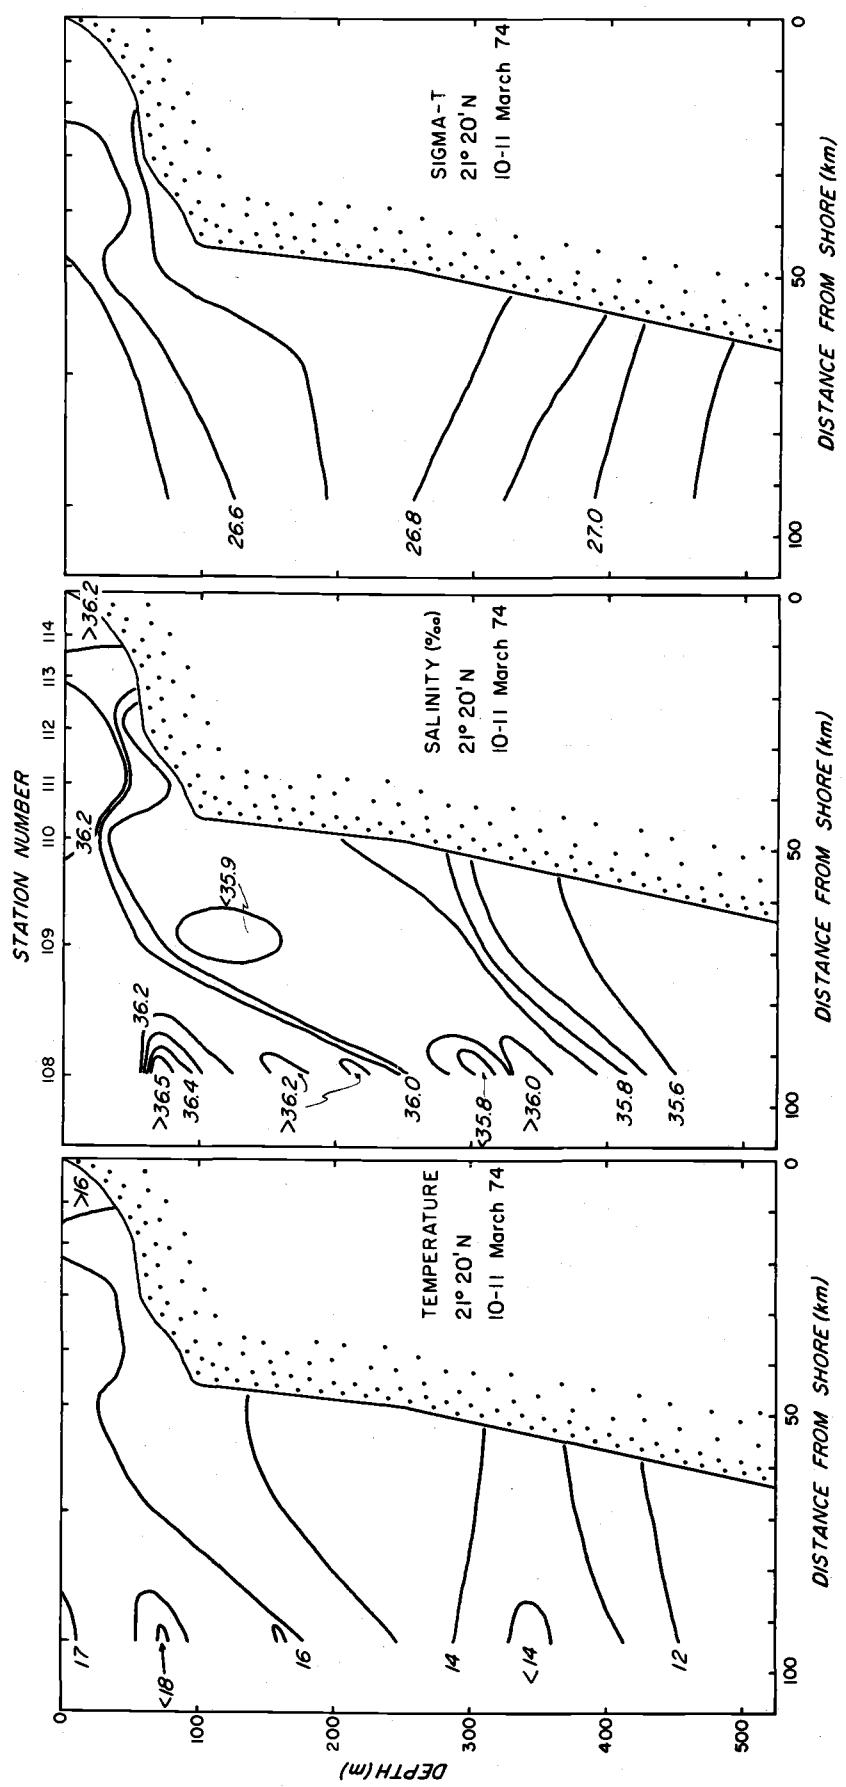

L-line hydrographic sections ($21^{\circ}40'N$):

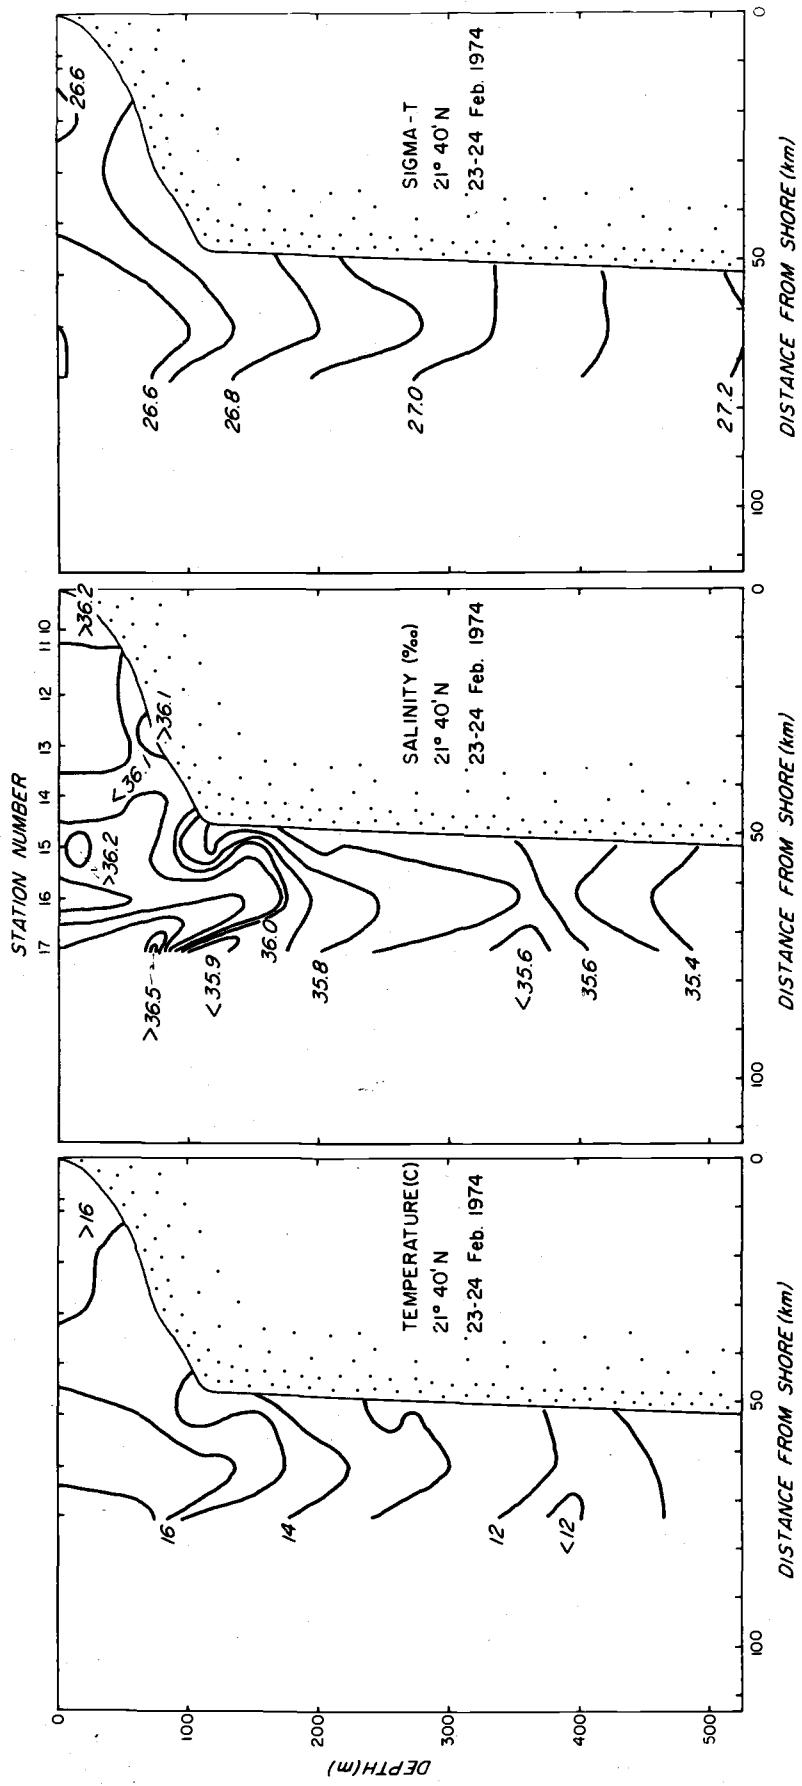

Stations 19-27, 23-24 February	10
Stations 31-37, 4-5 March	11
Stations 39-49, 5-6 March	12
Stations 50-59, 6-7 March	13
Stations 60-66, 7-8 March (extended line)	14
Casts 67-88, 8-9 March (anchor station)	15
Stations 95-102, 9-10 March	16
Stations 115-124, 11-12 March	17
Stations 130-136, 12-13 March	18
Stations 137-144, 13 March	19
Stations 145-151, 14 March	20
Stations 170-175, 16 March	21
Stations 176-182, 16-17 March	22
Stations 187-196, 24-25 March	23
Stations 212-219, 27 March	24
Stations 235-242, 1 April	25
Stations 243-252, 5-6 April	26
Stations 253-261, 6-7 April	27
Mean section along L-line, 23 February - 7 April	28

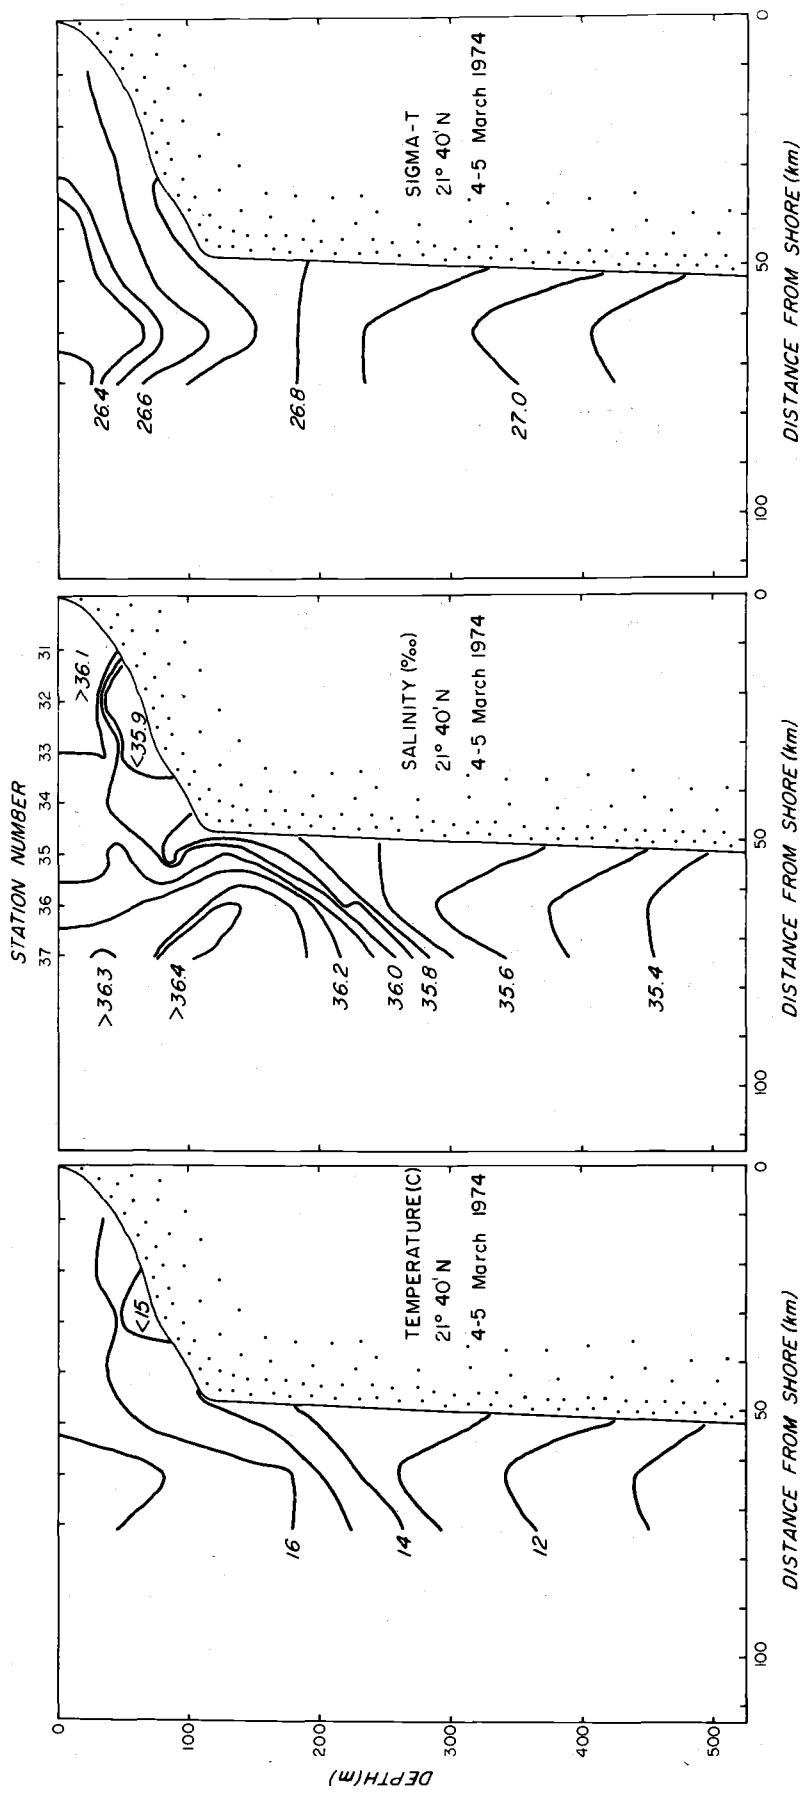

Current and wind measurements ($21^{\circ}40'N$):

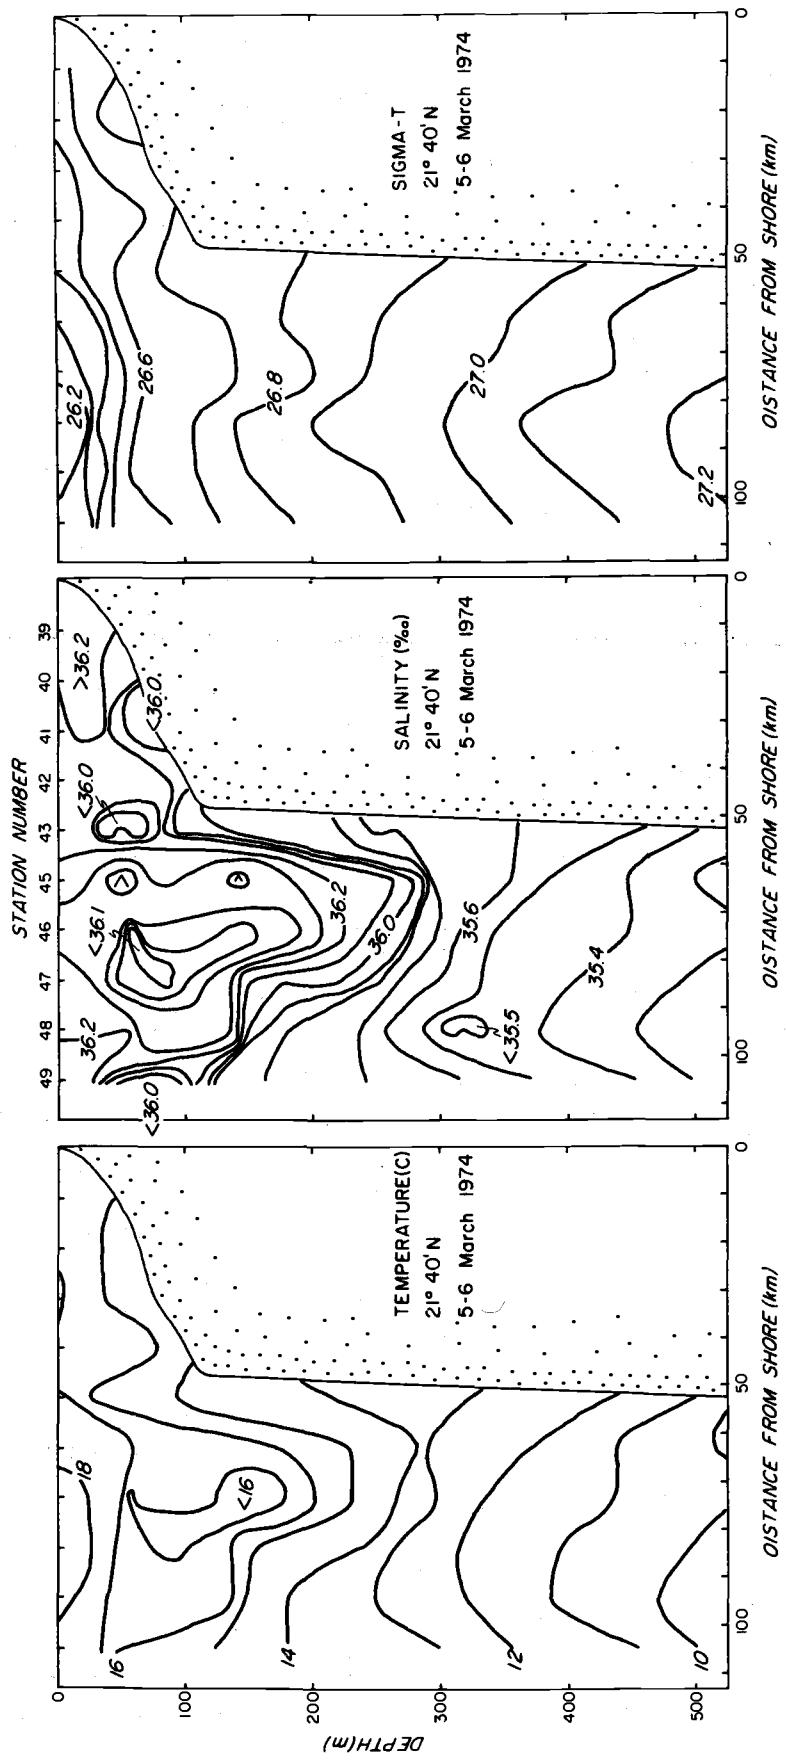

Section of mean northward (v) and eastward (u) components of the flow	29
Profiles of mean northward (v) and eastward (u) components of flow	30
