ABSTRACT

Current meters, moored during JOINT-I in the coastal upwelling area off Northwest Africa along 21°40'N measured current speed and direction, temperature and, in some cases, conductivity and pressure. In addition, surface buoy meteorological stations were installed at some current meter strings to record wind speed and direction, as well as air and water temperature.

The sampling intervals of the instruments were 5 and 10 minutes. The data have been filtered and are shown here by means of pertinent statistics, real time plots, progressive vector diagrams and rotary spectra of hourly values.

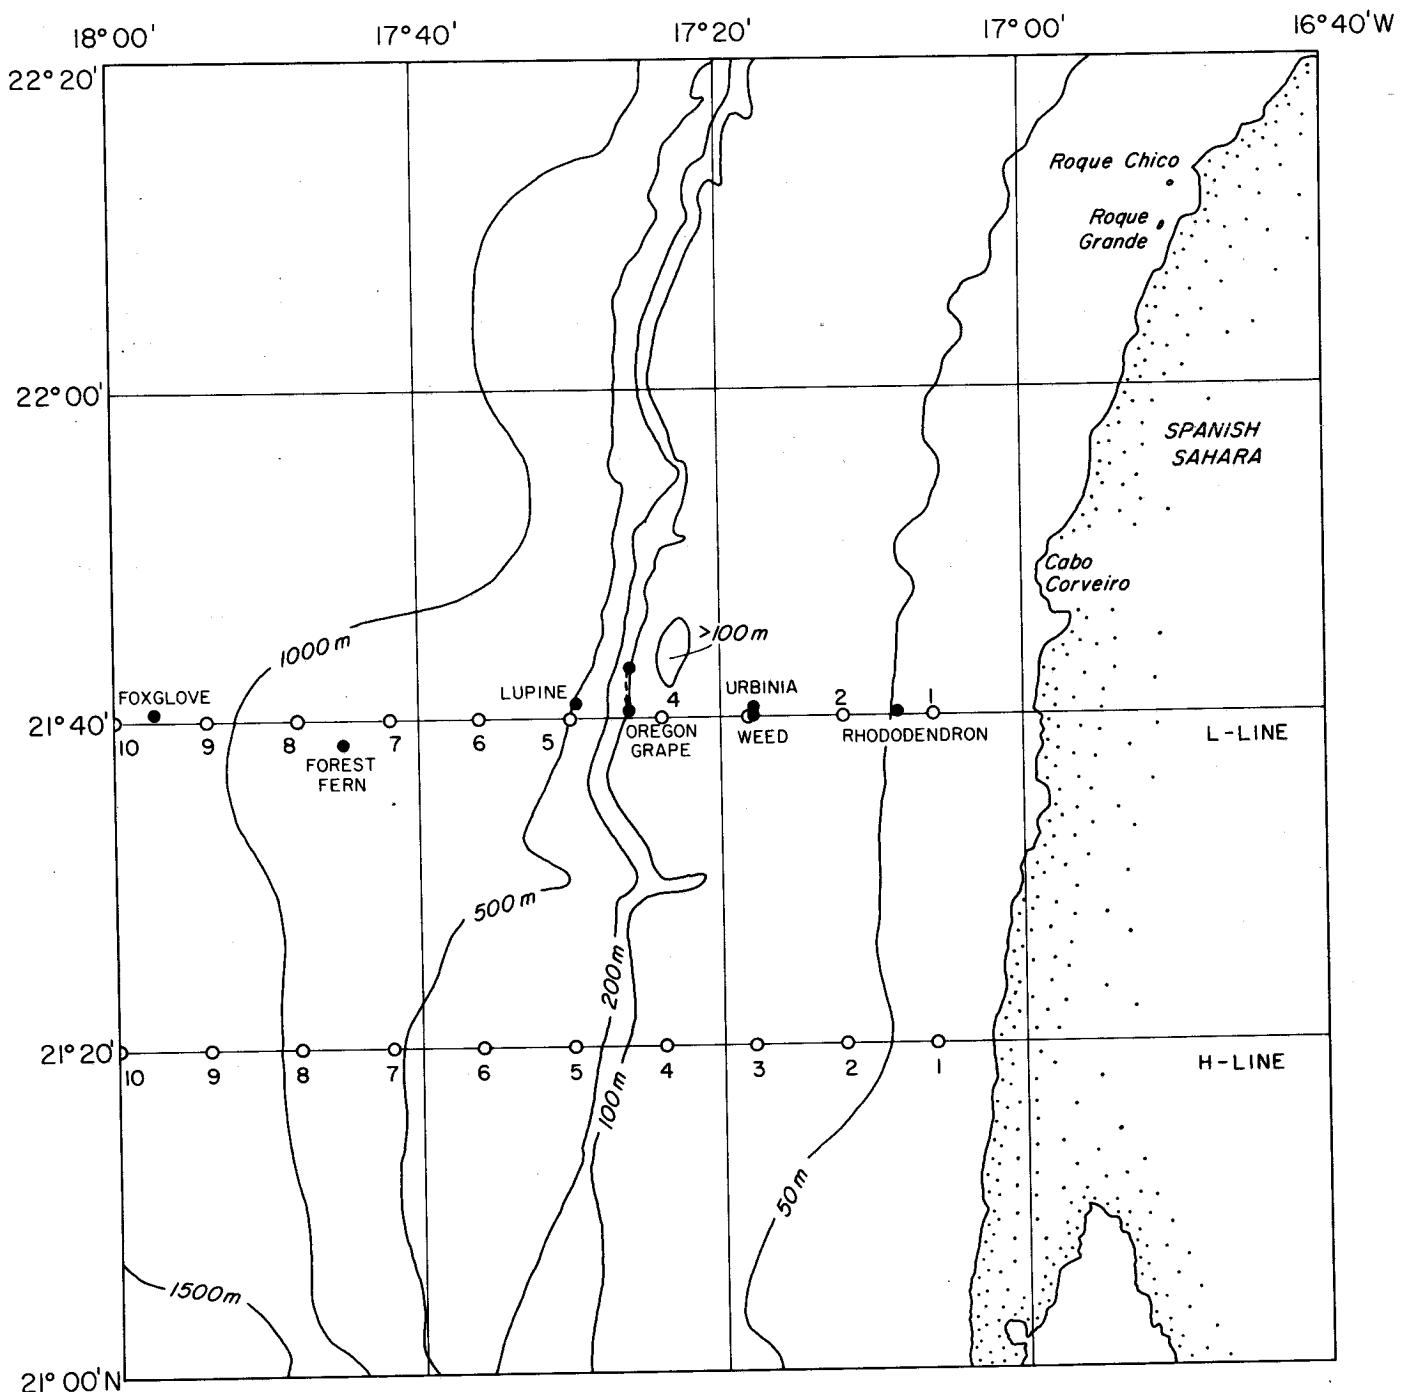

Figure 1. Locations of the current meter moorings Foxglove, Forest Fern, Lupine, Oregon Grape, Urbinia, Weed and Rhododendron during JOINT-I (February - April 1974). Solid dots indicate current meter moorings and open dots are hydrographic stations.

Introduction

During February - April 1974 an interdisciplinary experiment called JOINT-I was conducted in the coastal upwelling area off Northwest Africa. This experiment was part of the NSF International Decade of Ocean Exploration Coastal Upwelling Ecosystems Analysis Program (CUEA). The goal was to understand the physical dynamics and biological implications of upwelling phenomena.

Current meters and meteorological buoys were installed by Oregon State University (OSU, Corvallis), the Deutsches Hydrographisches Institut (DHI, Hamburg), and by the Pacific Marine Environmental Laboratory of NOAA (PMEL, Seattle). This volume presents only the data from current meters and meteorological buoys of OSU and DHI. A compilation of associated hydrographic data obtained by R/V GILLISS has been prepared by D. Barton et al. (1975).

The Current Meter Program

The current meter strings were aligned normal to the coast of Spanish Sahara along 21°40'N, extending from the inshore region seaward to a water depth of 1200 meters (Fig. 1).

The current meter moorings were subsurface taut wire moorings. The distribution of the instruments is shown in Fig. 2. Aanderaa current meters were used. These sampled an averaged current speed and the instantaneous current direction at 10 minute intervals.¹ At the same time, all meters recorded water temperature, and some measured conductivity

¹ The records of Rhododendron 1 and Urbinia 1 are based on 5 minute sampling intervals.

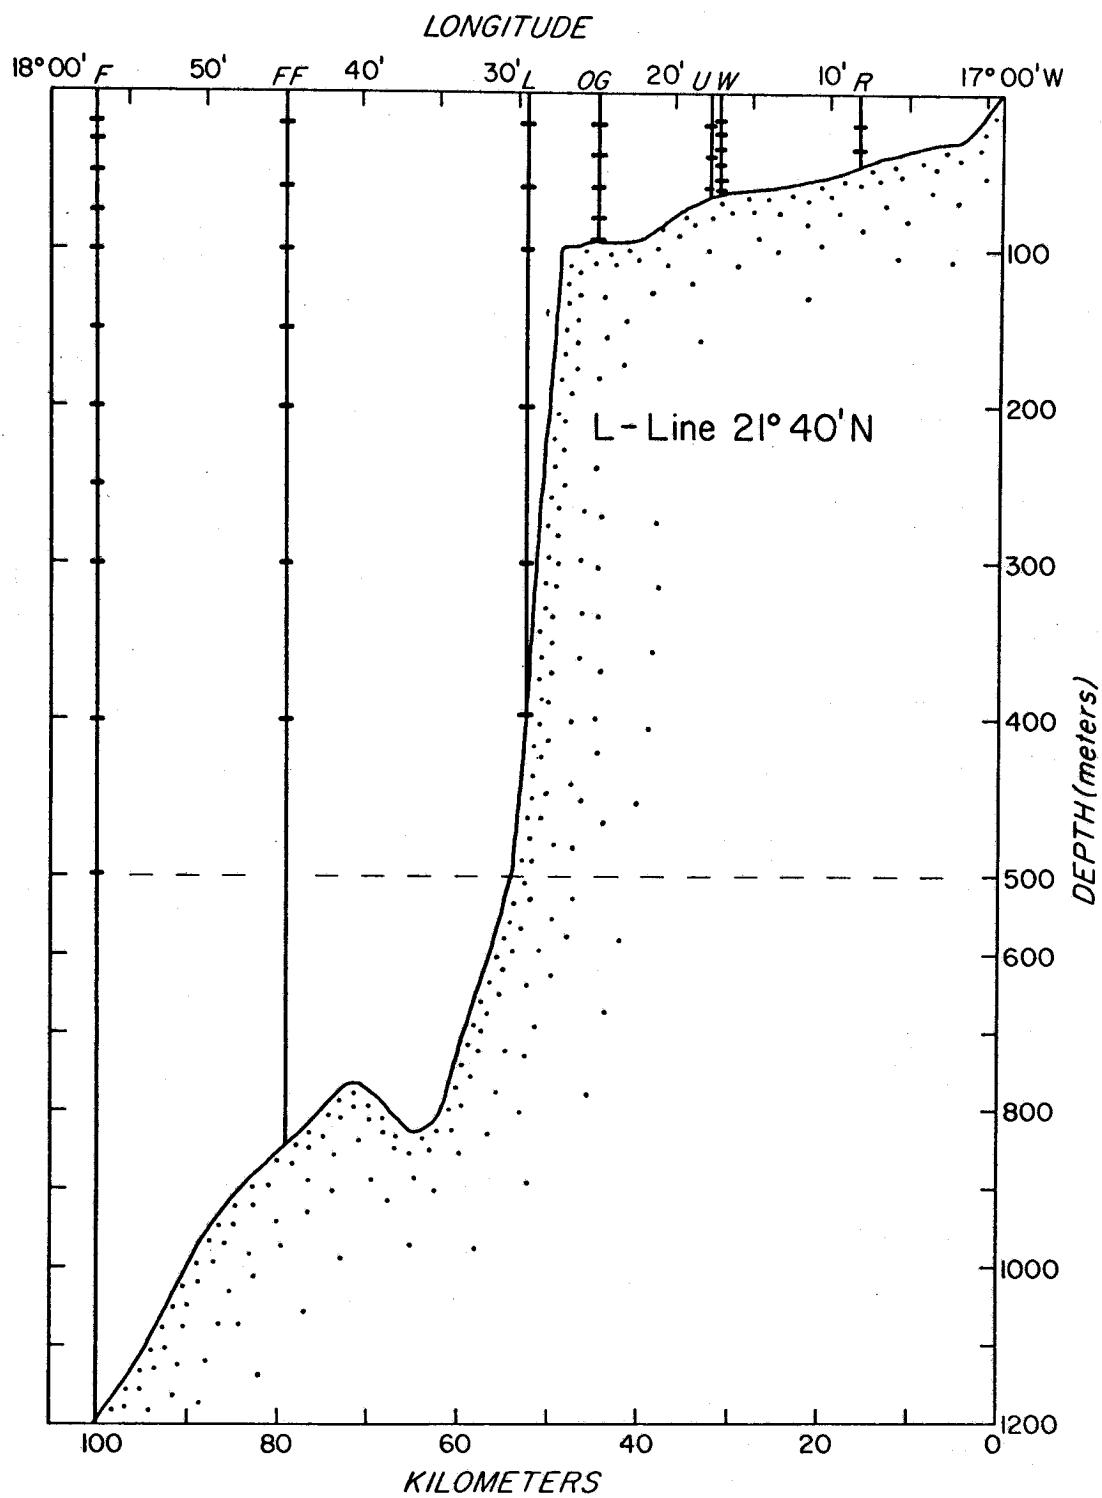

Figure 2. The vertical distribution of current meters along the mooring line during JOINT-I. Each bar represents a current meter.

and pressure. Depending on the water depth, two or five current meters at each array were equipped with pressure sensors to monitor the motion of the string and the true mean depths of the deployed instruments.

Wind data presented here were measured at Rhododendron, Urbinia and Forest Fern. Winds were recorded on Aanderaa data loggers. The sensors for wind speed, wind direction and air temperature were attached to a light metal mast at a height of about 3 meters above the sea surface. All meteorological parameters including surface water temperature were sampled every 10 minutes.² The wind speed is averaged over the sampling interval, the wind direction is instantaneous.

Two current meter strings were lost. One of these arrays was installed at shallow depths inshore from Rhododendron, and the other was the second installation of Oregon Grape. It is assumed that trawlers caused these losses.

Strong winds and high seas occasionally impeded launching and recovery activities, so the lengths of the time series and the periods of common operation were partially impaired by the weather as well as by the fishery (Fig. 3).

Description of the Processed Data

OSU current meters were calibrated before the experiment. All measuring units exhibited satisfactory reproducible data. The method of calibration and the subsequent procedure of data processing is explicitly described by R. D. Pillsbury et al. (1974).

² The records of Rhododendron 1 and Urbinia 1 are based on 5 minute sampling intervals.

JOINT-I Current Meter Array

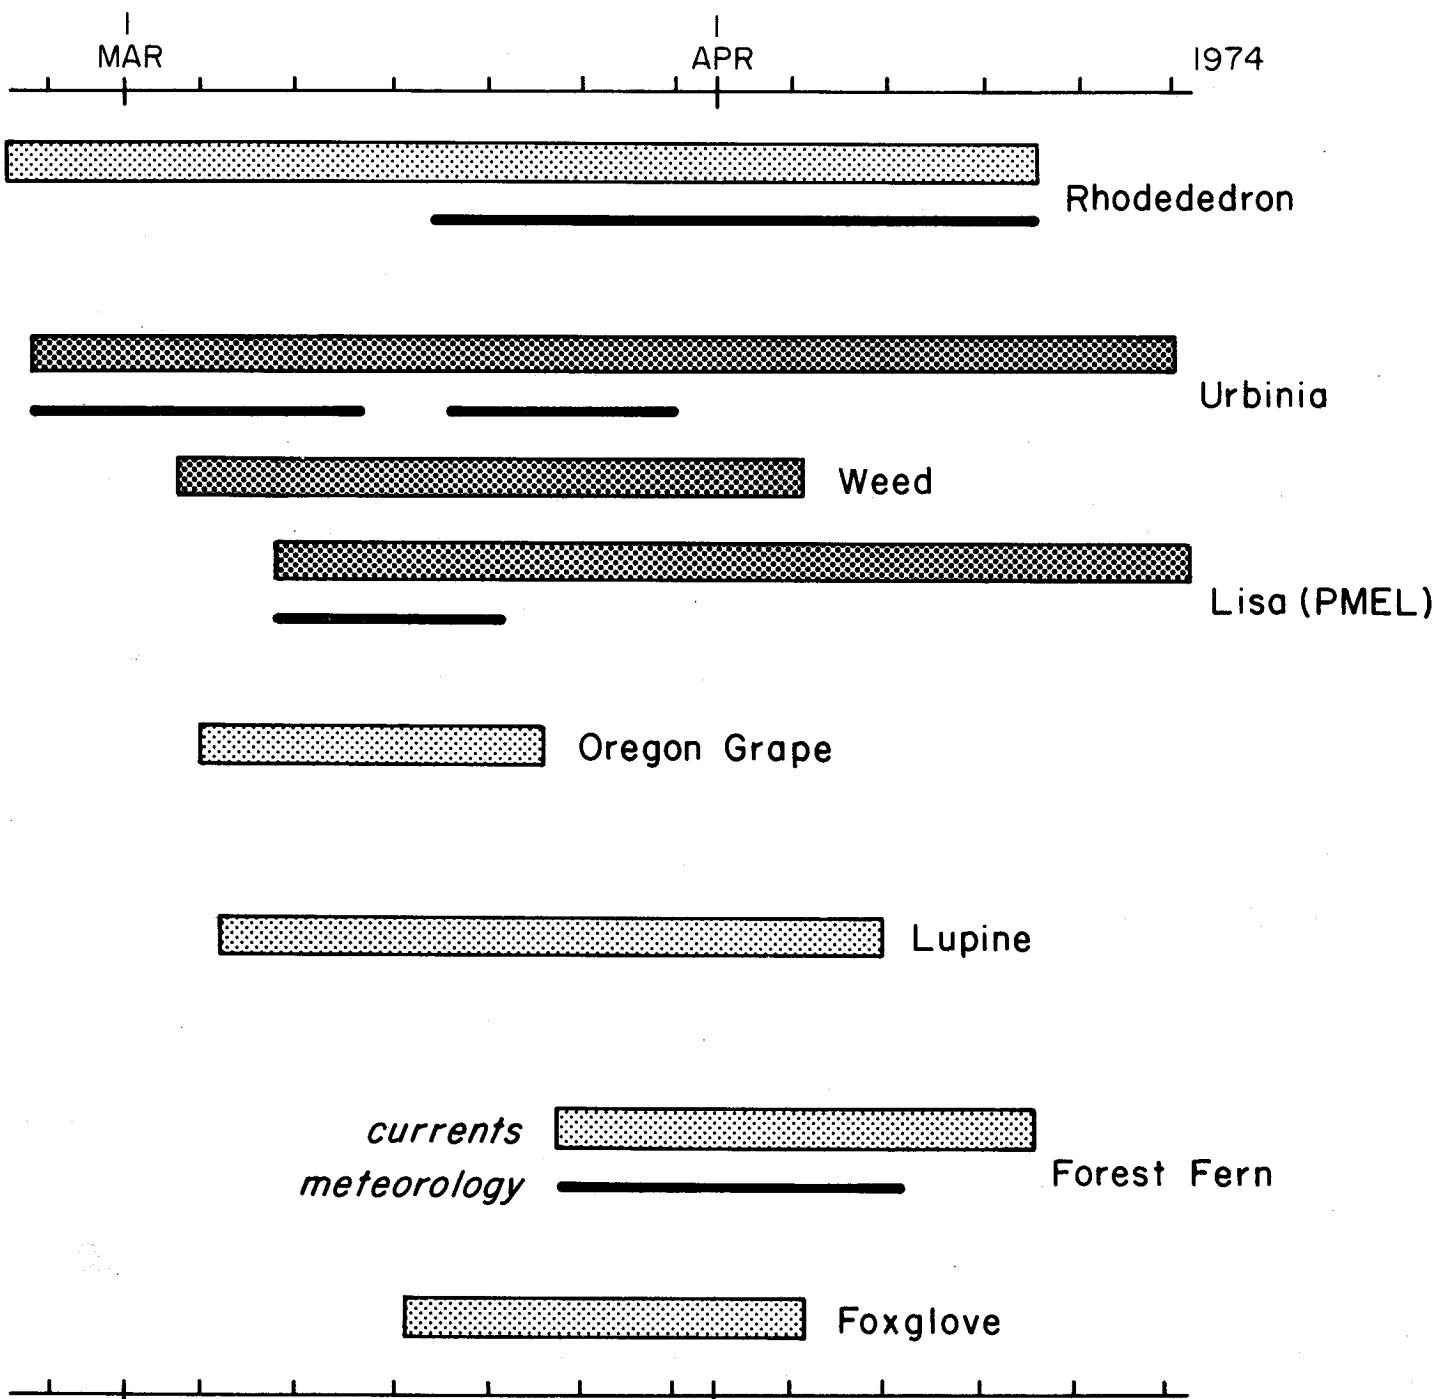

Figure 3. Operation time of the different moorings during JOINT-I. The PMEL installation Lisa was located in the proximity of Urbinia and Weed (less than 1 nm apart). Shaded beams denote the current measurements; thick black lines denote the wind measurements.

Data from each string of current meters are presented separately. The header page gives information about the location of the string, the data interval, and a general statement about the kind and quality of the data. The depth of the instruments is given two ways. The intended depth is based on mooring wire length and intended water depth. When the current meter had a pressure sensor, the actual depth of the instrument is given by the mean pressure. However, each meter record is identified by intended depth.

Each meter has a serial number assigned to it by the manufacturer. Each successive tape recorded by that machine is numbered with the serial number and the tape number. Thus, 485/10 indicates the tenth tape from machine number 485.

The table of statistics presented next gives the arithmetic mean, the standard deviation, the skewness, kurtosis, the maximum value, and the minimum value.

Real time plots of the hourly values follow the table of statistics. (For a discussion of the filter used to produce these hourly values, see Appendix 2 of Pillsbury *et al.*[1974]). For ease in comparison, the plots of the winds and the currents have been grouped by true east-west (U) components and true north-south (V) components.

There are errors in the presented wind components from Urbinia 1 during the 13 to 16 March. Before and after this period these time series of the winds are reliable. This has been established by comparing the data from Urbinia 1 with shipboard measurements and the simultaneous wind records at Lisa. A heavy sand storm just prior to the instrumental malfunction was believed to cause the failure of the direction sensor. After

16 March Urbinia 1 was picked up (17 March). The wind sensors were replaced, the magnetic tapes changed, and the string was moored again.

The progressive vector diagrams (PVD's) are all scaled to page size, and all scale numbers are in kilometers. These plots represent a pseudo-trajectory, and each dot on the PVD is 0000 GMT of successive days. The spectra presented are rotary spectra as discussed by Mooers (1970) and Pillsbury (1972). Figure 4 shows the conversion from cycles/hour to cycles/day.

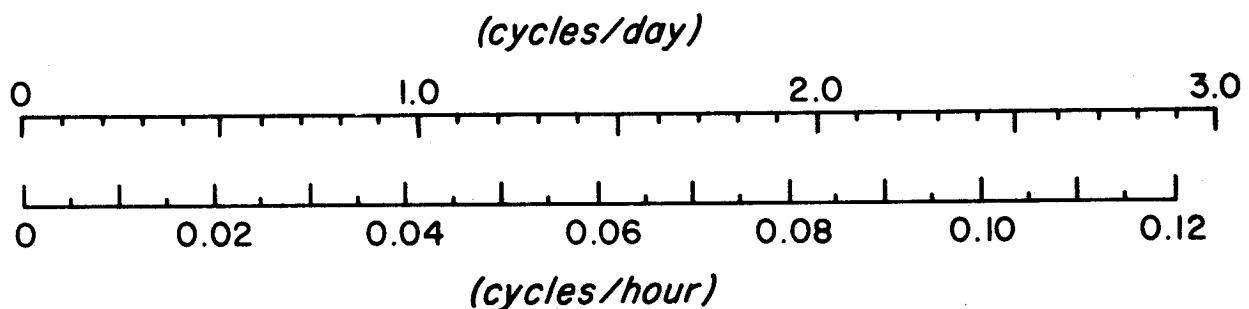

Figure 4

ACKNOWLEDGMENTS

The funds for the program came from National Science Foundation grant GX-33502, a support which is gratefully acknowledged. We are indebted to Dr. R. L. Smith, who contributed to designing and coordinating the experiment. Many thanks go to B. Moore and D. Barstow for the calibration and preparation of the instruments as well as for their effort during the fieldwork. Appreciation also is expressed to D. Root and W. E. Gilbert for their invaluable assistance in the data processing. Special thanks are due to K. Tamura who typed this report, and C. Christenson for the drawings and the final editing of the data. Finally, we gratefully acknowledge the cooperation of Captain Hagan and his crew from R/V GILLISS, which made the operation during JOINT-I successful.

The windspeed sensor malfunctioned intermittently and it was necessary to replace hundreds of speeds during the first 9 1/2 days of the installation by interpolated values. Because of the probable effect of this on the spectrum, no current spectrum were computed.

Depth of Water: 1200 m

Surface buoy set at 1400 GMT 7 March 1974 by R/V GILLISS

Subsurface moorings set at 0721 GMT 17 March 1974 by R/V GILLISS

Retrieved at 1036 GMT 6 April 1974 by R/V GILLISS

Data Interval: 0721 GMT 17 March to 0121 GMT 6 April

Instrumentation

<u>Intended Depth</u>	<u>RCM4 Serial No./Tape No.</u>
0 m	D124/9
18 m	911/1
30 m	912/1
50 m	914/1
75 m	915/1
100 m	790/1
150 m	791/1
200 m	453/26 917/1 (flooded)
300 m	990/1
400 m	910/1 792/1

Data were recorded every 10 minutes. The surface buoy was set on 7 March, but the subsurface instruments were not installed until 17 March due to inclement weather. All subsurface meters recorded temperature, current speed and direction except the 250 m instrument which was flooded. Pressure sensors failed on the 50 m, 75 m and 200 m instruments. On the 500 m instrument, the speed rotor apparently stalled for about a day and a half, starting near 1200 hours 2 April. But it produced good speeds both before and after this malfunction. The surface buoy measured air and water temperature.
