Introduction to BRANCHES project

BRANCHES - Boosting rural bioeconomy networks following multi-actor approaches

- HORIZON2020 project
- 12 partners for Finland, Germany, Italy, Poland, Spain
- Duration 1.1.2021-31.12.2023
- Total budget 2 M€
- www.branchesproject.eu

Background and aim

- Bioenergy technologies are becoming more **innovative, advanced and diverse**
- **New technological progress and knowledge** to foster rural bioeconomies has been created in scientific projects
 - The generated information and knowledge is in danger of remaining **untapped**
- **BRANCHES fosters knowledge transfer** of innovative bioeconomy practices in agriculture, forestry and rural areas to strengthen the connections between science and practice
 - Aim to **foster renewable energy uptake** in rural areas and **boost the regional bioeconomy**

BRANCHES-consortium has 12 partners from five European countries: Finland, Spain, Italy, Poland and Germany.

Approach

- Information of **currently available and innovative** bioenergy technologies and recent research findings are **screened and summarized**
- The **practice-oriented knowledge** of the most innovative and cost-efficient solutions are shared to farmers, foresters and practitioners via:
 - **Practice Abstracts**
 - Bottom-up oriented activities such as **workshops and showcases**

BRANCHES BOOSTING RURAL BIOECONOMY NETWORKS FOLLOWING MULTI-ACTOR APPROACHES

31 PRACTICE ABSTRACT

Climate-smart food production

The Oviija organic farm is a pilot farm that follows the innovative principle, taking into account both nutrient recycling and carbon sequestration. The aim of the farm is to mitigate climate change and to increase biodiversity. In addition, emissions to Baltic Sea are minimized.

Cows, horses and sheep graze on the farm. Carbon sequestration and biological cultivation is the aim in the fields. All the fields (180 hectares) are on grassland, which aims to improve the structure of the land. The farm is gradually switching into a crop rotation with the emphasis on native species and nitrogen-binding plants.

In addition to food production, the farm has a biogas plant and a wood gasification plant, from where the gas is utilized in electricity and heat production. The farm also utilizes solar power.

Grass and manure from the farm are used as a feed for the biogas plant. The produced biogas is upgraded, after which biomethane can be used as a vehicle fuel or on heat and electricity production.

Biogas contains always around 40% of carbon dioxide. Instead of releasing it to the atmosphere, in Oviija the carbon dioxide is fed to OPower's biological methanation pilot plant, which utilizes microbes to produce methane from carbon dioxide and hydrogen. Hydrogen for the pilot plant is obtained from electrolysis and from the wood gasification unit. Plant's efficiency is 82%, and at its best, the methane production can be doubled.

Digestate from biogas plant is used as fertilizer on the farm. By improving the soil structure and using recycled fertilizers according to plant needs, nutrient leaching is minimized and carbon sequestration in the fields is increased. All work is done for the climate and the Baltic Sea, biodiversity being the foundation for all actions.

KEY WORDS
Biomethane, carbon neutral agriculture

31 PRACTICE ABSTRACT

ADDITIONAL INFORMATION

The key principle of Oviija farm is to control climate change, and to protect Baltic Sea and biodiversity, and this is reflected in all practices and techniques used at the farm. One example of these practical control methods is plant-based carbon sequestration. The efficiency of carbon sequestration in farms is affected by the assortment of carbon-storing plants present in the farm. For example, both deep-rooted grasses and leguminous plants are excellent at absorbing and storing carbon. In addition to the assortment of plants, the method of harvesting has also an impact on the amount of stored carbon.

For instance, leaving grasses taller after cutting allows the plants to keep photosynthesizing and their roots recover more quickly from cutting. In the fields of Oviija, the height of the grass has been left to 15 cm instead of the previous 10 cm, which has been documented to affect the duration of greenhouse gas emission release after the cutting. The carbon sequestration of grasses based on grass with number of growth cycles (perennial grass), continuous vegetation cover and on photosynthesis resulting in deeper and wider root system. The carbon bind by the roots is consumed by microbes present in the soil. The carbon bound by the dead microbes improves the humus content of the soil, which is directly reflected in growth conditions and the security of crop supply. In addition, it improves the tolerance of the arable land against the extreme weather conditions caused by climate change.

Grazing is also an effective method to improve the effectiveness of carbon sequestration of grass and plants. In Oviija, cows, sheep and horses graze utilizing a hardened pasture cycle, where a large herd graze in a single grazing area only for a short time and then move all at once to another grazing area. This cycling allows the plants to regrow while also keeping the farm animals fed until the cycle is repeated. Agroforestry, a farming method where trees and bushes are cultivated alongside crops, is also an effective method of carbon sequestration. The broader biodiversity of plants in these farmlands also improves the balance of microbes and fungi that are beneficial for carbon sequestration. Over 700 ha of forest grow at the Oviija farm, utilizing the continuous forest management method, where the trees are allowed to regenerate naturally. These agroforests contain different trees of different size and age and thus retain their biodiverse ecosystem better than typical cultivated forests. Wood obtained from thinning is used locally on the farm in the wood gasification process to produce heat and electricity.

ABOUT BRANCHES
BRANCHES is a H2020 "Coordination Support Action" project, that brings together 12 partners from 5 different countries. The overall objective of BRANCHES is to foster knowledge transfer and innovation in rural areas (agriculture and forestry), enhancing the viability and competitiveness of biomass supply chains, and promoting innovative technologies, rural bioeconomy solutions and sustainable agricultural and forest management.

THE PARTNERSHIP

A minimum of 25 Practice Abstracts (PAs) are produced to distribute knowledge of innovative bioenergy technologies. Find all available PAs [here](#).

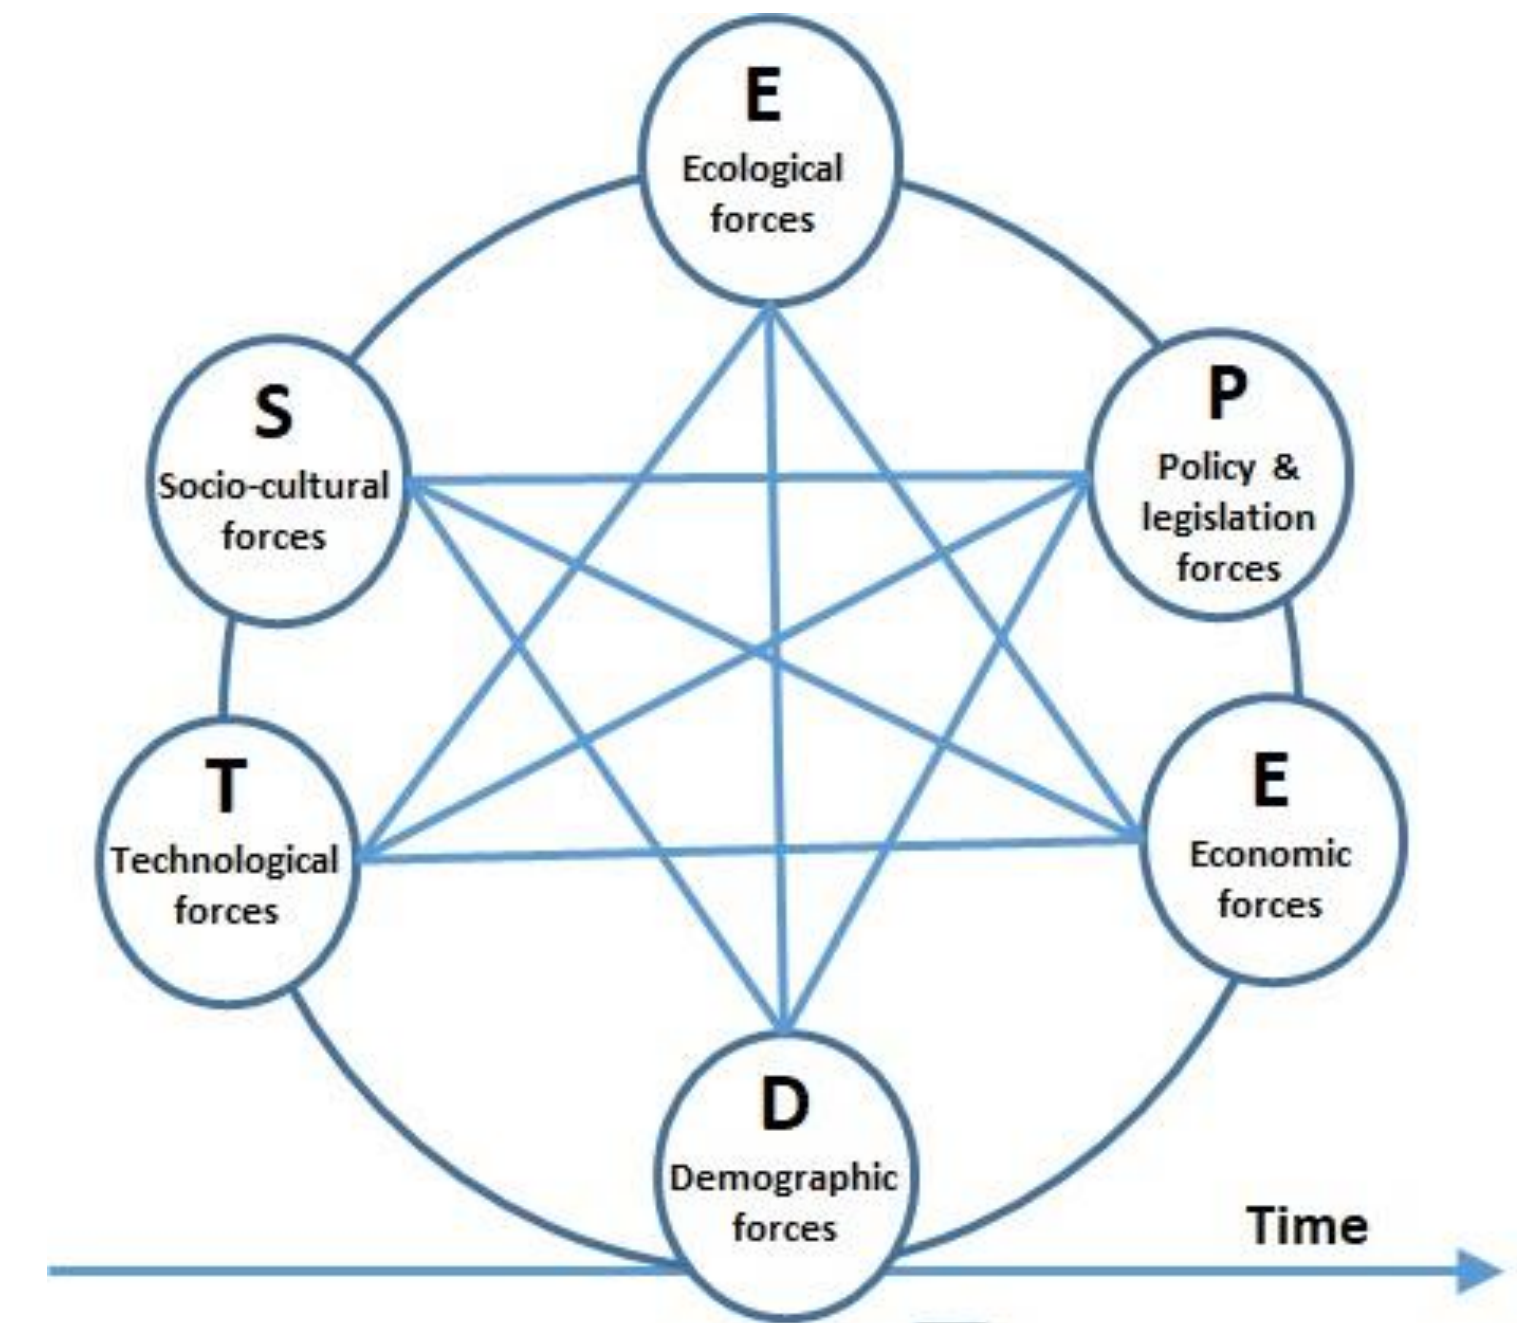

Workshops are organized to share information and collect feedback of the innovative solutions.

Drivers and barriers

- In addition to knowledge transfer, BRANCHES aims also to understand the **drivers and barriers** behind the innovative and available bioeconomy practices
- The drivers and barriers are based on discussions with **practitioners or related technology providers** while summarizing the information for the Practice Abstracts and while discussing the practices in workshops
 - In addition, the **technical and sectorial partners** of the BRANCHES consortium can evaluate drivers and barriers according to their expertise

DEPEST analysis tool is used for collecting the drivers and barriers of the shared practices.

Objectives of the presentation

Objectives of the presentation

- Explore **drivers** that promote the adoption rural bioenergy technologies
- Discuss the **barriers** that hinder their widespread implementation
- Presents **case examples** of rural bioenergy solutions in which certain driver or barrier applies

Drivers for Rural Bioenergy Technologies

Drivers for Rural Bioenergy Technologies

Environmental Benefits

Economic opportunities

Energy Self-Sufficiency and Security

Environmental benefits

- Bioenergy production provides **ecological benefits** and **reduction of carbon footprint** in **heat, power** and **transportation fuel production**
- Benefits can be achieved **throughout the overall value chains**
 - Farmers, municipalities, industries..
- Harnessing value from agricultural side products has also positive impacts on **waste management**
 - Reduces e.g., fire risk and need for landfilling

Economic opportunities

- Rural bioenergy production can create **employment** and hence foster **economic growth** in rural areas
- Farmers can obtain new sources of income by e.g.:
 - Supplying **feedstock** for bioenergy/bioeconomy plants
 - Producing **energy** (electricity/heat)
 - Producing **transportation** fuels such as biomethane
- An innovative example comes from Germany, where local farmers cultivate meadow grass and sell it for a local bioeconomy company Biowert for biobased thermoplastics and biogas production as a source of income

Harvesting meadow grass. Photo: [Biowert](#).

Energy Self-Sufficiency and Security

- Using local biomass sources:
 - Promotes **energy independence** in rural communities
 - **Reduces reliance** on imported fossil fuels and volatile energy markets, at the moment, the cost of fossil energy is high
- As an example, a municipality of Kisielice in Poland has replaced fossil fuel use in district heating with heat generated from local by-product straw
 - Cereal straw is bought from local farmers
 - Ash returned for free to be used as fertilizer in the fields
- Another Polish municipality Barciany has steadily developed its energy independence and replaced coal use in heating by:
 - Biomass-based district heating using wood chips from trimming roadside shrubs, and forest and garden residues as raw materials
 - Geothermal heat pumps and solar PV supply heat for municipal buildings

Straw is a by-product of agriculture, that can be used for local energy production. Picture CIRCE.

Barriers for Rural Bioenergy Technologies

Barriers to Rural Bioenergy Technologies

Financial Constraints

High investment costs
Accessing finance

Technological Challenges

Technology maturity, scalability, cost-efficiency, lack
of replicates

Policy and Regulatory Framework

Inconsistent regulations

Policies to facilitate R&D

Case Examples to Overcome Barriers

Incentive Programs

- **Investment costs** for bioenergy production can be high
 - Financial constraints can prevent uptake of the technologies in rural regions
- **Incentive programs/financial mechanisms** such as **grants** to support the investment costs can encourage the adoption of rural bioenergy technologies
- Investment grant from Rural Development Fund was an important driver for investment in a Finnish berry farm
 - The farm invested into a hybrid energy solution consisting of solar PV and a wood gasification unit for combined heat and power production
- The farm consumes a lot of electricity throughout the year due to berry freezing
 - The hybrid solution enables the farm to obtain energy self-sufficiency and to financially secure the operation of the berry farm from increasing electricity prices

The berry farm is energy self-sufficient thanks to the hybrid solution. Photo: Luke

Wood gasifier starts operating in late summer when the berry season reaches its peak and is operated for 9-10 months. Photo: Luke

Collaboration and Partnerships

- Collaboration and partnerships bring together different stakeholders to share financial burden and create shared benefits
- **Collaboration** between food company and farm has enabled rural biomethane production in Finland
- Biomethane production has a **chicken-egg** problem
 - **Guaranteed and stable demand** is a prerequisite to make the production profitable
- A milk truck of a food company Valio has **committed to buy biomethane** generated at a dairy farm
 - New business opportunities and sources of income for the farmer
 - Reduced carbon footprint for the food company

Collaboration and Partnerships

- Another example of a successful partnership can be found from Theuma, Germany
- Partnership between **municipal government** and **agricultural cooperative** has created a supply chain to process locally sourced agricultural residues into biogas
- **Big parts of the community** are involved in the value chain and are benefiting from it:
 - Farmers find use for agricultural and livestock residues
 - Biogas and CHP plants provide employment in the community
 - Electricity and heat in the municipality are produced and sourced locally, excess heat used by local industries, e.g., wood chip drying
 - Digestate from biogas production used as fertilizer in local fields

Biogas production in Theuma. Photo: [Sachsen.de](#)

Research and Development

- R&D needed to **advance** bioenergy technologies to overcome technological challenges (e.g., maturity and scalability) and to make technologies more cost-efficient
- Qvidja experimental farm in Finland provides premises for **versatile R&D** for rural bioenergy production:
 - Biogas production
 - Biological methanation
 - Wood gasification
- In biological methanation, microbes are utilized to produce methane (CH_4) from carbon dioxide (CO_2) and hydrogen (H_2)
 - The plant can utilize CO_2 separated from biogas process
 - Hydrogen for the pilot plant is obtained from electrolysis
 - Aim to obtain more biomethane from organic feedstock and to reduce the demand of CO_2 purification

Qvidja farm provides a R&D environment for various renewable energy technologies. Photo: [“The farmer isn't the problem, they are the solution”](#)

Conclusion and next steps

- **BRANCHES** project fosters knowledge transfer of innovative bioeconomy practices in agriculture, forestry and rural areas
- Based on the on-going research in the project, main drivers and barriers identified for rural bioenergy technologies are:

Main drivers

- Environmental benefits
- Economic opportunities
- Energy self-sufficiency and security

Main barriers

- Financial constraints
- Technological challenges
- Policy and regulatory framework
- Several good case examples already exist on how the barriers have been solved
- Elaboration of drivers and barriers continues in the BRANCHES project
 - Final results at the end of the project in 12/23
- In addition to identifying drivers and barriers, BRANCHES project will create policy recommendations for selected biomass value chains in agriculture and forestry
