The study concluded that the Decentralized Vine Multipliers were trained on good agronomic practices, the business model was not effective due to lack of training for DVMs on business management, inadequate inputs, lack of sweet potato seed market, low price of sweet potato vines. Therefore, it was recommended that farmers should make effort to form clusters of sweet potato vine multipliers to enable them attend regular trainings on good agricultural practices and business management to ensure high yields and quality assurance through certification by the National Agricultural Seed Council (NASC).

ABSTRACT

Atrazine and nicosulfuron are persistent herbicides widely used for weed management in maize. The persistence of these herbicides extends the duration of weed control but may injure associated and follow-up crops of maize. Hence, soil amelioration may be necessary to deter the phytotoxic effect of herbicide residue on these crops. A screenhouse experiment was conducted to investigate the effect of sawdust on atrazine and nicosulfuron residue in the soil using *celosia argentea* as a test crop. A 4 x 5 factorial experiment was laid out in a completely randomised design with four replicates. The first factor comprised four herbicide levels: herbicide-free (control), atrazine at 3.0 kg a.i ha^{-1}, nicosulfuron at 40 g a.i ha^{-1}, and a mixture of atrazine and nicosulfuron at 750 g a.i ha^{-1} and 60g a.i ha^{-1}, respectively. The second factor comprised five levels of sawdust; 0% (control), 5%, 10%, 15%, and 20% by volume in the potting soil. The number of celosia leaves per plant and the plant heights were recorded weekly from 3 weeks after transplanting (WAT) to 6 WAT. The fresh and dry weights of the celosia plants at 6 WAT were also recorded. Findings indicated that residues of the herbicide levels in the soil did not significantly (P<0.05) reduce the number of leaves, plant height and fresh weight of celosia. However, nicosulfuron impacted the dry weight of celosia shoots negatively. Sawdust at a low proportion of 5% and 10% improved celosia growth, whereas a 20% proportion reduced celosia growth. The interaction of atrazine and nicosulfuron with 5% sawdust resulted in enhanced growth and yield of celosia over untreated soil. Hence, for the follow-up crops of maize, the addition of 5% sawdust is recommended within the rooting depth of atrazine and nicosulfuron-treated soil.

INTRODUCTION

Atrazine and nicosulfuron are selective herbicides used for weed management in maize production (Akadiri et al., 2017). The persistence of these herbicides in the soil may negatively affect the growth of vegetables cultivated in maize plots in a relay cropping system or as catch crops (Aladesanwa, 2001; Mamnoie, 2021). Increasing the pre-plant interval to avoid reduced vegetable yield in atrazine and nicosulfuron-treated plots may invalidate the fitness of vegetables for the relay cropping system. Hence, it is imperative to alleviate the harmful effect of herbicide residue by reducing its availability to sensitive vegetable crops without significantly disrupting the sowing dates.

Organic matter is an important absorbent for herbicides (Spark & Swift, 2002). Applying soil organic amendments may increase herbicide persistence by increasing the sorption process (Mehdizadeh et al., 2019). However, the sorption of herbicides by organic matter makes them less available for plant uptake (Williams et al., 2001). Celosia (*Celosia argentea*) is a commonly cultivated vegetable in Nigeria and has been reported to be sensitive to atrazine and nicosulfuron (Aladesanwa et al., 2001; Mishra et al., 2016). Hence, this study investigated the effect of sawdust on atrazine and nicosulfuron residues using celosia as a bioassay.

MATERIALS AND METHODS

Collection of materials and preparation of potting media

Seeds of *Celosia argentea* (TLV 8) were sourced from the National Horticultural Research Institute (NIHORT), Ibadan, Nigeria. The seeds were stored in a paper bag and kept in a dry environment before planting. Topsoil within 0-15cm depth was collected from the Faculty Garden of Adekunle Ajasin University, Akungba-Akoko, Ondo State, Nigeria. The soil was air-dried, sieved with 2mm mesh, and used to fill polythene plant pots measuring 5 cm x 3 cm. In preparing the potting media, ratio-based volume mixing of topsoil and sawdust was adopted. Each sawdust level (0%, 5%, 10%, 15%, and 20%) was used to fill sixteen pots. Hence, eighty filled pots were arranged 1 m apart in the screenhouse. The topsoil used is a sandy clay loam with a neutral pH, 0.96% organic carbon, 1.65% organic matter, 0.08% nitrogen, 3.5 mg kg^{-1} phosphorus, and 0.61 mg kg^{-1} potassium. The soil's sodium, calcium and magnesium contents were determined to be 0.81, 1.4 and 0.7 cmol kg^{-1}, respectively. The sawdust had 94.82% organic carbon, 5.24 mg kg^{-1} phosphorus, and 2.77 mg kg^{-1} potassium. The sawdust's sodium, calcium and magnesium contents were analyzed to be 2.61, 3.21 and 1.86 cmol kg^{-1}, respectively.

Experimental design and treatments

A 4 x 5 factorial experiment in a completely randomised design (CRD) was laid out in a screenhouse at Adekunle Ajasin University, Akungba-Akoko, Nigeria and replicated four times. The first factor comprised four herbicide levels; herbicide-free (control), atrazine at 3.0 kg a.i ha^{-1}, nicosulfuron at 40 g a.i ha^{-1}, and a mixture of atrazine and nicosulfuron at 750g a.i ha^{-1} and 60g a.i ha^{-1}, respectively. The second factor comprised five levels of sawdust in the potting topsoil; 0% (sawdust-free control), 5%, 10%, 15%, and 20%.

Herbicide application in the screenhouse

For per hectare herbicide application proration, four plots measuring 1 m x 1 m each were marked out in the screenhouse. Twenty pots were arranged within each plot such that the five levels of sawdust were replicated four times. Thereafter, different herbicide levels were singly applied to each plot using a knapsack sprayer. Only water was applied to the herbicide-free control.

Transplanting of celosia seedling

Two weeks after sowing (WAS), celosia seedlings at a two-leaf stage were transplanted from the nursery to the potted soil in the screenhouse. The seedlings were transplanted six weeks after herbicide application. The bed was watered thoroughly before transplanting to avoid root damage. Transplanting was done in the morning to reduce water loss through transpiration.

Data collection and analysis

The height and number of leaves of celosia were recorded weekly, starting from 3 weeks after transplanting (WAT) and continued till 6 WAT. Celosia plants were uprooted and analyzed for fresh and dry weight at 6 WAT when the plants had attained commercial maturity. Data obtained were subjected to Analysis of Variance using SPSS version 23 software. The treatment means were separated using Duncan Multiple Range Test at a 5% probability level.

RESULTS

Effect of herbicide residue on growth and yield of celosia

Generally, the number of leaves per plant and height of celosia increased progressively with plant age. There was no significant difference ($P<0.05$) in the number of leaves at the herbicide levels at 3 WAT and 6 WAT, unlike 4 WAT and 5 WAT (Figure 1a). Atrazine had the highest number of leaves per plant at 4 WAT (11 leaves) and 5 WAT (25 leaves). Its number of leaves was significantly ($P<0.05$) higher than herbicide-free control and all herbicide levels at 4 WAT and 5 WAT, respectively. The number of celosia leaves recorded per plant in the herbicide-treated soil was not significantly ($P<0.05$) lower than in the herbicide-free soil throughout the trial.

Celosia plant heights were significantly ($P<0.05$) different across the herbicide levels at 3, 5, and 6 WAT (Figure 1b). At the aforementioned stages in the trial, atrazine had the highest celosia plant height (3.44 cm, 8.78 cm and 14.39 cm) and its celosia plant heights were significantly higher than the herbicide-free control (2.47 cm, 6.09 cm and 9.82 cm) which had the least.

There were no significant differences ($P<0.05$) in the fresh weights of celosia among the herbicide levels at 6 WAT (Figure 1c). Hence, the effect of herbicide residue on the fresh weight of celosia was insignificant. Celosia plants in potted soil treated with atrazine had the highest fresh weight of shoot (11.4 g) and root (2 g), while nicosulfuron had the least (5.6 g and 1 g, respectively). The dry weights of celosia shoot and root were significantly different ($P<0.05$) at 6 WAT (Figure 1d). Celosia plants in herbicide-free control had the highest dry weight of celosia shoot and root (1.05 g and 0.35 g). Herbicide-free control had a significantly higher weight of celosia shoot and root than nicosulfuron (0.42 g and 0.18g), which had the least. The dry shoot and root weight of celosia in nicosulfuron-treated soil were significantly reduced ($P<0.05$) compared to herbicide-free control. However, the atrazine-nicosulfuron mixture and atrazine had comparable celosia dry weights with the herbicide-free control.

Effect of sawdust on growth and yield of celosia

The number of leaves and plant height of celosia were significantly different ($P<0.05$) among the sawdust levels from 3 WAT to 6 WAT (Figure 2a&b). Throughout the trial, the highest number of celosia leaves (8, 14, 31, and 49 leaves) were recorded from 5% sawdust. Contrarily, 20% sawdust had the least number of celosia leaves (4, 5, 7 and 14 leaves), and it was significantly ($P<0.05$) lesser than 5% sawdust throughout the trial. Notably, 20% sawdust resulted in a significantly ($P<0.05$) reduced number of leaves at 3 WAT and 4 WAT compared to sawdust-free control (0% sawdust). However, it had a comparable number of celosia leaves per plant with sawdust-free control at 5 WAT and 6 WAT. Judging by the sawdust-free control, the 10% sawdust and 15% sawdust resulted in a significantly increased and a comparable number of celosia leaves, respectively.

Similarly, weekly results from 3 WAT to 5 WAT showed that 5% sawdust had the highest celosia plant height (4.09 cm, 6.94 cm, 10.77 cm and 17.71 cm). It was significantly ($P<0.05$) different from 20% sawdust which had the least plant height. The 5% sawdust and 10% sawdust resulted in celosia plant height significantly higher than the sawdust-free control (0% sawdust), whereas 15% sawdust and 20% sawdust resulted in a comparable plant height and a significantly reduced ($P<0.05$) celosia plant height, respectively.

The fresh and dry weights of celosia across the sawdust levels were significantly different at 6 WAT (Figure 2c&d). The 5% sawdust had the highest shoot, root and total fresh weight (15.94 g, 3.06 g and 19 g), whereas the lowest shoot, root, and total fresh weights were recorded in 20% sawdust (1.94 g, 0.06 g and 2 g). The shoot, root and total fresh weights that resulted from 5% sawdust were significantly higher than the sawdust-free control, whereas 10%, 15% and 20% sawdust had a comparable shoot, root, and total fresh weight. The dry weight of the celosia plant followed the same trend as the fresh weight across the sawdust levels.

Interaction of herbicide residue and sawdust on growth and yield of celosia

The number of celosia leaves differed significantly ($P<0.05$) among the herbicide and sawdust interactions. (Table 1). Based on weekly results, atrazine and 5% sawdust (A+S5%) recorded the highest number of celosia leaves from 3 WAT to 6 WAT (9, 21, 47, and 64 leaves). In contrast, atrazine and 20% sawdust (A+S20%) had the lowest number of celosia leaves at 3 WAT and 4 WAT (3 and 5 leaves). The interaction of nicosulfuron and 20% sawdust (M+S20%) resulted in the lowest number of celosia leaves at 5 and 6 WAT (7 and 11 leaves). Remarkably, the number of celosia leaves from atrazine and 5% sawdust (A+S5%) interaction was significantly higher ($P<0.05$) than in untreated soil (C+S0%) and herbicide-free soil with 5% sawdust (C+S5%). Also, untreated soil (C+S0%) had a comparable number of celosia leaves with all other interactions, except for the significantly increased number of celosia leaves at 4 WAT and 5 WAT by nicosulfuron and 5% sawdust (N+S5%) and interaction of atrazine and 10% sawdust (A+S10%) at 5 WAT.

The plant height of celosia differed significantly ($P<0.05$) with respect to herbicide and sawdust interaction. The interactions of atrazine and 5% sawdust (A+S5%) and nicosulfuron and 5% sawdust (A+S5%) had the highest celosia plant height at 3 WAT (5.25 cm) and 6 WAT (22.85 cm). Also, atrazine and 5% sawdust (A+S5%) resulted in the highest celosia plant height at 4 WAT (9.18 cm) and 5 WAT (14 cm). Notably, throughout the study, atrazine and 5% sawdust (A+S5%) had a significantly higher height of celosia plants than untreated soil (C+S0%). A similar trend was also found in nicosulfuron and 5% sawdust (N+S5%). None of the interactions had significantly ($P<0.05$) reduced celosia plant height compared to the untreated soil (C+S0%).

The fresh and dry weight of celosia per plant differed significantly ($P<0.05$) among the interactions of herbicide and sawdust. Atrazine and 5% sawdust (A+S5%) had the highest fresh shoot, root and total weight (26.75g, 5g and 31.75g) among the interactions. The least fresh shoot, root and total weights (1.25g, 0.10g and 1.35g) were found in nicosulfuron and 20% sawdust. However, the least fresh shoot, root and total weights were comparable with untreated soil (3.50g, 0.75g and 4.25g).

Herbicide-free and 5% sawdust (A+S5%) had the highest dry shoot, root and total weights of celosia (2.97g, 1.06g and 4.03g) among the interactions. The interaction of nicosulfuron and 20%

sawdust had the least dry shoot, root and total weight of celosia (0.08g, 0.02g and 10c), and it was comparable with the untreated soil (C+S0%).

DISCUSSION

This study showed that celosia could be transplanted into atrazine-treated soil six weeks after treatment without a decrease in yield. The transient increase observed in the growth parameters of celosia plants in atrazine-treated soil might have resulted from the hormetic effect (low dose stimulation and high dose inhibition of growth) of atrazine residue. Lytle & Lytle (2005) observed stimulatory growth in *Sesbania vesicaria* and *Vigna luteola* exposed to low concentrations of atrazine. The absence of atrazine phytotoxicity in this study might have resulted from the mitigated concentration of atrazine through decomposition and sorption. Atrazine catabolism and sorption by soil components reduce the concentration of atrazine in the soil, thus causing the stimulatory effect at a low concentration.

The reduced dry weight of celosia in nicosulfuron-treated soil was probably due to the phytotoxicity of nicosulfuron residue. Rahman et al. (2011) reported that nicosulfuron residue reduced the dry weight of mustard plant (*Sinapis alba*), unlike atrazine applied on the same day. The use of herbicide mixture for weed management is justified in this study as soil residue of atrazine and nicosulfuron mixture was not phytotoxic to celosia even at a higher concentration of nicosulfuron, which solely reduced celosia dry weight.

For a longer duration of this trial, the improved growth of celosia in soil treated with 5% and 10% sawdust was probably due to the ability of sawdust to decrease the soil bulk density and increase the soil organic carbon content. The decrease in celosia growth caused by 20% sawdust could be attributed to nitrogen immobilization commonly associated with soil amendments with a high carbon-to-nitrogen ratio (Iroegbu et al., 2020). This study corroborates the findings of Siddiqui & Alam (1990) that sawdust as soil amendment improves the growth of plants.

The comparable growth of celosia in atrazine-treated soil without sawdust and untreated soil disagrees with Aladesanwa et al. (2001), who reported reduced growth of celosia sown within twelve weeks pre-plant interval on atrazine-treated soil. It is opined that the difference in the soil textural class used for this study may be responsible for this different outcome. Further studies on the role of the higher clay content in the soil may provide more helpful information. The improved growth of celosia resulting from the interaction of atrazine and nicosulfuron with 5% sawdust over the interaction of herbicide-free and 5% sawdust indicates the synergistic effect of 5% sawdust and residues of atrazine and nicosulfuron.

CONCLUSION

The soil residues of atrazine and atrazine-nicosulfuron mixture are not injurious to celosia transplanted at a pre-plant application interval of six weeks. Using a mixture of atrazine and nicosulfuron for weed management in maize mitigates the phototoxic effect of sole nicosulfuron residue on follow-up celosia. Applying 5% sawdust to atrazine and nicosulfuron-treated soil improves celosia growth.

56th Annual Conference
Agricultural Society of Nigeria
24 - 28 Oct., 2022

ABSTRACT: This study was conducted to evaluate weed species composition based on observation and changes in response to trash mulch and weed control measures in two sugarcane genotypes in 2016 and 2017. The treatments are two sugarcane genotypes (Bida local and NCS 001), four sugarcane trash mulch levels (0, 3, 6, 9 t ha^{-1}) and four weed control measures (weedy check, 5 monthly hoe weeding (5 MHW), pre-emergence (PE) application of diuron at 2 kg a.i ha^{-1} + Post-Emergence (POE) of 3-maize force at 179.2 g ha^{-1} + two hoe weeding (2 HW)] and PE diuron + POE 3-maize force arranged in a split plot design and replicated three times. Weed control measures and trash mulch constitute the main plot while sugarcane genotypes constitute the subplot. Based on the importance value, the results indicated that *Paspalum scrobiculatum* (L.), *Brachiaria deflexa* (Schumach) C.E Hubb. exRobyns, *Eleusine indica* (L.) Gaertn, *Brachiaria jubata* (Fig & De Not.)Sosef, *Seteria barbata* (Lam.)Kunth, *Dactylactenum aegyptium* (L.) Wild, *Digitaria milangina* (Rendle)Stapf), *Kyllinga squamulata* (Vahl), *Phyllanthus niruri* (L.), *Commelina. Benghalensis* (L.), *Corchorus olitorius* (L.), *Hyptis suaveolens* (L.) Poit, *Digitaria nuda* (Schumach.) and *Cyperus esculentus* (L.) were the most important weeds in sugarcane (Bida local and NCS 001) genotypes in both years. In conclusion, the most notable weeds associated with the sugarcane genotypes were grasses followed by sedges families. Weed control methods in sugarcane should be made towards the control of grasses and sedges species.

Keywords: Genotype, sugarcane, trash mulch, weed flora, weed management

INTRODUCTION:

Sugarcane accounts for about 75 % of the world's sucrose production (Da Silva and Bressiani, 2005). Besides the production of raw sugar, of which sugarcane is mainly produced for, sugarcane also represents an important supply of renewable energy which has recently gained attention because of ethanol production (Smeets and Lewandowski, 2009). Weeds pose tough competition to sugarcane crop because of wide spacing, slow germination and initial growth, heavy fertilization and frequent irrigations (Refsell and Hartzler, 2009).. Crop- weed competition in sugarcane is enhanced by the Initial slow growth and wider row spacing between ridges. Apart from the quantitative damages caused by weeds, they also cause a reduction in crop yield. In order to determine the yield losses of sugarcane in relation to weed species and their density, the weed species abundance should be documented. This information will be useful in determining the occurrence and relative importance of weed species in sugarcane crop production system (Firehun, and Tamado, 2007).. It is therefore imperative that if the weed population and their reproduction characteristic are known, this information could be used to guide farmers and estate producer's options in integrated management systems (Akobundu *et al.,* 2016),. No such information is available from this area. Hence, the aim of the research were; to determine the phytosociological characters of weeds, and to identify the most important weeds associated with sugarcane crop in this area

MATERIALS AND METHODS:

The upland sugarcane experimental field located at the National Cereals Research Institute, Badeggi (lat. 9^0 45′N, long. 06^0 07′ E) was used as the experimental site in 2016 and 2017 rainy season. The total rainfall during the experimental period was 1504.1 mm in 2016 and 1045.4 mm in 2017, respectively. The mean air temperature during the sugarcane plant cropping season was 35 to 38°C in 2016 and 34 to 36°C in 2017 plant cropping seasons. The experiment was initiated in the month of February in 2016 and 2017, respectively. The vegetative cover of the experimental site was manually cleared, ploughed and harrowed with a tractor before cultivation. Healthy stalks of sugarcane were used as planting material. The planting material were cut into setts each containing three eye buds and laid horizontally end to end per row. The PE diuron was applied within twenty four after planting at the rate of 2.0 kg a.i/ha while the POE metolachlor was applied at five weeks after planting (WAP) at a rate of 179.2g a.i/ha. The identification of weeds was observed using the handbook of West African Weeds [6]. Basal application of 120 kg ha^{-1} N fertilizer as urea, 60 kg P ha^{-1} as single superphosphate and 90 kg K ha^{-1} as muriate of potash were split – applied. Half was applied at planting while the remaining was applied at 8-10 WAP during the earthing up in form of band placement. Fertilizers application was carried out by side banding at about 5 cm away from the seedlings and at about 5 cm deep along the ridge. The treatments consisted of two sugarcane genotypes, Chewing cane (Bida local) and Industrial cane(NCS 001), four cane trash mulching levels, (0, 3, 6, 9 t ha^{-1}) and four weed control measures [(weedy check, 5 monthly hoe weeding (5MHW), Pre-emergence of Diuron at 2 kg a.i/ha (PE) + Post-Emergence(POE) metolachlor at 179.2 g/ha + Two hoe weeding (2 HW) and PE diuron + metolachlor] arranged as a split plot and replicated three times. Herbicides application was done using knapsack (CP3) sprayer at a spray volume of 4l/ha. The main plot consisted of weed control measures and trash mulching, while sugarcane genotypes were allocated to the subplot. The gross plot size was 35 m^2 (7 m x 5 m), while the net plot size was 17.5 m^2 (3.5 m x 5 m). Each net plot consists of four rows of 5 m long.. Weed samples were collected from a (1 x 1 m^2) quadrat placed discreetly in each plot at 9 months after planting (MAP). A total of 96 sugarcane planted plots were sampled. Weed seedlings in each quadrat were pulled out, counted and separated by species. The weeds were observed using the handbook of West African Weeds (Akobundu *et al*., 2016). Irrespective of trash mulch and weed control measures, the weed phytosociological parameters collected in the two sugarcane genotypes were frequency, density, dominance, and their relative values and importance value index. The composition of the weed species was analyzed using the importance Value Index (IVI) of each species within each plot as follows:

Importance Value Index (IVI) = [Relative frequency (RF) + Relative density (R. Dn.) + Relative dominance (R. Do.) (Ramirez and Plaza, 2015)

Where

Relative frequency (RF) = $\frac{Number\ of\ occurrence\ of\ a\ species}{Sum\ of\ occurence\ of\ all\ species} \times 100$

Relative density (R. Dn.) = $\frac{Total\ number\ of\ individuals\ of\ a\ species\ in\ all\ quadrats}{Total\ number\ of\ individuals\ of\ all\ the\ species\ in\ all\ quadrats} \times 100$

Relative dominance (R. Do.) = $\frac{Abundance\ of\ a\ species}{Sum\ of\ abundance\ of\ all\ species} \times 100$

$= \frac{A}{\sum Ai} \times 100$

Where 'A' is the abundance of a species and '($\sum Ai$)' is the sum of abundance of all species

RESULTS AND DISCUSSION

In terms of relative frequency, a total of 46 weed species were identified across the fields of sugarcane genotypes (Table 1). The most frequent weed species in NCS 001 with relative frequency above 10 % were *P. scrobiculatum* and *E. indica* (L.) in 2016, and *C. dactylon* (Linn.) and *H. suaveolens* (Poit.) in 2017. On the other hand, in Bida local, the most frequent weed species were *P. scrobiculatum* and *E. indica* (L.) in 2016. However, in 2017, *C. dactylon* Linn. and *H. suaveolens* Poit were observed. The outcome of this study shows that the high frequency of this species is an indication of their importance as troublesome weeds of sugarcane. This could be attributed to adaptability to the local conditions and compete efficiently with the sugarcane crops. In a previous study, Blanco (2014) stated that weed species may exhibit high frequencies only in environments that they are adapted to irrespective of the disturbances in the ecological conditions of the site.

LC-Life cycle, MG- Morphological group

Furthermore, the phytosociological study shows that nine species were most dominant in 2016 in both genotypes (Table 2) namely *P. scrobiculatum, B. deflexa, E. indica, B. jubata, S. barbata, D. aegyptium, D. milangina, K. squamulata and C. esculentus*. In 2017, the weed species with highest important value index in both genotypes were *P. niruri, B. deflexa, C. esculentus, C. benghalensis, D. aegyptium, C. olitorius, H. suaveolens, D. nuda, B. diffusa, S. chamaelea* with *P. scrobiculatum* and *C. dactylon* in NCS 001 genotype only and *C. diffusa* in Bida local only. The high important value of these species indicated their dominance and ecological success was due to their high phenotypic plasticity, more competitive characteristics such as large production of seeds, alternating forms of propagation and a high capacity of spread. Similar observation were made by Blanco (2014).

LC-Life cycle, MG- Morphological group

CONCLUSION

This study was able to establish that the most important weeds that were associated with sugarcane genotypes in this trial were mostly grasses, a few broadleaved and sedges. The weed species of importance in sugarcane in both seasons were *P. scrobiculatum*, *B. deflexa*, *E. indica*, *B. jubata*, *S. barbata*, *D. aegyptium*, *D. milangina*, *K. squamulata* and *C. esculentus*. The weed species with high IVI in sugarcane suggest their adaptation and ability to produce high amount of seeds in the soil bank. Effective weed management strategy should focus on the control of growth and reproduction of the grass and sedge weed species infestation.

ABSTRACT

Seed-borne pathogens are responsible for seed rot in soybeans, resulting in poor germination and seedling mortality, leading to low productivity. Thus, the present study investigated the effects of storage types and seed disinfection period on seed germination and seed-borne fungi of soybean. Seed samples were tested for seed-borne fungi using the blotter and agar plate method after treatment with three disinfection periods (0, 3 and 6 minutes) and under two storage environments; cold storage and warehouse. Fungi were identified based on colony morphology and microscopic characteristics. Germination percentage and seedling vigour were also determined. A total of seven fungi species; *Aspergillus flavus, A. fumigatus, A. niger, Fusarium spp.*, *Penicillium* sp., *Rhizopus* sp., *and Curvularia* sp. were isolated from the soybean seeds, irrespective of the storage type and disinfection time. *Fusarium* and *Curvularia* species were not isolated by the blotter method. The seed disinfection period showed a significant effect ($p>0.05$) on the percentage incidence of fungal infection. *Aspergillus flavus* had the highest percentage occurrence, with 32.8% and 29.5% from the blotter and agar plate method, respectively, in 0-minute seed lots, while *Penicillium* species had the least occurrence in both storage types, with 12.9% and 15.67% on the blotter and agar plate method, respectively, in the plate disinfected for 6 minutes. The study showed that surface disinfection period and storage methods considerably affect fungal infection and quality of soybean seed. Therefore, seed-borne fungi can be reduced by seed treatment and better storage conditions.

INTRODUCTION

Soybeans are the world's leading legume among oil seed crops (Sanginga *et al.*, 2002). It is a vegetable protein oilseed extensively grown in the tropical, sub-tropical, and temperate regions (Soybean Encyclopedia, 2022). The plant is classified as an oilseed rather than a pulse by the UN Food and Agriculture Organization (FAO). The cultivation of the crop is increasing in Nigeria as a result of its importance as a cash crop used in the food and feed industry (Sanginga *et al.*, 2002; Ugbabe *et al.*, 2017). Nigeria is the second largest producer of soybeans in Africa after South Africa, producing 630,000 Mt in 2019 (FAOSTAT, 2019).

Optimum soybean cultivation is hindered by lack of good quality seed (Amin *et al.*, 2009; Rahman *et al.*, 2013). Seed-borne pathogens cause losses in soybeans both in seed quality and quantity. The microflora reduces seed germination and seedling vigour index of the crop and can be a vehicle for plant pathogenic agents that are known to be responsible for seed rot, abortion, deformation, seedling blight, bacterial pustules, root/stem rot, as well as pod blight diseases (Carvalho and Nakagawa, 2012; Bandara *et al.*, 2020; Roth *et al.*, 2020).

Several factors affect the quality of stored seeds and predispose them to infection. These factors include the moisture content, nature or type of packaging materials, temperature, relative humidity, and chemical composition of the seeds (Santos *et al.*, 2016). At maturity, harvesting stages and or in storage, the seeds get exposed to fluctuations in humidity and temperature, and hence develop several kinds of moulds which result to seed spoilage (Arya and Monaco, 2007). Poor storage conditions greatly affect seed vigour (Wawrzyniak *et al.*, 2020), reduce respiration and seedling size. Therefore, maintaining seed quality during storage is essential in soybean production chain. To increase the production of soybean qualitatively and quantitatively, farmers require healthy seeds with a high percentage of germination and purity, because fields planted with high-vigour seeds yield higher (Bagateli *et al.*, 2019). Thus, the present study investigated the effects of storage type and seed disinfection period on germination and seed-borne fungi in soybean.

MATERIALS AND METHODS

Samples Collection

Soybean seed (TGX 1448-2E) used for this experiment was obtained from the Soybean Programme of the National Cereals Research Institute, Badeggi, Nigeria. The seed samples were brought to the laboratory and stored at room temperature for subsequent studies.

Experimental Design and Treatment

The seed samples were divided into three and separately disinfected in 1% aqueous solution of sodium hypochlorite for 0, 3 and 6 minutes. This was followed by rinsing in three changes of sterile distilled water and drying between two layers of soft tissue paper at two storage environments; cold storage (CS) and warehouse (WH). The experiment was laid out in a completely randomized design with three replications.

Detection and Identification of Fungi

The seed-borne fungi in the seed samples were detected and enumerated by the blotter method and the agar plate method.

Blotter Technique

Three pieces of filter paper were soaked in sterilized distilled water and placed at the bottom of a 9 cm diameter Petri dish. Soybean seed samples from each treatment were taken randomly and placed on the filter paper at the rate of 10 seeds per Petri dish and incubated at 25^{o} C for seven days. After incubation, the seeds were examined under a microscope to record the seed-borne fungal infection observed on the incubated seeds.

Agar Plating Technique

Ten soybean seeds samples from each treatment were placed in a Petri dish containing potato dextrose agar (PDA) and incubated for seven days at 25°C. The fungal pathogens associated with the seeds was identified following sporulation.

Fungal Identification

Pure cultures of individual fungal isolates were critically examined and identified. Fungi were identified based on colony morphology and microscopic characteristics. Colony identification was based on characteristics such as colour, texture, and type of pigmentation. Microscopic characteristics of spores such as shape and colour were also used to identify the pathogens associated with the seeds. Percentage seed infection was calculated as the proportion of soybean seeds showing symptom of infection and the total number of seeds used, expressed as a percentage.

Seed Viability Test

The standard germination test was used to evaluate seed viability. One hundred (100) seeds per treatment, per replication, were placed on filter paper moistened with water and placed inside a growth chamber for 7 days. Percentage seed viability / germination was calculated as the proportion of viable seeds and the total number of seeds used, expressed in percentage.

Seed Vigour Test

Seed vigour was evaluated using the accelerated aging (AA) test according to the formula, Seed vigour = (Mean root length+ Mean shoot length) × Germination (%).

Statistical Analysis

Data on type and frequency of occurrence of identified fungal species were recorded. The percentage of seed infection and percentage seed germination were subjected to analysis of variance (ANOVA) using SAS software. The mean was compared using the Least Significant Difference (LSD) at 5% probability level.

RESULTS AND DISCUSSION

A total of seven fungi species in five genera (*Aspergillus flavus*, *A. fumigatus*, *A. niger*, *Fusarium* spp., *Penicillium* sp., *Rhizopus* sp., *and Curvularia* sp.) were isolated from the seed samples, irrespective of the storage method used (Table 1). These fungi have been reported to be seed-borne in soybean by previous researchers (Shovan *et al.*, 2008; Lević *et al.*, 2012). All the species were isolated by the agar plate method, except *Fusarium* and *Curvularia* spp, both of which were isolated by the blotter method. This is because PDA is more sensitive in detecting even traces of infection. This is corroborated by the findings of Shovan *et al.* (2008) and Seweta *et al.* (2011) who reported that the percentage of mycoflora isolated by the agar plate was higher than blotter method in soybean. This study also indicated that time of seed disinfection has a significant difference ($P > 0.05$) on the percentage of fungi isolation and seed infection. *Aspergillus flavus* had the highest percentage of occurrence (48.8% and 29.5% on blotter and agar plate, respectively), in a 0-minute seed treatment, while *Penicillium* spp had the least percentage of occurrences, with 12.9% and 10.8% on blotter method and agar plate, respectively, in 6 minutes. Similar results have been reported on groundnut seed by Rasheed *et al.* (2004). Tariq *et al*. (2005) also concluded that A. *flavus* and *A. niger* were the predominant storage fungi of soybean seed. These species have been reported to reduce seed germination, damage seeds in storage and produce mycotoxins. The highest seed infection (100%) was observed in the control treatment i.e. seed without disinfection, while the lowest seed infection (32.0%) was recorded in the plate containing disinfected seeds with a longer time of disinfection (6 minutes), indicating that disinfection time has a significant effect on fungal pathogens associated with the seeds. Dawar *et al*. (2007) reported that surface disinfection reduces external fungal contamination while disinfection time has no significant effect on germination potential and seedling vigour. Storage environments had a significant effect ($P > 0.05$) on seed viability and vigour. From this study, there was a significant difference in seed vigour of 83% in CS compared to 52% in WH. The decrease can be attributed to fluctuation in relative humidity of the WH. De Vries *et al.* (2007) and Vieira *et al.* (2001) opined that seed viability is intricately linked to seed moisture content, which in turn, depends on the relative humidity of the storage environment.

CONCLUSION

Storage method and surface disinfection period affect fungal infection and quality of soybean seeds. These factors are crucial for seed survival in storage. There is a need to reduce the pathogenic fungi by seed disinfection and the use of cold storage medium, so as to reduce mycotoxins produced by these fungi on soybean seeds. It is recommended that further work on different storage methods be conducted to identify other major pathogenic fungi associated with seeds of other soybean varieties so as to develop a comprehensive integrated control measure for reducing losses due to seed-borne fungi.

ABSTRACT
Understanding the performance of cultivars in area of production is key to increasing productivity in farmers' fields. In order to assess the growth and rhizome attributes of the two newly registered ginger and local cultivars under the savannah transition agro-ecology, a field trial was conducted at the National Root Crops Research Institute, Iresi Out-station experimental field in Osun state in the 2021 cropping season. The experiment was laid out in a Randomized Complete Block Design with three replicates. Analysis of variance showed significant ($p < 0.05$) differences among the three cultivars for all the growth and yield attributes except plant height. Cultivar UG1 and UG2 had higher number of tillers, number of leaves and leaf area index compared to the local (check) cultivar, while leaf area for local cultivar was higher than the registered cultivars. UG1(yellow) and UG2 with rhizome yield of 35.11 t/ ha and 33.67t/ha, respectively were superior to the 18.16t/ha of the local cultivar. While plant height had no significant ($p>0.05$) relationship with rhizome yield, all other attributes (except LA with correlation coefficient (r) = -0.92), showed strong and positive relationship with rhizome yield with their various 'r' ranging between 0.79 and 0.89. The superior performance of the two newly registered ginger cultivars above the local one gives farmers in the savannah transition agro-ecology sustainable means of increasing their ginger productivity.

Keywords: Rhizome yield, morphological traits and correlation rhizome yield-morphological traits

INTRODUCTION
Ginger (*Zingiber officcinale* Roscoe) is an important spice in the family *Zingiberaceae* with 90 species (Kizhakkayil and Bhas, 2011). Ginger plant is refreshingly aromatic but it is the rhizome (raw or processed) that is valued as a spice (Mary et.al, 2021). As a spice, it is high valued and export-oriented, and plays an important role in the agricultural economy of the countries that grow them, supporting the livelihood and improving the economic level of many ginger growers (Sodangi, 2020). Nigeria, with production figure of 160,000 metric tons, is the 4th highest ginger producing country with India (702,000 metric tons), China (388,886 metric tons) and Nepal (216,289 metric tons) being the first three countries (FAOSTAT, 2014).

Although Nigeria is the largest producer and exporter of ginger in Africa, the level of production is generally low compared to other export crops, while productivity has remained abysmal due to several factors which include poor soil fertility, shortage of improved cultivars, poor agronomic practices and effects of pests and diseases (Hailemichael and Tesfaye, 2008; MOARD, 2007; Amadi et al., 2010). Majority of Nigeria's ginger production comes from the southern part of Kaduna State with average yield 2-5t/ha which is far below actual yield of the crop under improve cultivation (Sodangi,2020). Ginger is also grown in South-west Nigeria. As one of the major shortcomings of ginger production in Nigeria is lack of improved cultivars of ginger which resulted to low yield. The National Root Crops Research Institute, Umudike, through its ginger breeding program, developed and registered two ginger cultivars which have been tested in many locations. The results presented in this paper were from the evaluation of the new cultivars under the savannah transition agro-ecology.

MATERIALS AND METHODS;

The study was conducted at the research field of National Root Crops Research Institute, Iresi out-station (Longitude 7.94^0 N, Latitude 4.84^0 E and Altitude 494m above sea level) in Osun state in the savannah transition agro-ecology of South-west Nigeria during the 2021 cropping season. Treatments comprising of three ginger varieties (UG1, UG2 and local cultivar) were laid out in a randomized complete block design with three replicates. The field was cleared, ploughed and harrowed. The ginger setts or rhizomes weighing 10 g of each cultivar were planted on a bed plot measuring 2 m x 3 m and raised to 0.5 m crest with inter- and intra -row spacing of 0.2 m x 0.2 m giving plant population density of 250,000/ha. Each rhizome was planted 7 cm beneath the soil with the growth buds facing up so that the shoots can grow towards the surface. Mulching was carried out immediately after planting using a mixture of *Chromolaena odorata* (L.) commonly called siam weed and grass materials found in the area at the rate of 3.5t/ha. Poultry manure was applied and worked into the soil before planting at the rate of 20 t/ha. Weeds were manually controlled at 6 and 10 weeks after planting. Data were collected on the following growth parameters at 4, 6, 8, 10, 12, 14 and 16 weeks after planting; establishment count, plant height, number of tillers, leaf number, leaf area (using leaf length and width x 0.6475 according to Kandiannan et.al, 2009 and leaf area index. Rhizome yield per plot were estimated at harvest. All the data collected were subjected to analyses of variance (ANOVA) using the generalized linear model procedure of the System Analyses Software (SAS, 1992 version). The treatment means were separated using fisher's LSD at 5% of probability.

RESULTS AND DISCUSSION

Table 1 shows the performances of the two registered and one local ginger cultivars evaluated for plant height (cm), number of tillers, number of leaves, leaf area, leaf area index and rhizome yield. All the measured cultivar growth and yield attributes showed significant differences ($p<0.05$) among the cultivars except in plant height where all the cultivars were statistically the same with a range of 96.33 – 106.00 cm. Chukwudi et al. (2020) and Sodangi (2020) reported same findings in their studies, except that while they both found plant height to be significantly different, Sodangi (2020) also reported no cultivar variation for number of tillers per plant and number of leaves per shoot. For all the attributes (except in leaf area (LA) where the local cultivar had higher LA), the registered cultivars showed marked superiority against the local cultivar. This is unexpected as the registered cultivars have passed through some selection process. The rhizome yields of the two registered ginger cultivars (UG1 = 35.11 and UG2 = 33.67 t/ha) almost doubled that of the local cultivar (18.16 t/ha).

Table 2 shows the relationships between rhizome yield and other measured attributes. Plant height had no significant ($p>0.05$) relationship with rhizome yield. However, all other attributes (except LA with correlation coefficient (r) = -0.92), showed strong and positive relationship with rhizome yield with their various 'r' ranging between 0.79 and 0.89. These results were similar to the findings of Islam et al. (2008) who reported positive and significant relationship between rhizome yield and number of tillers per plant, plant height and leaf area attributes. The strong and positive 'r' suggests that rhizome yield tends to increase as the values of these attributes increase, which explains the huge yield differential between the registered cultivars and the local cultivar as the registered cultivars had significantly higher values for the important growth traits. The strong genotypic correlation between these traits and rhizome yield reported by Islam et al. (2008) further suggests that the observed relationship has genetic background.

The superior performances of the registered cultivars, especially in rhizome yield will lead to increased productivity in farmers' fields. With such a good performance of these cultivars in the transition savannah ecology of the south-west Nigeria outside ginger's known cultivation hub of southern Kaduna and the entire guinea savannah that controls over 80% of ginger production in Nigeria ((Sodangi, 2020), ginger's agroecological production zones in Nigeria will further increase (Amadi,2012).

Table1: Rhizome yield and other attributes of newly registered ginger cultivars evaluated in the Savannah transition agroecology of Iresi, Osun state in 2021.

Cultivars	Plant height (cm)	Number of tillers	Number of leaves	Leaf area (m^2)	Leaf area index	Rhizome yield (t/ha)	Flesh colour
UG1	96.33^{a}	8.44^{a}	22.39^{a}	0.01^{b}	0.010^{a}	35.11^{a}	Yellow
UG2	103.06^{a}	8.89^{a}	20.39^{a}	0.01^{b}	0.009^{ab}	33.67^{a}	Black

Table 2: Correlation coefficients Relationship between yield and morphological traits of ginger cultivars evaluated under the savannah transition ecology of Osun state.

Plant height(cm)	Number of tillers	Number of leaves	Leaf area (m^2)	Leaf area index	Rhizome yield (t/ha)
Plant height (cm)	-0.032^{ns}	-0.459^{ns}	0.416^{ns}	-0.134^{ns}	-0.223^{ns}
Number of tillers	---	0.784*	0.801**	0.716*	0.795**
Number of leaves		---	0.967***	0.865**	0.894**
Leaf area (m^2)			---	-0.766*	-0.921**
Leaf area index				---	0.795*

CONCLUSION

The evaluation of the newly registered ginger cultivars in the savannah transition ecology of the south-west Nigeria and the superior performance of these new cultivars over the local cultivar will help increase the agro-ecologies that can produce ginger in Nigeria, and further increase productivity in farmers' fields. The findings about the relationships that exist between rhizome yield and other growth attributes has further enhanced the knowledge on how to improve the crop's breeding.

ABSTRACT

Experiment was carried out at National Root Crops Research Institute Umudike research farm, to evaluate the effect of different liquid organic fertilizers on selected growth parameters and yield of fresh Turmeric rhizome. The treatments comprises of four liquid organic fertilizers (Boast Extra, Black Diamond, Super-Gro and Pro-Plant) and control, given a total of 5 treatments. The experiment was laid out on manually prepared seed beds of 3 m X 2 m, arranged in RCBD and replicated 3 times.Pre-cropping soil sample was collected at the depth of 0-30cm, air dried, processed and analyzed in the laboratory using standard soil analytical methods.Liquid fertilizers were diluted (100 mls in 10 liters of distilled water) and applied on turmeric leaves using hand sprayer one month after planting. Growth data were collected at 2, 3, 4, 5 and 6 months after planting. While yield data were collected at harvest (7 months after planting). Data collected were subjected to ANOVA, while significant means were separated using LSD at 5% probability level. Result from the study showed that different liquid organic fertilizers significantly improved selected growth component tested. Plant height increased from 60 – 135 cm, number of tiller increased from 3 – 8 numbers. Turmeric yield also increased across the treated plots, with plots treated with Boast Extra given highest yield of 20.03 t/ha followed by 18.67and 17.93 t/ha from Super-Gro and Black Diamond respectively. This study has shown that application of different liquid organic fertilizers can improve Turmeric growth and yield while serving as an alternative to expensive inorganic fertilizer for poor resource farmers in Umudike.

Key words: liquid, organic fertilizer, turmeric

INTRODUCTION

Application of organic fertilizer as a component of sustainable agriculture apart from soil mineral provision, contributes to soil quality by improving the structure,chemistry and biological levels of soil. They have an advantage of gradual release of nutrients and reusing soil organic matter content (Ukoje, 2012). In Nigeria and in global world deviation from inorganic to organic agriculture is becoming the content and is imperative for healthy sustainable agriculture (Obasi, 2019). The disadvantages of inorganic fertilizer are high cost and long term environmental damage which perhaps outweighed the advantages and this also affects the poverty level of Nigerians and fragility of ecosystem (Adesina, 2012).Turmeric whose active ingredients is curcumin and one of the root crops in NRCRI Umudike, requires fertilization to improve yield and productivity. Much work has not been done on organic fertilization of Turmeric and there is dearth information on the use of liquid organic fertilizers on Turmeric production. Therefore, the objective of this work is to determine the effect of different liquid organic fertilizers as foliar spray on the growth and yield of Turmeric in Umudike.

MATERIALS AND METHODS

Four different liquid organic fertilizers (Boast Extra, Black Diamond, Super-Gro and Pro-Plant) were evaluated using Turmeric (*curcuma longa*) as a test crop at the research farm of NRCRI Umudike in 2021 farming season. The experiment was laid out in a Randomized Complete Block Design (RCBD). Plot size was $6m^2$ with a plant spacing of 50cm x 30 cm, liquid fertilizers were diluted (100 mls in 10 liters of distilled water) and applied on leaves using hand sprayer. The application was done 6 weeks after planting and repeated 16 weeks (4 months) after planting, followed by other field activities like weeding. Growth parameters were collected during the growth period while the yield data was collected at harvest (7 montha after planting). Data collected were subjected to Analysis of variance (ANOVA), Mean separation was carried out using least significant difference(LSD) at $p<0.05$.

RESULT AND DISCUSSION

Result of plant height (Fig. 1) shows that growth increased profusely across the growing period of the experiment. Plant height ranged from 33 to 67 cm at 2MAP, 41.7 to 79.69 cm at 3MAP, 46 to 94 cm at 4MAP, 56 to 122 cm at 5 MAP and 60 to 135 cm at 6 MAP. Highest values of plant height were recorded on plots treated with Boast Extra, followed by Black Diamond while Pro-plant recorded lowest values among the liquid organic fertilizer tested though higher than values obtained from control plot. Number of tillers (Fig. 2) ranged from 2 to 5 at 3 MAP, 2 to 7 at 4MAP and 3 to 8 at 5MAP. Highest number of tillers were obtained from plot treated with Boast Extra followed by Super-Gro while control plot had lowest number of tillers.

The effects of the organic amendment as shown on the vegetative parameters also reflected on the yield (Table2) where highest value of fresh turmeric rhizome was obtained on plot treated with Boast Extra (20.03 t/ha) followed by Super-Gro and Black Diamond (18.67 and 17.93 t/ha) while lowest yield was recorded on control plot (6.67 t/ha). The significant ($p<0.05$) increase recorded on plots treated with Boast Extra could be attributed to the traces of inorganic content (20%) combined with organic (80%) content in Boost Extra, while Black diamond, Super-Gro and Pro-plant contains 100% organic.Consequently, this agrees with the findings of Fauzie, *et al*, (2015), who reported in their work that plants absorbs inorganic fertilizer through their leaves faster than the organic fertilizer.

CONCLUSION

Application of liquid organic fertilizers increased Turmeric yield across the treated plots, with plots treated with Boast Extra given highest yield of 20.03 t/ha followed by 18.67 and 17.93 t/ha from Super-Gro and Black Diamond respectively. This study has shown that application of different liquid organic fertilizers can improve Turmeric growth and yield while serving as an alternative to expensive inorganic fertilizer for poor resource farmers in Umudike.

ABSTRACT

Yam is one of the preferred staple foods in West Africa. Resistance to diseases and high yield potential has led to a persistent retention of these yam crops in the various environmental locations where they were collected. The variability and stability in disease resistance and yield productivity of the yams can form a strong basis for future yam breeding and selection of hybrid yams for the teaming population. The experiment was laid out in randomized complete block design involving 57 yam cultivars and three replications. Variability of 57 cultivars from *Dioscorea rotundata* were evaluated on quantitative characters such as plant sprout percentage at two months after planting, number and weight of tubers at harvest and, qualitative characters including plant vigour, yam anthracnose disease (YAD), yam mosaic disease (YMV), nematode and oxidation. Results of the work showed that all the yam cultivars gave good sprout at two months after planting with Okotebogba which gave a sprout percentage of 100 % which did not differ significantly (P<0.05) from popular cultivars Dan-nacha (99.4%) and Ekpe (98.9%). The plant vigour of the yams ranged from 1.7 to 3.3 on a scale of 1-5. The cultivar, Amola gave the highest yield of 31 t/ha which did not differ significantly from the yield of many of the yams cultivars evaluated, although some yams gave yields as low as 13.0t/ha as observed in Okpambe. Approximately 79% of the yam cultivars were tolerant to YMV, 70.1% were highly resistant YAD and 96.5% were highly resistant to nematode which are the major diseases of *D. rotundata* that they were evaluated. The oxidation of the yams ranged from slight oxidation to none oxidation. These qualities of the yams may be the reason behind the high acceptability of the yams in the various environments from where they were collected,

Keywords: Yam landraces, Disease resistance, Anthracnose, Virus, Severity

INTRODUCTION

Yam (*Dioscorea* spp.) is a tuberous crop that is mostly grown in the African tropics, Asia and the Pacific zones. It is one of the staple food crops and therefore has great significance

(Nwachukwu *et al*., 2011, Babowale, 1994). The crop is an important source of calories for millions of farmers across the globe. They are tuber crops widely grown for food and feed. They are an important source of carbohydrates and calories in many parts of the tropics and also serve as a valuable cash and subsistence crop. The world's most important multipurpose yam is *Dioscorea rotundata*, often referred to simply as the common yam, white guinea yam or round yam, which accounts for up to 80% of all global yam production and is grown in more than 60 countries.

The crop requires improvement in breeding to develop new seeds that are potentially superior to the already existing yams across the locations. This can be achieved through characterization and evaluation of landraces that have been with farmers and growers over time. The landraces have been important sources of quality genes for high yield, starch, disease resistance which are not known or documented. Farmers will continue to refuse adopting new improved yams from breeders if the new improved yams do not possess qualities better than their existing landraces.

There is no detailed information describing the landraces' profile beginning from their morphological expressions in the field to the point of post-harvest characteristics including the food quality and nutrient status. There is need to have a reliable, accessible, comprehensive documentation of the popular yam landraces which farmers have tenaciously refused to let go due to some inherent qualities of the landraces that are not readily found in the improve hybrids.

Information of this nature will serve as guide to producing replacement that can easily be accepted and adopted. The objective of this work was to assess the yam landraces of Nigeria to create a standard or bench mark for yam breeders' future yam breeding plan.

MATERIALS AND METHODS

Yam landraces were collected from various parts of Nigeria through Africa Yam Project during the on-farm evaluations in 2017, 2018 and 2019 for characterization, profiling and documentation in NRCRI, Umudike. In 2020` cropping season, 57 yam landraces of *D. rotundata* were planted in NRCRI Umudike experimental field. The experiment was established in a randomized complete block design with three replications, each block containing 57 plots and totaling 171 plots for *D. rotundata.* The yams were planted with the standard spacing of 1 m x 1 m in each plot of 5 m x 2 m (10 m^2). Data were collected on vegetative, harvest and post-harvest performances of yams.

RESULTS

All the yam cultivars gave good sprout count percentages of above 70.0 although low sprout count percentages were obtained in some of the yam cultivars such as observed in Yandu which gave a low sprout count percentage of 67.8. The plant vigour of yam cultivars was fairly good with scores of above 3 on a scoring scale of 1 - 5 except in Chiyo and Ojuiyawo both of which scored 1.7 in plant vigour. The results from the work showed that Abi, Anasue, Anyamayuwa, Meccakusa, Okotebogba and Amola gave a yield of more than 30 t/ha while which did not significantly differ (P<0.05) from many other cultivars. The yam land races were tolerant to the yam diseases for which they were evaluated for especially yam anthracnose disease severity (YADS) and nematode. Generally, the tolerance of the yams to yam mosaic virus severity (YMVS) with some of the yams score above 2.5 on a virus scoring scale of 1 – 5. Many of the yams were white in tuber flesh colour showing none oxidation or slight oxidation. This shows that many of the yam landraces in Nigeria have great potentials in disease resistance, yield and other qualities not assessed in this work. Breeders can tap into these yam qualities for developing new yams.

CONCLUSION AND RECOMMENDATION

Many of the landraces showed high yield potentials consistently over the two years and yet they are unpopular. It is therefore recommended that Okotebogba, Sandpaper, Dan-nacha, Punch, Ikookutom, Anasue, Anyamayuwa, Igbudugadu, Yotoyo, Ekpe, Ikohaakere, Abi, Ojuiyawo, Ogine, Ogoja, Asangwu, Ifara, Oyoyo, Myiomiyo, Fakesta, Yandu, Alumaco, Chiiyo and Pouna should be included among yam landraces to be nominated for registration. This will enable those yam landraces with high quality potentials to come to lime light in Nigeria for farmers' cultivation and use.

56th Annual Conference
Agricultural Society of Nigeria
24 - 28 Oct., 2022

ABSTRACT

Laboratory experiment was conducted twice to compare the effects of aqueous extracts of some botanicals; leaves of brimstone (*Monrinda lucila*), bitter leaf (*Vernonia amygdalina*), Neem fruit (*Azadirachite indica*) and peel of sweet orange (*Citrus sinensis*) with that of Carbofuran (a synthetic nematicide) on the root-knot nematode *Meloidogyne incognita*). The experimental design was a 5x5 factoria experiment comprising of 5 treatments (plant materials and carbofuran) and five levels of application (0, 25, 50,75 and 100%) concentration of aqueous extracts of plant treatment and Carbofuran at (0, 2500, 5000, 7500 and 10000ppm) respectively. The various concentrations of aqueous extracts were tested on nematode egg hatch and juvenile mortality of *M. incognita*. The bioactive chemical component of the test plant materials were also determined appropriately. The mean value obtained from the two trials was determined and analyzed. The result from the experiment showed that the plant extracts and Carbonfuran caused significant reduction ($P \leq 0.05$) in nematode egg hatch as compared with control on day seven of the experiment. Egg hatch was 91% in control compared to 3.5%, 5.0%, 9.0% and 5.5% in 25% brimstone, bitter leaf, neem and citrus, while no egg hatch was recorded in 50, 75 and 100% in all test plant extracts and Carbofuran. The level of egg-hatch inhibition increased with increase in concentration of plant extracts and Carbofuran. Juvenile mortality was significantly higher

($P \leq 0.05$) in test plants and Carbofuran than in control. Within two days of the experiment, 100% mortality was observed in 1000ppm concentration of Carbofuran and all test plant extracts as compared to 0% mortality in the control. This observation showed that the test plants extracts are toxic to *M. incognita* and can be developed as raw materials for Bio-pesticide production and as replacement for h synthetic nematicides. Phytochemical analysis of the botanicals revealed the presence of flavonoid, taninin, alkaloids and flavonoids in the test plant extracts and are known to be toxic to parasitic nematodes.

INTRODUCTION

Plant parasitic nematodes are recognized as one of the major pests of tomato throughout the world, particularly on field crops in the sub-tropical regions. Many different species are known to cause damage but the most destructive nematode responsible for enormous yield loss of tomato are the root-knot nematodes belonging to genus *Meloidogyne*. The most wide spread and devastating root-knot nematode species on tomato are *Meloidogyne incognita*, *M. javria*, *M. arenaria*. Other species are *M. hapla, M. thamesi. M. gramicola* are known to infect crop in different parts of the world (Anonymous, 1983). The root-knot nematode *M. incognita* has been identified as a major constraint in production of most crop especially tomato (Ogunfowora, 1977, Abolusoro, 2014 Abolusoro 2019 ,Abolusoro,2020). The disease caused by this group of nematodes is root-knot disease characterized by numerous pronounced swellings, or galls on the roots of susceptible hosts plant. It is widely distributed and has extensive host range and interacts with other organisms such as fungi, bacteria and viruses in disease complex. The overall effect is to drastically reduce the quality and quantity of yield. In Nigeria, it has been estimated that over 140 plants are host to the root-knot nematode (Caveness, 1978; Oyedunmade *et al.*, 2000).

Scarcity, high cost, environmental safety and global restriction on the importation of chemical nematicides have spurred scientists to search for alternative control measures against nematode pests of economic crops (Anonymous, 2004). The use of palnt extracts for the control of nematodes pests had been suggested (Hoan and Davide, 1979). Application of plant extracts into the soil has the potential advantage of being economical, rapidly available and environmentally safe (Abolusoro, 2020 ,Olabiyi, 2004; Maqbool *et al.*, 1987).

The study was designed to evaluate the nematicidal action of some botanicals (*Morinda lucida, Vernonia amygdalina, Azadirachta indica, Citrus sinensis peel* and a synthetic nematicide (carbofuran) on the egg-hatch and juvenile mortality of *M. incognita* and to evaluate the various bio-active chemical components present in each of the test plants.

MATERIALS AND METHODS

Preparation of aqueous extracts of the test materials and the rates applied

The leaves of bitter leaf and brimstone, peel of sweet orange as well as fruit of neem were separately collected, air-dried and crushed into small pieces. One kilogramme of each plant was weighed on beam balance and soaked in one litre distilled water for a day. The content was filtered. The resultant filtrate was taken as the stock solution of the strength 100% (1,000,000ppm). Several dilution were made from the stock solution by adding appropriate amount of distilled water to obtain a solution of 25, 50, 75% in concentration as shown below:
1ml concentration plant extract + 3ml distilled water = 25%
2ml concentration plant extract + 2ml distilled water = 50%
3ml concentration plant extract + 1ml distilled water = 75%
Stock solution of 1,000,000ppmwas also made from carbofuran and water and then distilled in the manner similar to plant extracts to the following: 250, 500, 750 and 1000ppm respectively.

Extraction of M. incognita Eggs

Galled root collected from *Celosia argentea* on which a pure culture of *M. incognita* was properly washed under running water tap so as to get rid of the attached soil. The roots were cut into smaller pieces and shaken with 0.5% sodium hypochlorite solution in 500ml capacity conical flask (Hussey and Barker, 1973). The content was then sieved through a 200 mesh sieve nested on 500 mesh sieve. The upper 200 mesh sieve collected plant debris and small stones. The 500 mesh sieve now containing the eggs was placed under a running water on the laboratory so as to wash off any residual sodium hypochlorite solution. Rinsing was done for 20 minutes. Egg suspension was made inside a beaker of 500ml capacity. The number of eggs in 1ml suspension contained approximately 100 freshly hatched *M. incognita* egg.

Source of Root-knot Nematode Juveniles

Freshly extracted eggs were incubated at 28±2°C for 72 hours in the incubator to hatch out the second stage juveniles from them. Standardization of number of juveniles per unit volume was done so that 1ml juvenile suspension contained approximately 100 juveniles.

Laboratory experiment I: Effects of Carbofuran and plant extracts on M. incognita egg-hatch

Aliquots of 1ml *M. incognita* egg suspension containing a count of approximately 100 freshly extracted eggs of a *M. incognita* were dispersed into each of 105 transparent glass petrish-dishes containing 10ml of test plant extracts or carbofuran or distilled water only (control) as the case maybe. The concentrations of the aqueous extracts of test plants were 0, 25, 75 and 100% while the concentrations of carbofuran solution were 0, 250, 500, 750 and 1000ppm. The control represented 0% (0ppm). Treatments including control were repeated five times each and incubated at a room temperature of 28±2°C inside the incubator. The dishes were covered to prevent evaporation. The experimental design was a 5x5 factorial experiment. A count of un-hatched eggs and juveniles were made at 24hours interval for seven consecutive days under stereo microscope.

Effects of carbofuran and test plant extracts on the mortality of M. incognita Juveniles

Ten (10)ml of carbofuran solution at 0, 250, 500, 750 and 1000ppm concentration and 0, 25, 50 75 and 100% aqueous extracts were introduced into separate petri-dishes. Distilled water served as control (0%) standardized 1ml juvenile suspension containing 100 juvenile of *M. incognita* was introduced into each of the transparent petri-dish containing different treatments at various concentrations and were incubated at temperature of 28±2°C.

The petri-dishes were covered with glass to prevent evaporation. The experimental design was 5x5 factorial experiments. Each treatment was replicated five times. Counts of dead juveniles were made initially after 6 hours; 12 hours and 24 hours interval respectively for a period of 6 consecutive days. The juvenile that did not respond to touch of needle were recorded dead.

Phytochemical Screening

<u>Test for Alkaloids</u>

Principle: Alkaoids form an orange precipitate when mixed with Dregendorff's reagent (Harbone, 1976 and Cuile, 1969).

Procedure: 0.5g of each of the powdered plant materials were dissolved in 2ml methanol in a test tube, shaken vigorously and then heated for 2 minutes in a water bath. 2 ml of Dragendorff reagent was added. The bright blue colorizations in UV light and change of colour to orange red when sprayed with Dragendoff's reagent indicates the presence of alkaloids in the plant extract.

<u>Test for Flavonoids</u>

Principles: the formation of yellow colouration with sodium hydroxide solution was taken as an indication for the presence of flavoids in plant materials according to Trease and Evans (1989).

Procedures: 0.5g of each of the four powdered plant material was dissolved in 2ml method and heated in water bath for 2 minutes.

The supernatant was then decanted into another test-tube, into which 2ml of sodium hydroxide solution was added. The mixture was then observed for colour change. A reverse in colour change to colourless on addition of hydrocholric acid indicates the presence of flavonoids.

<u>Test of Saponins</u>

Principle: Saponin growth when shaken vigorously and precipitate in the presence of Feliling's A+B solution (Trease and Evans, 1978; Sofowora, 1982)

Procedure: 5g each of the powdered plant materials were dissolved in 50ml distilled water in 250ml beaker and allowed to soak for 3 hours. This was then filtered in Whatman No. 1 filter papers. The filterate was poured into a test tube, shaken vigorously and then heated in a water bath for 2 minutes. The persistence of growths indicates the presence of saponins.

<u>Test for Tannins</u>

Principles: Tannin forms a blue black, green or blue green precipitate with ferric chloride reagent (Tease and Evans, 1989.

Procedure: About 5g of each of the powdered plant materials were stirred with 10ml distilled water in a 250ml beaker and filter with Whatman's No. 1 filter paper. Ferric chloride was then added into the filterate in the same test tube. The formation of a blue black or blue green precipitate was taken as evidence for the presence of tannins.

RESULTS

Effects of Carbofuran and test materials on the egg hatch inhibition of *M. incognita* egg

The experimental results on the effects of Carbofuran, test plant materials and level of application on the egg-hatch of *Meloidogyne incognita* is presented in table 1.

Table showed that the test plant extracts were as effective as carbofuran in inhibiting the nematode egg hatch while all concentrations of the materials used for the treatment were significantly more effective than the control in inhibiting egg hatch. The lowest concentrations of the treatments were not as effective as higher concentrations. The table further showed that egg hatch was significantly lower in all the treatment throughout the experimental period than in the control.

.% level=test plant materials ,

,ppm level = carbofuran

Table 2 is the analysis of variance on the effects of Carbofuran and test plant extracts on the mortality of *Meloidogyne incognita.*

Table 2 showed that the test were as effective as Carbofuran in causing juvenile death while all the concentrations of the applied treatment materials caused significantly higher nematode death than the control. A hundred percent mortality was recorded at day 2 in all the treatments. The control experiment has the lowest percentage mortality during the experimental period. The level of juvenile mortality increased with increase in the exposure period. At the end of the experiment, an average of 100% juvenile mortality was observed in the test plants compared with the mean of 8.15% mortality in the control experiment.

DISCUSSION

The results from the experiment on the effects of plant extracts and carbofuran on egg-hatch inhibition and juvenile mortality showed that carbofuran and test plants were effective in inhibiting egg-hatch of *M. incognita* at the various concentrations they were tested. These observation showed that the fruit of *Azadirachta indica*, leaf of *Vernonia amygdalina*, the peel of sweet orange (*Citrus sinensis*) and leaf of *Morinda lucida* as well as Carbofuran were effective in causing egg-hatch inhibition in *M. incognita*. This inhibitory act increases with increase in concentration of the treatment applied. It was also observed that the longer the exposure time, the more the effectiveness of the treatments against the root-knot nematode egg-hatch and juvenile survival. The observed nematotoxic effects of the test plant extracts can be attributed to presence of nematicidal chemical components that were seriously injurious to *Meloidogyne incognita* egg and infective second stage juveniles. The use of plant extracts in control of phyto-nematodes have been reported by earlier researchers. Pandey (1990) reported the efficiency of aqueous extracts of the roots and shoots of the *Lactna sativa, Ammi majus Artemisia annua* which at concentration of 100% resulted in 100% *M. incognita* mortality within 24 hours of exposure in of exposure.Zavaleta-Mojia et al 1993, reported the the bio-nematicidal effects of Tagetes Species on root knot nematode pests.

Other researchers like Olabiyi 2005, Aboluroso *et al.*,2004, Adegbite and Adesiyan 2005, Abolusoro et al, 2018 reported effectiveness of different plant extracts in suppressing egg hatch and juvenile death of *Meloidogyne incognita* and other nematode genera. The result of this study showed that bio-nematicidal components are present in the leaf extracts of the utilized botanicals *(Vernonoia amigdalina, Morinda lucida, Azadirachta indica*) and this is responsible for their nematicidal properties against root-knot nematode *M. incognita.* This agrees with earlier researchers (Zuren et al 1984., Pandy, R 1990 Oyedunmade ,2000) who reported similar observation in their various research. .The bioactive agent, flavonoid was found in all the test plant materials. This is probably the reason responsible for the efficiency of the plant materials in reducing soil nematode population. This observation agress with Olabiyi (2004) who reported effectiveness of flavonoid in reducing *M. incognita* population as well as enhancing egg hatch inhibition. Further result obtained on analysis of saponin content of the test plant showed that all the test plant extracts contained saponin. In summary, one can conclude that alkaloid, flavonoid, saponins and tannins are the major bioactive components of the test plant materials. This observation agreed with by the findings of Sofowora (1982), Olabiyi (2005) who reported that alkaloids, flavonoids, saponins and tannins are principally contained in most medicinal plants in our environment, and incidentally, all the plants utilized are medicinal plants.

CONCLUSION

Various plant materials utilized for this research work are biochemically active and hence biocidal against root-knot and other parasitic nematodes of crops. The potential of these plant materials as biocidal agents against parasitic nematode has been established from this research findings. They can therefore be used as botanical control agents for managing plant parasitic nematodes as suitable replacement for environmentally harmful and bio-toxic synthetics that are currently been used for managing parasitic nematodes and others related biotic-stressors, ravaging crops and thereby reducing yield in quality and quantity. Agro-chemical companies can leverage on these plants as raw material for manufacturing nematicides of plant origin as a way of reducing environmental hazards due to the use of harmful synthetic chemicals for managing plant parasitic nematodes as well as other biotic stressors that tend to bring about yield reduction.

56th Annual Conference
Agricultural Society of Nigeria
24 - 28 Oct., 2022

ABSTRACT
Ten open-pollinated maize varieties developed between 1979 and 2008 classified into two breeding eras (1979 – 1999, Era 1; 2000 – 2008, Era 2) were crossed in a partial diallel fashion to generate 45 F_1 hybrids and their parents were studied for combining ability in five locations. Parent AMATZBR-WC_2B (era 2) with higher GCA effects, and cross combinations DMR-LSR-W (Era 1) x BR9928DMRSR (Era 2) and BR9922DMRSR (Era 2) x TZBRELD-$4C_0W$ (Era 2) with higher SCA for grain yield under low-N environment were identified as promising candidates for the development of nitrogen use efficient varieties for low-N environments. This study revealed the superiority of the cross combinations within the mordern maize varieties to the older ones. Parents TZBRELD-$4C_0W$ (Era 2) on the other hand, was the best general combiner for grain yield, and so could be used in the extraction of productive inbred lines for use in hybrid breeding programmes with a view to increase the yield level. It also an indication that the modern maize varieties combined well with other lines for maize grain yield. The study also revealed no environmental influence on combining ability for grain yield.

Keywords: combining ability, maize, eras, environmental, grain yield

INTRODUCTION
Development of population with high combining ability is a prerequisite to the efficient use of heterosis. In other words, the value of any population depends on its genetic potential *per se* as well as its combining ability when used in crosses. Consequently, analysis of combining ability allows the choice of parental populations to be used in breeding programmes. The use of genotypes with high combining ability is premised upon the belief that their progenies will give superior hybrids and segregating populations with large genetic variability. Combining ability can be classified as either general combining ability (GCA) or specific combining ability (SCA). The

concept of GCA and SCA was introduced by (Spague and Tatum, 1942) to distinguish between the average performance of parents in crosses (GCA) and the deviation of individual crosses from the average of the crosses (SCA). Lines that combine well with most others are said to have good GCA while those that combine well with only few other lines exhibit SCA. The Diallel mating design proposed has been used to determine the best parental combinations for hybridization either to exploit GCA effects and/or identify the best specific combinations (SCA) for both production and breeding purposes. Combining ability is not only good for improving population *per se* or predicting the best combiners, but it is also good for extraction of superior inbred lines for hybrid production. The heterosis and combining ability of tropically adapted early and intermediate matured maize germplasm of International Wheat and Maize Improvement Center (CIMMYT) was studied by using five CIMMYT gene pools and five maize populations to form the diallel crosses (Beck et al, 1990). The parents and their crosses were evaluated at five locations in Mexico, and one each in Colombia, Ecuador, India, and Thailand. Data were collected on plant and ear height, 50% days to silking and grain yield. The authors reported significant GCA effects for grain yield, plant and ear heights and days to silk and SCA effect only for ear height. Comparison of GCA with SCA sums of squares revealed predominance of additive genetic effects for both plant and ear heights. On the basis of good performance of intra-population hybrids observed in the study, the authors suggested that consideration should be given to the development of hybrids from lines from the same pool or population. In another experiment conducted by (Han, Vasal, Beck, et al., 1991) to examine the combining ability effects of inbred lines derived from maize population at CIMMYT. Fifty S_3 lines selected from different populations based on *per se* performance were divided into six sets to make six diallel crosses. Each diallel included 8 to 11 lines derived from 2 or 3 populations and crosses in each diallel set were evaluated in 3 to 4 locations during the 1986 and 1987 growing seasons. The results from the study showed that inter-population crosses were superior by between 4 and 16 percentage (%) over the intra-population crosses for grain yield. The authors also observed that while means of all inter-population crosses had positive SCA estimates, the intra-population line crosses gave negative SCA estimates for grain yield. The authors therefore concluded that on the average, inter-population crosses expressed greater heterosis for grain yield than intra-population crosses. Based on the observed differences in genetic diversity among population and pools, the authors hypothesized that as long as there is large genetic diversity within a population, crossing of lines from the same population or pools could also produce hybrids with good performance. Consequently, inter-population will therefore have little advantage over intra-population line crosses of the good population.

Combining ability and heterosis for grain yield and yield components in maize by crossing seven white was estimated using medium maturing inbred (S_6) lines from the IITA in all possible combinations to generate 21 F_1s (Ojo, Adedzwa, Bello., 2007). The 21 F_1s and their 6 inbred lines were evaluated during the early and late planting seasons of 1998 at the University of Agriculture, Makurdi, Nigeria. Data collected on ear length, ear diameter, shelling percentage and grain yield were used to estimate combining ability and high parent heterosis. Results of the study showed highly significant differences among hybrids for all the traits considered except ear length. As expected, hybrid means were significantly higher than the parental means for all traits except shelling percentage. Crosses involving Tropical x (Tropical x Temperate) lines produced hybrids with the highest heterosis for all traits. The highest inbred grain yield (4.79 t/ha) was obtained from Tropical x (Tropical x Temperate) hybrids while GCA and SCA means squares were not significant for ear length, ear diameter and shelling percentage. GCA mean squares were however highly significant and higher than SCA mean square for grain yield, indicating a predominance of additive gene action for grain yield. In another study (Yusuf and Ado, 2009), estimated the combining ability of quality protein maize (QPM) inbred lines evaluated at Samaru-Northern Guinea Savanna Zone of Nigeria. The 30 hybrids comprising fifteen single cross and fifteen reciprocal hybrids which were generated from the six QPM varieties along with the six inbred parents and 13 checks were evaluated for two years in a 7 x 7 partial lattice design. Their results showed highly significant GCA mean squares for all traits except for days to germination, emergence count and ASI. GCA effects were generally higher than SCA effects indicating predominance of additive over non-additive gene action. However, SCA effects were significant for % protein, moisture content, ear height and one thousand grain weight. Apart from highly significant negative SCA effects for days to maturity for some crosses which identified them as good candidates for developing early maturing hybrids, the authors also reported high but significant negative SCA effects for plant and ear heights which is an indication of short stature which is desired for mechanical harvesting.

The line × tester mating design involving five maize lines and four testers was used to estimate GCA and SCA effects and also determine high parent heterosis for maize traits under moisture deficit conditions in Northern Guinea and Sudan savannas of Nigeria (Aminu and Izge, 2013). Results in respect of combining ability analysis revealed that both additive and non-additive gene actions were important in days for 50% tasselling and silking, ASI, plant height and ear placement. However, there was a preponderance of non-additive gene action for almost all the traits investigated, with parents Ex-Damboa White, EVDT-99WSTRQPMCO, EVDT-99WSTRCO and TZE-COMP3DTC1 being the best general combiners among the parents. Cross combination EVDT-99WSTRQPMCO × Ex-Biu White was identified as the best specific combiner among the 20 hybrids evaluated in days to tasseling and silking. The hybrid also recorded high parent heterosis for grain yield. The authors therefore recommended the use of the hybrid in an area with marginal rainfall as a means for exploiting heterosis for grain yield and earliness. However, there is likelihood that continuous change in breeding objectives may alter positively or negatively the combining ability for some target traits. The objective of this study therefore was to compare the combining ability of ten tropical maize varieties developed between 1979 and 2008 classified into two breeding eras (1979 – 1999 Era 1/ older varieties; 2000 – 2008, Era 2/newer varieties). The study was also aimed at identifying the superiority of combining ability of crosses within newer and older, or between newer and older varieties respectively.

MATERIALS AND METHODS

The materials studied were ten tropical maize varieties developed between 1979 and 2008 classified into two breeding eras (1979 – 1999, Era 1/older varieties; 2000 – 2008, Era 2/newer varieties) The ten open-pollinated varieties were crossed in a partial diallel fashion to generate 45 F_1 hybrids at the International Institute of Tropical Agriculture (IITA), Ibadan, Nigeria. The 45 F_1 hybrids were tested under six environments viz: Ikenne (Latitude 6^0 53^1N, Longitude 3^0 42^1E) and Ile-Ife (Latitude 7^0 18^1N, Longitude 4^0 33^1E) (rain forest region) were regarded as optimal/stress free environments. Mokwa (Latitude 9^0 18^1N, Longitude 5^0N 4^1E) and Zaria(Latitude$12^0 00^1$N, Longitude 8^0 22^1E) (Guinea savanna) which were the last four for Nitrogen (N) study where the genetic materials were evaluated under high and low N conditions (30kg/ha and 90kg/ha) respectively. In all evaluations, two row plots were used. Each row was 6m in length, spaced at 0.75m between rows 0.25m within rows with four replications to give a population density of approximately 53,333 plants per hectare height.

ANALYSIS OF COMBINING ABILITY

Both general combining ability (GCA) and specific combining ability (SCA) were computed using method 4 model 1 (parents and crosses together without reciprocal) (Griffing., 1956)

3.5.1.2 GENERAL COMBINING ABILITY (GCA) effect was computed as

$g_i = 1/2n(Y_i. + Y._j) - 1/n^2 Y.,$

Where: g_i = general combining effect of i^{th} line

n =number of lines involved in the cross

$(Y_i + Y_j)$ =sum of cross products from diallel table

Y., = total sum of products from diallel table

RESULTS

Environmmental effects were not significant for maize grain under optimal condition in Ife and Ikenne, however, they were highly significant under low and high regime (Table 1). Variation among the genotypes for grain yield were not significant under optimal environment, but were highly significant under low and high N environments. Both GCA and SCA varied significantly for grain yield under low, while only SCA was significantly different under high N condition. G x E, GCA x Env and SCA x Env were not significantly different under across the six tested environments. The values of SCA/GCA were less than 1 i.e. GCA/SCA is greater than 1.

COMBINING ABILITY UNDER OPTIMAL ENVIRONMENT

The estimates for GCA effects in respect of grain yield and related traits across natural field conditions in 2012 (i.e. Ikenne and Ife) are presented in Table 2. GCA effects for grain yield was significant and positive for DMR-LSR-W, while it was negative but non-significant for other parents. Parent DMR-LSR-W obtained the highest values of the estimate of GCA effects for grain yield under natural field condition at Ikenne and Ife. However, all other parents had low and negative GCA effect across the environments. Maize grain yield assessment under natural field condition showed that DMR-LSR-W combined generally well with TZSR-W-1, TZSR-Y-1, TZSR-W-1, ACR99TZLCOMP-4DMRSR, BR9922DMRSR, BR9928DMRSR, BR9943DMRSR, AMATZBR-WC$_2$B and TZBRELD.4C$_0$W. All other cross combinations had low and non-significant GCA effects for grain yield under natural field environment

Across high-N environments, the estimates of GCA effects for grain yield were high and positive in parents BR9922DMRSR, BR9943DMRSR and TZBRELD.4C_0W (Table 4). Significant GCA effect was also recorded for number of ears per plant in DMR-LSR-Y under the same condition.

DISCUSSION

Formulation of comprehensive breeding strategies for yield improvement depends mostly on the understanding of the nature of gene action involved in the expression of specific traits. Thus, combining ability is one of the powerful tools in identifying the best cross combinations that may be used either to exploit heterosis or accumulate productive alleles for the desired traits. As a tool, it also facilitates the understanding of the genetic basis of expression of many characters that enable the plant breeder design effective breeding method for future improvement programmes. Furthermore, dominance (non-additive gene action) is desirable for developing superior hybrids while additive gene action implies that standard selection protocols would be effective in breeding strategy aimed at improving the character (Edwaqrds et al, 1976). The significant GCA and SCA mean squares recorded for grain in both stress and stress-free environments revealed that both additive and non-additive gene actions were important in the inheritance of the traits under the specific environments in which the studies were conducted. It also confirmed that there is wide genetic variability inherent in the populations that could be exploited for genetic improvement of grain yield. The results, therefore, suggest that additive type of gene action is primarily involved in determining grain yield across the different environments Tested. These results agree with the report of who found the preponderance of additive genetic effects in the control of most traits in maize. In earlier studies (Beck, Vaal, Carossa., 1990; Gama, Hallauer, Ferrao et al., 1995) reported the predominance of additive over non-additive gene effect for maize grain yield while (Bello and Olaoye, 2009) also reported the preponderance of GCA

effects in the expression of traits in maize genotypes under striga infested condition. Aly, Malik, Choudhry, et al., 1999) indicated that both GCA and SCA were significant for grain yield. This is similar to an earlier study conducted by (Amiruzzaman, Islam, Hassan, et al., 2010) on combining ability and heterosis for yield and component character in maize. The fact that both additive and non-additive gene action were important in genetic control of grain yield implies that there is existence of tremendous amount of variability in the genetic materials. The author observed that the significant positive SCA effects for ear length, kernels per ear and kernel weight were more frequently associated with significant estimate of SCA effects for grain yield. Parent AMATZBR-WC_2B with higher GCA effects and mean values for grain yield, and cross combinations DMR-LSR-W (Era 1) x BR9928DMRSR (Era 2) and BR9922DMRSR (Era 2) x TZBRELD-4C_0W (Era 2) with higher SCA for grain yield under low-N environment on the other hand, are promising candidates for the development of nitrogen use efficient varieties for cultivation in low-N environments. This study also revealed the superiority of the cross combinations within the more recent maize varieties to the older ones. Parents TZBRELD-4C_0W (Era 2) on the hand, was the best general combiner for grain yield, simultaneously possessed high mean values under high-N other environment, and so could be used in the extraction of productive inbred lines for use in hybrid breeding programmes with a view to increase the yield level. It also an indication that the modern maize varieties combined well with other lines for grain yield under adequate supply of nitrogen relative to older varieties.

CONCLUSION

Parent AMATZBR-WC$_2$B with higher GCA effects and mean values for grain yield, and cross combinations DMR-LSR-W (Era 1) x BR9928DMRSR (Era 2) and BR9922DMRSR (Era 2) x TZBRELD-4C$_0$W (Era 2) with higher SCA for grain yield under low-N environment, can be suggested for the development of low N nitrogen tolerant hybrid maize for cultivation in low-N soil condition. This study also revealed the superiority of the cross combinations within the more recent maize varieties to the older ones. Parents TZBRELD-4C$_0$W (Era 2), was the best general combiner for grain yield, so could be used in the extraction of productive inbred lines for use in hybrid breeding programmes with a view to increase the yield level. The study also revealed that modern maize varieties are good general combiners for maize grain yield, they are therefore better sources of genes for maize grain yield development compare to older varieties

ABSTRACT
Quality seed is a prerequisite to uniform stand establishment which fabricates a pathway towards high yielding forest seed products. Seeds are produced and dispersed in such a way as to optimize their survival from predators and in competition with other species. However apart from the dispersal mode, seed collection and handling play major role in the yield and quality of forest tree species meant for conservation and afforestation programs. Seeds of many tree species are easy to handle and store for long periods of time, whilst others are very difficult and need special treatment to maintain viability. This paper highlights the importance of postharvest techniques that should be put into consideration to avoid huge losses that could result to reduction in productivity and availability of species' seeds.
Keywords: Quality seed, Harvesting, Processing, Storage,

INTRODUCTION
Seed in its entirety is basically the biological material exhibiting a wide range of biological variation in morphology and physiology. For sustainable production of agricultural and forestry growth and establishment, production of quality seed remains high priority. Quality seed is a prerequisite to uniform stand establishment which fabricates a pathway towards high yielding forest seed products. Seeds are produced and dispersed in such a way as to optimize their survival from predators and in competition with other species. However apart from the dispersal mode, seed collection and handling play major role in the yield and quality of forest tree species meant for conservation and afforestation programs (Lars, 2007). Seeds of many tree species are easy to handle and store for long periods of time, whilst others are very difficult and need special treatment to maintain viability (Neya, 2006). Some seeds are liable to damage by insect pests and diseases even when they are maturing on the trees or under storage rendering them completely nonviable. The productivity and quality of tree species are affected by some constraints experienced by

absence of planting materials, harvest and most especially postharvest management. The postharvest seed storage between growing seasons is a necessary step linking plant regenerations and sustainability. The main factors responsible for postharvest losses are lack of proper packaging, no precooling, no proper transportation, lack of good storage techniques amongst others. All these factors have contributed to a great loss of seed quality and quantity at postharvest stage. Aidoo (1993) revealed that about 20 % losses results from majorly Africa and other Asian countries. Kader (2005) reported that less than 5% of resource allocation from agricultural research in developing countries is on postharvest while the remaining 95% is mainly on the production. In order to avoid huge losses right from the harvesting stage to production, preventive measures and handling practice must be put in place to reduce postharvest losses. In this paper we will examine the ways by which post -harvest losses can be reduced to prevent the risk of seed loss before next crop seasons and also increase the shelf life of harvested fruits/seeds.

Postharvest Techniques for Forest Seed Management

Healthy seeds must be stored for maintenance of high yielding crops. According to Watkins and Nock (2012) the primary objective of postharvest handling is to maintain quality by reducing metabolic rates and water loss that result in undesirable changes in colour, composition, wilting, shriveling, spoilage caused by decay and preventing development of freezing injury or physiological disorders. Once appropriate postharvest handling techniques are put in place there is possibility of moderate reduction in the losses of seeds and also achieve high quality seeds of both national and international standards.

Seed Collection and Harvesting

Seed quality is the measure of the potential to produce desirable quality, healthy, and high yielding crops at low planting rates (Greggs and Billups, 2010). It is imperative to note that a good tree starts from a good seed, thus it is justified to pay attention to what is being collected regardless of the succeeding procedures of seed handling. Although the act of seed picking from the ground floor seems to be the easiest and preferred but poses to be at risk of contamination, however seed collectors have come to realize that good seed must be collected from the mother tree before it falls or is dispersed. This will ensure that healthy seeds are collected right before they are dispersed or attacked by predators, insects and other degrading factors. After harvesting and collection, subsequent handling procedures are necessary to ensure that all data are noted for record purposes. Collection containers mostly used for bulk storage must be tight and cleared of all seeds and debris from previous collection as this will reduce the risk of contamination. Seeds to be stored or preprocessed must be viable until the processing stage.

Seed Cleaning and Processing

The essence of seed cleaning is to make seed storable, the ease or difficulty of cleaning seed may influence the collection method, most especially ground collection. Although ground picking/collection maybe easy, the collected seeds tend to more infested by pathogens more than those pick from the trees. Seed processing refers to the handling procedures between collection and storage or sowing which aims at achieving clean, pure seeds of high physiological quality (germinability) which can be stored and easily handled during succeeding processes such as pretreatment, transport and sowing (Lars, 2007). This process categorized into pre cleaning, procuring, extraction, dewinging, cleaning, grading and adjustment of moisture content. Seed processing should be done to get high quality seeds at a sufficiently high rate per hour to minimize the cost and make it commercially viable. In processing, a risk of damage or injury usually occur to some seeds; mechanical damage, heat damage, chemical damage and water damage. The more fragile the seeds the more sensitive it is to damage hence adequate care and precaution must be ensured during cleaning and processing.

Seed Storage

Storage may be defined as the preservation of viable seeds from the time of collection until they are required for sowing. One of the first considerations when deciding how to collect and handle seeds of a particular species is storage behavior. Although once seeds meant for regeneration and afforestation can be sown immediately after collection, no storage is needed. Seed lots should be sown before the germination percentage drops below 80-60%. Generally, seed lots are discarded once the germination percentage falls below 50%. The seed survival duration is different for different species and also depends on the actual condition of the seeds as well as the external factors; among those, seed moisture, storage room temperature, and the presence of diseases and pests are considered most important. Probert *et al.* (2007) explained that if fruits/seeds have a very high relative humidity at harvest (85%–100%) and if resources are available to create a controlled, non-desiccating environment, they should not be rapidly dried. Seed quality is likely to increase if such seeds are held under conditions (temperature, humidity) that are close to the conditions that they would experience if they remained on the maternal plant. Further research reveals that metabolic activities, age and longevity of seeds can be manipulating by controlling the humidity, temperatures and oxygen (Mohammed, 2014). Reduction of seed moisture content up to an appropriate limit as the seed could be damaged because of desiccation and seeds could be stored for a longer period due to a lower level of humidity.

Table 1: List of Tree Species, their seeding period, viability and number of seeds per kg

Species	**Seeding period**	**Storage period/ Viability**	**Number of seeds per kg**
Terminlia ivorensis	December-January	12 months and above	4,500
Terminalia superba	July-October	6 months	4500-4700

Storage losses

The main purpose of storage in any agricultural or forestry programme is to avoid biological and financial losses of the yield obtained after harvest, this help in reducing the crop losses. The damage that usually occur in different seeds is simply relative to their storage temperature, seed moisture content and rate of seed drying. Based on this vast information it is imperative that storage losses can be reduced to the barest minimum to avoid yield loss. Tree species are categorized into three storage behavior; recalcitrant, intermediate and orthodox. Different researches have been conducted to actualized and determine the storage behavior of some tree species and the results have shown a huge impact on how to differentiate the species (Hong and Ellis, 1996; Pritchard et al. 2004; Wood et al. 2000; Hay et al. 2000; Tuckett et al. 2010). This would also help in adjusting the appropriate measures on how to improve the storability of seeds. Desiccation-sensitive recalcitrant seeds are shed from the tree after maturation, with high moisture content, high metabolic activity and poor storage potential and this leads to significant challenge for ex situ conservation through seed-gene bank (Umarani *et al*, 2015). Berjak and Pammenter (2008) also gave practical advice for the conservation of recalcitrant seeds, seeds should be kept at their harvest (or shedding) moisture content and at the lowest temperature that does not incur chilling damage. Apart from the seed storage behavior other factors to consider during storage losses are the losses that directly affect the stored seeds. Pests namely rodents, insects, mites, birds, microorganisms such as mould and bacteria are among the biological factors that responsible for deterioration fruits/crops. The microbiological and biological effect on seeds can result from susceptibility to infection and damage by pathogens during storage.

Ways to prevent storage losses

Postharvest losses can be considered as one of major challenge undermining food security and income generation. The inability to maintain and sustain seeds of high quality can also be seen as a hindrance to its production and productivity in most developing countries. Good post-harvest handling is crucial in ensuring a quality product. When cultivation, harvest, and particularly postharvest operations are handled with utmost care, hence a good quality and a safe end-product are ensured. (Melanie & Michael, 2011). Seed quality needs to be maintained for the better quality fruits/crops. It is important to note that prompt harvesting at optimum stage, adequate transportation to processing units, handling and cleaning, well packaging methods and appropriate storage facilities are steps in reducing postharvest losses. Improved modern processing method is required to increase the shelf life and quality of seeds of tree species. Ability to access loan to buy improved postharvest facilities and equipment is also another fundamental way to enable smallholder farmers and small-to-medium enterprises to ensure reduction in losses. The storage capability of cold chain equipment and infrastructure can also help by substantially reduce losses of fresh produce directly from the farm. Access to good road network is another way to help minimize losses, improved road infrastructure from the forests/farms will lower transport time and also reduce the risk of damaging produce most perishables.

RECOMMENDATION AND CONCLUSION

Seeds are liable to damage by diseases even when they are maturing on the trees or under storage rendering them completely nonviable. To avoid damage and minimize postharvest losses, it is important to put in place necessary measures Appropriate prompt harvesting time and subsequent storage conditions should be maintained; Establishment of small and large processing facilities should be on readily available; During seed cleaning/ handling, infested seeds should be avoided and removed from the seed lot before storing, as this will reduce multiplication of infested seeds; Accessibility to right packaging; designing and manufacture of good quality and affordable packaging material for those that recalcitrant in nature and likely perishables; Avoid multiplication and further damage of storage seeds;The use of indiscriminate of non-recommended ripening chemicals should be avoided; Appropriate training manual and conduct of training by professionals and forest extension officers on various aspects of postharvest management can be considered a step in preventing wastage

ABSTRACT

Despite its medicinal purpose, *Shorea roxburghii* G.Don is considered threatened in Nigeria due to its collection and its slow growth via seed propagation. This study was conducted to assess the effects of growth hormones on sprouting and rooting ability of *Shorea roxburghii*. Stem cuttings from mature plants were treated with two different types of growth regulators: Indole-3-Butyric Acid (IBA) and coconut water while untreated cuttings were used as the control. The experiment was laid in a completely randomized design with five treatments replicated four times. The following parameters were assessed: percentage survival, number of roots, sprout count and root length. The results assessed show that the growth regulators had no significant effect on the sprout count. Other parameters assessed i.e. percentage survival, number of roots and root length were significantly different to the effect of growth application. From the result, it is observed that T4 (coconut water extract) indicates the highest mean value of 96.47 among the treatments applied. It can concluded that coconut water extract can be extensively used to establish mass propagation of *S. roxburghii*.

Keywords: *Shorea roxburghii*, IBA, coconut water extract, stem cuttings

INTRODUCTION

Shorea roxburghii G. Don is a deciduous tree with simple alternate leaves and belongs to the family Dipterocapceace. The species is predominantly found in dry deciduous forest of India evergreen or semi evergreen dipterocarp forest of Malaysia, Thailand and Indochina (Bolanle-Ojo *et al*, 2014 and Ho Wai mun *et al*, 2018). It is suitable for general utility purpose, light to medium construction, and is very popular as a plywood. The propagation of plants by seeds is comparatively easy, fast and reliable.

Seed can be considered as the starting structure in the life of seed plants. Successful seed germination depends on numerous internal and external factors. However, vegetative propagation or clonal multiplication has become popular and also shown an advantage of developing true-to-type and disease free clones of great importance both economically and commercially (Kochhar *et al*, 2008). Asexual or vegetative propagation of plants is that form of plant propagation in which this new individual possesses exactly the same characteristics as the parent plant from which it was taken (Sandra and Mack, 2011; Gupta *et al*., 2002).

Reproduction of new plants is very possible through the formation of adventitious roots and shoots because every cell of the plant contains the genetic information necessary to regenerate the entire plant (Amir, 2010). In cases where seeds are recalcitrant such as *Shorea roxburghii* as it affects its viability, it is equally important to devise a way to increase its mass propagation for environmental purposes (Noraliza *et al,* 2017). The effect of germination stimulants such as Indole butyric acid (IBA), Napthelene acetic acid (NAA) and Gibberelic acid (GA) are most evident on root initiation and shoot initiation and production. Natural extracts such as honey, garlic extract, *Eucalyptyus* spp, moringa extract, and coconut water extract that act as growth regulators are also often used as they are easily available at low cost purposes. Among natural extracts that can be used for sprouting ability in plants is the coconut water extract. Coconut water extract has been proven to contain some class of bio compounds such as auxins, gibberellins, cytokinnins and other natural inhibitors (Yong *et al*, 2013; Ge *et al*, 2007 and Mamaril *et al*, 1988). This natural extract is considered as a cheap source of growth regulators which is easily assessable and environmentally friendly. Coconut water extract is well known as an organic supplement containing mineral nutrients and phytohormones such as cytokinnis, auxins, gibberellins and abscisic acid. Its influence on stem cuttings of forest tree species has proven to be effective and easy to use unlike synthetic growth regulators. Due to its organic components, noticeable changes are observed in its usage to stimulate cell growth, shoot formation and production, apical bud formation and rapid root formation (Razdan, 2003; Kieber, 2002; Caboni *et al*, 1997; Blazkova *et al*, 1997). This paper therefore aims to compare the influence of natural extracts (coconut water extract) and synthetic growth hormones at different levels on the vegetative propagation of *S. roxburghii* G. Don with a view of determining its sprouting ability so as to domesticate and conserve while propagating it with appropriate methods.

MATERIALS AND METHOD

One hundred single node leafy stem cuttings of *Shorea roxburghii* were obtained from 18 month old seedlings. The seedlings were decapitated and stem cuttings were obtained from the single node position of the seedlings. The cuttings were then treated with Indole butyric acid (IBA) at the following concentrations, 0, 50, 100 and 150 mgL^{-1} and coconut water. The cuttings were treated with the growth regulators using the quick dip method (Akinyele, 2010) and set in washed sterilized river sand in germination trays, watered twice daily with a hand sprayer and laid out in a completely randomised design under the high humidity propagator. Twenty cuttings were allotted to each treatment and replicated four times with treatments as follows T1 (IBA 50), T2 (IBA100), T3 (IBA150), T4 (Coconut water) and T5 (Control). Data was collected after 60 days for percentage survival, sprout count, number of roots and length of roots per cuttings. The length of roots was assessed with the use of metre rule while the other parameters were assessed using physical count. The data collected was then analysed using analysis of variance (ANOVA) and treatment means were compared using LSD test at probability level of 0.05%.

RESULTS AND DISCUSSION

The retention of leaves is important for cuttings as they do not possess large reserves and the persistence of physiologically active leaves and development of buds into branches are prominent signs of rooting of cuttings (Fadwa and Yahia, 2014; Akinyele, 2010). From the result below, T4 (coconut water extract) has shown the highest mean values from the parameters used in this study as compared to the application of synthetic growth regulators. T1 (IBA 50) shows the least value from the parameters observed.

Table 1: Effect of plant growth regulators on the stem cuttings of *Shorea roxburghii* G.Don

PLANT REGULATORS	NUMBER OF ROOTS	ROOT LENGTH	PERCENTAGE SURVIVAL	SPROUT COUNT

Effect of coconut water extract and IBA on the survival percentage of cuttings of *S. roxburghii* G. Don

The study reveals that the stem cuttings of juvenile seedlings of *Shorea roxburghii* gave high rate of survival as most of the stem cuttings retain their freshness 4 weeks after planting with different concentrations of both IBA and coconut water. Untreated cuttings gave the best survival percentage (95.567±0.12), as this further support the work done by Aini *et al* (2010) who found that untreated cuttings also gave highest survival percentage and best rooting percentage in *Gonystylus bancanus*. Gbadamosi and Sulaiman (2012) also confirmed that coconut water significantly enhanced the viability and shooting in *Irvingia gabonensis.*

Effect of coconut water extract and IBA on the sprout count of cuttings of *S. roxburghii* G. Don

The number of sprouts gave a higher indication. In a study conducted by Akinyele *et al*, 2020, it was observed that IBA was less effective at inducing the formation of callus formation especially at high concentration. This report indicates that the use of synthetic growth regulators should be reduced.

Effect of coconut water extract and IBA on the root length and number of roots on cuttings of *S.roxburghii*

The number and length of the roots also indicate higher value in coconut water though the control showed little variation. In this study the maximum number of roots was observed in the treated cuttings with coconut water extract (14.4467±0.014) as compared to other treated with IBA and untreated cuttings. This study is in line with the findings of Brintha and Harris (2016) where coconut treated cuttings had a significant effect on the number of roots in *Ixora coccinea.* Coconut water increased the length of roots in this study significantly at p<0.05. this results confirms the investigation of Muhammad *et al* 2015 where the root length of potato increased significantly due to application of coconut water extract at 3 months

CONCLUSION

This study has indicated that macro-propagation techniques could be utilized to rapidly enhance the rooting ability of *Shorea roxburghii*. It was concluded that the sprouting, rooting performance and percentage survival of *S. roxburghii* stem cuttings performed better with coconut water extract as compared with those treated with Indole butyric acid (IBA) at different concentration levels.

ABSTRACT

This study assesses the effect of different pre-treatments (hot and cold water, mechanical scarification and Tetraoxosulphate (VI) acid (H_2SO_4)) treatments on early germination of *Faidherbia albida* seeds. The seeds were soaked in cold water for 24 hours and hot water at varying time interval, scarified at the helium with file, and soaked at different time interval in concentrated (H_2SO_4) acid. The result of various pre-treatments showed that they all had uniform germination percentage of 100% while seeds soaked in (H_2SO_4) for 15 min and 10 min had the highest germination value (GV) of 65.25 and 65.00 respectively, followed by 15 mins soaking in hot water (47.14GV) and the least germination value was recorded in seeds scarified mechanically (33.31 GV). Analysis of Variance (ANOVA) revealed that there was no significant difference in the treatments. Although, seeds treated with H_2SO_4, at 15 min and 10 min had the best performance in germination value compared with other treatments, but due to economic reason (cost of purchasing the acid) among others, hot water treatment for 15 min is recommended.

Keywords: Pre-treatment, germination value, seed quality, *Faidherbia albida* and peak value.

INTRODUCTION

Faidherbia is a genus of leguminous plants containing one species, *Faidherbia albida*, which was formerly widely included in the genus *Acacia* as *Acacia albida*. The species is native to Africa, its common name is apple-ring acacia, their circular, indehiscent seed pods resemble apple rings (Michael, 2010). This species has been known as *Acacia albida* for a long time. It is a thorny tree growing up to 6–30m (20–98 ft) tall and 2m (6.6 ft) in trunk diameter. Its deep-penetrating tap root makes it highly resistant to drought. The bark is grey, and fissured when old. In Southern Africa it is absent throughout most of the territory, avoiding dry and upland areas or areas of winter rainfall, but occurs along the floodplains of the Zambezi and Limpopo, in Kruger National Park, Pongoland, around Gaberone, in the northern Okavango, the Caprivi Strip, Kakaoveld, western Gaza and Maputo Province (Armstrong, 2015).

Faidherbia albida is important for raising bees, since its flowers provide bee forage at the close of the rainy season, the seed pods are used for raising livestock, are used as camel fodder in Nigeria, and are eaten by stock and game in Southern Africa (Bramm, 1997). They are relished by elephant, antelope, buffalo, baboons and various browsers and grazers, though strangely ignored by warthog and zebra (Kevin, 1990). The wood is used for canoes, mortars, and pestles and the bark is pounded in Nigeria and used as a packing material on pack animals. Ashes of the wood are used in making soap and as a depilatory and tanning agent for hides. The wood is used for carving; the thorny branches useful for a natural barbed fence, pods and foliage are highly regarded as livestock fodder. Some 90% of Senegalese farmers interviewed by Felker (1981) collected, stored, and rationed Acacia albida pods to livestock. It is valued in agroforestry as it fixes nitrogen, and a high yield has been achieved in at least one test plot of maize crops grown amongst the trees at a density of 100 to 25 tree per hectare (Bayala, 2010). According to a 2018 article by the Guardian, monocultures of this species are popular in parts of Niger, where it is known as gao in Hausa, to use for intercropping (MacLean, 2018). It is also used for erosion control. Its value as an agroforestry tree larges partially in the fact that the tree drops its leaves during the rainy season, and therefore does not compete with crops for sunlight (Becking, 2020). An extract is used to treat ocular infections in farm animals, the bark is used in traditional medicine in Southern Africa, and Niger (MacLean, 2018).

F. albida is hard seeded which produces seeds with tough and hard seed coat (Connor, 2009). This condition does not encourage even germination but rather results in erratic germination of seeds (Alderete-Chavez et al., 2011). To achieve rapid and synchronous germination artificially, therefore, the seeds must be subjected to some physical or chemical treatment (Islam *et al*., 2009) thus the need to investigate different pre-sowing treatments which can best enhance germination (Butola and Bedola, 2004). Studies by Anonymous (1998), Connor (2008) and Asiedu et al. (2011) suggested treatment of seeds with boiling water and scarification with 97% sulphuric acid to enhance germination. Several other pre-sowing treatments have been suggested to enhance germination in hard seeded seeds. These include gibberellic acid, potassium nitrate (Alves *et al.*, 2000), succinic acid (Ghadiri and Torshiz, 2000); HCl, nitric acid, boric acid, acetic acid, ethanol, methanol, benzene, xylene (Idu et al., 2007); thiourea, benzyl adenine (Schmidt, 2000), among others.

It has been noted by Orwa *et al.* (2009) and Asiedu *et al.* (2011) that very little work has been done on the plant thus the need to conduct further study to determine the maximum number of seeds which can germinate under optimum conditions (Willan, 1987). This experiment was thus conducted to investigate the effect of some pre-sowing treatments on the germination of seeds of *F. albida*.

MATERIALS AND METHODS

Matured fruits of *F. albida* were collected from Ogbomoso area of Oyo State, and seeds were extracted from the pods. Washed and sterilized river sand was filled into perforated plastic trays (30cm X 12cm) for germination investigation under mist propagator chamber. The experiment was subjected to 10 pre-germination treatments that consist of mechanical scarification, cold (24 hours), hot water (soaked in for 3min, 5min, 10min and 15min) treatment and acid (soaked in for 3min, 5min, 10min and 15min) treatment. Mechanical scarification involved filing at the micropyle end round the circumference. All the treated seeds (500 seeds) were sown in perforated plastic germination trays under a mist propagator chamber in a Completely Randomized Design (CRD). The geminated seeds were monitored and data collected were analyzed using descriptive statistics and Analysis of Variance (ANOVA).

Germination assessment: The effects of pre-sowing treatment were assessed by daily counting of number of germinated seeds. Germinated seeds were counted and removed from the date of sowing until there was no more germination. A seed was considered to have germinated when the tip of the radicle emerged free of the seed coat (Auld *et al.*, 1988). Daily germination percentage was summed up to obtain cumulative germination on each assessment.

Germination period was determined as the number of days from first observed germination to where there was no more germination but energy period was arbitrarily defined in 12 days (Willan, 1993). Germination pattern was also determined by number of seeds that germinate at the different days after sowing (Viswanath *et al.*, 2002).

Germination energy defined as the percentage by number of seeds in a given sample which germinate within a definite period such as 7-14 days under optimum or stated condition (Willan, 1987) was determined. Germination energy is also a measure of the speed of germination and hence, a measure of the vigour of seedlings (Willan, 1993). In addition, germination value which is a composite value that combines both germination speed and total germination was also determined. Germination value is an objective means of evaluating results of a germination test and is calculated using the formula proposed by Hartmann *et al.* (1997) as follows:

GV = MDG X PV

Where:

GV = Germination value

(MDG) = (Final) Mean daily germination

PV = Peak value mean daily germination

Total germination is expressed as Mean Daily Germination (MDG), calculated as the cumulative percentage of full seed germination at the end of the test divided by the number of days from sowing to the end of test period. Speed of germination was determined and expressed as peak Value, which is the maximum mean germination reached at any time during the period of the test (Willan, 1993).

Table 1: Various Pre-germination treatments and the methodology involved in pretreating *F. albida*

S/N	Treatment	Methodology
T1	Mechanical Scarification	Scarified at the helium
T2	Cold Water (24 hours)	Seeds soaked in cold water for 24 hours at room
T3	Hot water (60^0)	temperature
T4	Hot water (60^0)	Seeds soaked in hot water for 3 minutes
T5	Hot water (60^0)	Seeds soaked in hot water for 5 minutes
T6	Hot water (60^0)	Seeds soaked in hot water for 10 minutes
T7	Concentrated Acid	Seeds soaked in hot water for 15 minutes
T8	Concentrated Acid	Seeds soaked in concentrated H2SO4 for 3
T9	Concentrated Acid	minutes
T10	Concentrated Acid	Seeds soaked in concentrated H2SO4 for 5
		minutes
		Seeds soaked in concentrated H2SO4 for 10
		minutes
		Seeds soaked in concentrated H2SO4 for 15
		minutes

RESULTS AND DISCUSSION

The result revealed that the treatments had uniform 100% germination percentage. Seeds soaked in concentrated Tetraoxosulphate (VI) acid (H_2SO_4) for 10 and 15 minutes had the highest peak value 17.40 and 17.33 respectively as well as germination value of 65.25 and 65.00 respectively followed by hot water treatment with peak value of 12.57 and germination value of 47.14 while the least value was recorded in mechanical scarification with peak value of 9.33 and germination value of 33.31 (Table 2). Analysis of Variance (ANOVA) revealed that there were no significant differences in all the treatments (Table 3).

Table 2: Comparison of Various Pre-treatment and germination value of *F. albida* seeds

Treatment	Germination percentage (%)	Peak Value (PV)	Mean Daily Germination (MDG)	Germination Value (GV) = PV X MDG
T1	100	9.33	3.57	33.31
T2	100	12.01	3.75	45.04
T3	100	10.88	3.75	40.80
T4	100	10.63	3.75	39.86
T5	100	9.39	3.57	33.52
T6	100	12.57	3.75	47.14
T7	100	10.90	3.75	40.88
T8	100	11.13	3.33	37.06
T9	100	17.33	3.75	65.00
T10	100	17.40	3.75	65.25

Peak Value (PV) = Cumulative percentage of total seed germination divided by number of days
Mean Daily Germination (MDG) = Cumulative percentage of total seed germination divided by peak value
Germination Value (GV) = Mean Daily Germination multiplied by Peak Value

Table 3: Analysis of Variance (ANOVA) for the germination of *F. albida* under different pre-treatment

Treatment	10	0.59	0.058	1.72	1.83^{ns}
Error	154	5.19	0.034		
Total	164	5.78			

ns- not significant (p>0.05)

CONCLUSION

F. albida seeds are glossy due to the presence of wax in the seed coat which prevents easy penetration of water. Mechanical scarification treatment in the study had least performance while acid treatment had the highest performance. Therefore, in order to enhance optimum and uniform germination as well as, uniform seedling production, soaking of *F. albida* seeds in concentrated H_2SO_4 for 15 min is recommended but considering the cost of acid, hot water treatment can be considered since it performed better after the acid treatment. This will definitely facilitate the availability of seedlings for reforestation and agroforestry programs on sustainable basis.

ABSTRACT

This research was to investigate the potential of *Chasmanthera welwitschii* fibre for the production of wood plastic board by making use of low-density polyethylene (recycled pure water sachet) as the board binder. The aim was to determine the effect of mixing ratio and board density on the dimensional stability together with the strength properties of the board produced. Eighteen boards were produced at mixing ratio of 1:1 and 2:1 (Resin to Fibre) with board densities of 300 kgm^{-3}, 400 kg m^{-3}, and 500 kg m^{-3} (each has three replicates). The boards produced were subjected to mechanical properties test, modulus of rupture, modulus of elasticity test. The result revealed that board produced from mixing ratio 1:1 (Resin to Fibre) and board density 500 kgm^3 was more dimensionally stable having the least mean value (5.6900E± 658.73354) in selected physical properties test and highest mean value in all the mechanical properties tested. The mixing ratio and board density has significant effect on the dimensional stability of the board. Increase in mixing ratio and board density resulted to improved dimensional stability and better strength properties of the board produced.

Keywords: Plastic board, Board binder, Board density, Mixing ratio, Dimensional stability.

INTRODUCTION

Wood plastic board is an engineered product formed by breaking down hardwood or softwood residuals into wood fibres, often in a defibrator, combining it with wax and a binder and forming panels by applying temperature and pressure (Spence, 2005). Fibre boards are classified based on density, a fibre board with density above 800 kgm^3 is classified as high density fibre board and a fiber board with density below 500 kgm^3 classified as wood plastic composite board (ASTM, 1978). Types of fibre board in order of increasing density include particle board, medium density fibre board (MDF) and hardwood density fibre board. It is used to form dashboards, rear parcel shelves, and inner door shells. These pieces are usually covered with skin foil or fabric such as cloth or leather. MDF has also replaced thin plywood and wet process hardboard in the production of molded and flush door skin (Kzysik *et al*., 1999).

Production of MDF and high density fibre board using formaldehyde has raised a lot of concern as it is very essential to use more friendly chemicals. Binding of the board can be improved upon during hot pressing by components that are part of the ligno-cellulosic material (Back, 1991, Bouajila *et al*., 2005). Paraffin wax is always added in small quantity to improve the poor water resistance. Fiber boards produced using annual plant materials and agricultural wastes have been reported to have poor water – resistant properties than wood (Ye x p, 2007). Recently, improvement has taken place in the MDF industry because MDF production has increased greatly. This research was carried out to produce wood plastic board from *Chasmanthera welwitschii* fibre using low density poly-ethylene so as to determine the effect of mixing ratios and board density on physical properties of the board produced.

MATERIALS AND METHODS

Chasmanthera welwitschii used for the research was collected from Akinyele cattle market, Ibadan. The recycled pure water sachet was bought from Aleshinloye market, Ibadan, Oyo State. The mould for the board production was constructed by metal fabricators at Ekotedo, Dugbe Area, Ibadan. *Chasmanthera welwitschii* was sun dried for two weeks precisely, after which it was mechanically fiberized into required sizes using electrically powered grinding machine and it was sieved with 4 mm wire mesh. The quantity of the materials used for the production of the fibre board of size (200 x 200 x 10) mm was calculated based on the mixing ratio of the component comprising the mass of the fibre board. The required quantity of *Chasmanthera welwitschii* and the recycled pure water sachet to be used were poured into a plastic bowl and then mixed together thoroughly after which it was blended together in an electrically powered blending machine. The mixture was put inside the mould to form the mat. The mat was taken to hydraulic hot press for composite production. Mould (200 x 200x 10) mm made with aluminum frame was coated with engine oil to prevent sticking of the formed fibre board on the mould. The mould containing the mixture of fibre and adhesive was taken to the press and subjected to pressure of 18psi and temperature of 2000 c for 15min.The boards produced were trimmed and cut into test samples using cross cutting machine and kept under a controlled laboratory environment prior to testing.

Test for physical properties:

Water absorption (W.A %): A Test sample with dimension (50 x 50) mm was used for the test. The initial weight of the boards was recorded using weighing balance before immersion in water. The final weights of the board were also recorded after 24 hours of soaking in water (Fuwape 1995).

$$\mathrm{WA} = \left(\frac{W_2 - W_1}{W_1}\right) \times 100$$

Where: W1= Initial weight (g), W2= Final weight (g)

Thickness swelling test (T.S %): Test samples of dimension (50 x 50) mm were placed in cold water at 250C. The initial thicknesses of the boards were taken using veneer caliper before the immersion in water. The final thickness of the boards was recorded after 24 and 48 hours respectively (Fuwape, 1995).

$$\mathrm{TS} = \left(\frac{T_2 - T_1}{T_1}\right) \times 100$$

Where: T1=Initial thickness (mm), T2=Final thickness (mm)

Test for mechanical properties:

The mechanical property determined were modulus of Rupture (MOR) and Modulus of Elasticity *(MOE). Internal Bonding Strength:* Internal bonding strength is also known as the tensile strength perpendicular to the surface. It provides measure of how well the panel is glued together. It was determined using three conditioned specimens of 50 mm x 50 mm from each composite board. Each panel was cut to width of 50mm, thickness 4mm, and length of 50mm for Internal bonding in accordance with INSTRON, 3369. The length grip of the machine with the material is at a distance of 10mm.

$$\text{IB} = \frac{P_s}{bl}$$

Where: IB = Internal bonding strength (pascal), Ps = rupture load (kilogram force), b = width (centimeter) and L = length (centimetre).

Modulus of rupture (MOR): Modulus of rupture is a parameter for measuring bending strength of non-wood materials. It measures the stress equivalence in the extreme fibres of the specimen (panshin and Dezeeulo 1980). Modulus of rupture is the maximum bending strength of stalks. To test for this, Hunfield tensiometer was used. Test samples were cut into dimension 195 × 50 thickness according to British standard, 1989. This was carried out by mounting the test samples one by one on the machine and the load was applied at the centre with the aid of an electromechanical motor till the point where failure occurs. The recording of the ultimate failure load (p) was estimated on the mercury meter.

The point of failure is the maximum Load (p). Modulus of Rupture (MOR) was then calculated by the formula.

$$\text{MOR} = \frac{3PL}{2bh^2}$$

Where: MOR = modulus of rupture (N/mm^2), P= Failing load, L= Span between centers of support (mm), B= Width of specimen (mm), h= Slope from the graph.

Modulus of elasticity (MOE): Modulus of elasticity is the ability of material to regain its original shape and size after being stressed (panshin and Dezeewo 1980). The modulus of elasticity was calculated from the load deflection graph during the Modulus of Rupture on (MOR). While the panel's stiffness (MOE) was determined from the bending test performed on each specimen and calculated using the formula:

$$\text{MOE} = \frac{3PL^3}{4bd3H}$$

Where P= Failing load, L= Span between centers of support (mm), B= Width of specimen (mm), h= Slope from the graph

RESULTS AND DISCUSSION

From Table 1, it could be observed that the mean values for thickness swelling ranged from 0.072% to 0.188% at 24 hrs and 0.161% to 0.289% at 48hrs while the mean values for water absorption ranges from 0.985 % to 2.079 % at 24 hrs and 2.33 % to 3.805 % at different board densities of 300 kg/m^{-3}, 400 kg m^{-3}, 500 kg m^{-3} using mixing ratio of 1:1 and 2:1 (binder/fibre). From the above result it was observed that the lowest mean of thickness swelling was obtained from the mixing ratio of 1:1 and board density of 300 kgm^{-3} with mean value of 0.0736±0.0326 at 24 hrs of immersion. While for the water absorption the lowest mean was obtained from board density of 300 kg m^{-3} and mixing ratio of 2:1 with the mean value of 0.985±0.088 at 24 hrs of immersion. As the mixing ratio (binder/fibre) increases from 1:1 to 2:1 for the board density of 300kgm^{-3} the water absorption rate decreases.

Table1: Mean value of physical properties of wood plastic board produced from *Chasmanthera welwitschii*

Board density (kg/m^3)	B/F	W.A (%) 24HRS	W.A (%) 48HRS	T.S(%) 24HRS	T.S(%) 48HRS
300	1.1	1.366±0.678	2.994±0.410	0.072±0.033	0.161±0.084
300	2.1	0.985±0.088	3.865±0.016	0.149±0.035	0.601±0.195
400	1.1	2.079±0.324	3.261±0.442	0.117±0.012	0.188±0.046
400	2.1	1.168±1.475	2.333±0.954	0.101±0.014	0.201±0.027
500	1.1	2.062±0.825	3.343±0.954	0.101±0.049	0.205±0.007
500	2.1	1.086±0.261	2.615±0.146	0.188±0.0456	0.289±0.065

B/F = Binder to Fibre, M.R-mixing ratio, W.A-water absorption rate, T.S-thickness swelling.
From Table 2, the mechanical strength of the selected mechanical (MOR, MOE and IB) properties was obtained at different mixing ratios and densities. For MOR board density of 500kgm-3give the highest mean value with the means value of 6.219±0.238, the board of 300kgm-3 with the mean value of 8.30E2±180.58273 gives highest mean value for MOE, while for IB it was obtained from the board density of 500 kg m^{-3} with mean value of 5.6910E±668.73354 all at the mixing ratio 1:1. This shows that as the board density increases the MOR and IB increases.

Table 2: Mean values of mechanical properties of wood plastic board produced from C*hasmanthera welwitschii*

Board density (kg/m^3)	L/B	MOR (N/mm^2)	MOE (N/mm^2)	IB (m)
300	1.1	5.843±1.178	8.3079E2±180.58273	1.6557E3±359.98758
300	2.1	4.061±0.435	6.5948E2±3.71482	1.3149E3±6.99552
400	1.1	5.676±5.0191	5.3201E2±302.50493	1.0583E3±720.14064
400	2.1	5.934±1.728	1.0902E3±238.77054	2.1744E3±479.03837
500	1.1	6.219±0.238	2.8761E2±329.26595	5.6910E2±668.73354
500	2.1	5.519±0.797	5.1412E2±150.71466	1.0234E3±701.9273

MOE = Modulus of Elasticity, MOR = Modulus of Rupture, IB = Internal Bond. L/B = fiber to nylon (mixing ratio)

CONCLUSION AND RECOMMENDATIONS

It has been clearly shown that wood plastic board is feasible from *Chasmanthera welwitschii* fibre when using polyethylene (recycled pure water sachet) as binder. The result also shows that mixing ratio and density has effect on the dimensional stability of the produced board as it was observed. Board with mixing ratio 1:1 and density of 300g/dm^3 has the lowest thickness swelling while board with 2:1 mixing ratio and density of 300g/dm^3 has the lowest rate of water absorption so it can be utilized in light constructions. On the basis of mechanical stability, board density of 500Kg/m^3 and mixing ratio 1:1 has the best dimensional stability and high strength properties.

ABSTRACT
The experiment was conducted at the Rubber Research Institute of Nigeria, Gum Arabic Sub-Station Gashua, Yobe (12^0 $46'^N$, Longitude 11^0 $00'^E$ and Altitude 360m above sea level) to assess the growth performance of *Acacia species* seedling as influenced by sowing depth. The experimental materials consisted of top soil, river sand, cow dung and polythene bags. Polythene bags measuring 7.5 cm x 20cm were filled with potting mixture consisting of top soil, river sand and cow dung in a ratio 2:2:1. The polythene bags were laid out in Randomized Complete Block Design (RCBD) replicated three times. Two seeds were sown per pot at a depth of 1cm, 2cm, 3cm and 4cm and were thinned to one seedling per pot. At 1 month after sowing (MAS), seedlings growth traits (height, stem diameter and number of primary) of *Acacia specie* were statistically similar regardless of sowing depth. However, at 2, 3 and 4 months after sowing (MAS), seedlings of *Acacia seyal* significantly gave superior seedling heights compared to *Acacia senegal*. Irrespective of growth stage *A. specie* seeds sown at 2cm depths in the nursery improved seedling growth performance considerably

Keywords: Gum Arabic, Nursery, Seedling, Sowing Depths, Potting Mixture.

INTRODUCTION
Gum arabic is the dried exudates obtained from stems and branches of *Acacia senegal* or closely rotated species that belongs to the family Fabaceae (Dorthe, 2000). In Nigeria, high concentrations of natural stands of *A. senegal* that produce grade one gum arabic are predominantly found in north eastern part of the country though the cultivated and some wild forms occur in North Western states from Kebbi, Sokoto, Zamfara, Katsina, Kano, Jigawa down to North East especially around latitude 10^0 $30'^N$ to 12^0 $00'^N$ (FDA, 2002). The volume of international trade on gum arabic by 15 African producing nations stands at 58,086 tons in

2018 (Okoro, 2020). The author further alluded that Nigeria production figure for same year was estimated at 1,472 tons coming a distance third position after Sudan and Senegal which account for 54, 803 and 1, 499 tons, respectively. Gum arabic is unique among the natural hydrocolloids because of its extreme water solubility. It gives excellent stabilizing and emulsifying properties to manufactured products such as food, beverages and pharmaceuticals. It is tasteless, odourless and non-toxic (Anderson, 1993). Other gum arabic not permitted as food additive include *Acacia seyal*, *Acacia laeta* and C*ombretum nigricans*. They have a positive optical rotation and are mostly used in printing, lithography, cosmetics, textiles, adhesives and soaps (Anderson, 1993). The plant is also useful for afforestation of arid tracts with desertification problems, soil reclamation and wind breaks (Duke, 1981). The leaf litters of *A. species* form an excellent source of nitrogen and organic matter which help to improve soil structure and fertility and when in association with microbial symbionts restores soil N through nitrogen fixation (Ojiekpon *et al.*, 2007).
The success of any tree planting exercise, depends largely on the use of good seedlings stock. Raising vigorous seedlings for filed transplanting will attractive premium price owing to the demand for gum arabic at both local and international market. This study was therefore conducted to determine appropriate sowing depths suitable for growth of gum arabic seedlings in the nursery.

MATERIALS AND METHOD

The experiment was conducted at the main nursery of Rubber Research Institute of Nigeria Gum Arabic Sub-Station, Gashua, Yobe state (12^0 $45'^N$ 11^0 $00'^E$ and 360m above sea level) in the Sahel savanna ecological zone of Nigeria. The potting mixture used were top soil, river sand and cow dung in ratio 2:2:1. Small hand dibbler was used to make a proper hole (Samthoth *et al.* 2020) in each of the polythene bags and four definite sowing depth of 1cm, 2cm, 3cm and 4cm were determined using meter rule to sow the two *Acacia species* (*Acacia senegal* and *Acacia seyal*) seeds. The experiment was laid out in Randomized Complete Block Design (RCBD) replicated three times. The seeds of *A. species* were collected from the sub-station plantation, top soil was collected from gum arabic experimental farm, river sand was sourced from sand vendor while cow dung was obtained from cattle Fulani settlement around the Sub-Station. Polythene bags of size 7.5cm x 20cm were used for the study. Two seeds were sown and later thinned to one seedling per polythene bag. Seedlings were watered morning and evening for four months except on days with rainfall. The growth data (plant height, number of primary branches and stem diameter) were determined monthly starting from one month after sowing (MAS) for up to four months.

The data were subjected to analysis of variance. Fishers test was used to test for significant difference among treatment means as described by Snedecor and Cochran (1987). Treatment means were compared using Duncan's multiple range test (Duncan, 1955). The data were analyzed using the general liner model procedure of statistics analysis system software version (SAS Institute, 2000).

RESULTS AND DISCUSSION

At 1, 2 and 3 MAS, sowing depth 1, 2 and 3cm though statistically similar significantly increase seedlings height compared with 4cm depth that gave the shortest seedlings regardless of the sampling month Table 1.

Table 1: Seedling height of *Acacia species* as influenced by sowing depth in the nursery

Treatment	Months After Sowing			
	Seedling Height			
	1	2	3	4
Sowing Depth (cm) SD:				
1	13.94a	26.11a	34.78a	46.14ab
2	13.75a	26.28a	26.27a	53.66a

SE±	0.094	1.925	2.592	4.219
Significance	NS	**	**	**
SD x SPP	NS	NS	NS	NS

Means followed by the same letter within a column of a treatment group are not significantly different statistically at 5% level of probability using DMTR **, significant at 5% level. NS not significant.

The increases in seedling height sown at depth 1, 2 and 3cm could be due to shallow sowing depth which gave rise to early emergence of *Acacia species* seeds which must have given the seedling growth an added advantage over the deepest seed sown at 4cm. The result collaborates the finding of Adeogum *et al.* (2012) who reported better seedling growth performance of Velvet tamarind (*Dialium guineense*) seeds at 3cm sowing depth compared with 4cm and 5cm depth.

At 2 and 3MAS, depths 1, 2 and 3 though similar statistically significantly increase stem diameter and number of primary branches of *A. species* Table 2 and 3.

However, *A. seyal* produce wider stem diameter and higher number of primary branches than *A. senegal*. The superior growth performance achieved by *A. seyal* may be due varietal and genetic influence since the two species were subjected to the same treatment as early suggested by Fakuta and Ojiekpon, (2009) in quantitative genetic variation of gum arabic provenances.

CONCLUSION

Form the result obtained from this investigation, sowing *A. species* at 2cm depth considerably increased seedling height, stem diameter and number of primary branches irrespective of seedling age. However, the experiment needs to be repeated before recommendation can be made.

56th Annual Conference
Agricultural Society of Nigeria
24 - 28 Oct., 2022

ABSTRACT
Agricultural activities depend greatly on climate. Therefore, any change in climate can enhance or limit the capacity of agriculture to play its major role as supplier of food and industrial raw materials. The study therefore, assessed the impacts of climate change on water resources, agricultural activities and food security in Zaria LGA, Kaduna State. The study used both primary and secondary data. Structured questionnaire was used to collect primary data from 384 respondents who were purposively sampled. Rainfall and temperature data were collected from Institute for Agricultural Research, Zaria. Data were analyzed using descriptive statistics such as mean, percentages and presented in Tables. Results showed that mean annual evapo-transpiration (2230mm) exceeds mean annual rainfall (1053mm) indicating likelihood of surface and groundwater deficiency in the area. Result also showed that climate change have posed significant impacts on crop production and food security especially as it led to the reduction in food availability and access as perceived by 80% of the respondents. The study therefore, recommended the need for effective water harvesting and introduction of high yielding, early maturing and climate change resistant varieties of crops in the study area.

Keywords: Agricultural activities, Assess, climate change, Food security, Water Resources

INTRODUCTION
Generally, climate, water resources, biophysical and socio-economic systems (including agriculture and food systems) are mutually interconnected in such a way that slight change in one, leads to changes in the others (Abdullahi and Adeogun, 2014). Climate change has seriously disrupted the entire ecological system of the earth. It has already impacted areas such as ecology, health, agriculture, water resources and so on. These impacts are felt by both the developed and developing countries. Unfortunately, the developing countries suffer more due to their poor economic, social and political capacity to adequately cope. Climate change is defined as the long-term variations in weather patterns which poses severe repercussions for man and the environment. Climate change has been predicted to worsen the incidence of drought and desertification. This may lead to severe water stress for agriculture and serious impacts on food security particularly in the rural areas where farmers mostly depend on rain-fed agriculture for survival (Ayinde, Muchie and Olatunji, 2011).

Climate change has posed a significant impact on water resources potentials of many areas particularly in Northern Nigeria. It is gradually altering the hydro-climatic characteristics of different ecological regions. This has led to severe negative consequences on the availability of water resources in both rural and urban areas. Studies (Hassan, 2013; Vaughan & Lenton, 2011; Odjugo, 2010) have shown that an increase in solar radiation and temperature leads to potential increase in the amount of evapo-transpiration thereby causing the decrease in the amount of surface and underground water resources. This is particularly more pronounced during the dry season in Northern Nigeria when the whole environment looks dry and thirsty (Abdullahi and Adeogun, 2014).

Today, many parts of Northern Nigeria (Zaria inclusive), are experiencing multiple climate change impacts on water resources. These areas faces severe climate change and induced extreme weather events such as devastating flood, drought, drying up of rivers, poor water quality and ground water availability, distortion of precipitation patterns, among others. The compounding effects of climate change on water resources in these areas therefore have devastating impacts on ecosystems, communities (including economic and social) and severe effects on agricultural activities from planting to harvesting, and food security which have seriously threatened the peaceful co-existence of the region (Adishi, and Oluka, 2018).

In simple terms, food security means access to basic nutritious food. It refers to the availability of food and ability of one to access it. It means 'all people at all times have physical, social and economic access to sufficient, safe and nutritious food that meets their food preferences and dietary needs for active and healthy life' (Kelechi & Vincent , 2022). A household becomes food-secure when the occupants do not live in hunger. Unfortunately, climate change affect food production as well as food availability of Northern Nigeria which is mostly climate dependent. Climate change has the potential of impacting on food safety especially on the incidence and prevalence of food borne diseases (Ikpe**,** Sawa, Ariko, Abdulhamid & Akpu (2022). It is also evidenced that climate change leads to potential changes in the nutritional quality of some foods like cereals and cassava. The concentration of proteins, vitamins and minerals in these crops is significantly reduced due to elevated carbon dioxide in the atmosphere. Climate change also poses a significant impact on the quality of drinking water which is a key element in the absorption of nutrients. It is also evidenced that, increased climate variability as well as increased frequency and intensity of extreme events will continue to affect crop production, stability of food supply, availability, access and utilization (Ayo, Amoshi and Suleiman, 2014).

Food production in Northern Nigeria is carried-out in both rainy and dry seasons. Crops such as maize, millet, sorghum, rice, groundnuts, tomatoes, onions, carrots, cucumber among others, are cultivated in the region. Most of agricultural production in this area is rain-fed (Ikpe**,** Sawa, Ariko, Abdulhamid & Akpu, 2022). Unfortunately, climate change-induced extreme events such as distortions in precipitation, devastating floods, prolonged dry spells, drying up of rivers and depletion of ground water sources which has severely affected water availability for food production in the area (Ayinde, Muchie and Olatunji, 2011). However, despite these prevailing challenges, there are paucity of research work on the impact of climate change on water resources, agricultural activities and food security. This paper therefore, assesses the impacts of climate change on water resources, agricultural activities and food security in Zaria Local Government Area (LGA) of Kaduna State. To achieve this, the following questions are raised:

i. What is the nature of water balance indices in Zaria LGA?
ii. What are the impacts of climate change on water resources in the study area?
iii. What are the impacts of climate change on agricultural activities and food security in

the study area?

MATERIALS AND METHODS

Zaria Local Government Area (LGA) is located between Latitudes 11° 0' and 11° 6' North and between Longitudes 7° 38' and 7° 48' East of the Greenwich meridian. The LGA has a Tropical Savanna Climate represented by Aw based on Köppen climate classification, with warm weather year-round, a wet season lasting from April to September, and a drier season from October to March. The climate in the area is divided into two: dry and rainy seasons. The dry season is usually from November to March and the temperatures recorded are within an average of 28°C towards the end of the dry season. The area is blessed with adequate rainfall and an abundance of fertile land for agriculture. Zaria has a mean rainfall of 1082m with a rain intensities raining between 25mm/hours and 125mm/hr. (Maiwada *et al.*, 2017). The predominant occupation of the area is agriculture. The LGA has a total population of 406, 990 (NPC, 2009).

The study used both primary and secondary sources of data. The primary data was collected through the use of structured questionnaire, while secondary data (climate data) was collected from the Institute for Agricultural Research (IAR), Zaria. Krejcie and Morgan's (1970) method of determining sample size, was used to select 384 respondents which formed the sample size for the study. In this case, respondents who were directly engaged in crop production among the seven (7) agriculturally active wards and who must have reached at least 30 years of age were purposively sampled. The data collected were analysed using descriptive statistics in form of mean, percentages and tables.

RESULTS AND DISCUSSIONS

The water balance indices of the study area are presented in Table 1.

Table 1: Water Balance Indices

Decadal mean	Rain (mm)	Evapotranspiration (mm)	Differences (mm)
1992 – 2001	1009.3	1999.68	990.38
2002 – 2011	1086.02	2199.96	1113.94
2012 – 2021	1063.95	2493.22	1429.27
Mean annual Total	**1053**	**2230.95**	**1177.95**

Source: IAR, Zaria

Table 1 show that the mean annual rainfall for the study period (1992 - 2021) was 1053 mm while the mean annual evapotranspiration data for the same period was 2230.95 mm. This indicates that the rate of evapotranspiration exceeds precipitation (rainfall). This is an indication of deficit in both surface and groundwater which might be exacerbated by the impact of climate change.

Table 2: Perception of the Impacts of Climate Change on Water Resources

Impacts of Climate change on Water	SD (%)	D (%)	U (%)	A (%)	SA (%)
Decrease in quantity/quality of water	17	12	5	32	34

Shrinking/drying up of surface water	14	8	2	24	52
Water related diseases	18	15	7	31	29
Increased frequency of drought/dry spell	31	22	3	20	24
Burden on women/children in search of water	12	11	5	34	38
Farmer/herder conflicts over scarce water	11	13	10	24	42
Wilting of crops due to water stress	11	14	5	34	36

Source: Field Survey, 2022

Table 2 show that 32% and 34% (66%) of the respondents had agreed and strongly agreed respectively that there was decrease in the quantity and quality of water resources in the study area; 24% and 52% (76%) agreed and strongly agreed respectively perceived the shrinking and drying up of surface water in the study area. This is particularly more pronounced during the prolonged dry season when everywhere looks dry and dusty. This scenario has serious impact on irrigation farming and other agricultural activities in the study area. Table 2 further shows that majority (60%) of the respondents opined that there was increasing water related diseases in the study area. This connotes that the area suffers from climate change exacerbated diseases such as cholera, diarrhea, dysentery and typhoid fever. More so, Table 2 further shows that majority of the respondents (72%) agreed that climate change induced water stress which has increased the burden on women and children who always roam around in search of water for domestic use. Table 2 also shows that majority (66%) of the respondents perceived increasing farmer/herder conflicts due to scarcity of water supply; while 70% indicated that climate change induced water stress have been causing partial drying of crops during the growing season. All these may have significant impacts on food security of the study area.

Table 3: Impacts of Climate Change on Crop Production and Food Security

Impacts of Climate change on Food	SD (%)	D (%)	U (%)	A (%)	SA (%)
Reduced food availability and access	16	14	4	32	48
Reduced nutritious quality of food	14	18	7	24	37
Food stability is severely hampered	13	21	6	38	22
Reduced fresh water availability	18	22	7	38	15
Prevalence of food-borne diseases	16	19	4	24	37
Frequent food spoilage after storage	21	22	4	18	35

Source: Field Survey, 2022

Table 3 indicates that 32% and 48% (80%) of the respondents agreed and strongly agreed respectively that climate change has significantly affected crop production, availability and access to food in the study area. This is exacerbated by climate change induced conflicts in wards such as Wucicciri, Dutsen Abba and Kufena. The people in these areas are forced to migrate to another area which leads to decrease in food availability and access or undernourishment. That climate change has significantly affected crop production in Zaria agree with the report of Ikpe**,** Sawa, Ariko, Abdulhamid & Akpu (2022) which reported that climate change has led to a decline in the yield of grain crops in Sokoto State thereby affecting the availability of food. Table 3 also shows that 61% of the respondents perceived that climate change has led to the reduction in the nutritious quality of food. Typical example of this, is the continuous rise in carbon dioxide level in the atmosphere which reduces plants nutrients and vitamins needed for human survival (Ikpe, 2021). Table 3 further shows that majority (60%) of the respondents agreed and strongly agreed that food stability is seriously hampered by the effects of climate change in the study area, which implies that food availability for human consumption is seriously affected by the impact of climate change.

More so, fresh water availability for domestic consumption has significantly reduced as shown in Table 3 (53%). This owes to the rapid drying up of surface water and depletion of groundwater particularly in the dry season. Table 3 further shows that majority (61%) of the respondents, perceived high prevalence of foodborne diseases in the study area. This is obvious as the rising temperature and increased precipitation promotes many foodborne disease like typhoid and cholera which are paramount in the area. Table 3 further shows that 53% of the respondents reported frequent food spoilage after storage. Increasing temperature and rainfall may promote pathogens proliferation and foodborne diseases outbreaks. Non-refrigerated foods are more susceptible to spoilage due to the impacts of climate change.

CONCLUSION

Based on the findings of the study, it is concluded that, mean annual evapo-transpiration exceeds mean annual rainfall, indicating likelihoods of surface and groundwater deficiencies in the study area. The study also concludes that climate change impacts had led to decrease in quantity and quality of water resources, increasing water related illnesses as well as climate change induced water stress. Climate change has also impacted on food security in that it led to reduction in food availability and access, reduction on nutritious quality of food and prevalence of foodborne diseases. Based on this, the study recommends the need for effective water harvesting particularly, during the rainy season to be used at the time of water deficiencies as well as the need for the introduction of high yielding, early maturing and climate change resistant varieties of crops to carter for food deficiencies in the area.

ABSTRACT

The aim of this study is to determine land use/land cover change and develop volume models for *Tectona grandis* plantation in Agudu Forest Reserve, Agudu Village in Lafia Local Government Area, Nasarawa State, Middle Belt Zone, Nigeria, with a view to provide information for stakeholders in forestry for sustainable management. Three plots were randomly selected from different area of the whole plantation. Perimeter measurement for each plot were; Permanent Sample Plot 1 (PSP1) with size 30.6m by 27.3m contained 117 tress, Permanent Sample Plot 2 (PSP2) with size 30m by 21.6m had 99trees, while Temporary Sample Plot 3 (TSP 3) with size 22m by 26m had 76 trees. Six (6) plus trees were identified in each of the plots. The results indicated that the Models generated for tree volume estimation area highly significant at ($p<0.01$) and have a high coefficient of determination (R^2), Model equation six(6) was chosen to be the best model because it is highly significant and has the highest coefficient of determination (R^2) = 94.20 for the stand trees, while model equation two (2) was chosen to be the best equation because it is highly significant at ($p<0.01$) and has the highest coefficient of determination (R^2) = 99.8. All the models generated were adequate and are recommended for *Tectona grandis* volume assessment in the study area. The stand volume equations, which incorporated various tree growth variables, will enhance future yield prediction of the trees in the study areas since they provide quantitative basis for estimating stand growth parameters. It is believed that these models and volume prediction equations will enhance sound and informed management decisions and conservation measures for the remaining *Tectona grandis* stands.

INTRODUCTION

Forest plantations are increasingly important forest resources in the world; some forest plantations provide the bulk of the wood in their country like Australia, etc. (Evans, 2002).

Agudu forest reserve/plantation is a permanent sample plot (PSP), composed of pole sized trees of Teak (*Tectona grandis*), which covers a total area of 36,000Ha. (88954.781 Acre). For proper management of (PSPs), there is a need for the regular assessment of these resources. Land use practices affect the distribution and supply of soil nutrients by directly altering soil properties and by influencing biological transformations in the rooting zone. For instance, cultivation of forests diminishes the soil carbon (C) within a few years of initial conversion and substantially lowers mineral sable of nitrogen (N) Majaliwa, *et al*., (2010). Land use changes, especially cultivation of deforested land may rapidly diminish soil quality, as ecologically sensitive components of the forest ecosystem are not able to buffer the effects of agricultural practices. As a result, severe deterioration in soil quality may lead to a permanent degradation of land productivity (Islam, K.R. and R.R. Weil, 2000). Forest vegetation and land use /land cover changes have been defined as the spatial and structural changes in the form of forest degradation and depletion, reducing the forest density and species diversity and the extension of arable land and other land use types inside the natural cover after its disturbance.
The land use planning for sustainable future requires investigations into possible land use changes and the impact it has on ecological functions and processes at the local level (Zebisch*et al*., 2004). One of the most important land use changes is that the world's forests, grasslands and woodlands have declined, while the cropped land areas have expanded by a similar magnitude (Slayback, 2003).

MATERIALS AND METHODS

Study Location

The study was carried out in Agudu Teak (*Tectona grandis*) plantation, obi local government area, Nasarawa State, Lafia. Located between latitude 08°N and longitude 09°E. The total area coverage by *Tectona grandis* plantation is 36,000 h. (88954.781 Acre). Obi local government in Nasarawa State has five districts namely; Obi, Agwutashi, Agudu, Daddare, Riri and sub-divided into 10wards for administration convenience. The area is predominantly inhabited by Koro (Migili), Alago, Gwandara and other tribes like Eggon, Hausa, and Fulani. The loamy and clay soils in swampy and water logged areas are been used as FADAMA. The climate is characterized by warm and humid with two seasons namely dry and wet seasons. The raining season starts from April through November and dry season starts from part of November through March, with a mean annual rainfall of 1150 mm to 1550 mm, and a mean temperature range between 26°C and 30°, It has relative humidity of 60-80%and falls within the Guinea Savanna vegetation zone (Metrological Department, 2009).

Method of Data Collection

Perimeter measurement for each plot were; PSP1 30.6 m by 27.3 m, PSP2 30 m by 21.6 m, TSP3 22 m by 26m, selected using simple random sampling method from different parts of the whole plantation. Each sample plot contained Permanent sample plot 1 (PSP1) of 117 tress, Permanent sample plot 2 (PSP2) of 99 trees, Temporary sample plot 3 (TSP 3) of 76 trees. Sample trees planted in a 4 x 4 spacement were systematically numbered for easy enumeration using the following: girth tape, Haga altimeter, Writing materials, Permanent marker, Cutlass, camera and pegs.

Result of models generated for tree volume estimation in Agudu Forest Reserve In Agudu Teak plantation 10 models were generated and 7 of the model prediction equations generated have negative intercepts (Table 1). This is as a result of the logarithmic transformation of the variables utilized in the models, thereby leading to value reduction vis-à-vis tilting of the variable values towards negativity. The standard error of estimate (SEE), which measures the overall predictive value of regression models and which is a common measure of goodness of fit in nonlinear regression models, with low value indicates better fit. In this study, the SEE of the models ranged between 0.14 and 0.51. These results suggest that all the models have good fit within the context of the field data. Comparing the 10 models tried in this study using the fit statistics, model 6, which is with diameter at the middle, basal area and form factor as the independent variable is the most appropriate (R^2 = 94.2, R^2- Adjusted = 94.2, SEE = 0.28 and F-ratio = 3448.00, Double Watson value = 1.61, significance = 0.000** highly significant at 1%P<0.01 level of probability. In other words, diameter at the middle is the best predictor of *Tectona grandis* stem volume among all the tested predictors.This may be due to the Newton's formula used in the estimation of the volume. Hence, more preference is given to diameter at the

4	LnHV = -5.05+23.18BD+(-18.82)BA+ 0.06MeanTH	292	99.1	99.1	0.06	9410.0	0.000**	1.62
5	LnHV = -5.05+ 23.18LogBD + (-18.82)BA + 0.06MeanTH	292	99.1	99.1	0.06	9410.0	0.000**	1.62

middle than those from base and top by having the highest (R^2 = 94.2) coefficient of determination (equation 6).

Table 2: Models generated for stump volume estimation in Agudu Forest
Dbh = Diameter at breast height, BG = Basal girth, BD=Basal diameter, DM = Diameter at middle, DT = Diameter at top, meanTH = Mean total height, BA = Basal area,CArea = Crown area, HV = Huber's volume, FF = form factor, Fq = form quotient.

In Agudu Teak plantation there are 46 stumps in permanent sample plot 1 (PSP1), 42 stumps in permanent sample plot 2 (PSP 2), 29 stumps in temporary sample plot 3 (TSP 3). 5 models were generated and all of the 5 model prediction equations generated have negative intercepts (Table 2). This is as a result of the logarithmic transformation of the variables utilized in the models, thereby leading to value reduction vis-à-vis tilting of the variable values towards negativity. In this study, the SEE of the models range between 0.02 and 0.06. These results suggest that all the models have good fit within the context of the field data. Comparing the 5 models tried in this study using the fit statistics, model 2, which is with basal diameter, basal area, and mean total height as the independent variable is the most appropriate (R^2 = 99.8, R^2-Adjusted = 99.8, SEE = 0.02 and F-ratio = 41350.0, Double Watson value = 1.55, significance = 0.000** highly significant at 1%P<0.01 level of probability. It is the most appropriate by having the highest (R^2 = 99.8) coefficient of determination (equation 2).

CONCLUSION

This project was carried out to know the volume estimated for each tree per plot and for each plot mean for exploitation. It is a known fact that the stand volume equations, which incorporated various tree growth variables, will enhance future yield prediction of the study area since they provide quantitative basis for estimating stand growth parameters. For instance, those growth variables that have very strong relationships, depicted by their high coefficient of determinations (R^2) and low standard error of estimate (SEE) with tree stem volume could be regarded as important determinants to be considered in stand volume assessment in Agudu Forest Reserve. The volume prediction equations provide the means through which the production potential of the existing stands can be estimated in the study area. It is believed that the equations obtained in this study will enhance sound and informed management decisions and conservation measures for the remaining stands.

ABSTRACT

The nutritional and chemical compositions of mushroom contributes significantly to their medicinal values. The study assessed the effects of different substrates combination on the phytochemical compositions of Oyster mushroom (*Pleurotus ostreatus*) in Makurdi Local Government Area of Benue State, Nigeria. Sawdust and various agrowastes (cowpea waste, cassava peels, maize cobs, guinea corn husk, and rice bran) were proportionately mixed at varying combination to form different substrate treatments. Phytochemical analyses of harvested matured oyster mushrooms were determined following prescribed standards. The results of findings revealed that a percentage composition ranging between 0.56 and 2.76 % (tannin content), 6.0 and 24.0% (saponins), 9.0 and 18.0 % (flavonoid), 6.0 and 9.0% (alkaloid) and, 0.50 and 16.0% (steroids) which are within the tolerable and acceptable limits of WHO. In view of these, various agro wastes can be utilized as substrates and therefore reasonably combined to actualize the phytochemical levels required in the mushrooms which could be used as excellent food material and also for medicinal purposes.

INTRODUCTION

Pleurotus ostreatus, commonly known as Oyster mushroom is among the immense array of mushrooms with untapped new compounds (Kuo 2005; Guggenheim et al 2014; Duru*et al* 2019). It can be found in the wild, and can as well be cultivated using different wood and agro wastes. *P.ostreatus* is edible and has tough texture on mastication.Mushrooms are regarded as small medicinal factory which nature has provided for humans. However, Oyster mushroom is highly medicinal and rich in dietary fibre, proteins, macro and trace elements. Its phytochemical content has made it a special diet for the prevention and treatment of hyper-cholesterolemia (Duru *et al* 2019, Hossain *et al* 2003). Mshigeni and Chang(2000), reported that people in developing and developed nations should be encouraged to cultivate mushrooms in large scale and use them to address health challenges. Bayo and odiaka (2021) conducted a survey and discovered large varieties of mushrooms in the wild with no history of cultivation in Benue state,Nigeria. Overtime researchershave explored various importance of Oyster mushroom particularly as it relates to food (Duru*et al*., 2018, Adedayo, 2011, Kayode *et al* 2013), as well as health value(Okwulehie and Ogoke2013, Maria *et al* 2015, Duru 2017). Due to the to the abundance of farm wastes in Benue state Nigeria, the study assessed the influence of different substrates as it relates to the presence of phytochemicals in *P.ostreatus.*

MATERIALS AND METHODS

Cultivation, Inoculation and Phytochemical analyses

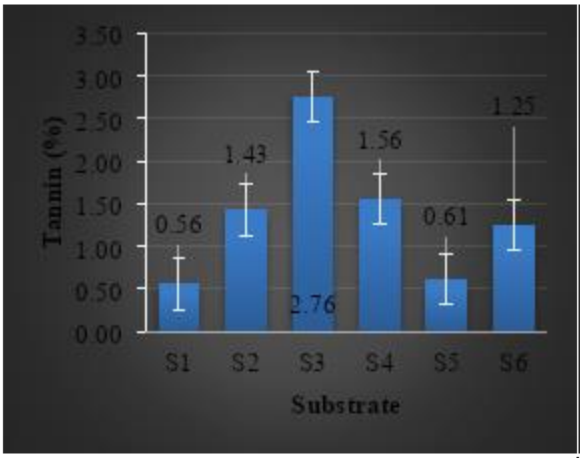
The substrates were collected from various mills in Makurdi Local Government Area of Benue state where these farm harvest processing takes place. The various mixed substrate combination includesS1: Sawdust. (control),S2: Sawdust / cowpea waste, S3: Sawdust / cassava peels, S4: Sawdust / Maize cobs, S5: Sawdust / Guinea corn huskS6: Sawdust / Rice bran. Other materials include spawn bottles of *Pleurotusostreatus* from Forestry research institute of Nigeria [FRIN], Ibadan.25 kilograms (25 kg) each of the selected substrates were weighed and composted for 30 days using lime (1%). The compost heaps were turned every three to five days. The substrates were pasteurized at 100^{o}C for 3 hours

The substrate bags were incubated and inoculated.The bags were exposed after primordia (pinhead) formation (35 days) and transferred to the fruiting room for subsequent fruit bodies' development. All bags were monitored daily for flushes of fruiting bodies.Matured fruiting bodies were harvested and the harvests were made across all substrate types in the course of the experiment andanalysed.

The tannin content was determined using the methods described by Kirk and Sawyer (1989), while the alkaloids and flavonoids were determined using the methods described by Trease and Evans (2004). Total saponins were extracted and yield determined by gravimetric method (AOAC, 1990).Qualitative tests and quantitative estimation of steroids was carried out using the methods of Edeoga*et al* (2005) and Madhu e*t al* (2016).

Results and Discussions

The experiment revealed the presence of several phytochemical compounds under investigation in various degrees. The tannin content ranged from 0.56 to 2.76 % (Fig. 1.). The content of saponins in the samples ranged from 6.0 to 24.0% (Fig. 2). Flavonoid and alkaloid contents ranged from 9.0 to 18.0 % and 6.0 to 9.0% respectively in all the samples (Fig. 3&5), while the steroids content ranged from 0.50 to 16.0% (Fig. 4). There was no trace of steroids in sawdust substrates being the control.



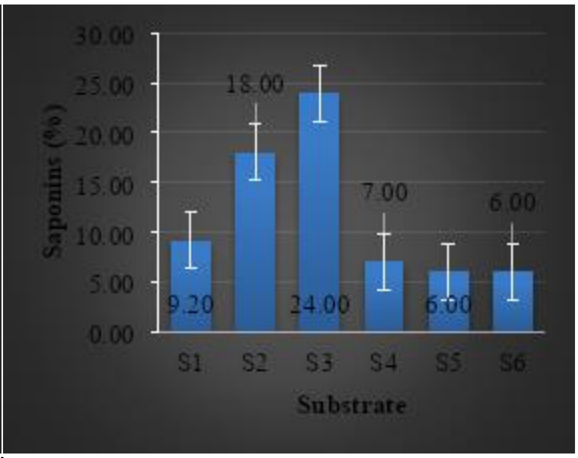


Fig. 1. Percentage composition of Tanins (mg/100g). Fig. 2. Percentage composition of Saponins (%)

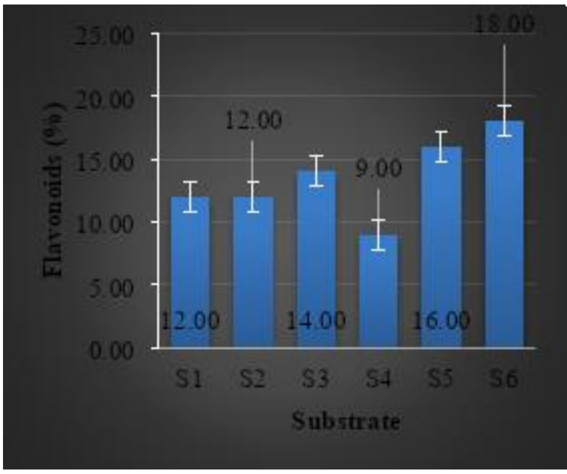

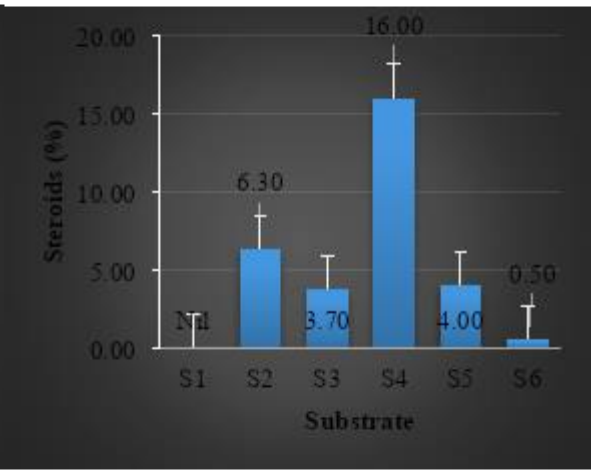

Fig. 3. Percentage composition of Flavonoids (%) Fig. 4. Percentage composition of Steroids (%)

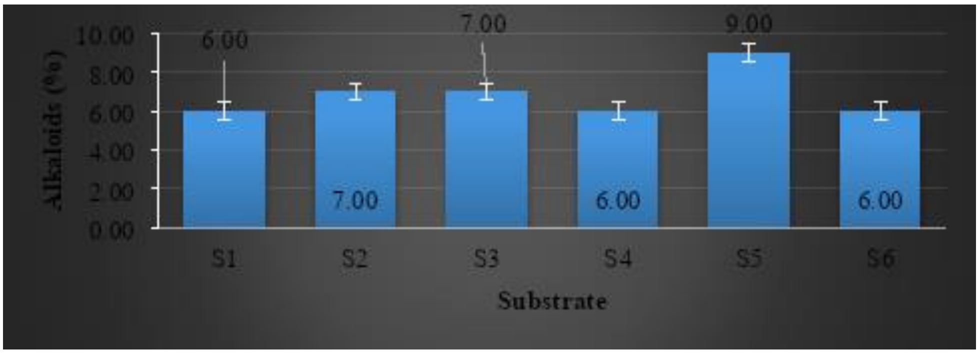

Fig. 5. Percentage composition of Alkaloids (%)

The phytochemical analysis of the cultivated *P. ostreatus* using proportional mixture of substrates revealed the presence of major bioactive constituents including flavonoids, tannins, saponins steroids and alkaloids as similarly reported by Lindequist*et al.* (2005), Iwalokun*et al.*, (2007), Kinge*et al.*, (2016) and Nsoh*et al.*, (2022). However, alkaloid was absent in the phytochemical analysis of mushrooms as documented by the above-mentioned research scientists. This observation can be attributed to the variation in substrate materials used in the cultivation of the mushroom which is in tandem with the assertion of Kinge*et al.,* (2016) and Muswati*et al.,* (2022) that the concentration and type of bioactive component varied depending on the substrate material used and the type of medicinal plant supplement. Accordingly, substrate mixture has significant influence on mushroom performance and productivity (Kinge*et al.,* 2016; Nsoh*et al.,* 2022; Muswati*et al.,* 2022) and it can also help in the optimization of the compositional features including water holding capacity, increased substrate structure, porosity that improves water penetration and gaseous exchange (Muswati*et al.,* 2022).

It has been asserted that the nutritional and chemical compositions of mushroom play significant roles in their medicinal values (Lindequist*et al*., 2005). The bioactive compositional constituents present in edible mushrooms are essential in promoting human health. For instance, saponins is made up of large family of related compounds reported to have a wide range of pharmaceutical properties, such as anti-malarial, anti-cancer, anti-inflammatory and anti-diabetic effects which are significant in the management of diabetes and inflammation related diseases values (Lindequist*et al*., 2005). Also, the antioxidant phenolic compounds present in mushroom possess a wide spectrum of medicinal properties such as anti-cancer and anti-inflammatory useful for the management of oxidative stress induced diseases (Pandimeena*et al*., 2015).

The saponin contents of the mushrooms were significantly higher than in the study of Afiukwa*et al* (2013). The values obtained for saponins in this study are however within the WHO maximumpermissible limit of (48.50mg/100g).The results suggest that these mushrooms could be safefor consumption and the substrates used in no way endanger the health values of the food material.The flavonoid compositions of this edible mushrooms are significantly lower thanthe tolerable limit (52.02mg/100g) (WHO, 2003) indicating that the mushrooms are equallysafe and could be good sources of anti-oxidants that boosts body immunity. The Tannin and Alkaloids contentsas revealed in this study are higher than those reported by Onuegbu*et al.,* (2020) whose ranges of values are between 0.14 and 0.52 %Tannin content and 1.66 to 2.37% for Alkaloids. This study has further revealed that the various substrates under investigation have substantial influence on the content of phytochemicals in the mushrooms grown. With the exception of steroids that was not found in mushrooms grown in pure sawdust substrates, all the five phytochemicals were found in significant amounts. Sawdust /cassava peels substrates gave highest tannin and saponins values, while sawdust/rice bran, sawdust/maize cobs and sawdust/guineacorn waste substrates, yielded highest values of flavonoids, steroids and alkaloids respectively.

CONCLUSION

The study was conducted to determine the effects of different substrates on phytochemical on oyster mushroom in Benue State, Nigeria. The results of findings revealed that mixed substrate combinations have significant effects on phytochemical constituents, particularly of *P. ostreatus* (Oyster mushroom). This has further validated the established facts that the nutritional and chemical compositions of mushroom are responsible for their medicinal values.

The phytochemical compositions in terms of flavonoids, tannins and alkaloids as indicated in the study are within WHO tolerable limits. Consequently, these substrates can therefore be reasonably combined to actualize the phytochemical levels required in the mushrooms which could be used as excellent food material and also for medicinal purposes.

24 - 28 Oct., 2022

ABSTRACT

Human play a very prominent role in a day to day environmental dynamics. The devastating effect of anthropogenic activities on Atakunmosa local government land scape was examined. Consequently, the effects of these mining activities in the environment were identified. An illegal mining activity of gold was discussed and their negative effect on the environment. The destruction of means of livelihood is worrisome as a result of uncoordinated activities of illegal artisan miners in the area. Strategies for effective environmental conservation need to be enforced like regulation of illegal mining and petroleum exploitation and also mass enlightenment of the public on environmental protection programmes in virtually all the local government areas in the country.

Keyword: Anthropogenic, Environment, Livelihood, Destructive, Conservation

INTRODUCTION

Environment describes all the physical, biological, social and cultural factors, which influence the wellbeing of an organism (Hammed T. B., 2013). Sadly, the natural resources we get from the environment are continuously being changed by man through his irrational exploitation with little or no desire for replacement. In order for man to survive, he has to delve into activities which affect the environment; like, mineral exploitation, domestic and industrial exploration e.t.c and resulting consequence of all these is the destruction of the natural habitat of both faunas and flora species. Gold is found native in association with other minerals. For instance, Bagdasarou and Simakov (1988) reported that native gold from the Karehakola region in the former USSR contained 4.2 - 5.4 % silver. The Itagunmodi gold ore in Atakumosa Local

Government Area of Osun State is a mixture of minerals (zirconite, ilmenite, cassiterite and monazite) and gangues. Other types of gold ores include but not limited to the following: chalcopyrite, pyrite, sylvanite, calaverite, petzite, auriferrous and argentiferrous ores (Eligwe, *et al.*, 1993). In view of the various challenges of deforestation, and illegal felling of trees, there is the need for conserving the forest and its content. Although different countries have different ways of conserving their forest from harmful human activities, the objective anywhere is to reduce the possibility of desertification. In Igun Ijesha gold city, the community depend on the forest and all that they can obtain from it for their livelihood

MATERIALS AND METHODS

Location

This study was conducted in Itagunmodi, located in Atakunmosa West Local Government of Osun State (Figure 1). Itagunmodi town (formerly known as Igbo Nla) is dwarfed by an imposing background of a vast Ora Mountain; on latitude (DMS) 7031’60’’, longitude (DMS) 4039’0’’ and altitude (meters) 347 the time zone is east (est). It has an area of 577 km² and a population of 68,643 at the 2006 census.

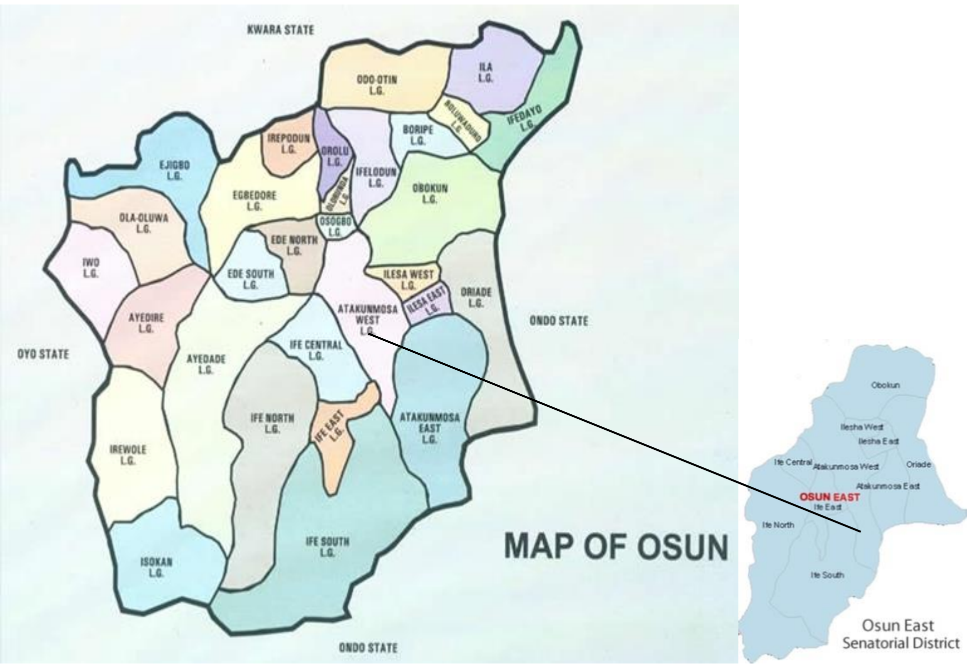

Figure 1. Study location

Description of the Activities at Itagunmodi, Atakunmosa Local Government Area of Osun State, Nigeria

Mining in simple terms is the removal of solid valuables from the earth for economic emancipation; such valuables are known as minerals. They are naturally endowed inorganic materials found in the earth for the benefit of mankind. Such natural substances which include, gold, tin, salt, coal, clay, diamond, iron ore, precious stones of varying types are expensive substance deposited in the earth to make life abundant for man. Exploration of valuable mineral materials from the soil are categorized into surface mining and underground mining which are extracted from deep in the soil. The surface mining is easier to do in terms of funding, time and technological support but the mother deposit is usually located only deeply underground. The surface mining is the most unorganized as the identity of miners are not known, they are mostly itinerants.

Subsequently, within the vegetation area known as Ilu Aaye, lies the procedures for the extraction of Gold from the soil. Plates 1, 2, and 3 explain the procedure; after digging the ground, not just the surface, dig deep ranging from 6 feet and more. In some cases, the pit could go as far as having a tunnel all in search for Gold (Arehart, G. B., 1996). The inner soil been dogged, are fetched with bowls or shovels and are placed on a constructed rail. This rail is made of two long irons supported by log of wood. The rails are made to be in a tilted position, about 90-degrees with the ground. A cut section of rugs are placed on the rail. The slanting position of the rail is to allow easy flow of water with the soil that will accompany it.

Afterwards, water is poured on the soil placed on the rail, and due to the slanting position of the rail, the soil is washed away with its content. Therefore, if there is Gold in any of the soil that is been washed, the Gold will settle or trapped on the rug. Plate 4 shows a sample of extracted pieces of Gold from the rug.

Impact of Mining on Itagunmodi Communities

If the outside world is scrambling for a share of this free-for-all fortune, it is expected that the people whose good fortune it is to be the natives (son-of-the-soil) of the community should be more visceral in the gold rush. However, the reverse is the case in Itagunmodi. The community's apathy to gold is writ large, not only in the pervading lukewarm attitude, but also in the town's dwindling population, occasioned by its younger populace migrating to nearby urban areas such as Ilesha and Ile-Ife.

Plate 1: Showing the rail used for extracting form mud

Plate 2: Showing a dug pit

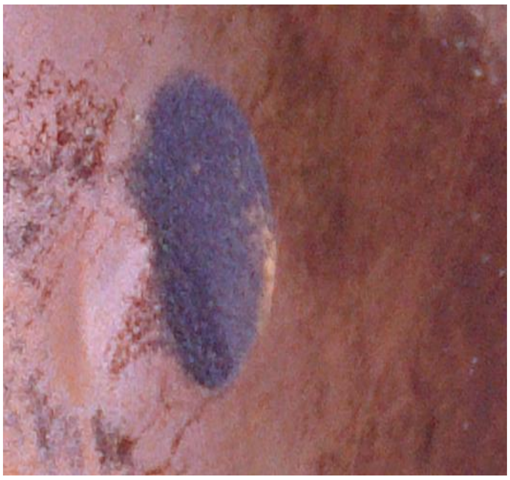

Plate 3: A devastating effect of the vegetation Plate 4: Showing little piece of gold extracted

Mineral deposits are supposed to be a source of joy and wealth to the communities where they are deposited and not a curse (Bello, A. A., 1997). But the reverse has been the case in many communities like Itagunmodi. Deforestation on the guise of anything, can be detrimental to the survival of living things around it, and its alteration has led to economic and environmental disasters (NEST, 1991)

Destruction of Farms, Erosion, Exploitation in Osun

Osun State communities have had their portion of the sour pill as experienced by Itagunmodi community in the Atakumosa West local government area, where gold is largely deposited. The communities suffered inhuman treatment from illegal miners who, apart from destroying their farmland with impunity, also experienced environmental degradation. Itagunmodi community revealed the scrapping of top soil that is good for farming, destruction of farm land, cutting down of economic trees such as cocoa trees, kolanut trees, citrus trees among others, encouragement of gully erosion, and construction of illegal underground mines that is causing environmental hazard by illegal miners. Besides these, the community were cheated and exploited because they were ignorant of the economic value of the mineral deposit and by the time they realized its value, much damage had been done.

It was gathered that following the report of the illegal exploration at the office of the department of mineral resources of the Ministry of Commerce and Industry by the communities concerned at Osogbo, the state capital, further mining activities were banned by the state government. Contrary to Joshua Dada and Obinna Ogbonnaya (2013) who reported as at then, no gold mining activity is going on at either Igun and Itagunmodi or any part of the state, but in December, 2015, there was evidence showing that there still exist these illegal mining activities going on.

Ways to Manage Forest Resources

Evidently, there is the need for the management of the forest resources and also to ensure its sustainability for the benefit of all. Okonkwo *et al.* (2002), outlined the strategies for successful monitoring and management of natural resource which will depend on:

- The level of commitment by the people living in that area

- The political willingness of the policy makers in ensuring the passage of laws that will sustain the forest
- Availability of resources to ensure total cooperation with the stakeholders.

CONCLUSION AND RECOMMENDATION

Generally speaking, at the itagunmodi Gold mining site, lots of effort are involved in the mining of this gold; the stress and energy involved, and the illegal way this mining is been done. Effort should be made, so as to make the mining of gold legal in the area. As this would secure the environment and vegetation of that area, because, what is been done by illegal miners destroys the vegetation, farmland and the lively hood of the people of Itagunmodi.

ABSTRACT

The best way to control indiscriminate disposal of waste water is to harness its full potential. However, the menace caused by the indiscriminate disposal of locust bean waste water is associated with land and water degradation as well as health risk that may constitute to human being, through inhaling of its unpleasant odour from the environment. This demand for thorough assessment of locust bean waste water for irrigation purposes. The fermented waste water sample of locust bean was collected from processing center and were taken to the laboratory for comprehensive analysis on chemical parameters such as salinity (Electrical conductivity), cations and Anions (Ca^{++}, Mg^{++}, K^{+}, Na^{+}, CT^{-}, $So4^{-}$, $Co3^{-}$, $No3^{-}$ and HCo_3). However, the results obtained from the analysis were compared with FAO standard and it was discovered that the pH value obtained in this study was 3.5±0.0764, which was found to be lesser than 6.5-8.4 recommended by FAO being the waste water, this increase the risk of mobilized toxic metal that can be absorbed by human. In conclusion, having verified the salinity level in terms of Electrical Conductivity (ECW) of 0.002ds/m value which falls within the standard range of threshold 0-3ds/m. Locust bean waste water could be used as irrigation water by local farmers.

Keyword; Locust Beans; Waste Water; Electrical conductivity; Irrigation.

1.0 INTRODUCTION

African locust bean is botanically known as *Parkia biglobosa* and usually called “iru” in yoruba. It is a perennial tree belongs to family of parkia (Anyanwu *et al.*, 2013). The tree is not usually cultivated but can be in population of two or more in the savannah region of West African (Hopkins, 2008). Research revealed that locust bean helps to promote sight and drives away hypertension and conditions like stroke and diabetes. Fermented African locust bean seed, “irú”, provides dietary fiber, energy, minerals and vitamins, and also improves sensory properties of food, including the organoleptic characteristics (appearance, aroma and flavor (Kolapo, 2007)

However, in recent decades, there have been growing concerns on the harmful effects created by locust bean waste water to the environment in which aquatic habitat are of no exception (Anyanwu *et al.*, 2013). Also, it may also pose human health challenges directly through inhaling of its unpleasant odour from the environment and depletion of oxygen. Consequently, this menace could be traced to indiscriminate disposal of most of agricultural produces in most part of developing countries, especially in Nigeria.

In order to control this ugly situation, it has become imperative to harness the potential of this fermented locust bean effluent water by assessing its suitability for production of crops without applying chemical fertilizers. Many researchers have not really paid much attention to this area. It is hypnotized that the effluent waters will be suitable for crop production when it's been firstly assessed in terms of its quality for irrigation without the use of chemical fertilizers. Therefore, this research work toward assessing locust bean waste water for irrigation purpose. This will help in hygiene of the environment as well as to prevent other associated menace cause by locust bean waste water.

2.0 METHODOLOGY

2.1 Description of the study area

The study area, Igboora, is the headquarters of Ibarapa Central Local Government Area of Oyo State, Southwest Nigeria. Igboora is located on longitude 7° 26' 1.79"N, latitude 3°17' 16.37' E. Igboora is approximately 66 km North-northwest of Ibadan, the Oyo State capital and about 32 km North of Abeokuta, the capital of Ogun State. Igboora share boundary with Ogun State to the South and West, Ibarapa North Local Government Area to the North-West, Iselin Local Government Area to the North-East and Ibarapa East Local Government to the East. (Adejumo and Adeyemi, 2021).

2.2 Sample Collection

Four days fermented locust bean waste water samples were collected from three different locations of locust bean processing Centre that uses the same processing techniques in Igboora, Ibarapa Central Local Government into each plastic bottle of 1litre and were taken to the laboratory for comprehensive chemical component analysis.

2.3 Laboratory Analysis

Comprehensive chemical analysis was carried out on the three different samples which were labelled sample A, sample B and sample C on locust bean waste water. The result obtained was compared with FAO standard for irrigation water.

3.0 RESULTS AND DISCUSSION

Table 1 Chemical analysis of locust bean waste water collected from three different locations

Water parameter	Symbol	Unit	Samples			Mean	SE Mean	St Dev	FAO Standard
			A	B	C				

Salinity									
Electrical Conductivity	ECW	Ds/m	0.002	0.002	0.002	0.002	0.000	0.000	0-3
Total Dissolved Solid	TDS	Mg/l	9.860	9.960	9.935	9.9183	0.0300	0.0520	0-2000
Cation and Anions									
Calcium	Ca^{++}	Mel/l	11.427	12.714	12.563	12.235	0.406	0.704	0-20
Magnesium	Mg^{++}	Mel/l	15.179	15.680	15.340	15.400	0.148	0.256	0-5
Sodium	Na^{+}	Mel/l	15.425	18.079	15.976	16.493	0.809	1.401	0-40
Chloride	CL^{-}	Mel/l	2.397	3.195	2.874	2.822	0.232	0.402	0-30
Sulphate	SO_4^{2-}	Mel/l	0.7525	0.9290	0.9320	0.8712	0.0593	0.1028	0-20
Carbonate	CO_3^{-}	Mel/l	0.000	0.000	0.000	0.000	0.000	0.000	0-0.1
Nitrate	NO_3^{-}	Mel/l	0.364	0.477	0.412	0.4177	0.0327	0.0567	0-10
Potassium	K^{+}	Mel/l	4.578	5.074	5.245	4.966	0.200	0.346	0-2
Miscellaneous Effect									
Bicarbonate	HCO_3	Mel/l	0.0262	0.0360	0.0286	0.03027	0.00295	0.00511	0-10
Ph Value	H		3.60	3.50	3.65	3.5833	0.0441	0.07641	6.0-8.5

The parameters for chemical analysis of irrigation water must focused on chemical components ranging from salinity (Electrical conductivity ECW), and Total dissolved solid (TDS), Cations and Anions (Calcium Ca^{++}), Magnesium (Mg^{++}), Sodium (Na^{+}), Chloride (Cl^{-}), Sulphate (SO_4^{-}), Carbonate (CO_3^{-}), Potassium (K^{+}), Bicarbonate (HCO_3), Nutrient (Nitrate NO_3^{-}) ditto to pH Value.

Salinity

The standard range of salinity ECW and TDS is between 0-3ds/m and 0-2000mg/l respectively while the ECW of the sample tested as presented in Table 1 is 0.002 for ECW and 9.9183±0.052mg/l for TDS. The value obtained falls within the FAO recommended range. This indicated that, locust beans waste water will not have adverse effects on both the growth and yield of plants since it falls within the standard value according to FAO.

Cation and Anions

The test result obtained for calcium (Ca^{++}) is 12.235±0.704mel/l as shown in Table 1 while the normal value range for calcium is 0-20 according to FAO, therefore the value obtained in this study falls within the range. However, this established that locust bean waste water will have positive effects on the root growth of the plant.

The test of the sample in Table 1 revealed that the result of the magnesium (mg^{++}) is 15.400±0.256mel/l, while the normal range according to FAO is 0-5. However, this fall outside the normal. The higher concentration of the magnesium is due to source of the water (waste water).

Sodium (Na^+) has moderate concentration value of 16.493±1.401mel/l while the standard value of sodium according to FAO is ranging between 0-40 mel/l as presented in Table 1. This implies that, the value obtained falls within the normal range. This will not have adverse effects on physical condition and soil structure which usually resulting in the formation of crusts, water reduced soil permeability as well as toxicity to certain types of crops. It will not have negative effect on sensitive crops.

The analysis of the test in Table 1 shows that, the value obtained for chloride is 2.822±0.402mel/l while the recommended range of value according FAO is 0-30mel/l. The result obtained falls within the normal range. However, this indicated that, the ability of plants to take up water which is usually leads to reduction in the growth rate known as osmotic effect and crop sensitivity will not be affected if locust beans waste is used as irrigation water.

The result of chemical analysis on the samples as shown in Table 1, indicated that sulphate (SO_4^{2-}) have a value of 0.8712±0.1028mel/l while the normal range value is from 0-20. However, this value falls within the normal range and this will not have negative effects on the growth and yield of the plant.

The analysis of the sample in Table 1 shows that the sample contained lower carbonate concentration of 0.0000mel/l while the normal value for carbonate according to FAO is 0-10mel/l. This implies it will not have negative effects on pH which is usually making nutrients less available to the plants

Nutrient

The test of the samples in Table 1 also shows the higher concentration content of nitrate (nutrient) with a value of 0.4177±0.0567mel/l while the standard value range according FAO is from 0-10mel/l. The result obtained in this study falls within the normal range. This clearly shows that the sample is rich in nutrient and it may not affect susceptible crop

Potassium (K^+) have higher concentration content of 4.966±0.346mel/l while the standard value range for potassium according to FAO is 0-2mel/l as shown in Table 1. However, this value falls outside the recommended range of 0.02mel/l. by FAO. The high value obtained in this study may have negative effect on infiltration, water availability and plant growth.

Miscellaneous Effect

The result of sample in Table 1 revealed that Bicarbonate HNO_3 value of 0.0303±0.0051mel/l was obtained which indicated a lower concentration of the normal value range according to FAO is 0-10mel/l. However, this value falls within the range of normal value. This lower concentration of bicarbonate will not have effect on calcium. And it will not also have effects on physiological effect on roots which usually reducing nutrients absorption.

The pH normal value range according FAO for irrigation water is from 6.5 to 8.4, which the results of pH value of obtained in the study as presented in Table 1 is 3.5833±0.0764. The value of the samples tested fall outside the standard range of value. The adverse or negative effect of this value is that, it may cause a nutritional imbalance or may contain toxic ion since pH Value test is a good indication of quality water. The reason behind this value is due to the source of this water sample (waste water).

4.0 CONCLUSION

Locust bean waste water was collected locust processing site in Igbo Ora, Oyo State. The chemical analysis test was carried out at the laboratory. The test was carried out on chemical parameters such as salinity (ECW), Cations and Anions (Ca^{++}, Mg^{++}, K^{+}, Na^{+}, Cl^{-}, SO_4^{-}, CO_3^{-}, NO_3^{-} and HCO3).

However, having compared the results obtained from the samples with the FAO standard, It was observed that pH Value of 3.5 is lesser to the normal range 6.5 to 8.4, magnesium (mg^{++}), and potassium (K^{+}) greater than normal range while, sodium, chloride, sulphate, carbonate, bicarbonate, nitrate and calcium falls within the normal range. Therefore, it can be concluded that the locust bean waste water is very rich in nutrients and could be useful for irrigation by local farmers.

Also, the locust bean waste water could be used precisely to grow vegetable having verified its salinity level in terms of Electrical conductivity (ECW) of 0.02 value which fall within the standard thresh hold. This could be rated as moderately sensitive (MS). However, further evaluation needs to be carried out on magnesium [mg++] potassium (K+) and pH value of the samples. In order to ascertain its suitability for vegetable productions without the use of chemical fertilizer [NPK].

ABSTRACT

Climate variabilities has been a subject of concern lately in the international community because of its devastating impacts on man and the ecosystem. According to Intergovernmental Panel on Climate Change (IPCC 2018), emission of anthropogenic co_2 into the atmosphere is the main driver of climate change. This study examines influence of anthropogenic co_2 concentration on the recent rainfall extremes along the Lagos coast. Results showed that as a result of the anthropogenic co_2 concentration in the atmosphere, the amount of rain is decreasing in the recent time but the number of extreme cases is increasing.

INTRODUCTION

Naturally, the sun's radiation heats both the ocean and the land surface, leading to water evaporation, which then moves around with winds in the atmosphere, condenses to form clouds, and falls back to the Earth's surface as rain or snow, with the flow to oceans via rivers completing the global hydrological (water) cycle. Precipitation varies from year to year and over decades, and changes in amount, intensity, frequency, and type (e.g., snow vs. rain) affect the environment and society. Steady moderate rains soak into the soil and benefit plants, while the same amounts of rainfall in a short period of time may cause local flooding and runoff, leaving soils much drier at the end of the day. Climate change alters the natural flowing of the hydrological circle, thus effectuating catastrophic events that will lead to an increase in the climatic extremes in terms of frequency and intensity of rainfall. Climatic extremes could contribute negatively (water scarcity or drought) or positively (flood) to rainfall. Anthropogenic activities such as burning of fossils are one of the major contributors to the climate problem (Oreskes 2004). Climate change and food security are related because climate change affects the climatic conditions responsible for optimum food production. Evidence is building that human-induced climate change (global warming), is changing precipitation and the hydrological cycle, especially the extremes as the atmospheric level of carbon dioxide has been greatly impacted. Lagos state economic hub of Nigeria and West Africa with five ports, houses about 65 % of the country's industrial establishments and 60 % of Nigeria's non-oil economy (Adelekan, 2010). The state accounts for about 32% of the overall national Gross Domestic Product of Nigeria (GDP) with an average internally generated revenue (IGR) between $32 million and $52 million (Filani, 2012). Furthermore, Nigeria's economy is closely tied to oil and gas as profits from petroleum exports currently account for 86% of Nigeria total income. These activities have contributed greatly to carbon emissions. Several studies have shown that carbon dioxide could impact the atmosphere through fast adjustment of surface temperature (Ekwurzel et al., 2017) possible changes in monsoon precipitation with the increase in carbon dioxide concentration have also been considered by several researchers (Loo *et. al.,* 2015, Sohn *et. al*., 2019). Rainstorm events which are known to be detrimental to agricultural production is evident in Lagos state lately with little knowledge on the major causes. This study examines the recent rainstorm events under the rising atmospheric co_2 concentration occasioned by anthropogenic activities in Lagos megacity.

MATERIALS AND METHODS

The climatological rainfall data used for the present study were acquired from Nigeria Meteorological Agency (NIMET) spanning from 1986 to 2020 (long term), and Nigerian Institute for Oceanography and Marine Research (NIOMR) meteorological station (Badore station) for the year 2021 (short term). Atmospheric co_2 concentration data were obtained from National Oceanic and Atmospheric Administration (NOAA) spanning from 2009-2021. Qualitative and quantitative quality control was performed on the data to meet the objective of the study. Data analysis was performed using SciPy software. Rainfall amount was classified according to the American Meteorological Society (AMS) as thus:

- Rain day: The amount of rain ≥ 0 mm
- Rainstorm: The amount of rain (≥ 10 mm, ≤ 50 mm)
- Violent Rain: The amount of rain ≥ 50 mm

RESULTS AND DISCUSSIONS

Climate is an important factor affecting agricultural productivity. Agriculture and food production depend fundamentally on climatic factors. Climate change is already affecting the earth's temperature, precipitation, and hydrological cycle. Continued changes in the frequency and intensity of precipitation, heat waves, and other extreme events are affecting agricultural production. Climatic changes due to anthropogenic factors have been identified as the main driver of these changes (Ekwurzel et al., 2017), championed by anthropogenic atmospheric co_2 emissions. Analysis of the monthly mean mass fraction of carbon in the air along the Lagos coast from 2009 to 2021 as shown in figure (1) shows that the anthropogenic co_2 is increasing with a slight drop in 2020. The slight drop in co_2 emission in 2020 could be linked to Covid-19 activities where the country was on total lockdown for nearly half of the year which consequently halted industrial activities. This exponential increase in co_2 emissions has greatly impacted the rain patterns and consequently increases rainstorm events in Lagos. Figure (2) show that there is no significant trend in the rainfall pattern throughout the study period but the number of extreme rainfall events is increasing lately. For instance, in 1985, the number of rain days was 104, and the number of rainstorm events was 40 which constitute about 38.48% of the total rainfalls throughout the year. The total amount of rainfall and yearly maximum recorded in the year was 1052.9 mm and 55 mm respectively with 1 violent drop of rainfall constituting about 0.96% as depicted in figure (3). On the other hand, the number of rainy days in 2018 was 80 and the number of rainstorm events recorded was 42, constituting about 52.5% of the total rainfall. The total amount of rainfall was 1339.8 mm, and the yearly maximum was 119.5 mm with 6 violent drops of rain constituting about 7.5% of the total rainfall. Similarly, the amount of rainfall is decreasing lately as shown in figure (4), but the number of rainstorms keeps increasing. For instance, the year 2021 has 44 rainstorm events and 4 violent drops of rain with a total rainfall amount of 1411.11 mm throughout the year as depicted in figure (5). Activities of rainstorm events could result in severe flooding events, consequently leading to soil degradation, damage to crops, increasing flood risk, and also may reduce fish density and biomass, influencing community composition (Milner et al., 2012).

CONCLUSIONS

Anthropogenic activities most especially emission of co_2 , which is the major greenhouse gas into the atmosphere is the major cause of climate change. The present study has examined the influence of anthropogenic co_2 concentration in the atmosphere on the recent rainfall extremes along the Lagos coast using NOAA atmospheric co_2 concentration and NIMET – NIOMR rainfall data with a well-structured analytical method. Results show that the amount of rain is decreasing lately but the number of extreme cases is increasing. This is attributed to the co_2 concentration in the atmosphere.

ABSTRACT

Plant biotechnology is the use of tissue culture and genetic engineering techniques to modify and produce new plants that exhibit desirable characteristics. Plant biotechnology provides plant scientists or breeders an opportunity to achieve certain goals that would otherwise be impossible through conventional plant breeding approaches. Plant biotechnological techniques have evolved rapidly in recent years from tissue culture to more advanced and sophisticated techniques like genomics-assisted breeding, next-generation sequencing methods, molecular breeding, gene editing, genetic engineering etc. These recent advancements have revolutionized plant breeding and crop improvement resulting in the creation of high-yielding, better adapted crop varieties that are resilient to climate change, pest and diseases. In the face of food insecurity, exacerbated by climate change and other natural disasters, plant biotechnology tools or techniques can be deployed as a strategy to combat these exigencies. Hence, this paper gives an overview of the advances in plant biotechnology that has aided the quantum leap in crop improvement in recent years, with profound implication for developing countries like Nigeria where food production is largely at the subsistence level.

Keywords: Plant biotechnology, food security, climate change, crop breeding, crop improvement.

INTRODUCTION

Fulfilling the goal of attaining food security for the present and future generations is of prime importance. Climatic related challenges like rapid changes in temperatures, alterations of rainfall patterns, floods or drought conditions, and outbreaks of pests and diseases extremes have caused a range of negative impacts on plants (Munaweera *et al*., 2022). As a result, plant scientists and breeders are under increasing pressure to develop smart crops with superior genes, that are highly resistant to disease and pest, and adaptable to a wide range of climatic variability, in a bid to tackle food and nutritional insecurity. Conventional plant breeding approaches, which have played a key role in food security until now seem to be insufficient. Several years ago, plant biotechnology comprised only a few applications of tissue culture, recombinant DNA technology and monoclonal antibodies. Today, transformation, and marker-aided selection and breeding are just a few of the examples of the applications of biotechnology in crop improvement (Izquierdo, 2000). The development of biotechnological approaches such as genetic engineering, genome editing, RNA-mediated gene silencing, armored with next-generation sequencing, and genome mapping have paved the way for precise and faster genetic modifications of plants.(Munaweera *et al*., 2022).

Some Modern Breeding Techniques:
Plant Tissue Culture

Plant tissue culture is the growing and multiplication of living plant cells, tissues, and organs in a liquid artificial media (in vitro), under aseptic and controlled environment conditions. Tissue culture techniques allow thousands of new plants to be obtained from a single plant, making the technology attractive to rapidly multiply new cultivars. Tissue culture has immensely contributed to the growth and development of many crops and it helps breeders save time during the breeding process such as helping with propagation of difficult to grow plants. Tissue culture has been used in the production and development of quality and improved cultivars (Lalitha *et al.*, 2014). It is useful for germplasm conservation, production of Genetically Modified Organisms (GMO), cryopreservation, and also helps industries with production of secondary metabolites (Prakash *et al.*, 2004). Cell regeneration by tissue culture is made possible due to the ability of a plant cell to form a multicellular organism, which is commonly called Tortipotency (Lima *et al.*, 2012). Along with the totipotent potential of plant cell, the capacity of cells to alter their metabolism, growth and development is also equally important and crucial to regenerate the entire plant (Thorpe, 2007). Regeneration of new species and improved culture techniques opened new horizons for practical breeding in number of crops (Tom *et al*., 2013). The tissue culture process can be divided into four steps or stages: explanting, multiplication, organogenesis and acclimatization. While tissue culture is a viable method of increasing the numbers of a single clone, compared with conventional asexual propagation methods, the success rate depends on the skill of the technician practicing it. Contamination is also a constant problem and leads to disappointing results. Also, each plant species has its own special growing requirements, although protocols have been established for many important species, there are many more species whose protocols are yet to be determined.

Genetic Modification And Engineering Applications

Genetically modified organisms (GMOs) are the ones in which the genomic material, DNA (deoxyribonucleic acid), has been transferred from a bacterium or a plant, or even an animal, into a different plant species to obtain the desired and improved quality. Genetic engineering modifies the genetic material of crops to display specific traits (Fernandez-Cornejo and Caswell, 2006). This technology is often recognized as “recombinant DNA technology” or “genetic engineering” and the resultant organism is said to be “genetically engineered,” “genetically modified,” or “transgenic”. Genetic modification entails series of laboratory techniques for cloning genes, splicing DNA segments together, and inserting genes into cells. Most genetically engineered crops are transformed to be either herbicide tolerant, to destroy weeds without damaging crops, or insect resistant, to shield plants from harmful pests (Khan and Hakeem, 2015). According to USDA standards for organic agriculture, seeds or other substances derived through GM technology are not allowed in organic production (Byrne, 2014). According to (Khan and Hakeem, 2015), several food crops have been modified to increase production and durability; the examples are cotton, sugarcane, tomatoes, soybean, Hawaiian papaya, potatoes, rice, rapeseed, sugar beet, field corn, and sweet corn.

Genome Editing

Genome editing is a revolutionary technology for the advancement of plant science and crop breeding (Chen *et al*., 2019). Genome editing enables modification of plants' owned genes, without insertion of external genes, as with GM crops. Genome-edited varieties possess no foreign DNA and are indistinguishable from crops developed through conventional plant-breeding methods, or using naturally occurring mutations (Hua *et al*., 2018). Gene editing has a broad spectrum of applications, from knocking out a gene to quickly generating a recessive but desired trait, such as fragrance and early maturity (Shan *et a*l., 2015), to generating new alleles by nucleotide substitution to create a novel trait (Hua *et al*., 2018). To date, several base and prime editor tools are developed based on CRISPR/Cas (clustered regularly interspaced short palindromic repeats -associated system), in order to perform more precise editing (Zhu *et al*., 2020). These editing tools are helping breeders modify target genes to the desired sequence for improving crops yield and quality, increase biotic/abiotic stress tolerance and herbicide resistance in crops (Chen *et al*., 2019). Genome editing is therefore considered the next generation breeding strategy.

Proteomics

Proteomics can be defined as the systematic analysis of proteome, the protein complement of genome (Pandey and Mann, 2000; Patterson and Aebersold, 2003; Phizicky *et al*., 2003). This technology allows the global analysis of gene products in various tissues and physiological states of cells. With the completion of genome sequencing projects and the development of analytical methods for protein characterization, proteomics has become a major field of functional genomics. The initial objective of proteomics was the large-scale identification of all protein species in a cell or tissue. The knowledge of key proteins that play crucial roles in the proper growth and development of a plant are critical to propel the biotechnological improvement of crop plants (Eldakak *et al*., 2013). The applications are currently diversified to analyze various functional aspects of proteins such as post-translational modifications, protein-protein interactions, activities and structures. Eldakak *et al.* (2013) reported the use of proteomics for genetic improvements in food and biofuel crops, including food quality, safety, and nutritional values, tolerance to abiotic and biotic stresses, manufacturing plant-based vaccines and proteomics-based fungicides. Apart from these, proteomics is also being used for several other crop improvement programs such as, pre- and post-harvest losses, and crop quality characteristics.

Molecular Breeding and Marker Assisted Selection And Molecular Breeding

Molecular breeding (MB) may be defined in a broad-sense as the use of genetic manipulation performed at DNA molecular levels to improve characters of interest in plants and animals, including genetic engineering or gene manipulation, molecular marker-assisted selection, genomic selection, etc. More often, however, molecular breeding implies molecular marker-assisted breeding (MAB) and is defined as the application of molecular biotechnology, specifically molecular markers, in combination with linkage maps and genomics, to alter and improve plant or animal traits on the basis of genotypic assays (Collard and Mackill, 2008). This term is used to describe several modern breeding strategies, including marker-assisted selection (MAS), marker-assisted backcrossing (MABC), marker-assisted recurrent selection (MARS), and genome-wide selection (GWS) or genomic selection (GS) (Ribaut *et al*., 2010). Marker-assisted selection (MAS), which is the employment of DNA marker in plant breeding programs, has extensively been used to select desired genes/quantitative trait loci (QTLs) in the development of a comparatively superior breeding line (Collard and Mackill, 2008).

Plant Metabolomics

After the establishment of technologies for high-throughput DNA sequencing (genomics), gene expression analysis (transcriptomics), and protein analysis (proteomics), the remaining functional genomics challenge is that of metabolomics. Metabolomics is the term coined for essentially comprehensive, non-biased, high-throughput analyses of complex metabolite mixtures typical of plant extracts (Hall *et al*., 2002). Plant metabolomics, a branch of metabolomics, is designed to study the overall changes in a large number of metabolites in plant samples and then conduct deep data mining and bioinformation analysis (Xiao *et al*., 2020). This potentially holistic approach to metabolome analysis is driven primarily by recent advances in mass spectrometry (MS) technology and by the goals of functional genomics research. Achieving the broadest overview of metabolic composition is very complex and entails establishing a multifaceted, fully integrated strategy for optimal sample extraction, metabolite separation/detection/identification, automated data gathering/handling/analysis, and ultimately, quantification. Both analytical and computational developments are essential to achieve this goal (Hall *et al*., 2002). Metabolomics information not only will assist in the establishment of a deeper understanding of the complex interactive nature of plant metabolic networks and their responses to environmental and genetic change but also will provide unique insights into the fundamental nature of plant phenotypes in relation to development, physiology, tissue identity, resistance, biodiversity, etc.

CONCLUSION

New technologies, such as plant biotechnology, if properly focused, offer a responsible way to enhance agricultural productivity for now and the future. Genetic modification can be a misleading terminology, in that virtually everything we eat has been modified genetically one way or another, especially through domestication from wild species, and many generations of selection by humans for desirable traits. So, to attain food security status, in the face of climate extremes, pest and diseases, developing countries like Nigeria need to take advantage of the various next generation plant breeding tools.

ABSTRACT

Tomato leaf diseases can be severe, causing defoliation and eventually killing the plant if not properly managed. Estimating disease severity is crucial for yield loss prediction and disease management. Identification of pathogens enable selection of pathogen-free planting materials that are essential for improved yield and quality. The present study identified the pathogens associated with foliar diseases on four tomato varieties and assessed their severity**.** Four tomato varieties (Tropimech, Tima, Roma VF and Omu-Aran Local) were raised in the nursery and transplanted to Sites A and B on the field. The experimental design was laid in a randomized complete block design with three replicates. Leaves of the tomato plants were observed for foliar disease symptoms. The pathogens associated with the diseases were identified and data were collected on disease severity at 2, 4 and 6 weeks after transplanting (WAT). Data collected were subjected to analysis of variance using SPSS package and means were separated using Duncan multiple range test at 5% probability level. The identified foliar diseases were early blight (*Alternaria solani*), bacterial wilt (*Ralstonia solanacearum*) and curly top (curly top virus). The lowest early blight severity (0.5) was recorded on Omu-Aran Local in Site A. At 4 WAT in Site A, Tima had the highest severity of bacterial wilt (3.5), followed by Tropimech (2.5). Bacterial wilt was the most severe foliar disease encountered in the study area. Roma VF and Omu-Aran local are recommended for planting in areas where bacterial wilt is widespread while Tima is suitable where early blight is prevalent. Findings from this study could be a bedrock for breeding and selection of foliar disease resistant tomato varieties.

Keywords: Tomato, early blight, bacterial wilt, curly top virus, severity

INTRODUCTION

Leaves constitute important organ in plants by virtue of their position as the site of photosynthesis (Kumar *et al*., 2015). Tomato is susceptible to several devastating foliar diseases that affects the crop at various stages of growth (Ramyabharathi *et al*., 2013). Tomato leaf diseases cause irregular growth, discolouration, defoliation and eventually killing the plant if not properly managed (Shijie *et al*; 2017; Ewekeye & Odebode, 2021). Any damage to plant leaf will invariably result in decreased yield, both in quantity and quality (Byjus, 2022).

Correct identification of a plant pathogen is a critical step in disease management (Ashqar *et al*., 2018). The ability to identify pathogens enable the selection of pathogen-free planting materials that are essential for higher yield and quality (Ayo-John & Odedara, 2017). Data on disease assessment is crucial to understanding and estimating yield losses, comparing phenotypes for disease resistance or susceptibility (Bock *et al*., 2021).

Leaf spot disease intensity can be evaluated by measuring disease severity, a criterion essential for classifying varieties into susceptibility groups (Wang *et al*., 2017). There is a paucity of data on disease severity on commonly cultivated tomato varieties, particularly in Nigeria. Therefore, the present study identified the pathogens associated with foliar diseases on four tomato varieties and assessed their severity**.**

Materials and Methods

This research was carried out at the Teaching and Research Farm of Landmark University, Omu-Aran, Kwara State, Nigeria. Omu-Aran is located at latitude of 80.9'N and longitude of 50'61 E, in the derived savannah ecological zone. The experiment was conducted at two locations (Sites A and B). The four varieties of tomato used in this study are Roma VF, Tropimech, Tima and Omu-Aran Local. Seeds of the tomato varieties were raised in polythene bags in the screen house for 3 weeks and later transplanted to the field. A land area of 22m^2 was cleared and partitioned into 12 beds at each site, with each bed measuring 1 m x 1 m. The experiment was laid in a randomized complete block design (RCBD) with 3 replicates. The treatments consisted of the four tomato varieties: Roma Vf, Tima, Tropimech and Omu-Aran Local.

Starting from one week after transplanting, the leaves of the plants were observed for symptoms of foliar diseases. Disease observation was based on macroscopic symptoms and infected leaf samples were collected in brown paper envelopes, labelled accordingly and taken to Nigeria Agricultural Quarantine Service, Ibadan, Nigeria and the International Institute of Tropical Agriculture (IITA), Ibadan, Nigeria, for pathogen identification.

For early blight disease, severity was assessed on a scale of 0-5 according to Rahmatzai *et al*. (2017), where, 0= No symptom on the leaf, 2= < 10% of leaf surface area infected, 3= 11-25% of foliage of plants covered with symptom, 4= 51-75% area of the plant's leaves, fruits and stems with the symptom, and 5= <75% area of plant part with disease symptom.

The plants were scored for bacterial wilt severity according to Tiwari *et al*. (2012), where, 0= No infection, 1= 1-10%, 2= 11-25%, 3=26-50%, 4= 51-75% and 5= 76-100% infection.

For curly top virus, severity was assessed based on the rating scale of Montazeri *et al*. (2016), where, 1= No visible symptoms, 2= Leaf thickened and veins cleared, 3= 2–3 leaves margins curled, and a mild vein swelling and crumpling, 4= 4–5 leaves margins are curled with minor vein swelling and crumpling, 5= Majority of leaves exhibit mild vein swelling, crumpling, and curling, 6= Most leaves having slight vein swelling, crumpling, and curling, 7= Most leaves having moderate vein swelling and crumpling, as well as severe leaf curling, and 8= Severe stunting, swollen and crumpled veins on most leaves, and curled leaf margins.

Fungal and bacterial isolation were carried out according to Rashid *et al*. (2016). Fungal identifications were based on colony characterization and examination under a compound microscope with a magnification of 40X while bacterial colony was observed on a stereomicroscope.Data collected were subjected to analysis of variance (ANOVA) using the SPSS package, and means were separated using Duncan multiple range (DMRT) at a probability level of 5%.

RESULTS

The foliar diseases identified in this study are early blight, bacterial wilt and curly top virus and the associated pathogens are *Alternaria solani*, *Ralstonia solanacearum* and curly top virus, respectively.

Early blight severity: The severity of early blight on the four tomato varieties is presented in Figure 1. In Site A at 2 WAT, there was no significant (P<0.05) difference in disease severity among the four varieties with Roma Vf having the highest value (1.3) and Omu-Aran local the lowest (0.3). At 4 WAT, Roma Vf had the highest severity (2.5) which was not significantly (P<0.05) different from Tima (1.3) and Tropimech (1.3). The lowest early blight severity (0.5) was recorded on Omu-Aran Local. At 6WAT, the highest disease severity (3.0) was recorded on Roma Vf and was significantly (P<0.05) higher than Tropimech (1.8), Tima (1.5) and Omu-Aran Local (1.5), all of which were not significantly (P<0.05) different.

In Site B at 2 WAT, there was no significant difference (P<0.05) in early blight severity among the four tomato varieties. At 4WAT, the highest disease severity (1.8) was recorded on Roma Vf and was significantly higher than Tropimech (0.8), Tima (0.8) and Omu-Aran Local (0.5), all of which were not significantly (P<0.05) different. AT 6 WAT, the highest disease severity was observed in Roma Vf (3.0) and was significantly (P<0.05) higher than Tropimech (1.3), Omu-Aran Local (1.3) and Tima (1.0).

Bacterial wilt severity: The severity of bacterial wilt on the four tomato varieties is presented in Figure 2. At 2 WAT in Site A, the highest disease severity (2.8) was recorded in Tima and was not significantly (P<0.05) different from Tropimech (2.0). The lowest severity was observed in Omu-Aran Local and Roma Vf, both of which were not significantly (P<0.05) different. At 4 WAT, Tima had the highest severity of bacterial wilt (3.5), followed Tropimech (2.5), both of which were not significantly (P<0.05) different. The lowest disease severity was recorded in Omu-Aran Local (1.3) and Roma Vf (0.5), both of which were not significantly (P<0.05) different. At 6 WAT, Tima had a significantly (P<0.05) higher severity (4.8) than the other varieties. There was no significant difference in bacterial wilt severity among Tropimech (2.8), Omu-Aran Local (2.5) and Roma Vf (2.0).

In Site B at 2 WAT, there was no significant (P<0.05) difference in disease severity among the four tomato varieties. At 4 WAT, Tima had a significantly (P<0.05) higher severity (3.8) than the other varieties. There was no significant difference in bacterial wilt severity among Tropimech (1.8), Omu-Aran Local (1.5) and Roma Vf (0.8). At 6 WAT, Tima had the highest severity (5.0), followed by Tropimech (3.3), both of which were not significantly (P<0.05) different. Omu-Aran Local (2.3) and Roma Vf (2.0) had the lowest severity of bacterial wilt, both of which were not significantly (P<0.05) different.

Curly top virus severity: The severity of curly top virus is presented in Figure 3 below. There was no significant difference (P<0.05) in disease severity among all the tomato varieties at 2, 4, and 6 WAT in both Sites A and B.

DISCUSSION

Findings from this study showed that the four tomato varieties (Roma Vf, Tima, Tropimech and Omu-Aran Local) are susceptible to foliar diseases. However, the varieties varied in their degree of susceptibility to these diseases. Roma Vf had the highest severity of early blight, Tima had the highest severity of bacterial wilt while Omu-Aran Local had the highest severity of curly top virus. Variations in pedigree of cultivars, varieties, genotypes or accessions could have influence on resistance or susceptibility to pathogens. This corroborates the findings of Mtui *et al*. (2015) that reported varying reactions of different tomato varieties to infection by pathogens. Adhikari *et al*. (2017) reported that majority of cultivated tomato varieties are susceptible to early blight whereas a few are resistant. This demonstrates varietal differences to early blight pathogen. Roma Vf was moderately susceptible to early blight in accordance with the classification table of Rahmatzai *et al*. (2017).

The severity of bacterial wilt disease increased because *R. solanacearum* is a soil-borne pathogen and the regular watering during the growing season might have favoured disease development and symptom expression. Curly top virus severity on the four tomato varieties were low at the two experimental locations. This could be attributed to the fact that curly top virus disease is transmitted by beet leafhoppers insect vector and plants in the Amaranthaceae family are the preferred hosts (Koike & Gilbertson, 2010), as opposed to Solanaceae to which tomato belongs.

The foliar diseases observed in this study are early blight, bacterial wilt and curly top virus and the pathogens attributable are *Alternaria solani*, *Ralstonia solanacearum* and curly top virus, respectively. A similar study conducted by Amuji et al (2012) identified *Fusarium* wilt caused by *Fusarium oxysporum* and soft rot incited by *Rhizopus stolonifera* as the endemic pathogens limiting tomato production in Nsukka, South-eastern Nigeria. Findings from Ewekeye & Odebode (2021) identified leaf spots, chlorosis, and wilting as symptoms of foliar diseases of tomato in Ogun State, Nigeria. Previous research carried out by Opoku *et al*. (2021) also documented early blight on tomato plants in Ghana.

The severity of these foliar diseases increased with tomato growth stages among the varieties evaluated. This observation supports previous research that reported a positive correlation between early blight disease and tomato plant age (Mailem & Singh, 2018). Similar findings were observed by Yerasu *et al*. (2019) who reported varying disease expression in seedlings and older plants.

CONCLUSION

Early blight (*Alternaria solani*), bacterial wilt (*Ralstonia solanacearum*) and curly top (curly top virus) were the identified foliar diseases in the study location. Bacterial wilt was however, the most severe, causing considerable damage to the foliage. Roma Vf and Omu-Aran Local are recommended for planting in areas where bacterial wilt is prevalent while Tima is suitable where early blight epidemic occurs. Roma Vf and Tima are recommended for planting in areas with outbreak of curly top virus disease. Findings from this could be a bedrock for breeding and selection of foliar disease resistant tomato varieties.

ABSTRACT

The research was conducted at the northern Kaduna selected arable soils, and intended to study the distribution of micronutrient on these soils. The major arable soils used were previously harvested maize, cowpea and rice soils (designated as Locations A, B and C respectively). The soils were delineated, and three profile pits dug in each along the line of transect of about 100 m apart. A total of nine profile pits were dug in the three delineations and samples collected from each pit according to their horizonations. Major micronutrients investigated were Cu, Fe, Zn and Mn. Virtually all micronutrients decreased down the profile in all studied locations with Cu and Zn displaying an irregular trend in all pedons of rice harvested soils in location C. Also, Fe rather increased in pedon 1 of location C as well. Micronutrients were all low to a deficiency level considering their critical limits in the tropical soils. Activities that will conserve organic matter such as accumulation of litter from harvested crops and alternative means of cattle rearing such ranching rather than freelance grazing should be employed, as efforts to replenish micronutrients through fertilization has not yielded the desired results.

Keywords: soil micronutrients, micronutrient variability, nutrients deficiency, critical limits, northern guinea savanna.

1. INTRODUCTION

Micronutrients is highly important in soil health maintenance and crops productivity. They are usually needed in small amount by plants for their growth and in the synthesis of human food which must come from the soil. The breakdown of certain soil micronutrients such as Zn and Fe with organic matter will oftentimes lead to the formation of root dependable types of these nutrients and also stop the formation of indissoluble types such as carbonates and oxides in soils (Schulin *et al.*, 2009). In tropical soils where acidity is high due to high level of leaching, Zn content of soils may be low resulting to low total Zn content or may be relatively high in total Zn, however crop-available quantity is low because of the chemical composition of soil which encourages the formation of poorly soluble Zn complexes (Rengel, 2002). The handiness or availability of soil Zn for utilization by crops may be hindered by pH, cation exchange capacity (CEC) of soil and liquidity of the mineral which is controlled by the exchangeable sites, build-up of complexes with organic matter and formation of precipitates (Baird and Cann, 2005).

Rufus *et al.*, (2012) carried out a study to investigate the total and extractable concentrations and profile distributions of the micronutrients, Cu, Zn, Fe and Mn, in the main agricultural soils in Northern Nigeria, and associated their variations to effects from lithology and other soil properties. Due to scanty information available on the micronutrient concentration and variability in Northern Nigerian soils, this research however investigated the variability of selected micronutrients in soils of Rigachikun, Northern Guinea Savannah, Nigeria.

2. MATERIALS AND METHODS

2.1 Location

The study area is located on the Latitudes 10^o 36' and 10° 60' N and Longitudes 7^{o}25' and 7° 40'E respectively and in the north western Nigeria**.** It has been characterized as a region where the rainfall is unimodal in pattern and between 900 – 1300 mm per annum (Uyovbisere and Lombin 1991). The region also has a wave-like but relatively plain relief, with general elevation from about 450 to 700 m, dominated by mostly sandy soils, which are usually very low in organic matter, may degrade rapidly under conditions of very high rainfall. The region is also known for its high annual average temperature (28-32°C), short wet season and long dry season (6-9 months). Generally, soil moisture and temperature regimes in the area are inferred to be ustic and isohyperthemic respectively. During the rainy season however, mean temperature drops to 25^{o}C – 28^{o}C (June to September) and decreases to less than 20^{o}C in the months between December and February (Gabasawa *et al.,* 2017). Tree cover varies from open woodland to light forest which has been reduced to bare land due to uncontrolled tree felling for fuel as well s farming activities (Carsky *et al.*, 1998) while abundant short grasses (<2 m) are also available (Sowunmi and Akintola, 2010).

2.2 Existing Information on Soil

The soils of the region mostly exhibit the characteristics of dry lands and its moisture movement in the soil may be slowly permeable, while most of its rain water gets lost by run-off (Fitzpatrick, 1980). They could have been created under severe dry condition from wind-stored desert sands that gathered together over a long period of time. Also, some soils in the northern guinea savanna found in states like; Kaduna, Katsina, Kebbi, Sokoto and Zamfara of northern Nigeria have been suggested to be ferruginous tropic soils (D'Hoore, 1965) and characterized as having mostly sandy texture, spreading through large areas of land having very low water-holding capacity and low organic matter, nitrogen and phosphorus content, neutral or moderately acidic in pH and also having a low cation exchange capacity. Large expanse of arable land exists in this region with potential for the production of largely grain crops like maize, sorghum, millet, rice and wheat (Shehu *et al.*, 2015).

2.3 Field Work

Soils were delineated into mapping units using the cropping land use. Depending on the identified soil groups, Pedons was sunk in each of the delineated mapping units. Three profile pits were dug in each cropping land use for maize, rice and cowpea giving a total of nine profile pits. About 1kg samples was collected from the different horizons of each pedon at the different arable crop grown soils for micronutrient and other soil physicochemical properties study. Samples were carefully packaged and labeled and transported to the standard Soil Science laboratory of ABU, Zaria for analysis.

2.4 Laboratory Soil Analysis

Micronutrients such as Mn, Fe, Cd and Zn were extracted using acid of method of 0.1M HCl and read with Atomic Absorption Spectrophotometer (AAS) as outlined by Kalambe (2021)

2.5 Statistical analysis

Coefficient of Variation (CV) was used to estimate the degree of variability existing among soil properties in the study site. Coefficient of variation (C.V.) ranked as follows; Low variation ≤15%, Moderate variation >15≤35%, High variation >35% was used as outlined by Wilding, (1985). Correlation was done using SPSS software package.

3. RESULTS AND DISCUSSION

Copper (Cu) generally decreased down the soil profile in all studied soils and had their highest concentrations in the first two horizons (A and AB) of all soils. The Cu content was highest in location A where maize was recently harvested from. Mean Cu distributions were as follows in the respective locations. Location A; 2.573, 1.646 and 1.025 mg kg^{-1}; Location B; 0.349, 0.443 and 0.953 $mgkg^{-1}$ and Location C; 0.281, 0.323 and 0.116 mg kg^{-1} in the respective pedons of maize, cowpea and rice harvested plots respectively. In the same vain Fe were more concentrated within the surface horizons and the plough layer but decreased significantly down the profile. More Fe were recorded when compared to other micronutrients in the studied soils. Pedons within Location A (maize harvested plot) recorded more iron content compared to others followed by pedons 3 in location C (rice harvested plot) where Fe content was reasonably higher than their counterparts in other pedons. Location B (cowpea harvested plot) had the lowest Fe distribution having less than 60 $mgkg^{-1}$ Fe in all their respective pedons. Mean Fe ranges in the studied locations were; Location A; 121.53, 88.905 and 83.66 mg kg^{-1}; Location B; 59.760, 47.04 and 58.613 mg kg^{-1}; Location C; 66.13, 53.483 and 107.13 mg kg^{-1} in their pedons 1, 2 and 3 respectively (Table 1). Zn does not seem to show a particular trend in their distribution pattern across pedons and locations, while it decreased in some, it increased in others. Zn has the following mean distributions in locations as thus; Location A; 1.95, 0.99 and 0.67 mg kg^{-1}; Location B; 0.214, 0.33 and 0.596 mg kg^{-1}; Location C; 0.671, 0.936 and 1.245 mg kg^{-1} in pedons respectively. Mn decreased down profiles with pedon means as follows; Location A; 34.121, 14.813 and 18.055 mg kg^{-1}; Location B; 18.728, 12.23 and 14.876 mg kg^{-1}; Location C; 11.27, 10.67 and 20.10 mg kg^{-1} respectively.

The distribution of these micronutrients in the studied soils were quite low and most of them far lower their naturally occurring quantities in tropical agricultural soils as suggested by Rufus *et al.*, (2012) and Dhaliwal *et al.*, (2019). Mean Cu contents were as follows in the respective locations. Location A; 2.573, 1.646, 1.025 mg kg^{-1}; Location B; 0.349, 0.443, 0.953 $mgkg^{-1}$ and Location C; 0.281, 0.323, 0.116 mg kg^{-1} in the respective pedons of maize, cowpea and rice harvested plots respectively. However, some of the ranges of Cu found this study especially location A precisely, were higher than what has been reported (0.54-1.6 mg kg^{-1} Cu) in soils of the semi-arid parts of northern India (Katyal and Sharma, 1991) whereas those of Location B and C were almost of the same range with the above reports. Rufus *et al*,. (2012) obtained the 0.1M HCl extractable Cu ranges of 0.29-3.63 mg kg^{-1} at the lower Benue valley of central Nigeria which falls within the range of Cu content of the studied soils of Northern Guinea Savanna of Nigeria. Matijevic *et al.*, (2014) discovered a considerable increment in total Cu content of soils resulting from organic matter application.

Mean Fe content of studied soils are as thus; location A; 121.53, 88.905 and 83.66 mg kg^{-1}; location B; 59.760, 47.04 and 58.613 mg kg^{-1}; location C; 66.13, 53.483 and 107.13 mg kg^{-1} in their pedons 1, 2 and 3 respectively (Table 1). Hamza (2008) gave the critical Fe level to be 100 mg kg^{-1} and toxicity to be above 400 mg kg^{-1}. Most of the soils in the studied location had their Fe contents below the critical levels except pedon 1 of location A (maize harvested field) and pedon 3 of location C (rice harvested field) where mean Fe contents were above 100 mg kg^{-1} indicating that Fe deficiency may be a threat to crop productivity of the studied soils. The redoximorphic properties and soil pH are among key components that determine the characteristics of Fe in soils. Formation of weakly composed Fe compounds (ferrihydrite) is encouraged by pH of 6.5 – 7.0, while more acidic and reduced conditions promote the mobilization of Fe minerals. Hamza (2008) noted that formation of solution in soils by Fe is an essential parameter that causes Fe deficiency in crops, common in soils dominated by calcium carbonate. Fe solubility reduces considerably in well aerated soils, as Fe is available in low soluble Fe^{3+} oxides and hydroxides. Hamza (2008) further stated that the alterations hinge on soil reactions and OM content, salt and temperature of the soil. Moreover, poorly aerated condition, common in compacted soils may lead to more solubilization of Fe, which may encourage Fe deficiency due to many tender roots getting injured or even destroyed. This ultimately decreases the absorptive potential of the whole root system. Freeing of Fe as a result of disintegration of rock materials is a very gradual procedure driven mainly by pH and O_2 concentration and by the dissolution–precipitation phenomena (Mengel, 1994). After aggregation due to weathering, the fate of Fe^{2+} is controlled by the oxidation-reduction reactions as well as pH status of the soil. Fe^{2+} released from primary minerals is readily oxidized under aerobic conditions and pH ranging from 5 to 8 (Dhaliwal *et al.*, 2019).

Table 2: Ranges of Micronutrients distribution in studied soil (mgkg^{-1})

*Micronutrients distributions in tropical agricultural soils (Dhaliwal *et al.*, 2019), +Hamza (2008); ++Obasi (2015)

From table 2, there is an obvious deficiency of Zn in all pedons studied in the various cropping locations according to Dhaliwal *et al.*, (2019) who gave Zn distributions of tropical soils to be in the range of 10 – 300 mg kg^{-1}. Obasi (2015) gave the critical limits of Zn as values less than 10 mg kg^{-1} whereas toxicity level may be as high as above 1500 mg kg^{-1} in tropical agricultural soils. The highest Zn values obtained were 2.97, 1.89 and 1.395 mg kg^{-1} on the topmost horizons of maize harvested pedons. For cowpea and rice locations pedons were 0.39, 0.63, 0.90 and 1.365, 1.425, 1.86 mg kg^{-1} respectively indicating severe deficiency of Zn in the studied soils. Deficiency of Zn has been a serious threat in in developing countries which depend mostly on cereals to fulfil their dietary needs and about half of the world population is found to be involved in this challenge (Cakmak, 2008). This concern is increasing on daily basis as Zn keeps playing significant position in biological activities of plants and human food needs being regarded as an essential micronutrient for growth and development (Alloway, 2008). Zn deficiency has ranked fifth as part of major causes of death and various sicknesses in sub-Sahara Africa and elsewhere in the world due to consumption of staple grains with low Zn contents such as rice [*Oryza sativa* L.], and maize [*Zea mays* L.] (Yang *et al.*, 2007). Therefore, stepping up Zn content in edible plant parts is of supreme importance in agricultural productivity to battle high level Zn deficiency in human nutrition across the globe (Cakmak, 2008).

Manganese (Mn) distribution of the studied soils could be said to be low considering the critical limits of (80 – 140 mg kg^{-1}) documented by Obasi (2015). Ranges of Mn distributions in pedons with highest Mn contents in each cropping locations are as thus; Maize; (6.63 – 100.04 mg kg^{-1}); Cowpea (5.895 – 54.18 mg kg^{-1}) and Rice (6.81 – 42.135 mg kg^{-1}) (table 3). Low organic matter content of the studied soils may have been responsible for the low Mn content observed in the soils. Green manuring and organic matter availability can lead to an upsurge the Mn content in soils. Submerged conditions leads to a more valent forms of Mn like MnO_2, Mn_2O_3 and Mn_3O_4 to get reduced to Mn^{2+} form which is easily taken up by crops (Ponnamperuma, 1972). Rainfall duration in northern Guinea Savanna Nigeria is very short, about four months (May – August). Also the possibility of green manure application on Rigachikun soils is hampered due to its conflictive use in the feeding of domestic animals.

The mean micronutrient distributions on the cropping soils, indicated that maize harvested soils (location A) had more Fe content in their respective pedons (121.53, 88.91, 83.66 mgkg^{-1}). This was followed by rice harvested soils in location C pedons (66.131, 53.48, 107.53 mgkg^{-1} respectively) while cowpea harvested soils in location B had lowest Fe content distribution indicating 59.76, 47.04, 58.56 mg kg^{-1} in their respective pedons although pedon 2 of rice harvested soil had a value lower than pedons 1 and 3 of cowpea soil. Mn had the next highest values after Zn distributing irregularly across study locations with highest occurring in maize harvested location A pedon 1(34.12 mg kg^{-1}). This was followed by rice harvested location C pedon 3 (20.10 mg kg^{-1}) and then cowpea location B pedon 1(18.72 mg kg^{-1}). Cu was the next highest in study locations pedons especially in maize (location A) and cowpea (location B) harvested soils while an irregular distribution of Cu with Zn was noticed at the rice harvested soil in location C. The Cu respective pedon values are as thus; maize (location A): 2.57, 1.65, 1.025 mg kg^{-1}, cowpea (location B): 0.349, 0.443, 0.953 mg kg-1, and rice (location C): 0.281, 0.323, 0.116 mg kg^{-1}. Mean Zn distributions had the lowest values in all locations though irregularly distributed with Cu especially in rice loction C. Pedon Zn contents in various locations are as thus; maize (location A): 1.95, 0.99, 0.67 mg kg^{-1}, cowpea (location B): 0.214, 0.33, 0.596 mg kg^{-1}, and rice (location C): 0.671, 0.936, 0.125 mg kg^{-1}. There is obvious deficiency of micronutrients in all studied locations as means obtained were lower than critical limits established (Hamza 2008; Obasi 2015). Values obtained were in consonance with those of other studies in northern guinea savanna of Nigeria (Oluwadare *et al.*, 2013). Deficiency of these nutrients may pose serious challenge to crop productivity and human health. Deficiency of Zn has been a serious threat to the growing third world populations ranking 5th causes of death due to consumption of staple grains with low Zn contents (Yang *et al*., 2007).

4. CONCLUSION

There was micronutrients decrease down the profile in all studied locations with Cu and Zn showing an irregular pattern in all pedons of rice harvested soils in location C. Mn only had significant and positive correlations with all other micronutrients (Cu, Fe and Zn) but non-significantly correlated with other soil properties. Micronutrient content of the studied soils were low and most below the critical limits of tropical soils. Constant crop removal, cattle grazing, burning of crop residues and erosion among others have contributed to low micronutrient contents. Inorganic fertilization application, a common practice in soils of northern guinea savanna have not yielded appreciable outcomes in micronutrients content and crops sustainability. Activities that will conserve organic matter such as accumulation of litter from harvested crops and alternative means of cattle rearing such ranching rather than freelance grazing should be employed, as efforts to replenish micronutrients through fertilization has not yielded the desired results.

Agricultural Society of Nigeria
24 - 28 Oct., 2022

ABSTRACT

This study was conducted to characterized and classified soils of the Teaching and Research Farm, Rivers State University, Port Harcourt. It covers 30 hectares of Land. A rigid grid soil survey method at very detailed level (100 x 100)m (1 ha) with two mapping units identified and delineated and each mapping unit, were represented by a soil profile that was described from bottom to the top of the profiles to avoid contamination. Soil samples were collected for laboratory analysis from the various horizons identified. The results obtained, showed that the soils were Inceptisols/Cambisol at order level, Udepts at suborder level, Eutrudepts Great group level and Typic Eutrudepts at subgroup level. Thus, soils of Teaching and Research Farm, Rivers State University, Port Harcourt which are largely Inceptisols/Cambisols, were greatly influenced by the drainage pattern, parent materials, climate especially rainfall and the vegetation of the area coupled with the geologic material, the sedimentary rocks that was weathered into coastal plain sands and buried under alluvium at varying degrees at different places in the study area.

Keywords: Characterization and Classification, Inceptisols, Rivers State University, Teaching and Research Farm, Udepts.

INTRODUCTION

Soil characterization and classification is a land evaluation assessment process that help to identify limiting qualities of soils and thus, provide a good basis to advise the farmers on appropriate land management practice to be adopted for optimum crop production (Peter, *et al*, 2021).Soil characterization, classification and evaluation help in establishing soil database for proper understanding of soil resources within our environment and for judicious uses of land resources (Jagdish et al. 2009; Udoh and Lekwa, 2014 and Peter and Umweni, 2021a). Proper soil characterization procedure provides the building block for understanding and appreciating the soil, and further classification. To minimized damage to soils and it environment, there is need for proper soil characterization and classification according to the proposed kind of used.

This is because, soil characterization and classification provides key information on the ability of land resources (soils) for sustainable crop production (Peter and Umweni, 2020a); thus, the classification of soils is usually done based on soil properties described in terms of their various diagnostic horizons and identifiable properties that are measurable in situ the field (Peter and Umweni, 2020b). Lack of soil characterization becomes obstacle to utilize the soil identify its production potentials and adaptation of better management practice to increase soil productivity. Soil resource inventory through characterization of the resources provides an insight into the potentials and limitations of soils (Arunkumar, *et al*, 2002). Generally, most lands in Nigeria are put to use without any form of land evaluation and sometime available land evaluation results are not utilized. In farming, risk is reduced by matching the requirement of land use to the land qualities, thus predicting the potential of an agricultural land (Musa *et al*, 2013; Peter and Umweni, 2021a). It also involves the interpretation of soil survey data in order that every hectare of land should be used in accordance to with it capability, suitability and limitation (FAO, 2006 and Peter *et al*, 2019). According to Rossiter, (1996) and Peter and Umweni, (2020a), Soil characterization and classification is procedure involving the use of scientific procedure essential to assess and determined the parent material from which the soils were formed and the potential of such soils for agricultural production, engineering, urban development, pollution control etc (Onweremadu et al, 2009 and Peter et al, 2022 a). Therefore, to maintain sustainable agriculture and land use planning, proper soil investigation need to be embarked upon using soil characterization and classification procedures at both local and international level (Sereke, 2002 and Peter and Umweni, 2020b). Thus, the main aim and objective of this research was to characterized and classified soils of the Rivers State University Teaching and Research Farm, Port Harcourt, Southern Nigeria

MATERIALS AND METHODS

The Teaching and Research Farm belong to the Faculty of Agriculture, Rivers State University, Port Harcourt, Nigeria. This land has been under intensive cultivation since the establishment of the University in 1979. It lies between latitude 4^0 $40^1 50^{"}$N and $4^0 51^1 40$''N and longitude $6^0 57^1 30$''^{o}E and 7^0 5^1 0''^{o}E. It has mean annual rainfall of 2000 – 3000mm and mean annual temperature of 25 – 28^{o}C (Peter and Aaron, 2019; Ikati and Peter 2019). The relative humidity varied between 70 – 85 % depending on season of the year. The study area also experienced a period of low precipitation (dry season) commonly called harmattan period (late November to February). The vegetation of the study area as described by Ikati and Peter, (2019) and Peter and Aaron, (2019) is that of the humid tropical ever green, but tremendously altered as a result of continuous cropping system normally practiced in the area. The study area is underlain by the coastal plain sands and alluvium of marine deposits (Peter and Aaron, 2019).

Field Study

A detailed soil survey was carried out on the 30 hectares of land covering the Teaching and Research Farm. The land area was geo-referenced and digitized in an Arc map environment to form the shape field of the study area. The digitized map was gridded using the rigid grid method of detailed soil survey measuring 100 m x 100 m (1 ha) per auger boring point. Thirty (30) auger boring points were identified, and auger boring was done at depth intervals of 0 – 30cm, 30 – 60cm, 60 – 90cm and 90 – 120cm. Soil samples were described in the field. Soil morphologically properties were ascertained in situ using soil colour, texture (by hand feeling), structure, drainage, presence or absence of mottles, concretions and other morphological properties. Soils with identical properties were assembled to form mapping units. And from the grouping based on similarities, two mapping units were identified and delineated. Soil profiles pit of 2m x 2m x 2m were dug in each of the mapping unit (pedon) and described starting from bottom to top according to FAO (1976) and Anderson and Ingram (1993).

Laboratory Analysis

Soil particle size was determined by the hydrometer method according to Bouyocus, (1962). Bulk density was determined by the clod method as described by Blake and Hartage, (1986). Soil reaction (pH) was determined in 1:1 water ratio using glass electrode pH metre (Hossner, 1996). Electrical conductivity was carried out using electrical conductivity meter; while soil organic carbon content was determined by Walkey and Black (1934) method. Total nitrogen was determined by the Micro Kjeldal digestion method (Hossner, 1996; Ibitoye, 2008). Available Phosphorus was also determined by the Bray-1 method (Bray and Kurtz, 1945). Exchangeable bases (Ca, Mg, K and Na) were all determined using Ammonium acetate saturation method (Ibitoye, 2008). Exchangeable acidity was determined using the EDTA Titration method (Ibitoye, 2008); while Effective Cation Exchange Capacity (ECEC) was determined by the summation of total exchangeable bases and total exchangeable acidity and Percentage Base saturation was determined by expressing the sum of total exchangeable bases as a function of cation exchange capacity.

$$\%\, Base\ Saturation = \frac{Total\ Exchangeable\ Bases}{CEC}\ x\ 100$$

Soil classification

Soils of the Teaching and Research Farm were classified using two conventional methods of the soil taxonomy of the United States Department of Agriculture (2014) and correlated with the World Reference Base for Soil Resources (2014).

RESULTS AND DISCUSSION

Morphological properties of soils of the study area

Soil morphological characteristics of the study area are shown in Table 1. It was observed that soil depths of the both pedons were deep (200 cm). It was also observed that the various peodns have different soil colour matrix. Pedon 1 had soil colour ranging from very dark greyish brown (10YR3/2) in the Ap1- horizons to strong brown (7.5YR 4/6) (moist) in the Bt2 – horizon, while in pedon 2, all the horizons had strong brown colouration (moist). The soils were well drained and the drainage condition of the soils in the study area accounted for observable changes in soil colours in the study area. This collaborates with the findings of Esu *et al*, (2008), Dumba and Peter, (2020) and Peter and Umweni, (2020b). The brownish colouration in most of the horizons was due to the presence of organic matter as the most influential colouring agent in the surface soils. This is also in line with the reports of Nuhu, (1983), Donald (2017), Peter and Umweni, (2020a), Peter *et al*, (2021), Peter *et al*, (2022a) and Peter *et al*, (2022b). Again, the degree of peodogenic activities (illuviation and eluviation) in the soils also contributed to the colour matrix of each pedon (Donald, 2017). Soil textural class for pedon1 ranged from sandy loam at surface horizon (Ap1) to sandy clay loam at subsurface horizons (Bt2 - horizon); while it varies from loamy sand to sandy clay loam in pedon 2. Soil textures in both pedons had sub-angular blocky to blocky structures, soil consistence were friable, sticky and plastic when moist depending on the depth with root abundance at soil surface region.

Physical properties of soils of the study area

Table 2 shows the physical characteristics of soils of the study area. It reveals that soils of the study area across pedon were well drained as indicated by the colour. Sand fractions decreased from 832 g/kg to 692 g/kg with mean value of 748 g/kg down the profile depth in pedon 1. In pedon 2, sand fractions decreased from 852 g/kg to 692 g/kg with mean value of 752 g/kg. There were reductions in sand fraction down the profile with an increase at soil surface horizons. The increase in sand fractions at soil surface horizons could be attributed to erosion and eluviation of clay particles resulting to the sandy nature of the soils at the upper horizons (Donald, 2017). Silt fractions were 26 g/kg across the horizons in pedon 1, but ranged from 26 g/kg to 46 g/kg with mean value of 32.2 g/kg in pedon 2. The clay fractions of the soils increased from 142 g/kg to 282 g/kg in pedon 1; while the clay fraction value in pedon 2 increased from 102 g/kg to 282 g/kg. It was also observed that, clay fractions increased down the depth of the profile in all the pedons. The increase in clay fraction with depth might be attributed to eluviation-illuviation processes as well as the geologic materials from which the soils were formed. This is in line with the reports of Ekuo *et al* (2002), Esu *et al*, (2008), Chikezie *et al (*2009), Donald (2017), Peter and Umweni, (2020 b), Peter et al, (2021), Peter *et at*, (2022 a) and Peter *et al*, (2022 b). Soil bulk density values in the study area were 1.59 to 1.89 g/cm^2 in pedon 1 and 1.63 to 2.09 g/cm^2 in pedon 2. The soil bulk density (1.75 – 1.8 g/cm^2) of the study area were higher than critical limits for root restriction as reported by Soil Survey Staff (2006). The increase could be attributed to the activities of farm machinery over time (Peter et al, 2022 a).

Chemical properties of the Study Site

Table 3 showed some of the chemical properties of soils in the study area. Electrical conductivity (EC) varied from 19.16 – 42.72 ds/cm^2 in pedon1 and 12.33 – 18.33 ds/cm^2 in pedon 2. Soil reaction (pH) in water (H_2O) ranged from strongly acidic to moderately acidic when compared to the rating of Singer and Munns (1999). Pedon 1 had soil pH (H_2O) that varied from 4.75 to 5.53; while pedon 2 had H values ranging from 4.59 to 5.16. The acidic nature of the soils could be attributed to erosion and high rate of leaching in the as a result of the high rainfall (2000 – 3000 mm) experienced in the area. This is in conformity with the finding of Silver *et al* (2004) and Peter *et al* (2022). Soils of the study area had very low organic carbon ranging from 0.27 – 0.98 g/kg in pedon 1 and pedon 2 recorded organic carbon level of 0.31 – 0.43 g/kg. it was observed that surface soils had more organic carbon than the subsurface soils. This could be attributed to deposition of organic materials on the surface soils leading to an increase in in the organic carbon content at soil surface horizons. Total nitrogen ranged between 0.01 – 0.07 g/kg in pedon 1 and ranged between 0.01 0.14 g/kg in pedon 2. The values were rated very low when compared to available standard as reported by Douglas and Peter (2016). The available P content in both pedons ranged from 1.75 – 48.59 mg/kg. It was also observed that available P level was above the minimum critical level requires for optimum crop productivity as stated by Oko-oboh *et al* (2018) and Peter *et al* (2021). CEC varied from 4.89 – 6.92 cmo/lkg in pedon 1 and 4.20 – 7.34 cmol/kg in pedon 2. CEC was moderate both in at surface soil levels but there was no increase with depth in pedon 1. This contradicted the finding of Magaji (2018), but there were increase in the CEC level with depth in pedon 2 conforming to the report of Magaji (2018). The concentration of exchangeable bases in soils of the study area showed that calcium in both pedons were medium (2.8 – 4.6 cmol/kg and 1.8 – 4.8 cmol/kg), magnesium was medium to high in both pedons (0.6 – 1.2 cmol/kg and 0.1 – 2.2 cmol/kg); while Potassium was low to medium in pedon 1 (0.11 – 0.21 cmol/kg) and low in pedon 2 (0.08 – 0.10 cmol/kg) The low to medium level of exchangeable bases (Ca, Mg and K) could be as a result of pedogenic process occurring in the soils (Obi et al, 2001) and the continuous cropping system and leaching and the origin (parent materials from where the soils were formed Peter et al, (2022b). Pedon 1 and 2 had high percent base saturation (87.68 – 94.69 %).

Soil Classification

The soils of the study area were classified according to the latest criteria laid down in key to Soil Taxonomy (USDA) Soil Taxonomy/Soil Survey Staff (2014) and FAO/ISIC/IUSS World Reference Base for Soil Resources (2014). Based on the morphological, physical and chemical properties the soils were classified at Order, Suborder, Great group and Subgroup level. Pedons 1 and 2 showed the development of colour and structural weak appearance of cambic B-horizons produced by soil forming factors and showed no evidence of accumulation clay, iron oxide, aluminum oxide or organic matter in sub-soils and they also have no distinct pedogenic diagnostic horizon, rather they possessed a cambic subsurface horizon with base saturation < 50% (by NH4OAc) in soil horizon thus fell under the inceptisols**.** Based on their hyperthermic soil temperature and udic moisture regime as a result of seasonal dryness for at least 90 days or more water cumulative days per year, they were placed under the Udepts suborder. The base saturation by NHOAc of 60 % or more in one or more horizons at a depth of 25 – 75 cm from the mineral soil surface qualified both pedon 1 and 2 into the Eutrudepts Great group. Pedon 1 and 2 also fits into Typic Dystrudept subgroup, this is because, they are moderately drained, and are not saturated with in any layer within 100cm of the mineral soil surface for 20 or more consecutive days or 30 or more cumulative days in normal years and do not have an ochric, kandic and or argillic horizons with regular decrease in soil organic carbon content. Using World Reference Base (FAO/ISIC/IUSS) (2014), both pedon 1 and 2 corresponds to Haplic Ferralic Cambisol

CONCLUSION

The soils of the Teaching and Research Farm had been under intensive crop cultivation due to an increasing student's population and urbanization pressure worldwide on land resources and, also there is need to increase crops cultivation to provide food for the teaming population. To achieve this task, it is imperative to obtain detailed and reliable information on the types of land resources (soils) in an area and their suitability. These soils of Teaching and Research Farm, Rivers State University are largely Inceptisols/Cambisols and these soils could be sustained for reasonable agricultural productivity. However, they require careful management to ameliorate acidity and nutrient deficiencies.

56th Annual Conference
Agricultural Society of Nigeria
24 - 28 Oct., 2022

ABSTRACT

Coffee production has contributed greatly to the economy and sustenance of livelihood. Therefore, suitability assessment of soils for its production cannot be overemphasized. Three mapping units were identified in the study area and one pedon established on each. Soil samples collected from each genetic horizon were analyzed for their physical and chemical properties. The result showed that the soils were sandy in texture, ranging in sand content from 492.0 to 852.0 g/kg, clay content ranged from 54.0 to 314.0 g/kg and silt content from 94.0 to 194.0 g/kg. The soils were slightly acidic (5.15 to 5.42). Soil organic carbon ranged from 1.20 to 16.20 g/kg. Nitrogen, Phosphorus and Potassium content of the soils ranged from 0.2 to 1.3 g/kg, 2.36 to 21.04 mg/kg and 0.09 to 0.33 cmol/kg respectively. The exchangeable content of calcium and magnesium ranged from 1.00 to 1.66 and 0.11 to 0.36 cmol/kg. The land use potentials for coffee was assessed using square root method (parametric method) of land suitability evaluation according to FAO framework. The result shows that the aggregate rating for both current (actual) and potential suitability are the same. The most suitable class (S1) was obtained at the lower slope while upper and middle slope were moderately suitable (S2). However, with proper fertility management, the soils would be highy suitable for *coffea robusta* production.
Keywords: soils, suitability assessment, coffee production

INTRODUCTION

Soil is an essential natural resource which is germane in plant and animal growth, therefore needs to be treasured. Land evaluation is the process of assessing the possible use of land for agriculture, forestry, engineering, industry, conservation and recreation purpose. It is the assessment of land for a specific type of land utilization such as rainfed farming, extensive grazing, irrigation and agriculture (Oluwatosin, 2005). It is essential to know appropriate areas for agricultural practices in order to improve crop production. Through this, land can be apportioned in terms of suitability for a specific purpose to facilitate for effective land use management and planning systems. Soil information gathered by systematic identification, grouping and delineation of various soils is therefore necessary when good interpretations towards land use potential are to be made (Balthaza *et al.*, 2003).

Coffee is one of the essential cash crops being exported. It is a source of income to farmers and a foreign exchange earner. It is also a source of industrial raw material and creates job opportunity for millions of people. Coffee is a perennial crop, which is productive for several years. It belongs to genus *Coffea* which is a member of the family Rubiaceae. Global annual consumption of coffee per capital is 4-5 kg on average (International Institute of Tropical Agriculture, 2021). International coffee organization (ICO) stated that about 1.4 billion cups of coffee is being consumed daily worldwide, while about 125 million people depend on coffee for their livelihood (Osorio, 2002). The first two types of coffee to be cultivated originated in Africa and they are *Coffea arabica* and *Coffea canephora* (*Coffea robusta*) (Negussie and Derese 2007). *Coffea arabica* which is cultivated on highland tropical and sub-tropical area, performs best at higher altitude and has lower caffeine content. The higher yielding robusta can be grown at sea level (lowland areas) and is generally used in instant coffee and in stronger roasts. Davis *et al.,* (2006) stated that *Coffea robusta* is extensively distributed, from West to East Africa in Ghana, Guinea, Guinea Bissau, Cote d'Ivoire, Liberia, Nigeria, Cameroon, Congo, Central African Republic, Democratic Republic of Congo, Gabon, Sudan, South Sudan, Tanzania, and Uganda and to the south of Angola.

Deficiency and imbalance of soil nutrients are one of the major constraints to production of crops in Nigeria. Little attention has been given to the suitability assessment of soils for coffee production. Therefore, assessment of soils in Nigeria to increase crop production is very essential. Hence, the need for this study. The objectives of this study is to evaluate the nutrient status of the soils and assess their suitability for *Coffea robusta* production.

MATERIALS AND METHODS

The study was carried out in Epe Local Government area of Lagos state, Nigeria. The location has a humid tropical climate characterized by distinct wet and dry seasons. The total annual rainfall based on 11 years climatic data was about 1800 mm (2010-2020), relative humidity was 86.58%, predominant annual wind direction was 226.43^o, while the mean annual temperature was 31^{o}C (NASA, 2020). Three mapping units (EP1, EP2 and EP3) were identified and representative pedons were established in each mapping unit. Geographical location of each pedon was recorded using GPS as follows: EP1 (Latitude 6°38′16.6″N and longitude 3°54′48.2″E), EP2 (Latitude 6°38′15.8″N and Longitude 3°54′52.0″E), and EP3 (Latitude 6°38′14.6″N and Longitude 3°54′53.9″E). The pedons were described according to FAO/UNESCO (2006) procedure. Bulk soil samples were collected from different genetic horizons identified within the pedons. The samples were analyzed for sand, silt, clay, pH (H_2O), total N, organic carbon (OC), available P, exchangeable K, Ca, Mg, Na, and percent base saturation using standard procedures. Using the method of Sys *et al.*, 1993, suitability of the soils for coffee production was assessed using parametric approach. Each pedon was assigned to suitability classes by matching their characteristics with the requirements for coffee production. Each feature was ranked using Square root method equation: $IP = A \times \sqrt{((B/100) \times (C/100) \times \ldots \times (F/100))}$. where; IP is the index of productivity, A is the overall lowest characteristic rating and B, C…F are the lowest characteristic ratings for each land quality group (Udoh *et al.*, 2006). Current and potential index of production for each pedon was calculated. In each pedon, only one member of each of the five land quality groups (climate(c), topography (t), wetness (w), soil physical characteristics(s) and fertility (f)) were used in the calculation because there were strong correlations among members of the same group (Ogunkunle 1993).

RESULT AND DISCUSSION

Morphological and physical properties of the soils

Generally, soil depth of the three mapping unit were moderate (92 – 110 cm) and well developed as evidenced by the presence of B (Argillic/Kandic) horizons with high base saturation (BS≥35%), which are characteristics of the Alfisols. Mapping unit EP1 was located at the upper slope with an elevation of 51 m while EP2 was located at the middle slope with an elevation of 3 m and EP3 located at the lower slope with an elevation of 21 m above sea level. The horizon boundaries were clear to gradual in distinctness and smooth to wavy in topography. The colour ranged from brown to reddish yellow in mapping unit EP1, reddish gray to pinkish gray in mapping unit EP2, while mapping unit EP3 varied from brown to light brown. The soil colour seems to be the function of chemical and mineralogical composition as well as textural make up of soils and conditioned by topographic position and moisture regime (Walia and Rao, 1997). The textural class of the soils ranged from loamy sand to sandy clay loam. Sand dominated the particle size distribution of the study area, this could be due to geological processes involving sorting of soil materials by biological activities, clay migration through eluviation and illuviation, or surface erosion by run off (Malgwi *et al.*, 2000). The sand content ranged from 492.0 to 852.0 g/kg; the silt content ranged from 94.0 to 194.0 g/kg while clay content varied from 54.0 to 314.0 g/kg. Its distribution in all the pedons was irregular.

Chemical properties of the soils

The soil pH of the soils in water was rated slightly acidic with pH ranging from 5.15 to 5.42. The pH range of 5.5 to 7.0 was established by Brady and Weil (2010) as optimum for overall satisfactory availability of plant nutrients. Organic carbon content decreased with increasing soil depth and ranged from 1.20 to 16.20 g/kg. The values were rated low irrespective of soil depth since the values were below the critical value of 30 g/kg suitable for ideal coffee production (Egbe *et al.*, 1989). Thus, management of organic matter for nutrient retention and for better aggregation to reduce susceptibility to runoff and erosion is required for sustainable production.

Nitrogen is an essential structural component of various compounds that are important for plant growth and development (Agbede, 2009). It is also important for carbohydrate utilization, growth and development. Total nitrogen content (0.2 to 1.3 g/kg) was moderate at the soil surface, the values were above the critical level of 0.9 g/kg Phosphorus (P) is a vital element in the establishment of new plantations due to its importance in cell division and root development (Akande *et al*., 2008). P (2.36 – 18.27 mg/kg) content of the soils was adequate for ideal coffee production. Its values were above the critical level of 6 mg/kg. Potassium (K) is necessary for formation and translocation of carbohydrates, cell division, regulation of osmosis or control of water in the plants and increases the resistance of some plants to certain diseases and insects attack as well as activator of various enzymatic systems (Ibiremo and Akanbi, 2015). Magnesium (Mg) is a major constituent of chlorophyll, it helps in seed germination, essential for photosynthesis and produces energy for the plants. Potassium (0.09 – 0.33 cmol/kg), Mg (0.11 – 0.36 cmol/kg) and Calcium (1.00 – 1.66 cmol/kg) were rated low, the values are below the critical value of 4, 8 and 8.9 cmol/kg respectively, for soils suitable for coffee (Egbe *et al*., 1989). Therefore, K, Mg and Ca based fertilizer should be applied on the studied soils for optimum production. Base saturation in the three pedons were rated high. Food and Agricultural Organization (1999) stated that soils with base saturation of >50 % are regarded as fertile soils, while soils with <50% are infertile. The exchangeable acidity (0.8 – 0.12 cmol/kg) inferred that acidity may not be a threat in the study area.

Suitability classes

Table 1 shows land use requirement for *Coffea robusta*, while Table 2 shows the assessment ratings resulting from matching land qualities with the properties of the soils. A land index was calculated from the individual ratings using the square root method (Sys *et al.*, 1993). The result shows that the aggregate rating for both current (actual) and potential suitability fell within the same suitability class (S2). The soils were placed at moderate to high suitability class for *Coffea robusta* production in the area.

Table 1: Land suitability requirements for *Coffea robusta* production

Parameter	**Suitability classes**				
	S1(100%)	S2 (85%)	S3 (60%)	N1 (40%)	N2 (20%)
Climate (C)					
Annual rainfall (mm)	1,600-2,400	1,400-2,400	>1,200	__	any
Mean annual temperature (°C)	>22	>20	>18	__	<18
Relative humidity (%)	45-80	35-90	30-100	__	any

Flooding		100(S1)	100(S1)	100(S1)
Physical Properties (S)				
Texture		60(S3)	100(S1)	85(S2)
Soil depth	(cm)	60(S3)	60(S3)	85(S2)
Coarse fragment	%	100(S1)	100(S1)	100(S1)
Fertility Characteristics (F)				
Soil organic carbon (top soil)	%	100(S1)	100(S1)	100(S1)
Base saturation (top soil)	%	100(S1)	100(S1)	100(S1)
Aggregate suitability (actual)		**55(S2)**	**55(S2)**	**78(S1)**
Aggregate suitability(potential)		**71(S2)**	**71(S2)**	**85(S1)**

CONCLUSION

Current and potential suitability rating were similar. Pedon EP1 and EP2 were moderately suitable for *Coffea robusta* production, while pedon EP3 was highly suitable. Proper soil fertility management is required for the potentials of these moderately suitable soils to be raised to highly suitable class. Soil fertility of the soils should therefore be improved through good management practices such as incorporation of organic and inorganic fertilizers.

ABSTRACT

Achieving food security for a rapidly growing population in Nigeria requires not only the intensification of food crops production on the existing cropland but also the use of sustainable agronomic practices, including appropriate cropping systems and soil fertility management strategies. In an attempt to achieve this, this experiment was conductedat the Teaching and Research Farm of Akanu Ibiam Federal Polytechnic, Unwana, Ebonyi State during 2015, 2016 and 2017 cropping seasons, to determine the effect of moringa based intercropping systems on organic matter distribution and nutrients release to growing crops.Randomized Complete Block Design (RCBD) with eleven treatments, comprising of sole and different intercropping systems of moringa (Mo) with maize (Ma), cassava (Ca) and sweet potato (Sp), each with three replications was used for the study. Pre-planting from the whole field and post-harvest soil samples from each treatment plot were obtained and analyzed in the laboratory for organic carbon and organic matter composition. Yield parameters including weights of cassava and sweet potato tubers, seed weight of maze and fresh leaf weight of moringa were obtained for each cropping season. All data collected were subjected to statistical analysis. Results showed significant ($P<0.05$) improvement on soil organic carbon and organic matter due to the inclusion of moringa in cassava, maize and sweet potato cropping systems and the increases were consistent with intercropping intensification and farming season. Thus, the treatment plot with Mo + Ca + Ma +Sp in the 2017 farming season gave the most appreciable increase in organic matter and organic carbon (5.03% and 4.08% respectively). However, yield components of the intercropped crops were not proportionally influenced with the intensification of moringa based intercropping systems. Sole cropping system for each crop had better yield than in the moringa based intercropping systems.

Keywords: Intercropping, Organic matter, Moringa, Cassava, Maize and Sweet potato.

INTRODUCTION

Nigeria still struggles on the path to food sufficiency despite several Government Agro-programmes and interventions.Attaining food sufficiency in Nigeria may remain a mirage without proper and sustainable cropping systems and soil management strategies. The soil is central to food production and healthy soils are essential to optimum crop productivity and food security. Widespread deficiencies in crop nutrients have been reported in most acid tropical soils of southeastern Nigeria (Azu *et al.*, 2019; Onwuka *et al.*, 2007). This has been attributed to partly the heavy tropical rains and poor agronomic and soil management practices (Osodeke, 1996). Therefore, understanding of soil nutrient dynamics and the formulation and adoption of viable and sustainable agronomic and soil management options is very crucial on the path to food security in southeastern Nigeria (Azu *et al.*, 2020).

Soil organic matter (SOM) and soil organic carbon (SOC) are the most important indicators of soil quality and productivity(Brady and Weil, 2008). Soil organic matter is byproducts of plants and animals and the remains of dead plants, animals and microorganisms. They play essential roles in the soil system including the biological, chemical and physical components of the soil (Brady and Weil. 2008). Mineralized organic matter apart from enhancing the biological and physical conditions of the soil, releases other essential nutrients to the soil. Maintaining organic matter in soil at optimum levels is important for soil fertility and productivity. Conservation agriculture which encompasses a range of such good practices through combining no tillage or minimum tillage with a protective crop cover and crop rotations and organic manure application are ways of improving soil organic matter (Farguharson *et al*, 2003; King *et al*, 2020). However, many common agricultural practices, especially ploughing, disc-tillage, vegetation burning, use of mineral fertilizer and other synthetic agro-inputs and intensification of cropping causes decline in soil organic matter, because the soil is exploited for crop production without restoring the organic matter and nutrient contents and maintaining a good structure, the nutrient cycles are broken, soil fertility declines and the balance in the agro-ecosystem is destroyed (Loveland and Webb, 2003; Bot and Beniter, 2005). Intensive farming through repetitive harvesting of crops, improper use of mineral inputs and inadequate effort to replenish organic matter to restore soil quality, distorts the natural soil processes including nutrient cycling, release and uptake by plants(Azu et al., 2008). Therefore, to ensure sustainability in crop production, there is urgent need to rebuild soil quality and health through appropriate farming systems that are sustainable, environmentally friendly, economically viable and productive. Against this background, this research work was designed to assess the effect of moringa based intercropping systems on t soil organic matter, organic carbon distribution and crop yield in Southeast Nigeria.

MATERIALS AND METHODS

The study was conducted at the Teaching and Research Farm of the Department of Horticulture and Landscape Technology, Akanu Ibiam Federal Polytechnic; Unwana, Ebonyi State, Nigeria(Lat. $05^0 20^1$N, Long. $07^0 02^1$E,Altitude 91m above sea level) during 2015, 2016 and 2017 cropping seasons. The area has annual rainfall range between 1500 – 3000mm, average temperature of $35^0$and relative humidity of 89 – 93%. The soil belongs to the order ultisol and has been classified as typic hapludult (Federal Department of Agriculture and land Resources 1985). The dominant vegetation is tropical rainforest that is tending towards derived savanna (Azu *et al.*, 2018). The experimental site had been left fallow for one year. Pre-planting soil samples taken at 0-20cm randomly from site was analyzed in the laboratory for organic matter and organic carbon according to standard methods.

A Randomized Complete Block Design (RCBD) with three blocks was used for the study. The experiment covered a total land area of0.102ha. Each block consisted of 11 plots measured 5m x 4m in area with spacing of 1.0m between plots and 2.0m between blocks. Eleven (11) treatments in total comprising of Mo, Ca, Ma, Sp, Mo +Ma,Mo + Ca, Mo + Sp, Mo + Ca + Ma, Mo + Ca + Sp, Mo + Ma + Sp and Mo + Ca + Ma + Sp.

Pre soil samples at 0 – 20cm depth were randomly taken at 4 points of the site after clearing, and the samples were bulked together for analysis. However, post composite soil samples were also collected on the site to determine the percentage of organic matter and organic carbon. Before planting, seed viability test on Moringa and maize was done and the seeds were planted 3 per hole at a distance of 1m × 1m at a depth of 3cm. On emergence, the seedlings were thinned down to 1 plant/stand and the thinned down seedlings were used as mulch materials. Cassava and Sweet potato stems and vines were cut at 25cm long with at least 5 nodes, and were planted at 1m × 1m apart, respectively. At harvest, yield data comprising of weight of cassava and potato tubers, weight of maize seeds and fresh weight of moringa leaf were measured. Also, post-harvest soil samples from each plot were taken and analyzed for organic matter and organic carbon according to Walkley and Black (1964) as modified by Udo *et al*., (2009). All data collected were subjected to statistical analysis of variance (ANOVA) as described by Akindele (2004).

RESULTS AND DISCUSSION

Organic Matter (%) and Organic Carbon (%) Composition of the Site before Planting at 2015, 2016 and 2017 Cropping Seasons is presented in table 1.Results showed that organic carbon and organic matter were relatively low prior the 2015 cropping season (0.90 and 1.62% respectively).

Table 1: **Organic Matter (%) and Organic Carbon (%) Composition of the Site before Planting at 2015, 2016 and 2017 Cropping Seasons**

Cropping Year	Organic matter (%)	Organic carbon (%)
2015	1.62	0.90
2016	3.27	1.94
2017	3.73	2.10

Cropping systems and climatic variables may have been responsible for this result. Osodeke and Ubah have previously reported low organic matter in acid soils of southeastern Nigeria. However, the concentration of both nutrients increased proportionally in 2016 and 2017 cropping seasons. The inclusion of moringa in the cropping system may have influenced this observed increase. Apart from the medicinal benefits of moringa, studies on moringa have shown that it has the ability of enhancing soil fertility status. Aze *et al*, (2020) and Essien *et al* (2015) had earlier reported increased soil fertility due to inclusion of moringa leaves compost in soil fertility management, leading to increased crop yield.

Results showed significant ($P<0.05$) improvement on soil organic carbon and organic matter due to the moringa cassava, maize and sweet potato intercropping systems and the increases were consistent with intercropping intensification and farming season (Table 2). Sole cropping treatment systems (SMo, SCa, SMa, SSp) produced the lowest values for organic matter and organic carbon. Thus, the treatment plot with Mo + Ca + Ma +Sp in the 2017 farming season gave the most appreciable increase in organic matter and organic carbon (5.03% and 4.08% respectively).

Table 2: Effect of Moringa Based Intercropping Systems on Organic Matter (%) and Organic Carbon (%) Composition during 2015, 2016 and 2017 Cropping Seasons

	2015	2016	2017	2015	2016	2017
Treatments	Organic matter (%)			Organic carbon (%)		
SMo	1.43	1.87	2.40	0.70	1.84	1.96
SCa	1.52	1.70	2.38	0.45	1.63	1.60
SMa	1.31	1.60	2.34	0.15	1.45	1.57
SSp	1.20	1.32	2.27	0.10	1.40	1.43
Mo + Ma	2.13	3.33	4.80	1.08	1.96	2.10
Mo + Ca	2.73	4.45	5.60	1.18	2.00	2.34
Mo + Sp	2.45	3.21	4.33	1.04	1.87	2.20
Mo + Ca + Ma	3.23	3.53	4.68	1.28	2.35	3.06

Mo + Ma + Sp	3.33	3.56	4.94	1.23	2.01	3.00
Mo + Ca + Ma + Sp	4.51	4.88	5.03	1.84	2.45	4.08
LSD (P≤ 0.05)	0.05	0.16	0.56	ns	0.02	1.23

SMo = sole moringa, SCa = sole cassava, SMa = sole maize, SSp = sole sweet potato, Mo = moringa, Ca = cassava, Ma = maize, Sp = sweet potato

The increase in organic matter and organic carbon in 2016 and 2017 cropping seasons with intercropping intensification could be an indication that within the period of cultivation, the litter falls from moringa and other crop leaves had decomposed to enrich the soils with organic matter (Brady and Weil, 2000).

The effect of moringa based intercropping systems on yield of moringa, maize, cassava and sweet potato is shown in table 3. Apart from yield of moringa in 2015 and 2017 cropping seasons, the yield of the crops both in sole cropping and intercropping systems, irrespective of the cropping season were statistically ($P<0.05$) influenced by the intercropping system. However, yield components of the intercropped crops were not proportionally influenced with the intensification of moringa based intercropping. Sole cropping system for each crop had better yield than in the moringa based intercropping systems. This result indicated that organic matter and organic carbon were not proportional to yield. The slow mineralization of organic matter to release nutrients mostly in the intercropped plots and the possibility of nutrient competition in the intercropped plots may have influenced this result. However, this suggests the possibility of potential residual nutrient effect for next crops. Azu.*et al.*, (2020), previously reported residual effects of moringa compost on soil organic matter.

CONCLUSION

Appropriate cropping systems provide useful index in soil quality management and sustainable crop production. Moringa based intercropping system improved the organic matter and organic carbon contents of soil. Sole cropping system for each crop had better yield than in the moringa based intercropping systems. Apart from promoting yields of sole cropping system, these intercropping systems have the potential of giving the soils long lasting fertility effects for sustainable crop production.

ABSTRACT

Bio-fertilizer is a component that carries living microorganisms that used into the soil as inoculants to provide certain nutrients for plants. This review portrays the role of bio-fertilizers in sustainable agriculture through meeting the needs of farmers and plant biologists whose work concentrate on creating clean and efficient means of improving soil quality by nourishing and maintaining the useful and natural flora of microorganisms. It shows the alternative use of fertilizer made from animal source in the field of agricultural management which exposes the potentials of the application in terms of increased nutrient profiles, plant growth and productivity as well as an improved tolerance to environmental stress. In view of these, this paper used analytical approach to review the term “bio-fertilizer,” Types of Bio-Fertilizers and their mode of work, differences between bio-Fertilizer and organic fertilizer, benefits of bio-fertilizer over chemical fertilizers and constraints to adoption of bio-fertilizer among farmers.

Keywords: Bio-fertilizer, agriculture,sustainability, environment, crops,farmer

INTRODUCTION

Agriculture has undergone series of advancement since the 12th century and is being practiced extensively throughout the world today. According to Food and Agricultural Development, 55% of people in Africa can earn a living through agriculture(Itelima , Bang, Onyimba, and egbere,2018). In Nigeria, agriculture is the basic means of livelihood for people in most areas especially the rural areas (Udemezue, Mmeremikwu, and Eluagu, 2021). Soil management strategies today are mainly relied on inorganic chemical-based fertilizers, which cause a serious problem to human health and the environment. Plants nutrients are essential for the production of crops and healthy food for the world’s ever increasing population. Biofertilizer has been identified as an alternative for increasing soil fertility and crop production in sustainable farming. The exploitation of beneficial microbes as bio-fertilizers has been important in agricultural sector due to their potential role in food safety and sustainable crop production(itelima,*et al*,2018; Udemezue, Mmeremikwu, and Eluagu, 2021).

Organic farming is one of such strategies that not only ensures food safety but also adds to biodiversity of soil (Raja,2013). The application of bio-fertilizer to the soil increases the biodiversity which constitutes all kinds of useful bacteria and fungi including the arbuscular mycorrhiza fungi (AMF) called plant growth promoting rhizobacteria (PGPR) and nitrogen fixers. There are so many microorganisms thriving in the soil, especially in the rhizosphere of plant(Udemezue, Mmeremikwu, and Eluagu, 2021).

With the current fall in price of crude oil which, today is Nigeria's major source of income; the President of Nigeria, Muhammadu Buhari GCFR emphasized that the nation must go back to agriculture, particularly crop farming which used to be the country's source of income before the discovery of crude oil . To get food to feed Nigeria's teaming population which according to Nigerian population census (2006) is expected to rise to 221 million by the year 2020, there is need for very fertile soils, for sustainable crop production(Itelima,*et al*,2018).

Agriculture plays an important role in meeting the food security of a growing human population, which has led to an increasing dependence on the use of chemical fertilizers and pesticides for increased productivity (Santos, Araujo, Leite ,2012)). Chemical fertilizers are industrially made substances which are composed of known quantities of nitrogen, phosphorus and potassium. The use of chemical fertilizers causes air and ground water pollution as a result of eutrophication of water bodies (Youssef and Eissa ,2014). According to Chun-Li, Shiuan-Yuh and ChiuChung (2014), though the practice of using chemical fertilizers and pesticides boosts soil acidification, it also poses the risk of contaminating ground water and the atmosphere. It also weakens the roots of plants thereby making them to be susceptible to unwanted diseases. As a matter of this, attempts have recently been made towards the production of nutrient rich high quality fertilizer (Bio-fertilizer) to ensure bio-safety. Therefore, Bio-fertilizer has been identified as an alternative to chemical fertilizer to increase soil fertility and crop production in sustainable farming. These potential biological fertilizers would play the key role in productivity and sustainability of soil and also protect the environment as ecofriendly and cost effective inputs for the farmers (Khosro and Yousef,2012).

Biofertilizers keep the soil environment rich in all kinds of macro and micro nutrients via nitrogen fixation, phosphate and potassium solubilisation or mineralization, release of plant growth regulating substances, production of antibiotics and biodegradation of organic matter in the soil(Sinha, Valani and Chauhan,2014). Biofertilizers, when applied as seed or soil inoculants, multiply and participate in nutrient cycling and leads to crop productivity. Generally, 60% to 90% of the total applied fertilizer is lost and the remaining 10% - 40% is taken up by plants. Hence biofertilizers can be important component of integrated nutrient management systems for to sustaining agricultural productivity and a healthy environment (Adesemoye and Kloepper,2009;Sinha, Valani and Chauhan,2014;Udemezue,Mmeremikwu and Eluagu,2021).

Concept of bio-fertilizer

Biological activities are markedly increased by microbial interactions in the rhizosphere of plants. Organic fertilizers on the other hand are obtained from animal sources such as animal manure or plant sources like green manure. According to Khosro and Yousef(2012), the term bio-fertilizer may be used to include all organic resources for plant growth which are provided in available form for plant absorption through microorganisms or plant associations or interactions. Bio-fertilizer is simply a substance which contains living microorganisms which when applied to the soil; a seed or plant surface colonizes the rhizosphere and promotes growth by increasing the supply or availability of nutrients to the host plant(Raja,2013). It is a modernized form of organic fertilizer into which beneficial microorganisms have been incorporated (Udemezue, Mmeremikwu, and Eluagu, 2021). Bio-fertilizer is most commonly referred to as selected strains of beneficial soil microorganisms cultured in the laboratory and packed in suitable carriers.

Therefore bio-fertilizers are those substances that contain micro-organisms' living or cells that increase the nutrients of the host plant when applied to their seeds, plant surfaces or soil by colonizing the rhizospher of the plant. They can be explained as formulations containing either living or latent cells of efficient strains of microorganisms that facilitate the uptake of nutrients from crop plants. They carry out this pivotal role through interactions in the plant rhizosphere when applied through seed or soil. Microorganisms that commonly used as bio-fertilizer components are; nitrogen fixers (N-fixer), potassium and phosphorus solubilizers, growth promoting rhizobacteria (PGPRs), endo and ecto mycorrhizal fungi, cyanobacteria and other useful microscopic organisms. These potential biological fertilizers would play a key role in productivity and sustainability of soil and also in protecting the environment as eco-friendly and cost effective inputs for the farmers (Itelima,*et al*,2018). In view of these, this study used available literature to review the economic analysis of bio-fertilizer as an alternative use by the rural farmers.

.

Types of Bio-Fertilizers and their mode of work

According to Itelima,*et al* (2018), Bio-fertilizers are classified into different types depending on the type or group of microorganisms they contain. They as follows:

Nitrogen fixing bio-fertilizers (NFB): Examples include Rhizobium Spp., *Azospirillum* Spp. and blue-green algae; these work by fixing atmospheric nitrogen and converting them to organic (plant usable) forms in the soil and root nodules of legumes, thereby making them available to plants. Nitrogen fixing bio-fertilizers are crop specific bio-fertlilizers.

➢ **Phosphate solubilizing bio-fertilizer (PSB):** Examples include *Bacillus* Spp., *Pseudomoona* Spp. and *Aspergillus* Spp. These work by solubilizing the insoluble forms of phosphate in the soil, so that plants can use them. Phosphorus in the soil occurs mostly as insoluble phosphate which cannot be absorbed by plants. However, several soil bacteria and fungi possess the ability to convert these insoluble phosphates to their soluble forms. These organisms accomplish this by secreting organic acids which lower the pH of the soil and cause the dissolution of bound forms of phosphate making them available to plants (Itelima,*et al*,2018).

- **Phosphate mobilizing bio-fertilizers (PMB):** Examples are *Mycorrhiza*. They work by scavenging phosphates from soil layers and mobilizing the insoluble phosphorus in the soil to which they are applied. Chang and Yang, (2014) stated that phosphorus solubilizing biofertilizer (PSB) sometimes act as phosphate mobilizers. Phosphate mobilizing bio-fertilizers are broad spectrum bio-fertilizers. Soil phosphorus mobilization and immobilization by bacteria.

- **Plant growth promoting bio-fertilizer (PGPB):** Examples of plant growth rhizobacteria are *Pseudomonas* Spp. etc: these work by producing hormones and anti-metabolites which promotes root growth, decomposition of organic matter which help in mineralization of the soil thereby increasing availability of nutrients and improving crop yield(Khosro and Yousef,2012; Bhattacharyya ,and Jha ,2012;Itelima,*et al*,2018). PGPB are crop specific bio-fertilizers.

- **Potassium solubilizing bio-fertilizer (KSB):** Examples include *Bacillus* Spp. and *Aspergillus niger*. Potassium in the soil occurs mostly as silicate minerals which are inaccessible to plants. These minerals are made available only when they are slowly weathered or solubilized. Potassium solubilizing microorganisms solubilize silicates by producing organic acids which cause the decomposition of silicates and helps in the removal of metal ions thereby making them available to plants. Potassium solubilizing bio-fertilizers are broad spectrum bio-fertilizers.

- **Potassium mobilizing bio-fertilizer (KMB):** Example of potassium mobilizing bio-fertilizer is *Bacillus* Spp. These work by mobilizing the inaccessible forms of potassium (silicates) in the soil. Some phosphate solubilizing bio-fertilizers such as *Bacillus* Spp. and *Aspergillus* Spp. has been found to mobilize potassium and also solubilize phosphorus.

- **Sulfur oxidizing bio-fertilizer (SOB):** Example of sulfur oxidizing microorganism is *Thiobacillus* Spp. These work by oxidizing sulfur to sulfates which are usable by plants.

Differences between Bio-Fertilizer and Organic Fertilizer

The term bio-fertilizer was used to include organic fertilizer.Technically; there is a big difference between them. Vishal and Abhishek(2014) in an attempt to distinguish between bio-fertilizer and organic fertilizer said “bio-fertilizers are microbial inoculants consisting of living cells of microorganisms like bacteria, algae, fungi, alone or a combination which may help in increasing crop productivity. Biological activities are markedly enhanced by microbial interactions in the rhizosphere of plants. Organic fertilizers on the other hand are obtained from animal sources such as animal manure or plant sources like green manure(Udemezue, Mmeremikwu, and Eluagu, 2021).

Benefits of bio-fertilizer over chemical fertilizers

The people's demand for fertilizer has greatly increased in the past few decades. According to Fertilizer Suppliers Association of Nigeria (FESPAN) (2007), Nigeria's fertilizer demand is estimated to be 12 million metric tons per annum. The use of inorganic fertilizers has been popularized in Nigeria and throughout the world because they are easily affordable and have the advantage of fast action due to their prompt release of nutrients. Despite this, there have been many findings on the demerits of inorganic fertilizers and these have indicated that they have disadvantages which cannot be overlooked. Most of the problems associated with harvested crops and some of the pollution of our natural environment occurred as a result of inorganic fertilizer use (Rosen and Horgan,2009;Itelima *et al*,2018). All the fertilizers used in Nigeria are imported and due to the high cost of importation, the price of the fertilizers becomes very high, thereby preventing resource poor farmers from accessing it. On the other hand, inorganic fertilizers when applied incorrectly, excessively and inadequately have negative effects. Many of the fertilizers imported into the country were wasted as farmers refused to purchase them due high cost and constraints associated with it(Itelima, et al,2018). However,different types of fertilizers are suitable for different soil types. To get fertilizers which will suit a particular soil, the soil needs to be analyzed. According to him, most of the fertilizers imported into the country are not suitable for our soil thereby giving negative rather than positive results; besides one requires a good knowledge before applying it but today, every illiterate farmer applies fertilizers without understanding how it works and its side effects. All these problems can however be avoided by the use of indigenous fertilizers which is environment friendly. These findings have led to the need for the provision of an environment friendly fertilizer known as bio-fertilizer. According to Itelima et al (Itelima *et al*,2018), yam farmers complained that the fertilizers were responsible for the early decay of harvested yam tubers. It is of no doubt that crops cultivated with inorganic fertilizers have fewer flavors, taste, and aroma than those cultivated without inorganic fertilizers. Excessive fertilizer application leads to salt burn and in most cases leads to the death of young plants(Laboski,2008; Itelima *et al*,2018). Due to they are non-biodegradable, long term use of inorganic fertilizers result in accumulation of harmful substances and acidification of the soil thereby causing a decrease in the fertility of the soil(Taylor, 1997;Itelima *et al*,2018).

Because of their high solubility in water, inorganic fertilizers applied to the soil could be leached deep into the soil (where plant roots cannot reach) and into underground water causing pollution. These fertilizers known as bio-fertilizers can achieve all that is achievable with inorganic fertilizers and even more without any side effects(Itelima *et al*,2018).Bio-fertilizers are environment friendly and do not cause pollution unlike inorganic fertilizers which often 'run off' into water bodies causing eutrophication and 'blue baby syndrome' (acquired methemoglobinemia) when the nitrate level is above 10 mg/L(Itelima *et al*,2018). The issue of excessive application does not arise in the use of bio-fertilizer and special skills are not required for its application. Bio-fertilizers have long lasting effects due to their slow nutrient release. The nutrients from biofertilizers are released to plants slowly and steadily for more than one season. As a result, long term use of bio-fertilizer leads to the buildup of nutrients in the soil thereby increasing the overall soil fertility. Moreover, bio-fertilizers have been found to help control of plant diseases such as pythium root rot, rhizoctonia root rot, chill wilt and parasitic nematode(Udemezue, Mmeremikwu, and Eluagu, 2021).Research has shown that some bio-fertilizers particularly those made with degraded tree barks and roots release chemicals that inhibit some plant pathogens. Disease control with bio-fertilizer has been attributed to four possible mechanisms: Successful competition for nutrients by beneficial microorganisms present in the fertilizer, production of antibiotics by the beneficial microorganisms, successful predation against pathogens by beneficial microorganisms, activation of disease resistant genes in plants by the microorganisms. Bio-fertilizer acts as a soil conditioner adding organic matter to the soil which helps to bind the soil particles together preventing soil eructing, desertification, and erosion while increasing the water retention capacity of the soil(Leaungvutiviroj,Ruangphisarn, Hansanimitkul ,Shinkawa and Sasaki,2010; Udemezue, Mmeremikwu, and Eluagu, 2021). It enriches the soil with beneficial microorganisms while boosting the already existing ones unlike chemical inorganic fertilizers which acidify the soil making it hard for microorganisms to survive(Leaungvutiviroj *et al*,2010). Bio-fertilizers contain a wide range of nutrients which are often absent in inorganic fertilizers (these include trace elements). Studies have shown that application of nitrogen fertilizer in some weather conditions cause emission of nitrous oxide which has a global warming effect potential 296 higher times than that of an equal mass of carbon dioxide (Itelima *et al*,2018;Udemezue, Mmeremikwu, and Eluagu, 2021). Methane emissions from crop fields (notably rice paddy fields) are increased by the application of ammonium based fertilizers whereas the composting of animal waste in a confined place or in an anaerobic condition (an important process in the production of bio-fertilizer), reduces the addition of methane to the atmosphere as these add methane to the atmosphere when left to decay on their own. Bio-fertilizer when compared to raw (undegraded) organic manure has the advantage of easier assimilation by plants and also the odor reduces after degradation (Swathi ,2010; Udemezue, Mmeremikwu, and Eluagu, 2021). The risk with raw organic manure is that it may contain pathogens such as Salmonella Spp. which may contaminate crops such as leafy vegetables and lead to the ingestion of the pathogen when the product is consumed. Bio-fertilizer also contains useful microorganisms which may not be present in organic (degraded) fertilizer(Khosro and Yousef,2012). These bio-fertilizers can be produced from cheap waste materials which are abundant in Nigeria and the cost of production is low compared to inorganic fertilizers which required high energy (Udemezue, Mmeremikwu, and Eluagu, 2021).

Constraints to adoption of bio-fertilizer among farmers

According to Udemezue, Mmeremikwu, and Eluagu(2021) ,some of the major constraints are as follows:

Lack of regulatory acts and facilities for testing the samples: Technical tests must be carried out to verify their safety at global scale. Current research of the use of biofertilizers in different regions of the world is necessary to obtain a framework that facilitates the development of future investigations in the agricultural sector and, consequently, promote the reduction of environmental impacts associated with the continuous use of chemical fertilization.

Reduction in the population of bacteria under certain climate conditions and influence of surrounding microflora and fauna: On application of bio-fertilizers to seeds, roots or soil, mobilizes the availability of nutrients through their biological activity and building up the microflorain particular and in turn the soil health in general. Their bio-efficacy is dependent on many biotic and abiotic factors of which unfavorable climate conditions such as changes in temperature and humidity can cause a decline in the bacterial populations.

Possible risks for the safety of consumers and the physicochemical and biological stability of soils: High contents of ammonia can burn the foliage and roots of plants; the presence of manure could increase the amount of weed flora. The presence of heavy metals such as mercury, chromium and lead brings a threat due to their carcinogenic potential and their capability of bio-accumulation and biomagnification in the food chain. Owing to this reason, the use of manure to fertilize soils should be well assessed.

Requirements for application: Extensive and long-term application may result in accumulation of salts, nutrients and heavy metals that could cause adverse effects on plant growth, development of soil organisms, water quality and human health. Excessive application can generate extreme levels of nitrogen, ammonia and salts that could lead to significant reduction of plant growth and problems for farmers and the soil.

Inadequate popularization of bio-fertilizers and low level of farmer acceptance: In spite of having various potential activities, bio-fertilizers have not yet gained popularity among farmers for proper adoption. There are a variety of factors affecting the adoption of bio-fertilizers by farmers. They are not aware of bio-fertilizers' usefulness in increasing crop yields sustainably. Their lack of awareness about the concentration, time and method of bio-fertilizer application; about the efficacy of bio-fertilizers compared to their familiarity with the use of conventional and tested inorganic fertilizers is a serious limitation of their widescale application. Knowing the different constraints faced by farmers in the use of bio-fertilizers, the extent of adoption of bio-fertilizers can be increased by tackling these issues and problems.

CONCLUSION

Persistence application of chemical fertilizers and pesticides has created dangerous and hazardous to human health. Based on this, attention is now moving from consuming food grown with chemical fertilizers to food grown with organic fertilizers because of the hazardous and harmful effects that these foods have in the body when consumed. Bio-fertilizers can help solve the problem of food need of the ever increasing global population. It is important to realize the importance of bio-fertilizers so as to apply it in modern agricultural practice to bring about poverty reduction and food security as well. Applications of bio-fertilizers contain beneficial microbes that promote to a large extent, crop productivity. These potential biological fertilizers play a key role in productivity and sustainability of soil and protect the environment as ecofriendly and cost effective inputs for the benefits of farmers. Using the biological and organic fertilizers, a low input system can help to achieve sustainability of farming. In view of the above,this paper analyzed the term "bio-fertilizer," Types of Bio-Fertilizers and their mode of work, Differences between Bio-Fertilizer and Organic Fertilizer, benefits of bio-fertilizer over chemical fertilizers and Constraints to adoption of bio-fertilizer among farmers.

ABSTRACT

Cola nitida is a commodity crop of economic importance at international market with great contribution to the GDP of producing countries. However, present global demand is in excess of production and studies to know the cause of the deficit is of great concern. Hence, the objective of this study was to identify and establish the importance of soil management with agronomic practices for optimum kola production in Nigeria. This investigation was carried out using secondary data from Journals and online documentations that were restricted to Nigeria since, Nigeria supplies over 50% of the world Kola nut produced. The study revealed that kola production is declining due to factors like poor soil management, old age of kola plantations, poor information dissemination on improved technologies and seedlings, lack of organized kola farmers' cooperative societies, non-vibrant Kola farmers' association and lack of good transportation system as being main issues. However, soil fertility and nutrient management was identified as one of the most essential factors that have direct impact on the yield and quality of Kola in Nigeria. The study concluded that, supplying the kola plants with the right kind and amount of nutrients was very germane to sustainable Kola production in Nigeria. Soil productivity enhancement through application of organic fertilizers/manures, inorganic fertilizers, liming and mulching were recommended for improvement of Kola production in Nigeria when the correct kola genotypes are planted.

Keyword: Economic growth, good agricultural practices, global market, kola farming, soil management

INTRODUCTION

Kola is a tropical tree crop with over 20 species, out of which, *Cola nitida* (Gbanja) and *Cola acumulata* (Abata) are the two main species cultivated in Nigeria and *Cola nitida* is the only kola of inter-regional and international trade. The consumption of *Cola acumulata* is greatly cherished by the Yoruba of south-west of Nigeria; the people of the northern and southeast Nigeria prefer the *Cola nitida* (Ojo and Ehinmowo, 2010). Pertinently, agriculture is the main occupation of the native Nigerians and its contribution to the national economy is noteworthy. In that despite the presence of oil, agriculture remains the main source of income for most Nigerians (FAO, 2020). Agriculture accounted for about 70 % of Nigeria GDP before the advent of petroleum, of which Kola nut export was a major contributor, representing about 70% of the world production. Presently, agriculture provides employment for about 35% of the populace (World Bank, 2020). Agricultural exportation monthly contribution to the foreign earnings on monthly basis improved greatly in between 2016 and 2020 with a value of N4.1billions in 2016 which rose to N25 billion by January 2017, while it was N289 billion from April 2019 – March 2020 (Ukpe, 2020), this contribution represents about 29.94% of Nigeria total GDP in the 3rd quarters of 2021 (Doris, 2022). Looking at the first 6 months of 2020 only, the value was N204.45 billion, which shows that productivity was increasing in the sector and it enables export growth. And presently, Nigeria exported agro-food items is valued at ₦162.27 billion as at 2nd quarters of 2021(NBS, 2021). The objective of this study was to identify and establish the importance of soil management with agronomic practices for optimum kola production in Nigeria.

Kola production in Nigeria

According to FAOSTAT (2015), Nigeria is the largest producer of kola nuts in the world with 132,000 metric tons (44.9% of total world production) followed by Cote D'Ivore, Cameroon, Ghana, and Sierra Leone with 82,000, 46,500, 24,000, and 8,645 metric tons respectively. According to Agbebaku et al., (2020), kola producing States in Nigeria includes Ogun, Edo, Imo, Oyo, Ebonyi, Ondo, Anambra, Osun, Kogi, Abia, Nasarawa, Niger, Ekiti, Akwa- Ibom, Delta, Cross River and Kwara states (Fig. 1). In the kola producing states, there are specialized markets for bulk kola nuts trade that are patronized by wholesale traders (middlemen) from long distance areas. The long distance traders earn the highest profits, since they are the merchants with market price monopoly. They dictate the selling prices because they have access to transport facilities and capital resources (Agbebaku et al., 2020). However, kola plantation cultivation in Nigeria is ecologically limited to the rainforest zones of the south and riverine areas as well as the fringe of the savanna region. Presently, Ogun state produces the largest amount of Kola nut in Nigeria, devoting about 65,000 hectares of land and producing over 80,000 MT of the crop in 2010/2011 (National Survey on Agricultural Exportable Commodities, 2013). Ndagi, *et al*. (2012) affirmed that there were large plantations of kola in Niger state. Nutritionally, Abolude (2004) reported proximate composition of *Cola nitida* nut as 2.3% moisture, 10.5% crude protein, 3.1% ash, 13.3% crude fat, 17.5% crude fiber, 5.3% total carbohydrate, with abundance of Na, Mg, K and P, 2.8% caffeine, 0.05% theobromine and low level of trace elements indicating that kola is of high nutritive value.

Agro-ecological and soil conditions for Kola production

Kola trees can be found at altitudes of up to 300 meters (980 feet) above sea level, in areas with deep rich soils and evenly distributed rainfall. However, it can thrive well in sandy, loamy or clay soils but does best in well-drained soil (Health benefits times, 2020). To obtain optimum production and high quality kola produce, kola plantations should not be sited on land that is not suitable. Suitable land for Kola production should have soils that are deep and well-drained (Opeke, 2005). World Agroforestry Centre (2007) opined that kola needs a hot humid climate with mean annual temperature in the range of 26 -35°C, and a mean annual rainfall of 1,200–1,800 mm. Managing and sustaining optimum soil nutrient levels is the key to maintaining a continuous kola production. Fagbami and Ogunlade (2021) reported that soil suitable for the growth of kola varied and texturally ranged from loamy sand to clay loamy soils. It was opined that suitable soil for kola should have the physical and chemical properties in the range of 65-70% sand, 14-19% silt, 15-20% clay, pH 5-6, N 0.14- 0.18%, organic carbon 1.6-2.0% as well as Carbon/Nitrogen ratio of 11:13, available P (Bray 1) 6-8mg/kg and exchangeable cation of 0.35-0.40, 0.32-0.35, 2.9-3.5 and 0.9-1.0 cmol/kg for K, Na, Ca and Mg respectively.

Uses of kola nut

Kola is important economically to a significant proportion of Nigerians who are involved in its farming, trading, industrial processing and utilization (Ndagi, *et al*., 2012). The nut has great degree of importance to the tradition and culture of the three major Nigeria ethnic groups, the Hausa, Igbo and Yoruba (Ndagi, *et al*., 2012). The nuts are cherished in many cultural activities as a sign of friendship and peace, and are consumed during reunions, meetings, ceremonies and festivals (Asogwa, *et al.*, 2006). It is the only stimulant allowed and consumed by the various religious faithful.

Industially, kola nut contains caffeine and theobromine that makes it a useful stimulan t for the production of beverages and wine and soft drinks. They are good raw materials for pharmaceutical companies for their various products due to the alkaloids and other phyto-compounds contents (Opeke, 2005). Kola nut also has its useful application in the textile industry as they contains tannin useful in dye, while the pod husks are useful in compounding organic fertilizers, and feed for ruminants, the seed coats are used for monogastric animals feed formulation (Babatunde and Hamzat, 2005). It is used as digestive aid prior to meals to stimulate gastric juice and bile production (Obeng and Brown, 2001). On job security, Adejompo (2014) reported a significant positive impact of kola nut production on poverty alleviation, employment creation, industrial development and socio-cultural values in Nigeria. Medically, it is useful for treating diarrhea, toothache, headaches, exhaustion, hunger (caffeine content makes it an effective appetite suppressant), malaria, nausea, poison antidote, tonic and stimulant (Obeng and Brown, 2001).

Constraints to kola production

The demand for kola nut is in excess of production due to several limiting factors. Soil fertility degradation and management is one of the most serious threats to kola production resulting to poor seedling establishment, reduced growth and yield, poor quality nuts and increase pest infestations. According to Fagbami and Ogunlade, (2021), continuous soil nutrients mining through yearly kola pod harvests without replacement through fertilizer applications, usually leads to serious soil degradation. This with time leads to non-sustainable kola production. Fagbami and Ogunlade (2021) reported that the average quantity of N, P and K ha^{-1} per year removed through harvest under kola cultivated soil is 130.9kg N, 10.3kg P and 138.74kg K respectively. Hence, inadequate information on the soil and its fertility status has been recognized as a major challenge to kola production. Without due consideration for the quality of the soil, to ascertain its suitability or otherwise for kola cultivation is a great concern. The use of chemical fertilizer on kola plantation had been hindered by its scarcity, high cost, incomplete nutrient supply as well as possible enhancement of soil acidity (Egbe *et al.*, 1989). Also, to propagate kola seedlings using rich top soil have become difficult due to deforestation and erosion hazards.

Adebiyi, *et al.* (2011) had reported that low kola production and productivity was attributed to low adoption of good agronomic practices on kola farms. That farmer still plant nut from their old kola trees rather than purchasing improved kola seedlings from reputable sources like Cocoa Research Institute of Nigeria (CRIN), they have poor farm maintenance with regards to proper weed, pests and diseases controls of their plantations. Further reports showed that lack of information dissemination on improved technologies, attack of fruits by wild animals; water logging, unviable kola farmers' association and poor transportation system are other challenges facing kola production in Nigeria (Ndagi, *et al.*, 2012). On regional level, land tenure system was the main constraint to large scale kola production in the South East, coupled with the soils being heavily leached and highly nutrient deficient. Generally, the long gestation period of kola trees, sterility and susceptibility to epiphytes are very germane (Asogwa, *et al.*, 2012).

Soil Fertility Management

The soils of sub-Saharan Africa and Nigeria inclusive are poor in nutrients with low organic carbon (OC), clay contents, and exchange capacity (EC) hence presently, more than 70% of African soils are infertile and or degraded due to agricultural practices, human, and animal pressure (Bationo et al., 2006). Soil fertility depletion in smallholder farms is the important biophysical root cause of declining per capita food production hence, soil fertility replenishment is considered as an investment in natural resource capital (Sanchez, *et al*., 1997). Reports had showed that order of importance of essential nutrients for kola was boron>copper>zinc>phosphorus>calcium>potassium>magnesium. Fagbami and Ogunlade, (2021) reported that the effect of different rates and sources of boron on yield of kola showed that non boron deficient trees consistently gave higher yield (nearly thrice) than the trees with boron deficiency symptoms with a marked decline in yield while, the amount of nutrient (NPK) removed from the soil in harvested kola and found that the husk and the seed coat have higher content of N, P and K than the nut and suggested that the coat could be a good source of fertilizer. The calculated amount of N, P and K removed from the soil was estimated as 130.91kg, 10.34kg and 138.74 kg respectively hence, minimum NPK fertilizer recommended for kola production was put at 131kgN, 21kg P and 139kg K ha^{-1}.

For adequate nutrient replenishment to enhance nutrient status of existing kola plantations, Adediran, *et al.* (2005) stated that effective soil characterization and assessment is needed, while the use of improved fallows planting of leguminous cover crops, efficient use and management fertilizers, adoption of low input technology involving use of organic manures supplemented with inorganic fertilizers, alley farming and bio-fertilization among others. However, it is necessary to document the soil and fertilizer resources, provide guidelines for the soil fertility management for the crop, while periodical assessment of the soils be put in place for sustainable soil management.

CONCLUSION

Soil fertility management was identified to be one of the most essential factors with direct impact on the yield and quality of Kola. Hence, appropriate nutrient replenishing methods on the soils should be used for its proper management. This will aim to prevent soil fertility depletion and guide against soil degradation which are the root causes of decline in kola productivity. This will involve effective soil characterization and assessment, efficient fertilizer use, mulching, liming, minimum land tillage and use of right cover crop at juvenile stage of cultivation. Suitability assessment of proposed sites for kola cultivation should be carried out before establishing any new kola plantation. Government should be supportive to kola farmers and other stakeholders along the kola value chain by granting soft loans, while scientist and extension agents should create needed awareness on new agronomic practices and technologies for better productivity and utilization.

ABSTRACT

The assessment of different rates of poultry manure on the growth and yield of turmeric (*Curcuma longa* L.) was conducted at the Teaching, Demonstration and Research (TDR) farm of the Department of Horticulture and Landscape Technology, Akanu Ibiam Federal Polytechnic, Unwana during the 2021 cropping season. The experiment was laid out in a Randomized Complete Block Design (RCBD) with three replications. Each replicate was made up of four (4) plots. The treatments include poultry manure at rates of 0, 4, 8 and 12 kg/bed. Evaluation on growth parameters were made at 4, 8, 12, 16, 20 and 24 weeks after planting (WAP) on plant height, number of leaves, leaf area, stem girth on each plot while yield parameters; number of rhizomes, weight, length and rhizome yield were determined at harvest. The analysis of variance (ANOVA) result shows that the application of poultry manure at 12 kg/bed significantly increased turmeric rhizome yield of 12.92 t/ha, weight 5.167 kg, length 8.97 cm, plant height, number of leaves, leaf area and stem girth. However, control plots consistently gave the least values on all the parameters assessed. Therefore, we recommend poultry manure application at 12 kg/bed for optimum production of turmeric in the study area.

Keywords: Application rates, Poultry manure, Turmeric, Yield

INTRODUCTION

Turmeric (*Curcuma longa* L.) belongs to family Zingiberaceae and is cultivated in about 19 States in Nigeria. It is a minor crop that plays significant role in the food chain supply in Nigeria (Olojede and Igbokwe, 2001). Nigeria plays a dominant role in turmeric production due to their favorable environmental condition. Turmeric serves as food colouring agent, useful in cosmetics and pharmaceuticals in treatment of various kinds of diseases (Semwal et al., 1997).

Considering the medicinal values of turmeric and the environmental problems caused by chemical fertilizer application, it is important to cultivate turmeric using organic manure (poultry manure). Poultry manure is regularly applied to many root crops for higher yield (Vanek, 2003). It supplies adequate organic matter in the soil with improvement in soil physical and chemical conditions and also enhance crop performance (Ano and Agwu, 2005). Ojeniyi (2000) reported that organic manure provides all the nutrients that are required by the plant, maintain the C:N ratio in the soil, thereby improves crop yield. Therefore, the objective of this study is to recommend the appropriate poultry manure rates required for the optimum production of turmeric in Unwana, South-eastern Nigeria.

Materials and Methods

The field experiment was conducted at the Teaching, Demonstration and Research (TDR) farm of the Department of Horticulture and Landscape Technology, Akanu Ibiam Federal Polytechnic, Unwana-Afikpo South Local Government Area in the South eastern part of Nigeria during 2021 cropping season. Unwana is located on the latitude 06^0 $05^'$N and longitude 08^o $03^'$E with an elevation of 300 m above sea level (NIMET, 2014). The climatic and vegetation types of the area are generally humid tropical rainforest with mean annual rainfall of about 3,500 m and mean daily temperature of 21^0C to 32^0C (Njoku et al., 2006). Before the commencement of the experiment, soil samples (0 to 20 cm depth) was randomly collected at the experimental site using soil auger at twelve (12) different points. The samples were bulked to produce composite samples which were air dried and sieved with 2 mm sieve. Also samples of poultry manure were subjected to chemical analysis.

The experimental site was cleared manually with cutlass and a raised bed of 2 x 2 m was made with hoe. The experiment was laid out in a Randomized Complete Block Design (RCBD) with three replications. Each replicate is made up of four (4) plots making a total of twelve (12) plots. The treatments comprised of poultry manure at the rate of 4, 8, 12 kg/bed and a control plot. Healthy turmeric rhizomes was obtained from National Root Crop Research Institute (NRCRI) Umudike, Abia State. The test crop was planted at a spacing of 50 cm x 45 cm. Decomposed poultry manure was applied two weeks after emergence at the rate of 0, 4, 8 and 12 kg/bed using band placement method. The site was weeded at interval of four weeks using cutlass and weeding hoe till harvesting period. Earthen up operation was done twenty four (24) weeks after planting (WAP).

Data were collected on plant height, number of leaves, leaf area, stem girth at 4, 8, 12, 16, 20 and 24 WAP while yield values; number of rhizomes, weight and length of rhizome were determined at harvest in each of the experimental plot. The data collected were subjected to analysis of variance (ANOVA) and the treatment means separated using Fishers Least Significant Difference at 5% level of probability as described by Obi (2012).

RESULTS

The result of the pre-planting chemical and physical properties of the soil in the experimental area is presented in Table 1. The pH was 5.80 which show that the soil slightly acidic. The soil is low in organic carbon and nitrogen. The soil of the site was classified as clay loam. The nutrient content of poultry manure is also presented in Table 1.

Table 1: Chemical Composition of Poultry Manure and Experimental plot

Elements	Poultry Manure Values	Experimental Plot
pH H_2O	7.62	5.80
Organic Carbon (g/kg)	28.22	14.30
Organic Matter (g/kg)	48.65	24.90
Nitrogen (g/kg)	4.50	1.50

Phosphorus (ppm)	2.86	7.80
Potassium (cmol/kg)	6.25	0.32
Magnesium (cmol/kg)	0.42	1.00
Calcium (cmol/kg)	5.20	3.00
Sodium (cmol/kg)	0.35	0.02
Sand	---	380
Silt	---	140
Clay	---	480

Plant Height (cm)

Poultry manure application significantly (P<0.01) increased the plant height from 4 to 24 weeks after planting (WAP) (Table 3). The taller plants (58.37cm) was obtained at 12 kg/bed manure rate at 24 WAP, followed by 8 kg/bed (50.57 cm). The plant height between 0, 4 and 8 kg/bed were statistically the same at 4, 8 and 24 WAP. Increasing poultry manure rates significantly (P<0.01) increased the plant height. The least values of plant height were consistently recorded at 0 kg/bed of manure rate.

Table 3: Plant Height (cm) of Turmeric (*Curcuma longa* L.) as affected by Poultry Manure Rates

Poultry Manure (kg)	4	8	12	16	20	24
0	8.43^{b}	12.67^{b}	17.47^{c}	24.10^{c}	31.67^{c}	42.67^{b}
4	10.67^{b}	14.33^{b}	22.43^{b}	29.00^{b}	37.00^{b}	45.3^{b}
8	11.00^{a}	16.67^{b}	23.90^{b}	29.87^{b}	38.23^{b}	50.57^{b}
12	17.33^{a}	22.50^{a}	31.10^{a}	37.80^{a}	45.83^{a}	58.37^{a}
F-LSD$_{0.05}$	3.109	5.009	4.787	5.100	5.276	6.485

Means in the same column having the same letters are not significantly (P<0.05) different using F-LSD N.S = Not Significant (P<0.05)

Number of Leaves

The difference in number of leaves per plant at 12 WAP was however not statistically significant (P<0.05). The highest number of leaves per plant of approximately 23 leaves was obtained at 12kg/bed manure rate at 24 WAP. The 0 kg/bed of manure consistently recorded the least number of leaves per plant (Table 4).

Table 4: Number of Leaves per Plant of Turmeric (*Curcuma longa* L.) as affected by Poultry Manure Rates

Poultry Manure (kg)	4	8	12	16	20	24
0	1.67^{b}	3.83^{b}	6.00^{a}	9.58^{b}	12.43^{c}	11.33^{b}
4	2.00^{b}	4.00^{b}	6.25^{a}	11.92^{b}	15.62^{b}	13.6^{b}
8	3.33^{b}	5.08^{a}	7.42^{a}	12.83^{b}	17.53^{b}	15.33^{b}
12	5.00^{a}	6.17^{a}	10.17^{a}	18.48^{a}	24.50^{a}	22.55^{a}

Means in the same column having the same letters are not significantly (P<0.05) different using F-LSD N.S = Not Significant (P<0.05)

Leaf Area (cm^2)

Increasing poultry manure rates significantly (P<0.05) increased the average leaf area per plant in turmeric from 12 WAP (Table 5). The highest leaf area per plant value of 138.3 cm^2 was obtained at 20 WAP using the poultry manure rate of 12 kg/bed. This is however, significantly (P<0.05) different from other leaf area per plant value obtained at 20 WAP. The 0 kg/bed poultry manure rate gave the lowest leaf area per plant, significantly (P<0.05) different from others throughout the period of the experiment from 12 WAP.

Table 5: Leaf Area (cm^2) of Turmeric (*Curcuma longa* L.) as affected by Poultry Manure Rates

Poultry Manure (kg)	4	8	12	16	20	24
0	7.50^a	21.80^a	37.70^b	43.80^b	43.00^b	36.20^c
4	4.60^a	17.40^a	74.20^b	86.00^b	86.50^b	87.70^b

Means in the same column having the same letters are not significantly (P<0.05) different using F-LSD N.S = Not Significant (P<0.05)

Stem Girth (cm)

Poultry manure application significantly (P<0.05) increased the stem girth from 16WAP. The highest stem girth value of 2.53cm was obtained at 20WAP using poultry manure rate of 12kg/bed, followed by 2.52cm at 24WAP. Stem girth increased as poultry manure increased from control plots to 12kg/bed across the various weeks assessed. The 0kg/bed poultry manure consistently gave the least values across board (Table 6).

Table 6: Stem Girth (cm) of Turmeric (*Curcuma longa* L.) as affected by Poultry Manure Rates

Poultry manure (kg)	4	8	12	16	20	24
0	0.53^b	0.80^a	1.13^a	1.28^b	1.45^b	1.47^b
4	0.67^b	1.40^a	1.45^a	1.37^b	1.46^b	1.52^b
8	1.43^a	1.16^a	1.60^a	1.65^b	1.76^b	1.87^b
12	1.45^a	1.44^a	1.54^a	2.48^a	1.53^a	2.52^a
F-LSD$_{0.05}$	0.783	N.S	N.S	0.738	0.786	0.782

Means in the same column having the same letters are not significantly (P<0.05) different using F-LSD N.S = Not Significant (P<0.05)

Number of Rhizomes

The highest rate of poultry manure application had positive effect on number of rhizomes produced (Table 7). 12 kg/bed of poultry manure gave the highest number of rhizomes of 157 which differed significantly from other rates of poultry manure. Number of rhizomes increased as poultry manure rates increased from control plots to 12 kg/bed.

Weight of Rhizomes (kg)

The weight of turmeric that received poultry manure significantly (P<0.01) differed from the control. The harvested rhizomes with weight of 4.167 kg were recorded in plants treated with 12 kg/bed of poultry manure. Weight of rhizomes produced at 4 kg/bed (3.667 kg) and 8 kg/bed (4.167 kg) were statistically the same. The control plants without any manure (0kg/bed) gave the least weight of rhizomes 2.388kg significantly (P<0.05) different from the other (Table 7).

Length of Rhizomes (cm)

The 12 kg/bed of poultry manure produced the longest rhizomes of 8.97cm differed significantly from others (Table 7). Length of rhizomes produced at 4 kg/bed and 8 kg/bed of poultry manure of approximately 7cm and 8cm respectively were statistically the same. The control plots gave the least length of rhizomes of 5.43 cm.

Rhizome Yield (t/ha)

Increasing poultry manure rates in turmeric significantly (P<0.05) increased the rhizome yield (Table 7). Application of poultry manure produced the highest rhizome yield of 12.92 t/ha, significantly (P<0.01) different from all others. Rhizome yield produced from 4kg/bed (9.17 t/ha) and 8kg/bed (10.42 t/ha) were statistically the same. The 0 kg/bed gave the lowest rhizome yield of 7.08 t/ha (Table 7).

Table 7: Number of Rhizomes, Weights, Length and Rhizome Yield of Turmeric (*Curcuma longa* L.) as affected by Poultry Manure Rates

Poultry Manure (kg)	Number of Rhizomes	Weight of Rhizomes (kg)	Length of Rhizomes (cm)	Rhizome Yield (t/ha)
0	42.00^{d}	2.388^{c}	5.43^{c}	7.08^{c}
4	83.30^{c}	3.667^{b}	6.73^{b}	9.17^{b}

12	157.00^{a}	5.167^{a}	8.97^{a}	12.92^{a}
F-$LSD_{0.05}$	27.86	0.644	0.940	1.612

Means in the same column having the same letters are not significantly (P<0.05) different using F-LSD N.S = Not Significant (P<0.05

DISCUSSION

The results of chemical and physical properties of the experimental plots showed that the surface soils were slightly acidic with pH values of 5.80. This is in line with the report of Azu et al. (2017) who reported high acidity in most soils of Ebonyi State. According to Azu et al. (2018), the high concentration of oxides of iron and aluminum coupled with the presence of 1:2 clay minerals in the clay fraction of most hydromorphic soils of Ebonyi State is responsible for high exchangeable acidity and pH as observed in the study. Total nitrogen and available phosphorus were low and below the critical level of 0.15% and 12 mg/kg as proposed by Osodeke and Ubah (2005). The organic carbon and organic matter were low indicating low soil fertility. Generally, the basic cations except calcium were low which might be responsible for the high pH.

The significant increase in turmeric rhizomes, weight, length and rhizome yield and other parameters with an increase in poultry manure rates is in agreement with the report of Manhas and Gill (2007), who stated that application of farm yard manure (FYM) increased the growth, yield and quality of turmeric. The application of 12 kg/bed of poultry manure gave the highest yield of turmeric in the experiment. This is also in line with the work of Ibeawuchi et al. (2012), who reported that, the use of high poultry manure without mineral fertilizer gave highest yield in respect of crop growth and yield performance in Cassava, groundnut and sorghum intercrop. Monapatra and Das (2009) reported that organic manure improved soil productivity and fertility which in turns improved yield and quality of such long duration crop like turmeric.

CONCLUSION

Poultry manure showed great potential on the growth and yield enhancement of turmeric (*Curcuma longa* L.) and also improve soil nutrient status. The application of poultry manure at the rate of 12 kg/bed proved to be the optimal rate for maximum production of turmeric in Unwana and therefore recommended.

56th Annual Conference
Agricultural Society of Nigeria
24 - 28 Oct., 2022

ABSTRACT

Cocoa is a major agricultural produce in Nigeria but decline soil fertility among many other factors has been reported to affect yield. This was confirmed by various research findings on physical and chemical properties which indicated that soils of the cocoa ecology were deficient in some nutrients as a result of continuous mining without replacement. Low cocoa output per hectare has been attributed to several factors while adequate soil nutrient amendment has been reported to mitigate effect of these factors with optimal cocoa yield and quality recorded. Inadequate adoption of several soil research recommendations on various nutrient amendments is evident in annual output decrease of cocoa beans and reduced foreign earning from agricultural produce for Nigeria. Lack of policy towards implementation of soil fertility management and high cost of fertilizer has made most farmers not to amend their depleted cocoa soil. However, formulation of policies to boost cocoa production by educating cocoa farmers on soil research findings and establishment of amendment programmes which adopt guided scientific recommendations will increase cocoa output and income generation from cocoa beans.

Keywords: Cocoa beans, soil amendment, policy, foreign earnings

INTRODUCTION

Cocoa, a leading agricultural produce is cultivated mainly in fourteen states of Nigeria known as the cocoa belt which comprise of states such as Abia, Akwa Ibom, Cross River, Delta, Edo, Ekiti, Ogun, Ondo, Osun, Oyo, Kogi, Kwara, Adamawa and Taraba (. The demand on climate, water as well as soil properties (Table 1) made it to adapt favourably to these areas measured by growth performance and yield. Cocoa beans (brown bean which is main commodity obtained from cocoa pod when fermented and dried) and it by-products have served as major source of foreign earnings for government, income for farmer and cocoa trader. It by-product also have been identified as raw material for industries and potential ingredient for several agro-inputs such as livestock feeds and fertilizer (Handojo, *et al.*, 2019**)**. However, Iremiren *et al.*, (2012) has observed that most cocoa plantations in Nigeria have experienced gradual decrease in yield and attributed this to poor soil management as well as late pod harvesting, lack of good agricultural practices, use of poor planting materials and age of the tree. To achieve better income when yield beginning to decrease, shifting cultivation has been the practice of early farmers but this is now impossible due to increase in population and land demand for various infrastructural facilities. Furthermore, It has been discovered that persistent low pod output in Nigeria is due to lack of readiness of farmer to rehabilitate their old cocoa trees because of high cost and difficulties always recorded in the process of establishing new cocoa farm. Many studies have shown that age of cocoa tree affect number of pod as well as beans per tree with recommendation that new tree be planted to replace the old ones (Mahrizal *et al.*, 2012; Gockowski *et al*., 2011). Pests and diseases have been reported as one other factor that is responsible for low cocoa production (ICCO, 2015). It has been confirmed that negative effect of pests and diseases lead to reduction in production through loss of cocoa pods and beans before harvest and during storage (Orisajo and Dongo, 2005). Moreover, there is a developed hypothesis that soil nutrients play major role in mitigating effect of these factors on yield of crop plant. Several cocoa soils have been researched on, with findings and recommendations available on nutrients management. Therefore to increase output in Nigeria, it becomes important to gather these findings for proper soil nutrient management targeted toward their adoption to enhance cocoa yield per tree per hectare. Results of physicochemical properties of cocoa soil in Ondo and Oyo state by Ogunlade *et al.*,2022, Cross river state by Ogunlade *et al.*,2012, Osun state Ogunlade *et al.*,2008 , eight states comprising Oyo, Kwara, Ogun, Ondo, Ekiti, Edo, Abia and Cross river by Ogunlade and Aipokpodion 2006, Abia, Cross River and Edo state by Agbeniyi *et al.*,2021, Kwara state by Ibiremo *et al.*, 2017 and Edo state by (Ipinmoroti and Ogeh 2012; Ogeh and Ipinmoroti 2013) as well as recommendations on cocoa soil in Nigeria were reviewed.

Research results on physiochemical properties of some cocoa soils

Results of soil physical and chemical properties (Table 3) and the critical values recommended for cocoa production (Table 2) indicated the textural classes of most cocoa soils to be sandy loam and loam soil with a range of 660-810% sand, 125-174% silt and54-200% clay. The silt + clay content ranged from 17.9-37.4% which showed that most cocoa soils are below ideal value of at least 32% silt + clay content recommended (Egbe *et al.*,1989). Halder (2013) emphasized on importance of soil texture and stated that it is a major factor that determined capacity to retain nutrient and water needed for plant growth. Soil organic carbon contents ranged from 0.096-29.90 g/kg for all state. The values were below 30.00g/kg recommended for cocoa production. The cocoa soil pH ranges of 4.43-6.67 were recorded, which showed slight acidity while Abia state with lowest value (4.43) indicated strong acidity. Snoeck (2016) like other studies has indicated soil pH as important factor that affect crop production and stated that soil chemical properties as well as plant nutrient uptake depend strongly on pH. Thus, it requires special management technique to obtain optimal productivity of cocoa. The report has shown that total N contents of cocoa soils ranged from 0.01 to 7.1%. The N content of Oyo state (Ibadan), Ondo state (Owena) and Edo state soils were below critical value of 0.9g/kg (Table 2) recommended for cocoa cultivation. Also, soils available P content ranged from 1.76-14.71mg/kg, which showed that Oyo state (Ibadan), Ondo state (Owena), Cross River state and Osun state soils were lower than 10.00mg/kg recommended for cocoa cultivation. Ogunlade and Aikpokpodion (2006) in their assessment of soils across cocoa ecologies of Nigeria reported that phosphorus is grossly inadequate for optimum cocoa yield. And this was supported by Aikpokpodion (2010) who reported that 6 to 8% of phosphorus has been loss through nutrient mining via pod harvest while some are washed away through rain water. The soils exchangeable K contents indicated a range of 0.07-0.83cmol/kg across the cocoa ecologies and most soils of the cocoa ecologies were below critical value of 0.30cmol/kg. Exchangeable Ca content was in the ranged of 0.76-28.44cmol/kg which showed that some of the soil were lower than critical value of 5.00cmol/kg. Cocoa soils Mg content of 0.56-4.65 cmol/kg showed that some soils were lower than 0.8cmol/kg which is the critical level for cocoa cultivation. Ipinmoroti *et al.,* (2009) confirmed low Mg content in some Cocoa plantations in Ibadan, south-western Nigeria and associated deficiency to high sand content, severe weathering, soil erosion and clay eluviation. The results of Mn content showed 2.94mg/kg value for Edo which is the lowest of all cocoa soils and indicated that values were above critical limit of 0.1mg/kg required for cocoa cultivation. Iron content was lowest in Ondo state (Owena) (25.70mg/kg) and highest in Edo state (124.00mg/kg). These values were higher than critical value of 4.5mg/kg required for cocoa cultivation. Copper content was lowest in Oyo state (0.74mg/kg) and indicated that some cocoa soils (e,g Ondo and Edo state) were below the critical limit of 2.5mg/kg required for cocoa cultivation. The Zinc content showed 0.56mg/kg value for Osun as the lowest of all cocoa soils which was higher than critical limit of 0.1mg/kg required for cocoa cultivation.

Research recommendations on cocoa soil amendment

Ogunlade *et al.,* (2004) reported that soil amended with neem leaves and fruits gave better cocoa seedling growth with highest P-uptake and recommended use of neem leaf as organic fertilizer in P deficient soil. Positive effect of cocoa pod husk (CPH) amendment on cocoa seedling growth was recorded and potential to increase nutrient uptake as well as serve as liming material was reported by Adejobi *et al.,* (2010) and recommended amendment of cocoa soil with 25tonnes per hectare CPH. Also, Ogunlade *et al.,* (2012) reported significant increase in cocoa yield with CPH compost and NPK fertilizer in the first year but observed significant yield increase in compost treated cocoa tree at the second year than others and therefore, recommended application of CPH for higher cocoa yield. Amendment with neem plant material fortified with CPH has been reported to supply basic cations, increase N and pH (Ogunlade *et al.,* 2008). Separate report from Adejobi, 2011 and Akanbi *et al.,* (2011) showed increase in the growth as well as nutrient uptake in cocoa seedlings when CPH was combined with organomineral fertilizer, and positive effect of oil palm bunch ash (OPA) on acidic soil respectively. These materials were recommended for use as sources of nutrients (N,P,K,Ca and Mg) and liming material. Also, Akanbi *et al.,* (2012) studied further on effect of CPH ash and OPA with and without NPK fertilizer and recommended the combine application of organic together with inorganic fertilizer to obtain better performance than sole applications of each in cocoa production. Ogunlade and Aipokpodion, (2006) reported negative effect of inadequate phosphorus on cocoa yield and recommended that farmer should be educated, encouraged and assisted to consider soil amendment materials for profitable production. Likewise, Iloyanomon (2008), reported long term benefit of 16kg P (37kg of P_2O_5) per hectare of Sokoto rock phosphate and recommended application for the adjustment of phosphate deficiency in soil. Also, Ogunlade *et al.,* (2005) recommended the application 10kgN per hectare to have a significant cocoa seedling growth in nitrogen deficient soil. Ipinmoroti et al., 2005 showed that organic materials (manure) were better sources of nutrients to plant with optimal nutrient released as well as increase in soil organic carbon content than inorganic fertilizers and this was confirmed by Ogunlade *et al.,* 2008 that observed no significant differences between the yield of cocoa tree amended with organic, organomineral as well as NPK fertilizer. Adejobi and Akanbi (2012) reported that cocoa seedling performance were enhanced by chemical and organic fertilizer treatments but recommended the use of organic materials as nutrient sources because of its promising effects on cocoa and soil. Likewise, Iloyanomom, (2008) reported that organic manure (CPH) served as alternative source of nutrient to cocoa tree and recommended it application in cocoa cultivation. Furthermore, Orisajo *et al.,*(2010) reported a significant increase in root mass of cocoa with poultry litter amendment and reduction of nematode number in the soil with 100% survival of cocoa seedling recorded 3months after transplanting to poultry litter amended plots on the field contrast to 35% dead in unamend plots and recommended cocoa soil amendment with poultry litter to have profitable field establishment.

Report of Ogbeide and Ibiremo (2021) showed that Cocoa Research Institute Nigeria in 1986 has recommended amendment of soil with 4g P/tree in the year of planting, 10g P/tree in the second and third year after planting and 11-23g P/tree for fourth and six-year old cocoa plantation when grown on land cleared from forest and NPK fertilizer practices of 10kgN+4kgP+4kgK/tree in the first year, 25gN+4gP +3gK/tree in second and third year after planting and 50-100g N+12g P+ 25gK/tree fourth and six-year of old cocoa plantation grown on land previously cropped with trees or arable crops. The increasing market for organic farm produce does not exclude cocoa beans and assessment of farmers' knowledge on organic cocoa production by Ogunlade *et al.*,(2022) showed that 61.1% of farmers did not know about organic cocoa and recommended proper education on need to make use of organic inputs (e.g organic fertilizers) toward improving quantity and quality of cocoa beans export. The evaluation of Nigeria land by Obatolu and Oduwole (2006) revealed that, it is highly suitable for cocoa production and they emphasized need to maximize this potential so as to increase production. Aipokpodion (2012), worked on remediation of heavy metal contaminated soil using Sokoto rock phosphate and found that available land suitable for cocoa cultivation and increase in output of existing plantation could be achieved through amendment of soil (contaminated) with Sokoto rock phosphate especially in the crude oil rich region and mining sites of the country.

Prospect of cocoa production through adoption of research findings

Nigeria has a high comparative advantage in the production of cocoa and therefore, it becomes necessary that government agencies educate farmers on the impact that adoption of cocoa soil research recommendations will have on cocoa performance. Specific policy programmes on soil fertility management to enhance national cocoa output and sustain continued supply of high quality and quantity cocoa bean to the world market should become government main target. The economic policy document by Federal Government of Nigeria to diversify economy with emphasises on the need to boost cocoa production should include soil management with focus on adoption of research findings and recommendations. High cost of procurement made most farmers not to use fertilizer (Asimiyu and Omonona 2013) and as such a subsidize fertilizer programmes by government for cocoa soil, geared toward increase output should be drawn up because cultivating cocoa on unfertile soil will among other factor leads to low productivity and poor returns (Asimiyu and Omonona 2013). Hence, establishing soil amendment programmes with view to adopt guided scientific recommendations will increase cocoa output and income generation from cocoa beans export which will contribute to the growth of Nigerian economy.

CONCLUSION

Deliberate Policies toward adoption of recommendations of cheap cocoa soil amendment research findings especially organic fertilizer production using materials such as cocoa pod husk, neem plant leave and Sokoto rock phosphate will increase cocoa output per hectare and reduce cost of production. Government policies should be targeted towards eliminating soil nutrient constrains to enhance cocoa yield and Nigeria foreign earning.

ABSTRACT

The effect of liming on some soil quality parameters of brackish water ponds of Nigerian Institute for Oceanography and Marine Research fish farm at Badore was investigated. Four ponds were selected for the study. Two ponds were limed with quick lime (calcium oxide) at the rate of 50kg/pond while the other two ponds were not limed. Selected soil quality parameters (pH, iron, magnesium, manganese, organic matter) were monitored during the dry season period which lasted from January to March 2019. Data obtained from the study indicated that pH of ponds ranged from 6.0 – 6.9 for the limed ponds and 4.0 – 5.2 for the unlimed ponds. Concentrations of iron ranged from 2.5 – 7.5mg/L for lime and unlime ponds respectively. Magnesium concentrations ranged from 5.0 – 80mg/L and 5.0 – 150mg/L for limed ponds and unlimed ponds respectively. Manganese concentrations ranged from 0 – 12mg/L and 5 – 12mg/L for limed ponds and unlimed ponds respectively. The organic matter content ranged for the soil from 5.1 – 5.4% for limed and 5.0 – 5.1% for the unlimed ponds. Liming and fertilization of pond soil could reduce soil acidity and invariably recondition of fish ponds and iron concentration of a pond.

Key words: Liming, soil quality, brackish water, fish ponds.

INTRODUCTION

The soil is a natural component of the environment that constitutes mineral matter, water, organic matter and living community that varies according to place and time (Sanhita *et al*, 2009 and

Fatima *et al*, 2012). Soil exert great influence on the environment and have an impact on the climatic conditions (Zornoza, 2015).

Soil quality is the continued capacity of soil to function as a vital living system within an ecosystem and land use boundaries, sustain biological productivity, and promote the quality of air and water environment and to maintain organism and human health (Doran and Safley, 1997). Changes in soil quality are not only associated with soil management, but also related to changes in temperature and precipitation (Andrews *et al*, 2004). Soil analysis is very essential to evaluate the quality of a particular ecosystem (Bhuyan and Islam, 2018, Islam *et al*, 2016, *Sharm et al*, 2014*).* Chemical properties like nutrient availability and soil pH affect the growth of organism in the pond (Jiao *et al,* 2009*).* Soil organic matter is the most important determinant of soil quality that is interlinked with soil pH (Brady and Weil, 1996).

Brackish water contributes to fish production in Nigeria (Dublin-Green *et al*, 2003.). The productivity of fish ponds in acid sulphate area is influenced by their state of reclamation, the treatment of the pond bottom with lime and fertilizer application. Growth of algae is observed when reclaimed acid sulphate soil limed with agricultural lime. Acidic bottom soil is a common problem in pond aquaculture, and fish farmers often apply agricultural limestone to ponds as a remedy. Aquaculture ponds are usually limed after draining for harvest and before refilling for the next crop (Boyd and Tucker, 1998).Proper reclamation and management of fish ponds in the soil can contribute to food production in Nigeria. The aim of this study is to determine the effect of liming on some soil quality parameters of brackish water fish ponds for the management control of soil acidity so as to improve fish growth rates and survival.

MATERIALS AND METHODS

The study was carried out at Nigerian Institute for Oceanography and Marine Research experimental fish farm Badore, Lagos. Four ponds namely Pond 5 (40.5m x 30.3m x 1.5), 6 (37.0m x 31.2m x 1.5m, 7 (35.5m x 28.5m x 1.5m) and 8 (38.5m x 28.5m x 1.5m) were selected for the study during the dry season from January – March, 2019. Ponds 5 and 6 were lime with quick lime (calcium oxide) at the rate of 50kg/pond while ponds 7 and 8 unlimed. The soil samples were collected from the pond bottom soil with the aid of soil auger. The soil samples collected were sun dried, grinded and sieved before analysis of pH and organic matter with the aid of Lamotte soil test kit. The concentration of manganese, magnesium and iron were analyzed using Atomic Absorption Spectrophotometer (AAS) (AAS – PG. AA500). The initial values of the soil quality parameter were taken and recorded before commencement of the liming.

The results obtained were subjected to analysis. Multiple variance of analysis (IBM SPSS Statistics 20). The analysis was carried out to test the significant difference between the four ponds bottom soil.

Table 1: Soil quality parameter of Badore fish farm before application of lime

Soil parameter	Pond 5	Pond 6	Pond 7	Pond 8
pH	4.8	4.9	4.2	4.8
Iron (mg/L)	2.7	2.8	2.7	7.0
Magnesium (mg/L)	5.0	5.0	20	5.0
Manganese (mg/L)	0.2	5.0	5.0	5.0
Organic matter (%)	5.0	5.0	5.0	5.0

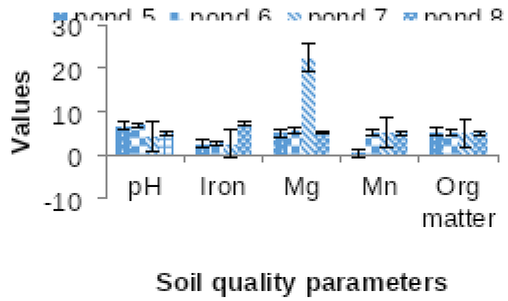

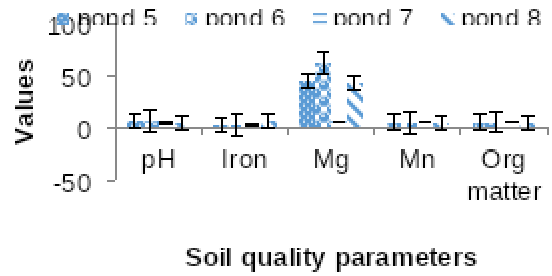

Figure 1: Mean soil quality parameters of four ponds observed in dry season (January 2019).

Figure 2: Mean soil quality parameters of four ponds observed in dry season (February,2019)

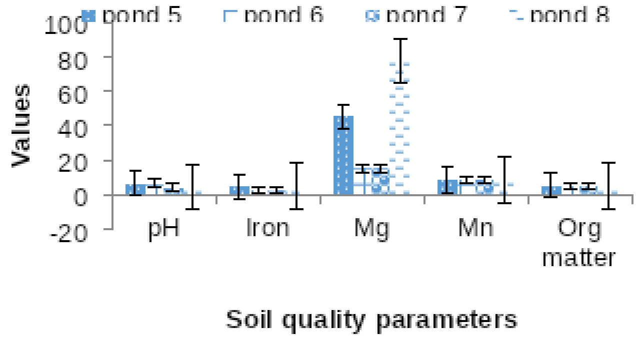

Figure 3: Mean soil quality parameters of four ponds observed in dry season (March, 2019)

RESULTS

The mean soil pH of ponds 5, 6, 7 and 8 were 6.75±0.05, 6.85±0.05, 4.25±0.25 and 5.10±0.10 respectively for the month of January during dry season. Pond 6 has the highest soil pH mean value of 6.85±0.05 while pond 7 has the lowest soil pH mean value of 4.25±0.25 in the month of January (Table 2 and figure 1). There were no significant differences ponds 5 and 6 at $P > 0.05$ but there were significant differences between ponds 7 and 8 at $P < 0.05$.

The mean soil concentrations of iron in the ponds 5, 6, 7 and 8 were 2.65±0.15, 2.75±0.05, 2.55±0.05 and 7.25mg/L respectively for the month of January during dry season. Pond 8 has the highest mean value of 7.25±0.25mg/L while pond 7 has the lowest mean value of 2.65±0mg/L in the month of January (Table 2 and figure 1). There were no significant differences between ponds 5, 6 and 7 respectively at $P > 0.05$. But there were significant differences between pond 8 and other three ponds at $P < 0.05$.

The mean soil concentrations of magnesium in the ponds 5, 6, 7 and 8 were 5.10±0.10, 5.55±0.25, 22.5±2.5 and 5.25±0.25mg/L respectively for the month of January during dry season. Pond 7 has the highest mean value of 22.5±2.5mg/L while pond 5 has the lowest mean value of 5.10±0.10mg/L (Table 2 and figure 1). There were no significant differences between ponds 5, 6 and 8 at $P > 0.05$. But there were significant differences between pond 7 and other three ponds sampled at $P < 0.05$.

The mean soil concentrations of manganese were 0.5±0.5, 5.1±0.1, 5.2±0.1 and 5.05±0.05mg/L for ponds 5, 6, 7 and 8 respectively for the month of January during dry season. Pond 7 has the highest mean value of 5.2±0.1mg/L while pond 5 has the lowest mean value of 0.5±0.5mg/L (Table 2 and figure 1). There were no significant differences between ponds 6, 7 and 8 at $P > 0.05$. But there were significant differences between pond 5 and other three ponds sampled at $P < 0.05$.

Mean soil of organic matter were 5.3±0.2, 5.3±0.1, 5.05±0.05 and 5.05±0.05% for ponds 5, 6, 7 and 8 respectively for the month of January during dry season. Ponds 5 and 6 have the highest mean value soil organic matter of 5.3±0.2% and 5.3±0.1% respectively. The lowest soil organic matter mean value was 5.05±0.1% for ponds 7 and 8 respectively (Table 2 and figure 1). There were no significant differences in all the ponds at $P > 0.05$.

Mean soil pH of ponds 5, 6, 7 and 8 were 6.75±0.05, 6.80±0, 4.45±0.25 and 4.7±0.7 respectively for the month of February during dry season. Pond 6 has the highest soil pH mean value of 6.8±0 while pond 7 has the lowest soil pH mean value of 4.45±0.25 in the month of February (Table 3 and figure 2). There were no significant differences ponds 5 and 6 at $P > 0.05$ also there were no significant differences between ponds 7 and 8 at $P > 0.05$.

Mean soil concentrations of iron in the ponds 5, 6, 7 and 8 were 2.5±0, 2.60±0.1, 2.5±0 and 6.25±1.25mg/L respectively for the month of February during dry season. Pond 8 has the highest soil iron concentration mean value of 6.25±1.25mg/L while ponds 5 and 7 have the lowest soil iron concentration mean value of 2.5±0mg/L in the month of February (Table 3 and figure 2). There were no significant differences between ponds 5, 6 and 7 respectively at $P > 0.05$. But there were significant differences between pond 8 and other three ponds at $P < 0.05$.

The mean soil concentrations of magnesium in the ponds 5, 6, 7 and 8 were 45±35, 62.5±57.5, 5.65±0.15 and 42.75±37.25mg/L respectively for the month of February during dry season. Pond 6 has the highest mean value soil magnesium concentration of 62.5±57.5mg/L while pond 7 has the lowest mean value soil magnesium concentration of 5.65±0.15mg/L (Table 3 and figure 2). There were no significant differences in all the ponds at $P > 0.05$.

Mean soil concentrations of manganese were 0.5±0.5, 5.1±0.1, 5.2±0.1 and 5.05±0.05mg/L for ponds 5, 6, 7 and 8 respectively for the month of February during dry season. Pond 7 has the highest mean value soil manganese concentration of 5.2±0.1mg/L while pond 5 has the lowest mean value manganese concentration of 0.5±0.5mg/L (Table 3 and figure 2). There were no significant differences between ponds 6, 7 and 8 at $P > 0.05$. But there were significant differences between pond 5 and other three ponds at $P < 0.05$.

Mean soil of organic matter were 5.3±0.2, 5.3±0.1, 5.05±0.05 and 5.05±0.05% for ponds 5, 6, 7 and 8 respectively for the month of February during dry season. Ponds 5 and 6 have the highest mean value soil organic matter of 5.3±0.2% and 5.3±0.1% respectively. The lowest soil organic matter mean value was 5.05±0.1% for ponds 7 and 8 respectively (Table 3 and figure 2). There were no significant differences in all the ponds at $P > 0.05$.

Mean soil pH of ponds 5, 6, 7 and 8 were 6.35±0.35, 6.70±0, 4.35±0.15 and 4.4±0.2 respectively for the month of March during dry season. Pond 6 has the highest soil pH mean value of 6.7±0 while pond 7 has the lowest soil pH mean value of 4.35±0.15 in the month of March (Table 4 and figure 3). There were no significant differences between ponds 5 and 6 at $P > 0.05$ also there were no significant differences between ponds 7 and 8 at $P > 0.05$.

Mean soil concentrations of iron in the ponds 5, 6, 7 and 8 were 5.0±2.5, 2.50±0.0, 2.5±0 and .2.5±0mg/L respectively for the month of March during dry season. Pond 5 has the highest soil iron concentration mean value of 5.0±2.5mg/L while ponds 6, 7 and 8 have the lowest soil iron concentration mean value of 2.5±0mg/L in the month of March (Table 4 and figure 3). There were no significant differences between ponds 6, 7 and 8 respectively at $P > 0.05$. But there were significant differences between pond 5 and other three ponds at $P < 0.05$.

The mean soil concentrations of magnesium in the ponds 5, 6, 7 and 8 were 45.2±34.8, 15.0±10.0, 15.2±9.8 and 77.6±72.4mg/L respectively for the month of March during dry season. Pond 8 has the highest mean value soil magnesium concentration of 77.6±72.4mg/L while pond 6 has the lowest mean value soil magnesium concentration of 15.0±10.0mg/L (Table 4 and figure 3). There were no significant differences in all the ponds at $P > 0.05$.

Mean soil concentrations of manganese were 8.55±0.15, 8.50±3.5, 8.75±3.25 and 8.6±3.4mg/L for ponds 5, 6, 7 and 8 respectively for the month of March during dry season. Pond 7 has the highest mean value soil manganese concentration of 8.75±3.25mg/L while pond 5 has the lowest mean value manganese concentration of 8.55±0.15mg/L (Table 4 and figure 3). There were no significant differences in all the ponds at $P > 0.05$.

Mean soil of organic matter were 5.35±0.15, 5.3±0.1, 5.05±0.05 and 5.05±0.05% for ponds 5, 6, 7 and 8 respectively for the month of March during dry season. Ponds 5 have the highest mean value soil organic matter of 5.35±0.15% while pond 7 and 8 lowest soil organic matter mean value was 5.05±0.05% (Table 4 and figure 3). There were no significant differences in all the ponds at $P > 0.05$.

DISCUSSION

pH of the soil ranged from 6.0 – 6.9 and 4.0 – 5.2 for lime and unlime ponds respectively during dry season (Table 2 – 4 and figure 1 – 3)). Susheela *et al*, (2014) observed pH of soil ranged from 6.9 – 8.9 during dry season.

The concentrations of iron in the bottom soil ranged from 6.0 – 6.9mg/L and 4.0 – 5.2mg/L for

Lime and unlime ponds during dry season (Table 2 – 4 and figure 1 – 3). Singh and Poernomo, (1984) reported iron concentrations levels of 3,321 and 3,378mg/L for unlime ponds, 3,140 and 1,867mg/L for lime ponds. Also Prihutomo *et al*, (2016) obtained iron concentrations levels for bottom soil of 50,400, 50,520, 56,060, and 50,220mg/L.

In this study concentration of magnesium in the bottom soil ranged from 5.0 – 150mg/L for lime and unlimes ponds during dry season (Table 2 – 4 and figure 1 – 3). The concentrations of magnesium in the bottom soil in this study were higher than (0.75 – 1.01mg/L) during dry season by Fatunbarin and Olojugba, (2014)

Concentrations of manganese in the bottom soil ranged from 0 – 25mg/L and 5.0 – 12mg/L for lime and unlime ponds respectively during dry season (Table 2 – 4 and figure 1 – 3). The values of manganese obtained in this study were lower than 18mg/L and 16mg/L for lime and unlime ponds respectively observed by Singh, (1985).

Organic matter obtained in this study ranged from 5.1 – 5.5% for lime ponds during dry season. The organic matter for unlime ponds ranged from 5.0 – 5.2% during dry season. The results obtained in this study were slightly similar to percentage organic matter (2.18 – 5.77%) observed by Rafiqul Islam *et al*, (2017) during dry season. In this study the pH of lime ponds were higher than unlime ponds. The higher the organic matter content, the more the lime required for a given change in the sediment pH (Barna and Zamal, 2011).

CONCLUSION

Liming of pond soil and fertilization could reclaim ponds thereby reconditioning deficiency of phosphate, low pH, and toxicity of aluminium, iron and manganese. Regular monitoring of water quality parameters is essential especially pH. If the ponds becomes acidic (below tolerance limit), a moderate and low rate application of powdered agriculture lime could be broadcast on the pond water in order to buffer the low pH and subdue the concentration of aluminium and iron. This would also reduce fixation of phosphate into acid sulphate bottom soil.

24 - 28 Oct., 2022

ABSTRACT

Rainfall is one of the determining factors in crop growth and development. The study examined the influence of rainfall distribution in the yield of oil palm in selected areas of Akwa Ibom state. The study was conducted in coastal areas (Eket and Oron) and upland areas (Uyo and Ikot Ekpene) Daily rainfall data were obtained from Nigeria Meteorological Agency (NiMet) and oil yield data were obtained from Akwa Ibom Ministry of Agriculture Uyo, for a period of 30 years (1989 – 2018) respectively. Descriptive statistics was used to determine the decadal rainfall amount and time series in was used to determine the relationship between rainfall and yield of oil palm. The result shows that upland upland areas witnessed increase in oil palm yield decade by decade whilst the yield of oil palm in coast areas continue to decline decade by decade. The upland areas of Ikot Ekpene and Uyo recorded increase of oil palm yield at the third decade with 14.40 mt/ha and 18.54 mt/ha respectively. Furthermore, all areas also witnessed increase in rainfall decade by decade with the coastal areas of Eket and Oron recording the highest at the third decade with 3765.40 mm and 3500.34 mm respectively. Also, the relationship shows decrease in yield of oil palm in Eket at $R^{2\,=}$ 0.1085 and $y = -0.0961x + 9.482$, Oron – $R^2 = 0.4226$ and $y = -0.0583x + 6.8127$; while yield of oil palm increase in Uyo at $R^2 = 0.2143$ and $y = 0.127x + 5.0344$, Ikot Ekpene – $R^2 = 0.3338$ and $y = 0.1583x + 4.9077$. This shows that sustainable production of oil palm could be achieves in upland areas under good management practices since the rainfall distribution the areas march with the crop water requirement.

Key words: Rainfall, Oil palm, crop production, coastal area, upland areas

1.0 INTRODUCTION

Oil palm (*Elaeis guineensis*) is as old as creation (Ndon 2006). All aspects of the tree are useful economically and for domestic purposes. It is commonly stated that oil palm originated in tropical rainforest area of West Africa (FAO, 2010). The fundamental belt goes through the southern scopes of Cameroon, Côte d'Ivoire, Ghana, Liberia, Nigeria, Sierra Leone, Togo and into Equatorial region of Angola and Congo (FAO, 2010; Ndon 2006). Processing of oil palm edible oil has been practiced in Africa for a large number of year and oil produced is profoundly hued and seasoned. It is a basic ingredient in a greater part of the conventional West African food. The traditional process is simple but tedious. Mature palms are single–stemmed and develop to 20 m tall. The leaves are pinnate and reach between 3 – 5 m long (Kei *et al.*, 1997). Three varieties of oil palm are accessible in Nigeria; specifically, Dura, Pisifera and Tenera (Nigerian Institute for oil Palm Research (NIFOR), 2009). The preferred variety among palm oil farmers in Nigeria is the half-breed Tenera, which is a crossbreed of the Dura (female) and the Pisifera (male). Tenera seedlings are produce by NIFOR and normally alluded to as extension work seeds (Thompson, 2010). Regarding examination, product of Tenera variety contains 25% oil by weight and Dura variety 18%. Therefore, a similar measure of Tenera can yield 30% more oil than the comparable product of Dura (NIFOR, 2010). Oil palm is likewise a basic food items. Around 90 percent of palm oil produced end in food products, while 10 percent is utilized in industries (Nwauwa, 2011).

Moreover, consistent soil moisture accessibility supports lively development and expanded yield of oil palm. Sufficient rainfall, good soil depth and water holding capacity add to water accessibility. In oil palm, as water insufficiency builds, stomata will stay shut and advancement and opening of spear will be repressed (Ndon, 2006). Water insufficiency antagonistically influences bloom inception, sex separation and hence brings about low sex proportion because of creation of more male inflorescences. Oil palm needs high measure of water to meet its monthly evapotranspiration needs (Udoh *et al.*, 2005). In regions, where lasting water source is accessible, basin irrigation system is conceivable. Where landscape is undulating and water is scanty during dry season, drip irrigation system is prescribed to keep four drippers for every palm in the weeded palm cycle to supply at least 90 liters of water for each palm every day during summer months, which will differ as per the evapotranspiration esteems in an area (Koh and Wilcove, 2007).

Temperature can be a restricting component for oil palm production. Best oil palm yields are acquired in places where a greatest normal temperature of 29 – 33^{o}C and least normal temperature of 22 – 24^{o}C are accessible (NIFOR, 2010). Higher diurnal temperature variation causes botanical fetus removal in districts with a dry season. The plant requires 1800 – 2000 daylight hours every year, consistent daylight of at least 5 hours of the day for better oil palm yield. Moist, deep and well-drained medium textured soils rich in humus content are viewed as ideal. Gravel and sandy soils, especially the coastal sands are not ideal for oil palm development (NIFOR, 2009). Heavy clay soils with helpless seepage properties may present issues of air circulation during rainy seasons (Basiron, 2007). Oil palm cultivation is vulnerable to the effect of climate change. It required average annual rainfall of 2000 – 2800mm (FAO, 2010). Rainfall patterns have an impact on the growth and development of palm trees, which has an impact on the output of oil palm. In addition to harming fresh fruit bunches (FFB), excessive rain also lowers the quality of plantation roads and paths, stifles harvesting, and results in flooding. Because of the length of the annual dry season, it affects oil palm productivity (Rizal *et al.*, 2008). The availability of soil moisture, which is influenced by the amount of rainfall received and, in certain circumstances, irrigation, is by far the most important factor in influencing the FFB yield of oil palm (Paterson, 2020b). Lack of moisture in an oil palm plantation slows growth, lowers yield production, and increase the risk of fire. The threat of floods and drought is anticipated to increase dramatically in the twenty-first century as a result of the effects of climate change (Ahemd *et al.*, 2021).

The cultivation of oil palm in Akwa Ibom State may be under great risk from the effects of floods in the coastal areas of the state. The capacity to produce palm oil is reduced in the areas of production within the state. Over the coming decades, Akwa Ibom State may witness frequent and severe floods due to the its proximity to water bodies. The harvesting of FFB is hampered or delayed by heavy rain brought on by a La Nina event, which also lowers the quality of crude palm oil (CPO) and results in rotten FFB and waterlogging (Paterson, 2020a). Long-term climate changes will affect Nigeria and other oil palm-producing countries. According to climate change estimates, the cultivation of oil palm will be hugely affected by climate change, with significant effects for the economy of rural dwellers, as well as the palm oil industries. Therefore, the aim of this study was to assess the influence of rainfall on the yield of oil palm in selected areas of Akwa Ibom State.

2.0 MATERIALS AND METHODS

2.1 Description of study area

The study was carried out in the coastal and upland areas of Akwa Ibom State. Four local government area were selected (figure 1) i.e., coastal area (Eket and Oron) and upland areas (Uyo and Ikot Ekpene). Akwa Ibom State lies between longitudes $7^{0}25'$ and $8^{0}25'$E and latitudes $4^{0}32'$ and $5^{0}30'$N. It has a humid tropical climate, characterized by distinct wet and dry seasons. Annual rainfall varies from 3,000 mm along the coast to 2,250 mm in the northern fringe, with 10 – 11 months of rainfall in the coastal and upland areas respectively. Temperature values are relatively high in Akwa Ibom State throughout the year with mean annual values varying between 26 and 28°C. Moreover, relative humidity remains at average of 70 – 80 percent throughout the year. Average sunshine circulates to 1,450 hours per year and the annual evaporation rate range from 1,500 – 1800 mm (Ekpeyong, 2013).

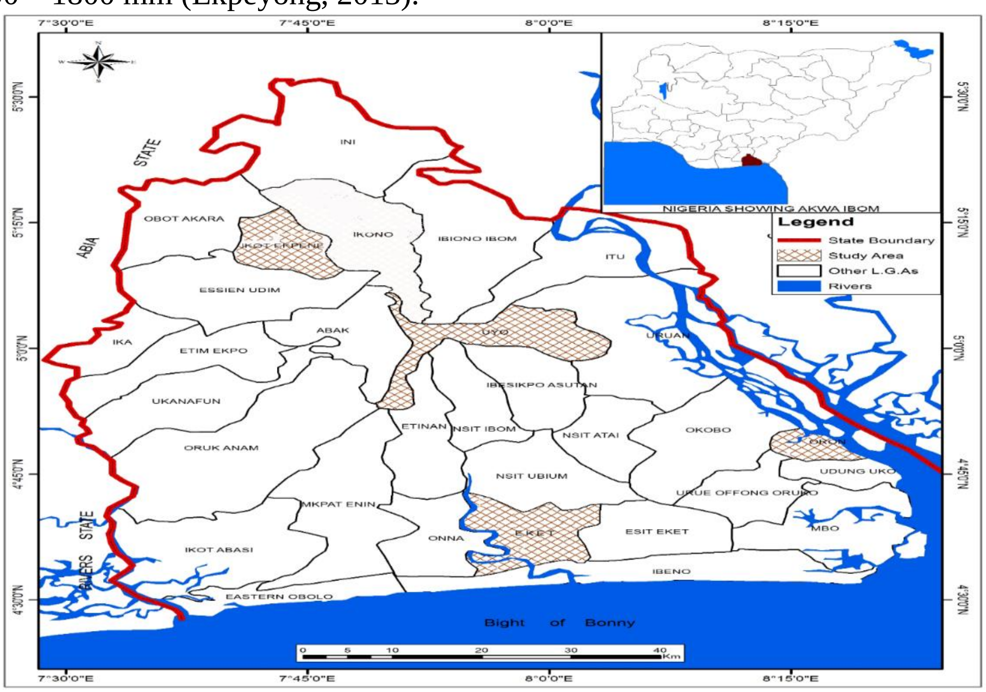

Fig. 1 Akwa Ibom State showing the study locations

2.2 Data collection

Daily rainfall data for coastal area (Eket and Oron) and upland area (Uyo and Ikot Ekpene were obtained from Nigeria Meteorological Agency, Abuja, for a period of 30 years (1988 - 2018).

Table 1. Geographical characteristics of the weather stations

Location	Latitude	Longitude	Elevation (m)
Eket	04°38'47.43"N	07°58'00.20"E	17.67
Oron	04°48'27.24"N	08°15'00.52"E	30.16
Uyo	05°30'45.36"N	07°55'56.16"E	54.23
Ikot Ekpene	05°11'22.39"N	07°42'55.40"E	70.10

Source: NiMet, 2018

2.3 Statistical Analysis

Descriptive statistics was used in determining the decadal rainfall amount and time series in was used to determine the relationship between rainfall and yield of oil palm.

3.0 RESULT AND DISCUSSIONS

3.1 Decadal rainfall and oil palm yield in coastal and upland areas of Akwa Ibom State (1989 – 2018)

The result in figure 2 and 3 shows average annual decadal rainfall and yield of oil palm respectively. The decadal rainfall in Eket, Oron, Uyo and Ikot Ekpene shows that first decade recorded 2943.65 mm, 2830.48 mm, 2093.53 mm and 1752.52 mm respectively; second decade recorded 3138.46 mm, 2953.74 mm, 2166.85 mm and 1853 mm respectively; and third decade recorded 3765.40 mm, 3500.34 mm, 2416.88 mm respectively. The highest amount of rainfall was recorded in the third decade with Oron recording 3765.40 mm, while the least amount of rainfall was recorded in the first decade i.e. Ikot Ekpene with 2943.65 mm. Furthermore, the decadal yield of oil palm for Eket, Oron, Uyo and Ikot Ekpene show that the first decade recorded 8.42 mt/ha, 8.82 mt/ha, 12.62 mt/ha and 12.45 mt/ha respectively; second decade recorded 7.99 mt/ha, 7.27 mt/ha, 15.52 mt/ha and 12.45 mt/ha respectively; and third decade 6.29 mt/ha, 5.34 mt/ha, 18.54 mt/ha and 14.40 mt/ha. Meanwhile, the highest amount of oil palm yield was recorded in the third decade with Uyo recording 18.54 mt/ha, whist the least amount of oil palm was recorded in the third decade with Oron recording 5.34 mt/ha. The result revealed that the increase in the amount of rainfall in the coastal areas results in the decrease in the yield of oil palm and versa.

According to Inter-governmental panel on climate change (IPCC), 2011, the amount of rainfall in coastal areas and others wet tropical zones of the world will continue to increase due to its proximity to water bodies resulting from climate change. Ahmed *et al.*, 2021, also reported an increase in oil palm yield in areas where the amount of rainfall is sufficient for its growth and development.

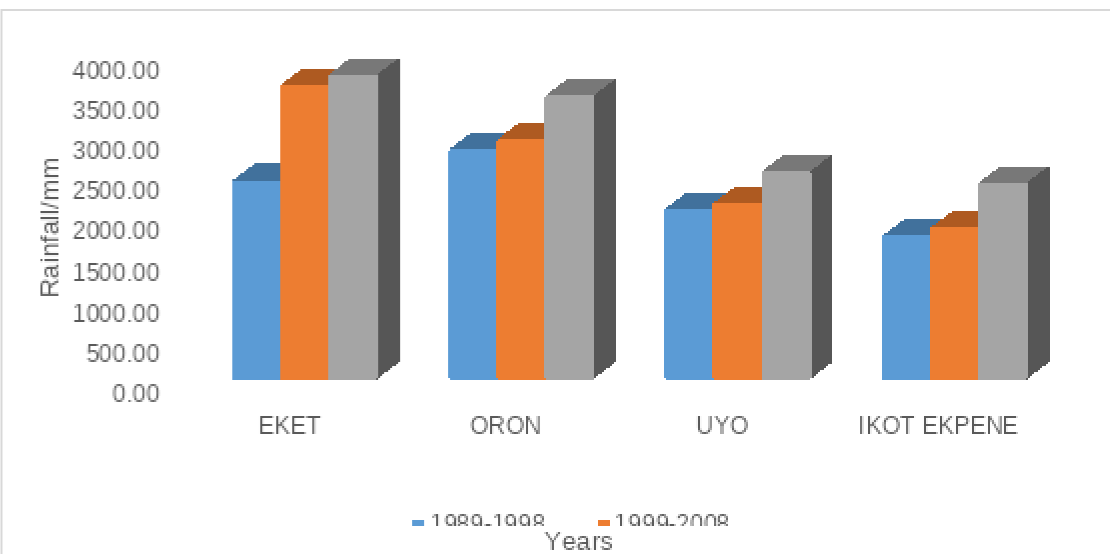

Fig.2: Average Annual decadal rainfall for Eket, Oron, Uyo and Ikot Ekpene (1989 -2018)

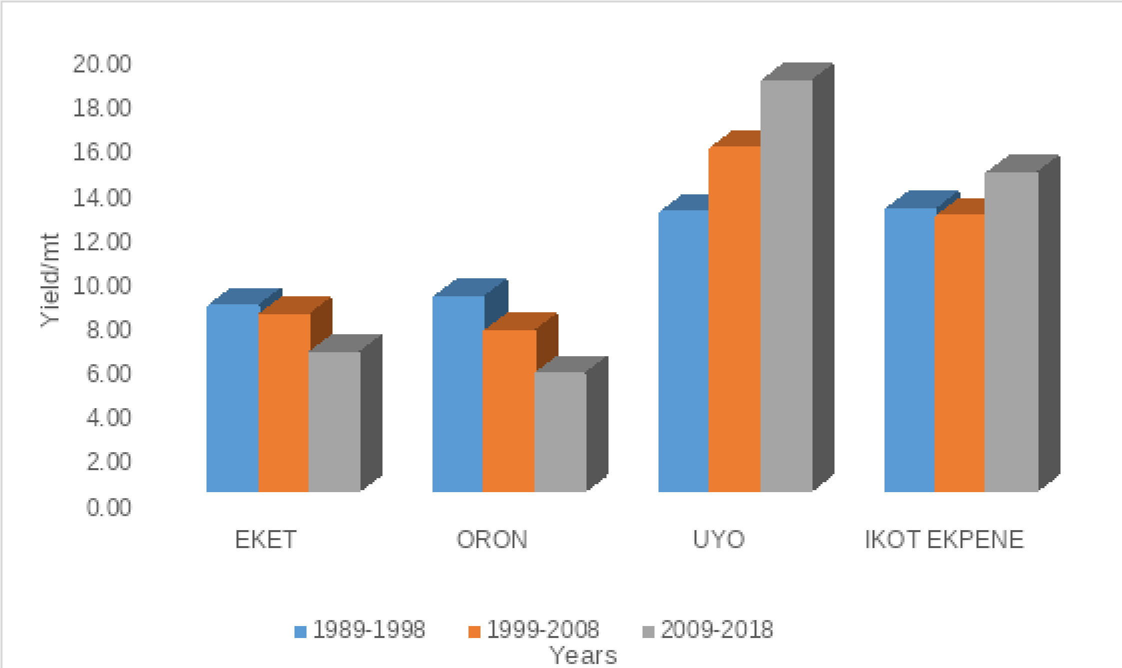

Fig.3: Average Annual decadal yield of Oil palm for Eket, Oron, Uyo and Ikot Ekpene (1989 - 2018)

3.2 Relationship between rainfall and yield of oil palm in coastal and upland areas of Akwa Ibom State (1989 – 2018)

Figures 3 – 7 show the trends of rainfall and yield of oil palm. The trend indicates decrease in yield of oil palm in Eket at $R^{2} =$ 0.1085 and $y = -0.0961x + 9.482$, Oron – $R^2 = 0.4226$ and $y = -0.0583x + 6.8127$; while yield of oil palm increase in Uyo at $R^2 = 0.2143$ and $y = 0.127x + 5.0344$, Ikot Ekpene – $R^2 = 0.3338$ and $y = 0.1583x + 4.9077$. The average yield recorded in Eket, Oron, Uyo and Ikot Ekpene were 7.95. mt/ha, 6.89 mt/ha, 15.22 mt/ha and 12.10 mt/ha respectively. The result shows that only Uyo and Ikot Ekpene recorded the yield that fall within the potential yields of 12 mt/ha and above predicted by NIFOR (2010) for rainforest agro-ecological zone of Nigeria; under condition of adequate nutrients, rainfall and other climatic variables, as well as good varieties. The decrease in oil palm yield in Eket and Oron may be attributed to increase in annual rainfall more than its requirement. Increase in yield of oil palm in Uyo and Ikot Ekpene may be due to increased average annual rainfall (i.e. average rainfall recorded in Eket, Oron, Uyo and Ikot Ekpene are 3822.50 mm, 3094.84 mm, 2272.24 mm and 2007.49 mm respectively). Oil palm is a tree crop that require annual rainfall of 2,000 – 2,800 mm for its optimal performance (Bello *et al.*, 2015). Ndon (2006) reported that oil palm and other tree crops has the capacity to tolerate high amount of rainfall more than the short duration crops (like maize, wheat, tomato, melon, sorghum, etc.) and tuber crops, since these are perennial crops and have medium potential for storing excess water (i.e. large body size, leaves, etc.) but not beyond its requirement.

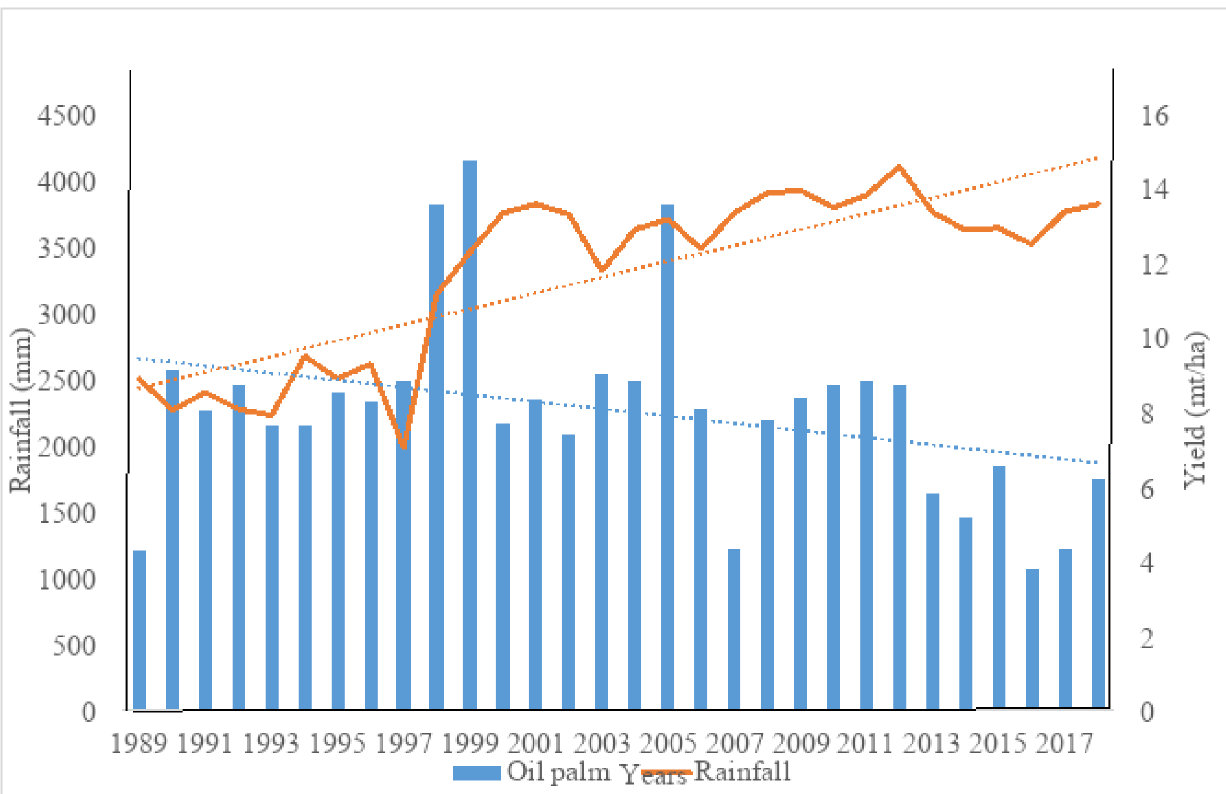

Fig. 4: Trend of rainfall and oil palm yield for Eket (1989 – 2018)

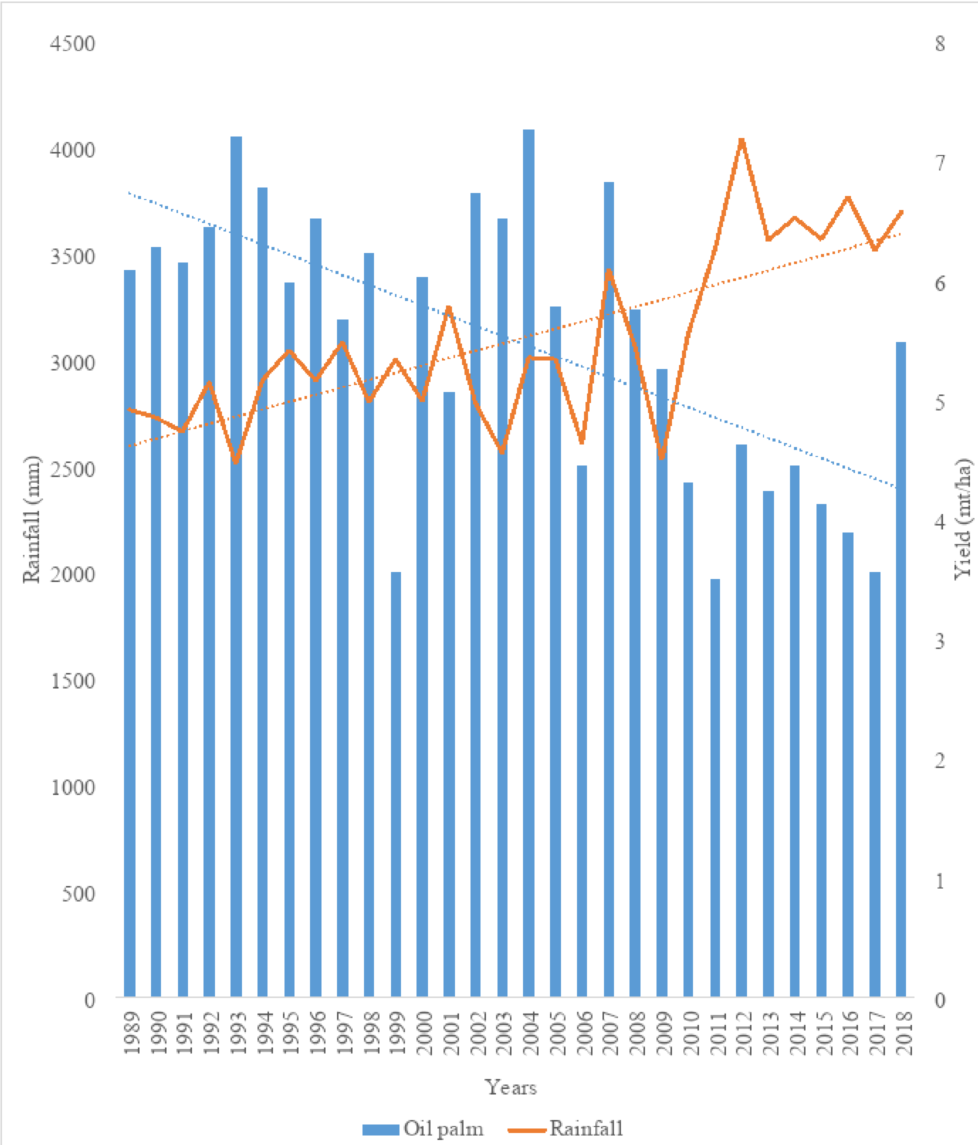

Fig. 5: Trend of rainfall and oil palm yield for Oron (1989 – 2018)

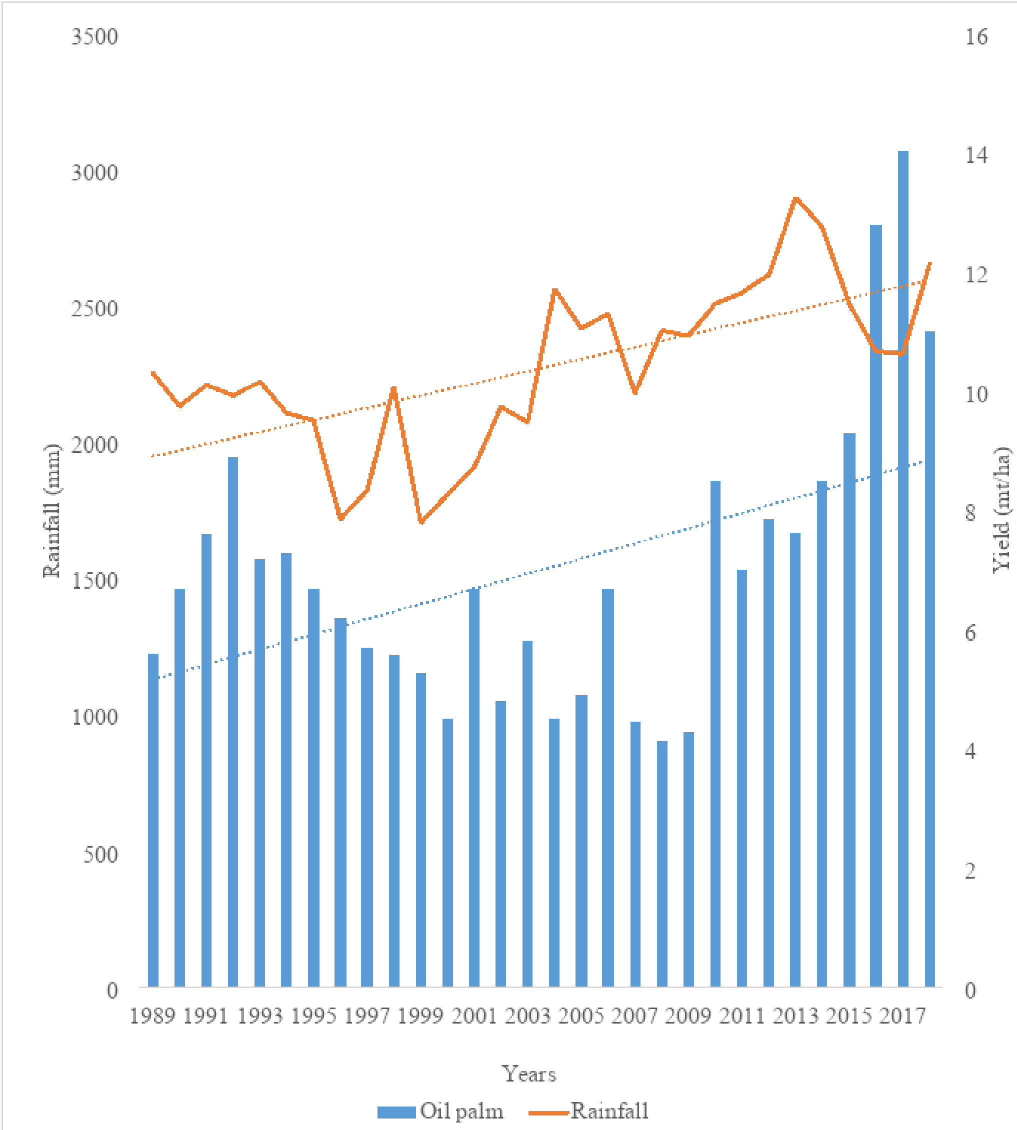

Fig. 6: Trend of rainfall and oil palm yield for Uyo (1989 – 2018)

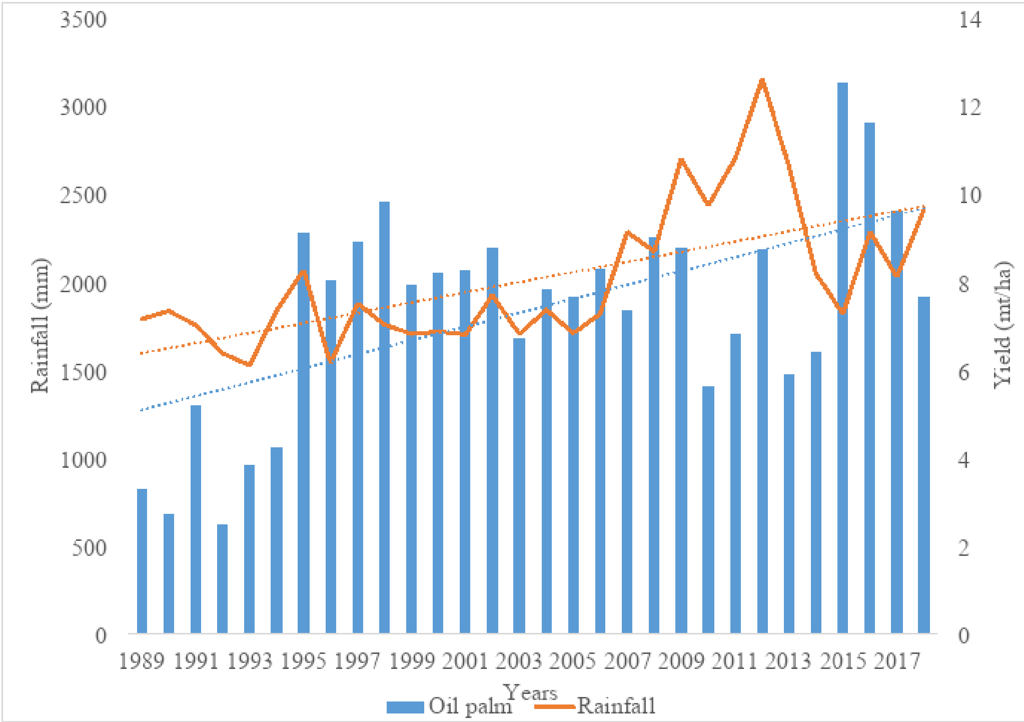

Fig. 7: Trend of rainfall and oil palm yield for Ikot Ekpene (1989 – 2018)

CONCLUSION

Rainfall influenced oil palm production alongside with other climatic variables. The study provides good insight into the influence of rainfall on oil palm yield in Akwa Ibom State. The results revealed that there is a significant increase in rainfall trends in all areas of Akwa Ibom State. Also, the yield of oil palm has increased in relation to rainfall in Uyo and Ikot Ekpene; while the yield of oil palm decreases in Eket and Oron. The decrease in the yield of oil palm may be attributed to an increase in rainfall and vis-visa. Therefore, sustainable production of oil palm could be achieved in upland areas of Uyo and Ikot Ekpene and in other areas with similar rainfall distribution pattern.

ABSTRACT

Soybean (*Glycine max* L. Merril) is cultivated in Nigeria for its nutritive, diverse domestic and industrial importance. Spent auto-engine oil is disposed indiscriminately on lands in Nigeria and huge amount of refinery effluent is released into the environment which pollutes both terrestrial and aquatic ecosystems, with adverse effects on crop growth and yield. This study investigated the effects of spent engine oil (SEO) on the growth and chromosomes of soybean. Soybean (TGX-1448-2E and local variety) were planted in pots filled with sandy-loam soil treated with 0, 0.1, 0.4 and 0.7% v/w SEO concentrations, in completely randomized design with six replications. Data were collected weekly on growth parameters. Cytological examination of the plant cells was conducted at four weeks after planting to investigate chromosomal aberration. Data were analyzed by ANOVA. Similar seed germination percentage was observed in both treated and untreated soils for both varieties although, the rate was higher in TGX-1448-2E (95±0 - 96±0.7%) than local variety (70±0.7 - 71±0.7%) among the four treatments. Treatments 0.4 and 0.7% SEO caused significant ($p \leq 0.01$) reduction in plant height, number of leaves, leaf length and leaf width whereas, 0.1% did to reduce growth parameters. The SEO polluted soils, especially at 0.4 and 0.7%, showed cytotoxic effects on soybean as they reduced chromosome numbers from 36-40 to 21-27), reduce cell division, mitotic index (68.5-70 to 20.8-22.6%) and produced 30.9 to 31.7% aberrated cells in both varieties. This study indicates that spent oil pollution, as low as 0.4%, is phytotoxic to soybeans.

INTRODUCTION

Nigeria is one of the major petroleum producing countries in the world, having oil as the mainstay of its economy (Adenipekun *et al.*, 2008). Over the years, exploration and exploitation of petroleum in Nigeria has brought so much pollution to the environments. A huge amount of refinery effluent is released into the environment which pollutes both terrestrial and aquatic ecosystems. However, pollution emanating from spent engine lubricating oil has been reported to be more widespread and prevalent than that of petroleum (Odjegba and Sadiq, 2002). Spent auto-engine oil is a waste produced from automobile workshops, mechanical and electrical engine repairer's shops after servicing vehicles, power generating sets and other types of engines (Okonokhua *et al.*, 2007). Spent engine oil (SEO) is obtained during routine maintenance of automobile and power generating engine and often indiscriminately disposed into gutters, municipal drainage systems, open vacant plots and lands in Nigeria by auto-technicians and allied artisans with workshop on the roadsides and open place (Anoliefo and Vwioko, 2005). Ahamefule *et al.*, (2017) reported that oil (petroleum) in soils has deleterious effects on biological, chemical and physical, properties of the soil depending on the dose, type of the oil and other factors. The spent oil has been reported to contain increased amount of heavy metals. Adverse effects of SEO on crops have been earlier reported. Agbodigi (2010) reported poorer germination response of cowpea with increasing dose of SEO.

Soybean (*Glycine max* L. Merril) is one of the most valuable, versatile, and nutritionally important legumes globally. It can be grown under a wide range of climatic conditions, using a variety of management practices, and for diverse purposes (Shea *et al*., 2020). Nigeria is the second largest producer of soybean in Africa, after South Africa, with annual production of about 600,000 tonnes (FAOSTAT, 2020). It is increasingly cultivated in Nigeria due to its high nutritive, and diverse domestic and industrial importance (Qiu and Chang, 2010). The key advantages of soybean are its high protein content, minerals and insoluble fiber (Fabiyi, 2006; Riaz, 2006). It is a good source of several vitamins and minerals, including vitamin K1, folate, copper, manganese, phosphorus, and thiamine (Fabiyi, 2006).

The capacity of SEO to inhibit cell division, reduces mitotic index and causes chromosome aberrations, and reduce growth has also be envisaged in some crops (Obute *et al*., 2016). Chromosomal aberration includes changes either in chromosome structure or number. Alterations in the chromosomal structure can be caused by breaks of DNA, DNA synthesis inhibition and modification in the DNA replication (Leme and Marin-Morales, 2009). In the absence of telomeres, chromosomes turn out to be "sticky" which may join to other fragmented chromosomal ends. Tanti *et al*., (2009) and Obute *et al*., (2016) have shown that heavy metals in SEO have strong toxic effects on soybean plants. Meanwhile, there is limited information on the growth retardation of soybean by SEO polluted soils while its potential cytotoxic impact on the crop is yet to be fully assessed. This study thus investigated the effects of SEO on seed germination, plant growth and chromosomal stability of soybean.

MATERIALS AND METHODS

Sources of planting materials The study was carried out at the experimental plot of the Department of Biological Sciences, Bells University of Technology, Ota, Ogun State Nigeria. The two soybean genotypes used were improved variety TGX-1448-2E sourced from the Institute of Agricultural Research and Training (IAR&T), Moor Plantation, Ibadan, Oyo state Nigeria and local variety obtained from "Oja Oba" market, Abule Egba, Lagos State Nigeria.

Soil treatments, planting and seedling maintenance

Sandy loam soil was collected at 15 cm depth (top-soil) from fallow land in Bells University of Technology, Ota, Ogun State. The SEO used was obtained from vehicles undergoing service maintenance at automobile workshop in Ota, Ogun State. The oil was left for three days to thicken before use in soil treatments. About 5 kg of the soil was weighed into 8-inch (20-cm) plastic pots and four soil treatments: 0, 0.1, 0.4 and 0.7 % v/w of SEO were prepared using of 0, 5, 20 and 35 ml SEO concentrations per 5 kg soil. The treated soils were left for 24 hours before planting so as to penetrate the soil. Five seeds were sowed per pot and seedlings were thinned down to two on the nineth days. There were 24 pots per variety, making a total of 48 pots arranged in a completely randomized design with six replications. The study was conducted between January and April, 2020. The potted plants were maintained by daily watering and weed control was carried out manually. Insect pests were managed with Cypermethrin insecticide ('Cyperforce', 10% EC) at 4 m/l sprayed four times at two weeks interval, starting from four weeks after planting (WAP). Growth parameters were recorded weekly from 1 WAP.

Cytological assessment of the root tips of soybeans

At 4 WAP, seedlings were uprooted and the root tips of the plants of both varieties were excised and washed with sterile distilled water. Root tips were collected from the treated and untreated (control) plants at 10am. The root tips samples were directly fixed in 3:1 ethanol (96 %) to acetic acid for 24 hr or 48 hr to arrest cell in metaphase without any pre-treatment. The fixed root tips were hydrolyzed in 18 % HCl for 5 minutes in order to degrade cell wall. The root cells were prepared for the chromosome counting using Squash method according to Ostergren and Heneen (1962). The cells were stained with FLP ORCEIN solution for 2 hr to allow enough dye accumulation. The prepared samples, mounted between slides and coverslip, were observed under 40X and captured using a compound light microscope at 100X, for each soil treatments. About seven (7) individual cells on different slides at metaphase stage were prepared from the plants and used to count the number of chromosomes and the average from the seven individual cells observed were used to evaluate the number of chromosomes counted. Another prepared samples, mounted between slides and cover slip were observed for total cells, including dividing cells and aberrated cells (chromosomal aberrations) under 100X magnification using the trinocular microscope (Euromax Microscopen, Spain) and cytologically observed photos were taken from the attached digital camera.

Data collection

Data were collected on seed germination rate at 7 days after planting (DAP) and plant height (cm), number of leaves, leaf breadth (cm) and leaves length (cm). Data were also taken on chromosome number at metaphase stage, number of cells, number of dividing cells and number of aberrated cells using cytologically observed photos through counting as earlier mentioned.

Data analyses

Seed germination rate was determined by the ratio of the number of germinated seeds to the total number of seed sown, expressed in percentage (Ahamefule *et al*., 2017). Data on growth parameters were subjected to analyses of variance (ANOVA) using the PROC GLM statement of Statistical Analysis System, version 9.2 (SAS, 2008) and means were separated using least significant difference ($p \leq 0.01$). For cytological analysis, a total of 1000 cells were counted at 100X magnification for different phases of cell divisions to check for chromosomal aberrations. Data on the cytological effects of the SEO on cell division and chromosomes number of soybean seedlings were estimated using the mitotic index (M.I.) and the chromosomal aberrations calculated according to the formulae described by Bakare *et al.* (2000) as follows:

$$\text{Mitotic index (MI \%)} = \frac{\text{Total number of cells in division}}{\text{Total number of analysed cells}} \text{ x } 100$$

$$\%\ \text{aberrated cells} = \frac{\text{Number of aberrated cells}}{\text{Total number of cells in division}} \times 100$$

RESULTS AND DISCUSSION

Effect of oil polluted soils on seed germination

The seeds of both soybean varieties (TGX-1448-2E and local variety) germinated in the untreated soil and those treated with 0.1, 0.4 and 0.7 % v/w SEO. Germination of seeds was observed from 4 to 7 DAP which was earlier (4 to 5 days) in the 0, 0.1, 0.4 % treatments but delayed (6 to 7 days) in 0.7 % SEO treated soils. Similar germination rate was observed in all the oil-treated and untreated soils for each soybean varieties whereas, percentage seed germination of TGX-1448-2E in the four treatments, were generally significantly higher (95±0 - 96±0.7 %) than that of the Local variety (70±0.7 -71±0.7%) (Table 1). This is contrary to the report of Katsivela *et al.* (2005) on hindrance to seed germination by SEO polluted soils. The inhibitory effect of SEO on germination has been reported to be dose dependent (Agbogidi and Ilondu, 2013) and the SEO concentrations evaluated in this study were lower than the 1 % (Agbogidi, 2010) and 3 % v/w (Ahamefule *et al.*, 2017) reported to have inhibited seed germination. The lower seed viability of the local variety obtained from the market than the improved variety might be due to poor seed storage conditions, or insect and pest damage to the seeds (Grau *et al*., 2004).

Growth parameters inhibition of soybean by spent engine oil polluted soil

The SEO treated soils produced chlorosis and reduced plant height, number of leaves, leaf width and leaf length of soybean. The trend of growth from the first to fourth WAP (Figure 1(a- d) showed higher plant height and number of leaves from untreated soil (control) than the SEO treated soils in both varieties. The two growth parameters reduced with increased treatment, with 0.7 % SEO producing the least growth. This treatment also showed high retardation in plant height from week one to two indicating stunted growth. The 0.1 % SEO did not show reduction in number of leaves whereas 0.7 % reduced the number of leaves of local variety and TGX-1448-2E from 2 and 3 WAP, respectively.

Table 1. Percentage germination of soybean seeds planted in spent engine oil (SEO) contaminated soil

Variety	SEO concentration (%)	Seed germination (%)
TGX-1448-2E	0	96 ± 0.7a
	0.1	96 ± 0.7a
	0.4	95 ± 0.0a
	0.7	95 ± 0.0a
Local variety	0	71 ± 0.7b
	0.1	70 ± 0.0b
	0.4	70 ± 0.7b
	0.7	70 ± 0.7b

Means with the same letter are not significantly different by LSD ($p \leq 0.01$)

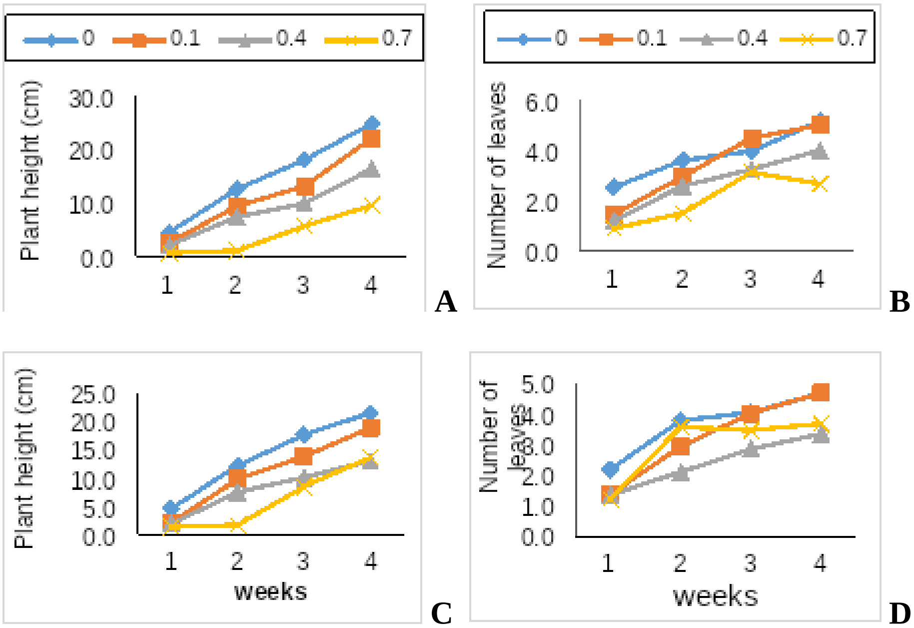

Figure 1 (A - D). Effect of spent engine oil treated soils on the rate of plant height and number of leaves of soybean varieties for four weeks: A and B = plant height and number of leaves of TGX-1448-2E, C and D = local variety

There were significant differences ($p \leq 0.01$) in plant height, number of leaves, leaf width and leaf length of the two varieties. For TGX-1448-2E, highest plant height of 24.9 ± 0.9 cm was observed in untreated soil (control), whereas 0.7 % SEO produced the least (9.6±8.0 cm) (Table 2). Similar trend was observed in the other growth parameters. However, there was no significant difference in the yield parameters produced by the untreated soil (control) and 0.1 % SEO in all the parameters evaluated in both soybean varieties, with the exception of plant height of the local variety. This implies that 0.1 % SEO did not significantly reduce growth parameters (Table 2).

The inhibitory effects of SEO on crop growth have been previously reported (Agbogidi and Ejemete, 2005; Ekpo *et al*., 2012). The lower growth parameters might be due to reduction of nutrient elements with increasing oil concentration in the soil (Odjegba and Atebe, 2007). For instance, a study on maize *(Zea mays*) showed that oil pollution made nutrient elements, especially macronutrients, in the soil unavailable for plants use (Udebuani *et al*., 2017). Another possible cause of the plant growth inhibition by SEO is either increased acidity in the soil or reduction in the catalase activity (Achuba and Peretiemo-Clark, 2007). Such increased acidity has be attributed to the production of organic acids due to microbial metabolism of the substrate (Udebuani *et al*., 2017).

The presence of some heavy metals in the SEO soil might have also contributed to the observed chlorosis and stunted growth of soybeans (Okonokhua *et al*., 2007). High concentration of cadmium as well as nickel, lead, copper and zinc have been reported in oil polluted soil and cadmium is highly toxic to plants, with its toxicity manifested in form of chlorosis, necrosis, stunting and reduced photosynthesis (Udebuani *et al*., 2017). Oil pollution usually has adverse effects on the physical, chemical, and biological properties of the soil (Agbogidi and Ejemete, 2005; Ahamefule *et al*., 2017). This response of soybean and its ability to tolerate most of the mineral contents in the oil polluted soil has presented the crop with high potential for phytoremediation of oil contaminated soils (Sanderson *et al*., 2018).

Table 2 Effects of spent engine oil (SEO) on growth parameters of Soybeans at week four

Variety	SEO concentration (%)	Plant height (cm)	No. of leaves	Leaf width (cm)	Leaf length (cm)
TGX-1448-2E	0 (control)	24.9±0.9a	5.2±0.5a	2.9±0.2a	7.6±0.7a
	0.1	22.2±0.6ab	5.0±0.5a	2.8±0.3ab	5.7±1.4ab
	0.4	16.4±1.0bc	4.0±0.5ab	2.5±0.3ab	5.8±1.6ab
	0.7	9.6±8.0c	2.7±2.3b	1.5±1.4b	3.4±2.9b
Local variety	0 (control)	21.5±0.5a	4.6±0.3a	2.7±0.2a	5.9±0.1a
	0.1	18.8±1.1b	4.7±0.8a	2.7±0.3a	5.7±0.9a
	0.4	12.9±0.3c	3.3±0.3b	2.3±0.3ab	4.5±0.4b
	0.7	13.5±0.4c	3.7±0.3b	2.1±0.1b	3.4±0.2c

Means with the same letter within column per variety are not significantly different by LSD ($p \leq 0.01$)

Cytotoxic effects: Chromosomal aberration: cell division, aberrated cells and mitotic index

The SEO treatments produced cytotoxic effects on soybean. The number of chromosome, number of cells in division, number of aberrant cell and mitotic index of the two soybean varieties varied among the SEO treatments. The number of chromosomes counted at metaphase stage of the soybean cells decreased with increase in concentration of SEO (Table 3). The numbers were higher (36 to 40) for plants from untreated soil in both soybean varieties which is within the expected chromosome number of soybean (2n=40) (Hailemariam and Tesfaye, 2018) than that from 0.7 % SEO treated soil (21 to 27). This implies that 0.4 and 0.7 % SEO treatments were cytotoxic to soybean plants indicating an aberrant changes in chromosomal numbers. Cytological observation of root tip cells of soybean raised in SEO polluted soil showed some cellular and chromosomal aberrations (Figure 2 (A – E)).

Table 3. Chromosome counts of soybean (2n = 40) root cells at metaphase stage at four weeks of growth
in spent engine oil (SEO) treated soils

Variety	SEO concentration	No. of chromosomes from seven cells at metaphase							
	(%)	1	2	3	4	5	6	7	mean
TGX-1448-2E	0 (control)	38	40	37	40	38	39	40	39
	0.1	34	32	32	35	32	29	37	33
	0.4	25	25	33	24	27	24	30	27
	0.7	22	23	26	22	23	27	21	23
Local variety	0 (control)	38	39	36	40	40	36	37	38
	0.1	29	30	33	29	36	31	32	31
	0.4	24	29	25	23	26	27	31	26
	0.7	22	21	20	26	24	23	25	23

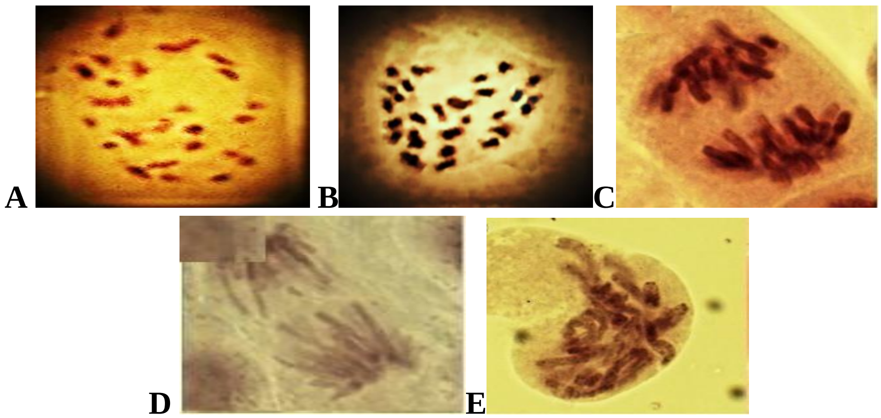

Figure 2 (A - E). Aberrations in mitotic cell division of soybean caused by spent engine oil polluted soil: A and B = stickiness of chromosomes at metaphase, C = stickiness with chromosome fragments D = bridge and laggard chromosome, E = chromosome bridge and disturbance in metaphasic spindle

The number of aberrant cells or percentage abnormality (% aberrant cells) was highest at the highest SEO concentration whereas, no aberrant cell was detected from untreated soil (control) (Table 4). The mitotic index (M.I.) also decreased with increase in SEO treatments. The highest values of 70 and 68.5 were obtained from untreated plants (control) whereas the least (22.6 and 20.8) were observed from the highest SEO concentration (0.7 % v/w) for TGX-1448-2E and local soybean varieties, respectively. The decreased mitotic index also indicated a strong trend of inhibition of cell division in soybean by oil treated soils. The observed reduction in the frequency of dividing cells might be due to lack of spindle fibres formation that would have introduced the cells from one stage to another (Timothy *et al.*, 2014). Borah and Talukdar (2002), similarly reported that the frequency of cells and chromosomal aberrations (abnormalities) was associated with the toxicity of the spent engine oil.

Such oil polluted soil have produced an abnormal increase in size (hypertrophy) of new cells of maize plant which later ruptured as the cells grew older (Udebuani *et al.*, 2017). Previous studies have indicated the cytotoxicity of plants at 1 % of SEO concentration and above (Agbogidi, 2010; (Ahamefule *et al.*, 2017). However, the observed phytotoxicity of SEO on soybeans, even at a concentration of less than 1 %, has not be previously reported.

Table 4. Mitotic index and percentage aberrated cells of soybean planted in spent engine oil (SEO) treated soil

Variety	SEO concentration (%)	Total cells observed	No. of cells in division	No. of aberrated cells	Aberration (%)	Mitotic index (%)
TGX-1448-2E	0 (control)	1000	700	0	0	70
	0.1	1000	560	38	6.8	56
	0.4	1000	355	49	13.8	35.5
	0.7	1000	226	70	30.9	22.6
Local variety	0 (control)	1000	685	0	0	68.5
	0.1	1000	515	36	6.9	51.5

	0.4	1000	368	53	14.4	36.8
	0.7	1000	208	66	31.7	20.8

CONCLUSION

This study shows that discharge of SEO on lands, farmlands and water bodies, has inhibitory and detrimental effects on the growth parameters of soybean plants. Soil pollution at 0.4 and 0.7 % v/w SEO resulted in significant reduction in the plant growth parameters. Discharge of spent auto-engine oil as low as 0.4 % in soil produced phytotoxic effects on soybean some which include: reduced mitotic index activity, cell and chromosomal aberrations in forms of Sticky chromosome, bridge and laggard chromosomes. This cytotoxic effects necessitate the need for soil test for oil pollution of farmlands before farming, especially those with close proximity to auto-mechanic stations. There is also the need for public health education and oil pollution campaign in Nigeria on the danger of indiscriminate discharge of oil and possible regulation and other environmental friendly solution to spent oil disposal by the government. This is important so as to ensure environmental and human health, especially on the high levels of heavy metals contamination in food crops. Field studies on the level of growth inhibition and reduction in the productivity of soybean by oil spillage is important for effective crop yield loss prevention.

24 - 28 Oct., 2022

ABSTRACT
This study examined the physicochemical properties of topsoil that were collected around the vicinity of Ota industrial estate, Southwestern, Nigeria. The study is important for understanding the potential for translocation of contaminants within the soils of the study area. Eleven representative samples including control were obtained and examined for parameters such as pH. Soil organic carbon SOC), Soil organic matter (SOM), granulometric fractions and cation exchange capacity (CEC). The result from vicinity of industrial area showed pH value to range between 4.93 to 6.68, SOC ranged between (0.30 to 1.81)% while SOM was found to be between (0.52 to 3.11)%. The granulometric property showed the soil to be mostly sandy, followed by clay and silt. CEC was low and found to range between (1.90 to 5.50)cmol/Kg. The result for control showed pH to be 6.97, SOC and SOM were 2.49% and 4.28% respectively. CEC was found to be 6.23cmol/Kg. The values obtained from the vicinity of the industrial estate could be attributed to improper waste disposal within the industrial estate. Therefore, a more stringent legislation about environmental management, as well as studies about the mineralogical composition of soils is recommended.
Key words: Physico-chemical parameters, soil, Industrial estate, Nigeria

INTRODUCTION
Soil is the dynamic link between the biosphere and lithosphere and constitutes a practically nonrenewable (very low rate of formation) natural resource, with a key role for the environment and for the agriculture (Moraetis et al., 2016). Soil pollution is one of the major problems that threatens plant and people's lives. Anthropogenic activities such as seepage from landfills or solid waste, discharge of industrial waste into the soil, percolation of contaminated water into the soil, rupture of underground storage tanks or excess application of pesticides or fertilizers (Seifi et al., 2010) could change the physicochemical properties of the soil. Properties such as pH, organic matter, cation exchange capacity (CEC) and soil texture could be affected. Soil pH affects nutrients availability and the optimal condition for this is at pH 5 to 7 (Arp and Krausse, 2006). The potential for elements present in soils and sediments to be mobilized/immobilized and be redistributed depends on several factors such as organic matter, type and amount of clay, pH and the prevailing redox conditions; and pathways. These elements can easily be mobilized and

transmitted through for example, water and the food chain to humans (Manga et al., 2017). Therefore, there is great need to investigate the physicochemical properties of soils for agricultural and environmental purposes.

Despite growing rates of industrialization, many developing third world countries pay too little attention to environmental issues. This is evident in the location of many industrial facilities near residential areas and the non-availability of adequate regulatory and enforcement measures to guard against pollution. One of such industrial facilities co-located with residential areas is the Ota Industrial/Housing Estate in the southwestern region of Nigeria (Figure 1). There are forty seven different factories within the estate dealing with a wide range of products that include chemicals, pharmaceuticals, plastics, paper and pulp, and metals/steel. A third of these industries which represents the primary industrial types are metal-based industries, producing either iron rods, steel or galvanized pipes and sheets. Co-located with these industrial types at very close proximity are residential houses. Emissions of particulates into the atmosphere, and improper disposal of solid wastes are common practices within the estate. This paper investigates the physicochemical parameters in topsoils within the vicinity of Ota industrial estate, South western Nigeria.

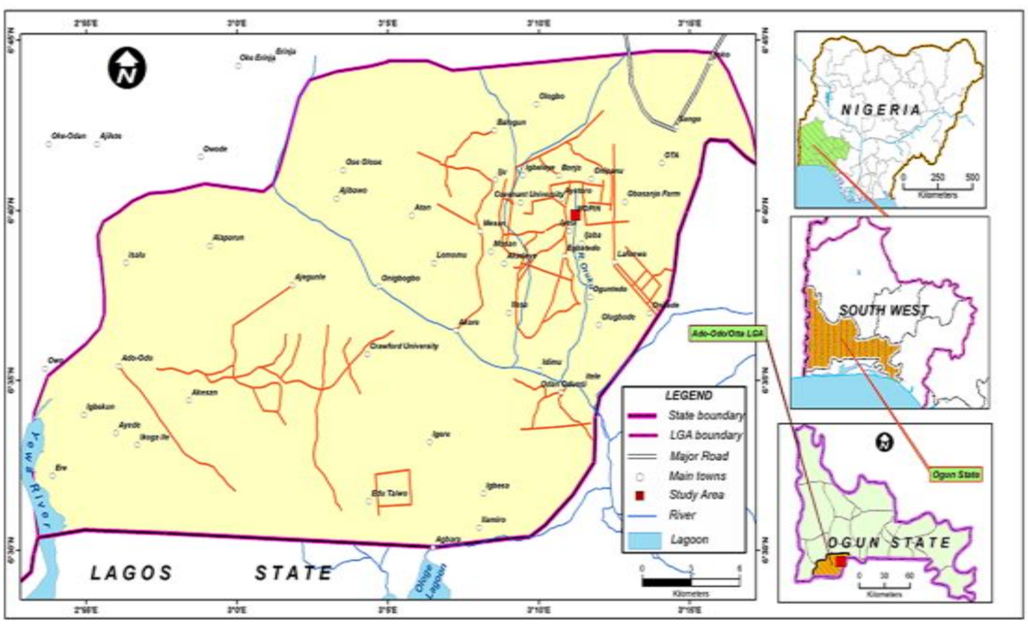

Figure I: Map of Ado Odo Ota local government showing the sampling location

MATERIALS AND METHODS

Description of Study Locations

The Ota industrial/housing estate, located on latitude $6^{0}32'$N and longitude $2^{0}57'$E, is sited on a 22.8 km^2 expanse of land in tropical southwestern region of Nigeria.

Sampling

Topsoils were sampled from five core industrial areas (TSI), three residential areas (TSR), two vegetation areas (TSV). Control sample (TSC) was obtained from other residential areas located about 1 km from the industrial estate and not affected by industrial activities. Field sampling were conducted at a depth of 0 to 15cm with the aid of an auger. The samples were collected into a black polythene bag and labeled.

Sample Preparation and Analytical

The soils were air-dried in a clean room in the laboratory and then passed through a 2 mm mesh sieve. Soil pH was determined by the electrometric method using a 1:1 soil water mixture (IITA, 2001). The hydrometer method was used for measuring soil granulometric properties (sand, silt and clay) (Bouyoucus, 1951), while the classical redox back-titrimetry procedure was used to determine soil organic matter content (Walkey and black, 1934).

CEC was determined by ammonium acetate, pH 7.0 method (FAO, 2022)

RESULT AND DISCUSSION

Table I: Physico-Chemical Properties of Soils in the vicinity of Ota Industrial Estate, South western, Nigeria.

	TSI-1	TSI-2	TSI-3	TSI-4	TSI-5	TSR-1	TSR-2	TSR-3	TSV-1	TSV-2	TSC

Cation exchange capacity (cmol/Kg)	4.50	4.30	4.60	3.25	2.75	1.90	3.25	4.75	4.00	3.26	6.23

The results of the physicochemical properties of soils in the vicinity of Ota industrial estate, Southwestern Nigeria was presented in Table I.

The soil pH value within the vicinity of the industrial estate showed pH to vary between very strongly acidic (TSI-2) to slightly acidic (TSI-5) according to the ratings from Hazelton and Murphy (2007). pH of the control (TSC) was neutral. The degree of acidity and/or alkalinity is considered a master variable that affects nearly all soil properties-chemical, physical and biological. While some organisms are unaffected by a rather broad range of pH values, others may exhibit considerable intolerance to even minor variations in pH (Obasi et al., 2012). The soil pH also affects the availability of various nutrients, toxic elements and chemical species to plant roots. The pH is therefore a very good guide to some expected nutrient deficiencies and toxic effects (Brady, 1984). In a similar study, Osakwe and Okolie (2015) found that the soil pH had a mean value of 5.15 ± 0.48.

According to the rating established by Hazelton and Murphy (2007), the soil organic carbon (SOC) contents were in the low to high range. Low value of SOC were recorded in the core industrial area (TSI-1 to TSI-5), only TSR-2 recorded low SOC while others were high. High content of SOC and SOM were recorded in the control sampleSoil organic carbon is the basis of soil fertility. It releases nutrient for plant growth, promotes the structure, biological and physical health of soil, and is buffered against harmful substances. Increasing soil organic carbon helps in mitigating climate change, improves soil health and fertility. SOC also has influence on releasing or holding CO_2 from the atmosphere through various channels, thereby possibly affecting the atmosphere-soil carbon balance (Wu et al., 2001; Jiang et al., 2007). The low values could be attributed to improper waste disposal and the sandy nature of most of the soils. Particle size was dominated by sand, followed by clay and silt, which revealed coarse soils with low supply of nutrients and moisture (Osakwe and Okolie, 2015). Etim and Onianwa 2013 recorded low value for organic carbon and organic matter in a similar study

The cation exchange capacity (CEC) was rated low in all the soil samples studied except in the control. This rating was done according to Benton (1999); Hazelton and Murphy 2007. CEC is the capacity of the soil to hold and exchange cations. It provides a buffering effect to changes in pH, available nutrients, calcium levels and soil structural changes. As such it is a major controlling agent of stability of soil structure, nutrient availability for plant growth, soil pH, and the soil's reaction to fertilisers and other ameliorants. A low CEC means the soil has a low resistance to changes in soil chemistry that are caused by land use. Fomenky, et al 2018 also recorded low CEC in soils around some rivers in Cameroon.

CONCLUSION

The result from the study area showed the soil pH to vary between very strongly acidic to slightly acidic except for the control that was neutral. The SOC and SOM ranged from low to high. CEC showed low value for soil sample but high CEC content in the control. The values obtained from the vicinity of the industrialestate could be attributed to improper waste disposal within the industrial estate. Therefore, a more stringent legislation about environmental management, as well as studies about the mineralogical composition of soils is recommended.

ABSTRACT

Barley (*Hordeum vulgare*) grown in Tigray regions usually undergoes salinity problem due to poor water quality and drought stress at the different stages of growth. Study was conducted at the green house of the Department of Crop and Horticultural Sciences, Mekelle University, Ethiopia on response of barley to different levels of salt and moisture stress. Treatments used were T_0 = 3 litres of water + No salt, T_1 = 1 litres of water + 150g of salt, T_2 = 2 litres of water + 100g of salt, T_3 = 3 litres + 50g of salt, T_4 = 1 litre of water + 50g of salt, T_5 = 2 litres of water + 150g salt and T_6 = 3 litres of water +100g salt) and replicated five times. The experiment was designed in a Randomized Complete Design. Data were taken on germination percentage, plant height, leaf area, fresh and dry weight of the shoot biomass, fresh and dry weights of the roots and length at harvest. Data collected were analyzed by Analysis of Variance (ANOVA) and means comparisons were done at 5% level of probability. From the result,T_0 gave the highest response from all parameters evaluated, followed by T_4 and T_3 at early stages and T_6 later while T_1 gave the least values. Also, T_3 produced significantly higher results in all parameters measured compared with others. Thus, Barley roots length, fresh and dry biomass weights were significantly affected with increasing salt concentration. Hence, moisture is needed in barley production and yield is negatively influenced by the amount of salt concentration in the soil.

Key words: Arid environment, Barley, Yield, Moisture rates, Salt concentration

INTRODUCTION

Barley (*Hordeum vulgare* L.) is one of the oldest domesticated crops where consumption is as early as 1500BC (Smith, 1995). It is an essential crop in Africa, especially in the arid and semi-arid regions and serves as a staple food and feed crop for humans and livestock respectively.

Inadequate moisture and salinity are considered major environmental factors limiting the growth and productivity of crops. Prolonged periods of drought stress resulted in major losses in grain yield of rain fed crops in Ethiopia and characterized by a semi-arid Mediterranean climate. Similarly, rain is scarce, irregularly distributed, and varies from one year to another in the Tigray region (FAO, 1999).

Salinity has a two-fold effect on plants; the salt in the soil solution decrease the availability of water to the roots (osmotic stress) and the salt taken up by the plant can accumulate to toxic levels (ionic stress) in plant tissues (Munns *et al*., 2006). In a similar vein, James *et al*. (2002) further reported that salt stress unfavourably affected plant growth and productivity at all developmental stages with the views that salinity decreases seed germination, retards plant development and reduces crop yield.

Irrigation as a source of water supply can cause salinization, water logging and soil degradation, which are evident in many areas of the world (Wang, 2004). At the same time, water stress could result in lower nutrient mining and disturbance of metabolites transportation to the grains. To this end, Salinity affects leaf water potential, leaf osmotic potential and leaf pressure potential of plants. As salinity increases, leaf water potential and leaf osmotic potential decreases whereas leaf pressure potential increases (Acquaah, 2002). Barley is known to be tolerant to salinity and moisture stress, the objective of this study was to determine physiological factors that makes barley tolerate salt and moisture stress and its response to different levels of salinity and moisture stress. Hence, the purpose of this study was to evaluate the effects of different salt concentration and precipitation rates on the growth and development of barley.

MATERIAL AND METHODS

The investigation was conducted in the screen house of the Department of Crop and Horticultural Sciences, Mekelle University, Ethiopia in two consecutive seasons. The barley cultivar, *Birguda* variety, a native of Tigray region in Ethiopia was used as test crop for the project.

Base-line analysis of the soil sample was carried out to validate the status of the soil. The soils were sieved and filled into plastic pots. The pots were perforated to enhance proper drainage of water and arranged in the greenhouse. The experiment was designed in a Randomized Complete Design and replicated five times.

Seeds obtained from the seed-bank of the Department of Crop and Horticultural Sciences, Mekelle University, Ethiopia were selected based on physical appearance (size, colour and length) to ensure viability. Saline culture solutions with different osmotic potential were prepared by mixing NaCl and $CaCl_2$ in a 2:1 Molar ratio at different concentrations (0, 50, 100 and 150 grams) and water volumes (1, 2, and 3 litres) respectively. The prepared solutions were added to the pots accordingly and left till the following day, after which five seeds were planted per pot and water was added in line with the treatment. The treatments include: T_0 = Control (No salt + three litres of water) ; T_1 = 1 litter of water + 150g of salt concentration,T_2 = 2 litres of water + 100g of salt concentration; T_3 = 3 litre of water + 50g of salt concentration; T_4 = 1 litres of water + 50g of salt concentration; T_5 = 2 litres of water + 150g of salt concentration and T_6 = 3 litres of water + 100g of salt concentration. The same quantity of water was added at two days intervalup to the time of harvest. Parameters measured included germination percentage. The leaf area (cm^2) were calculated from the TIFF file using a public domain software (Scion image) as suggested by O'Neal et al. (2002). Seedlings were harvested to determine root and shoot lengths (cm), root and shoot fresh weights (kg seedling^{-1}) and finally root and shoot dry mass (kg seedling^{-1}). Shoot length was measured from the soil surface up to the highest point of the longest leaf. Fresh shoot biomass and dry weight of the roots per pot as well as root length at harvest. Root length was measured from the crown down to the tip of the root. The dry mass was determined after the roots and shoots were dried in an oven at 80 °C for 48 hours in paper bags.

Data obtained were subjected to analysis of variance and means were separated using Statistical analysis of data was carried out with the use of JMP-5 soft ware's.Means comparisons were done at 5% level of probability with the use of Turkey –Kramer HSD approach.

RESULT AND DISCUSSION

The soil analysis revealed the nutrient status and nature of the soil (Table 1). There was low organic carbon, organic matter, high pH value of 8.2 and high electrical conductivity (EC) value indicating high alkalinity and salinity. The final germination percentage and root length of barley reduced significantly with increased salt concentration (Table 2). Treatment T_0 gave the highest germination (96%) and root length (13.12 cm) while the use of T_1 gave the least germination (44%) and root length (5.32 cm) respectively. The results suggested that Nacl salinity inhibits seed germination and root seedling growth of barley. Treatment T_0 is significantly different from other treatments on all parameters measured at $p < 0.05$.

Growth and development of barley was strongly affected by salinity levels; as the increased salt concentration resulted in reduction of germination percentage, plant height, leaf area, as well as both the shoot and root biomass weights (Table 3).The response of T_2, may be as a result of the toxicity effect owing to increasing Na^+ and Cl^- concentration and uptake rate of mineral nutrients. This result corroborated with the findings of Yousofinia *et al.*, 2012 in barley on wheat who indicated that with increased concentration of NaCl, both root and shoot lengths decreases. From Table 3, the ability of barley seed to germinate and survive at different levels of salt concentration is an indication that the crop exhibited salt tolerance. The increase in productivity resulting from an increase in water quantity supplied as revealed on all parameters measured confirms the work of Bello (2008) who stated that different levels of moisture content of the planting areas influenced the availability of nutrients that enhance plant growth.

CONCLUSION

The result indicated that barley seeds exhibited salt tolerance during germination period and at all stages of development. It also showed that both water and salt are major factors determining the production of crop in semi-arid to arid or water deficit environments. The marked improvement observed with increased water quantity which reduced the effect of salinity by improving vegetative growth, biomass yield and root length suggested that efficient use of irrigational water would aid crop performance in dry land farming.

56th Annual Conference
Agricultural Society of Nigeria
24 - 28 Oct., 2022

ABSTRACT

Nitrogen management practice is imperative in order to harness the benefit of organic matter application to improve soil fertility and crop productivity. Incubation studies of different organic manures: compost, cow dung, municipal solid wastes and poultry were investigated to determine their N release pattern in the soil. The organic manures were subjected to incubation studies in the laboratory for 0, 3, 7, 14, 42, 56, 84 and 98 days. Ammonium, Nitrate and net N concentrations; and N release of these materials were determined at different incubation periods. Result indicated that Poultry manure recorded a significantly higher net N release than all other organic manures. The N release increases linearly from 0 to 98 days with pattern showing poultry manure being > compost > municipal solid waste > cow dung. However, cow dung recorded the highest NO_3^- N concentration among the various organic manures. Results also showed that highest nitrate concentration in municipal solid waste and cow dung were observed at 7 days after incubation whereas highest concentration in poultry and compost were observed at 14 days after incubation. It therefore followed that best time for application of municipal solid waste and cow dung to synchronise with plant uptake is 7 days whereas for poultry manure and compost will be 14 days.

Key words: N – release, Nitrate and Ammonium concentration, Northern Guinea Savanna and Organic sources

INTRODUCTION

Soil organic matter (SOM) content of most savanna soils is reported to be very low (Chude *et al*., 2012) which made it susceptible to major chemical, physical and biological limitations thereby reducing crop yields. Furthermore, organic matter in these soils is continuously depleted as a result of Agricultural intensification. This therefore calls for organic matter application to these soils which plays important role in maintaining soil fertility and productivity. Soil fertility needs to be maintained in order increase crop yields, reduce environmental pollution, and achieve sustainable agricultural intensification. SOM is a storehouse and supplier of nutrients such as nitrogen, phosphorus, potassium and sulfur to crops (Schulten and Schnitzer., 1998), and improves the physical, chemical, and biological properties of soils. These SOM decompose via mineralization to release the nutrients required for crop growth and development (Diacono and Montemurro, 2010).

In order to obtain maximum economic value from these organic matters and minimize nitrate pollution potential, N management practices must be adjusted for expected N release from the organic matter. The amount of N released to crops depends on the chemical composition of organic matter e.g. N content, carbon: nitrogen ratio, and contents of cellulose and hemicelluloses, lignin, and polyphenols (Mohanty *et al*., 2011) and on the physical, chemical, and biological properties of soil microbes (Manojlovic *et al.*, 2010). Organic amendments with high N contents and low C:N ratios mineralize sufficient N to satisfy plant growth (Cordovil *et al* 2005). Conversely, N can be immobilized in organic matter with lower N contents and higher C:N ratios (Manojlovic *et al*., 2010).

Most farmers do not have knowledge on when these organic materials should be applied to the soil. Organic manures are simply taken and dumped in the farm without considering type, amount, source and time of application. They generally assume that N released is the same for all organic manures and at the same time. This would, as a result, lead to wrong estimation of N availability to plants. Consequently, the time of N release may not be synchronized with N uptake by the plants. This leads to N loss in the soil system without plants getting it. It is therefore important to manage these organic manures appropriately to avoid loss of N in soil and facilitate timely N uptake by plants. An understanding of the nutrient release dynamics would enable farmers to manage the organic resources in a manner that optimizes nutrient uptake and ultimately crop productivity. The aim of this study therefore, is to investigate N release of some organic materials in the Northern Guinea Savanna.

MATERIALS AND METHODS

Soil Sampling and preparation

A soil sample was collected from Institute for Agricultural Research (IAR) experimental site (N11^{o}10’31.3”, E0073^{o}63’8.9”). The soil was dried, crushed, sieved through 2mm sieve mesh. Eight hundred grams (800g) was put into a jar (1 liter) where the various treatments of organic materials were added.

Incubation Studies

The soil samples for incubation study was dried, crushed, sieved through 2mm sieve mesh. Eight hundred grams (800g) was put into a jar (1 litre) where the various treatments were added which included Compost, Cow dung, Municipal Solid Waste and Poultry manure. Each manure which is equivalent to 200 mg kg N kg^{-1} soil (that is 15.24g of Compost, 13.01g of Cow dung, 18.39g of Municipal sewage waste and 3.15g of Poultry manure) was added to the soil. The soil and manure were then mixed in the jar by stirring with a spatula and then repacked to approximately natural bulk density, brought to 60% WHC with deionized water. The moisture content was maintained at 60% WHC by weighing it periodically. The set up was incubated for 98 days. The jars were covered with lids but aerated for 1 h each day throughout the incubation period.

All treatments were replicated 4 times in a completely randomized design (CRD). There were therefore 4 treatments (Compost, Cow dung, Municipal waste and Poultry manure) and 4 replicates giving 16 number of set ups.

A 10 g soil sample was taken from each jar at 0, 3, 7, 14, 28, 42, 56, 84, 98, days after incubation and NH_4^+-N and NO_3^--N were determined therefrom. Nitrogen mineralization (release) from manure was calculated using Nitrogen mineralization model to predict N release at various incubation periods:

$$\mathbf{N_t = N_0\ ([1 - e^{-kt}])}\ \text{..................}\ \textbf{Equation 1}$$

Where:

$\mathbf{N_m}$ = the amount of N mineralized at time t [µgg^{-1}].

$\mathbf{N_o}$ = the initial amount of potentially mineralizeable N [µgg^{-1}].

k = first order rate constant day^{-1} taken to be 0.011 day^{-1}.

RESULTS

Effect of manures and incubation periods on NH_4^+ and NO_3^- and net N release

The analysis of NH_4, NO_3 and total N release is presented in Table 1 below. It showed that there were significant differences among the organic material. The organic manure N release showed that highest NH_4^+ release was recorded by Poultry manure and was significantly higher than all the other manures. It also revealed that NO_3^- release of poultry manure was higher that other manures but was statistically at par with compost manure. Similar trends were observed when the net mineralization was computed (Table 1).

Table 1: Effect of organic manures on Nitrogen release (mg.Kg^{-1})

Organic Manure	NH_4^+-N	NO_3^--N	Total Nitrogen
Control	4.07d	28.04c	32.39d
Municipal Waste	6.16c	31.11b	37.28c
Compost	9.03b	53.75a	62.78b
Poultry	15.19a	55.87a	71.06a
Cow dung	8.01b	27.58c	35.59c
SE ±	0.37	0.86	1.03

Means with the same alphabet are statistically similar. SE = standard Error.

The figure 1below showed the net N release in organic manures during the incubation period. It showed that N release linearly increased with incubation time. Poultry manure recoded the highest N release rate. The poultry manure was at par with compost manure from day 3 to day 14 (Fig 1). At day 28, 42, 84 and 98 days, poultry manure differed statistically higher than compost in net mineralization.

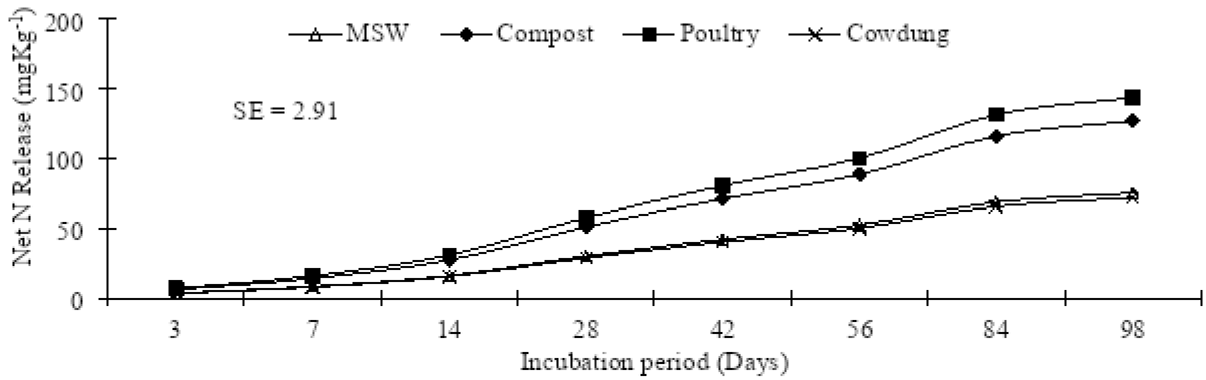

Figure 1: Effect of incubation period on Net N release in organic manures.

Effect of manures and incubation periods on NH_4^+ and NO_3^- concentration

The result of the analysis indicated that generally, there were significant variations among the organic manures in the N concentration in soil (Fig 2). Cow dung recorded the highest NH_4 concentration and was significantly higher than other organic manures. Municipal solid wastes and compost manures recorded statistically similar NH_4 dynamics and were significantly higher than poultry manure. However, the poultry manure recorded a significantly higher that municipal solid waste and cow dung in NO_3^- concentration but statistically at par with compost. Generally, the concentrations of NH_4 in all the organic manures were peak at day 14 after which it declines (Fig 2). The NO_3 concentration however varies with the manure. While concentration of NO_3 in poultry and compost were peak at day 7, that of municipal solid waste and cow dung were at day 14. Regardless of incubation period and type of manure, the concentration of NO_3–N was higher than NH_4–N.

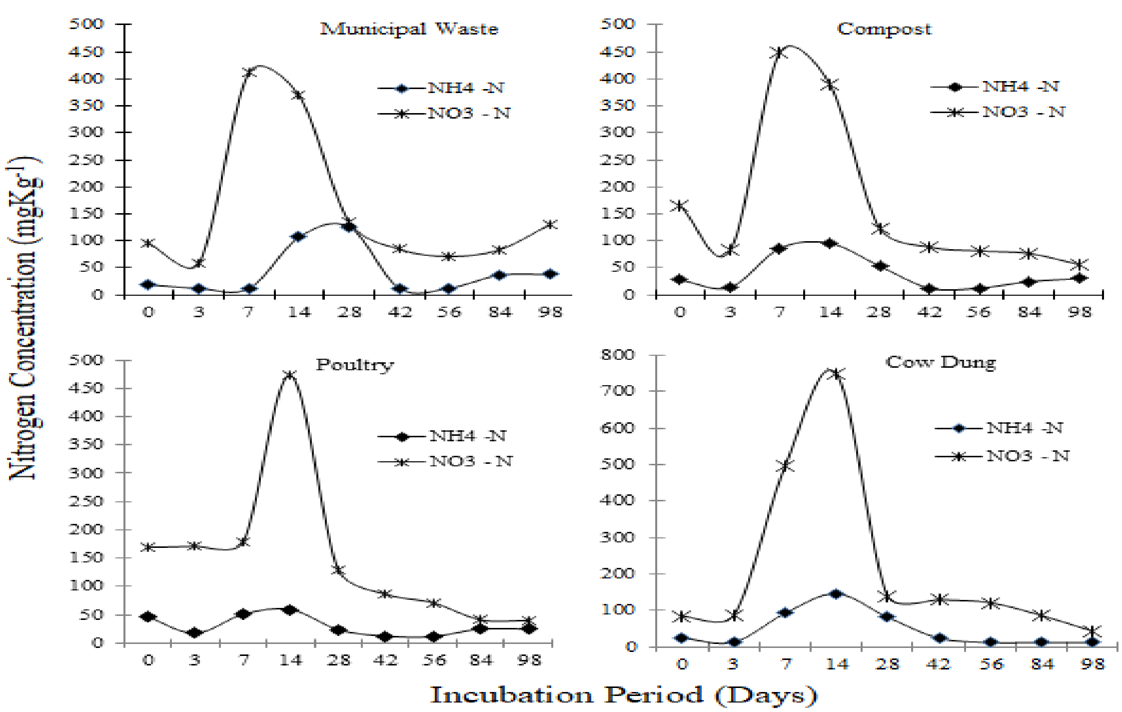

Figure 2: Effect of incubation period on Nitrogen concentration in organic manures.

DISCUSSION

The higher NH_4 release reported in this study in poultry manure was in agreement with the report of Alizadeh and Fallah (2012) which said poultry manure-treated soil had higher mineralization rate than cow manure treated soil. This could be as a result of soil changes in degree of dissociation of NH_4^+/NH_3, which becomes favourable to massive nutrient release and the decomposition of poultry manure rich in microorganism facilitated by moisture also led to faster release of NH_4^+. It also agrees with the report of Li and Li (2014) who suggested that N availability of cattle manure was lower than chicken manures.

The higher release of NO_3 in poultry and compost reported in this study could be as result of lower C/N ratios of the manures which connote the presence of simple organic compounds such as urea and uric acid which decompose very easily during the first few days after application in the soil. Similar results were reported by Maerere *et al.* (2001) who observed that applications of higher rates of animal manure resulted into increased levels of net available N.

The concentration of NH_4–N and NO_3–N linearly increased from day 3 (14.11 mg kg^{-1} NH_4 and 91.57 mg kg^{-1} NO_3) up to day 14 (97.27 mg kg^{-1} NH_4 and 423.15 mg kg^{-1} NO_3) while at day 28, there was a sudden decline in the NH_4 and NO_3 nitrate concentration up to day 56 while at day 84 and 98 there was a linear increase. The decline of soil NH_4^+-N within 28 days can be explained by rapid immobilization combined with nitrification and denitrification as also explained by Li and Li (2014). This is because microorganisms prefer NH_4 –N for their growth and utilize NO_3^-–N when NH_4–N concentrations are lower than 1µg N g^{-1} soil. Working on N release of chicken manure, pig manure and cattle manure, Calderon *et al*. (2005) also found the rapid decline of soil NH_4–N in a short period of time after incubation. This finding corroborates with the finding of this study. However, the content of NO_3^- measured gave higher concentration than NH_4^+-N with incubation time. This was because NH_4 was prone to losses through immobilization, volatilization, fixation and nitrification.

CONCLUSION

This study showed that nutrient concentrations and release vary differently with organic manure and therefore availability of nutrient for plant uptake will also differ. Results revealed that nutrient in poultry manure and compost would be most available (7 days) faster than cow dung and municipal solid waste (14 days). This therefore calls for importance of the knowledge nutrient management in timing the application of these organic materials. This will help in synchronising the nutrient availability with plant nutrient uptake in soil–plant systems.

ABSTRACT

A study was carried out to evaluate effects of different sources of organic manure (poultry manure, cow dung, goat droppings, pig waste and oil palm bunch) on selected soil chemical properties (soil pH, Organic matter, Total nitrogen, available phosphorous and potassium) and some growth parameters of Orange flesh Sweetpotato in Umudike. Treatments (poultry manure, Cow dung, Goat droppings, Swine waste and Control) were applied at 8 t/ha, laid out in RCBD and replicated 3 times. Plant data were collected at 4, 8 and 12 weeks after planting, while soils for analysis were collected at 12weeks after planting, air dried, sieved and analyzed for some chemical properties (pH, Organic matter, total Nitrogen, Available Phosphorus and Potassium).
Data collected from field and laboratory were analyzed statistically using GENSAT. The result showed that application of different organic manure significantly ($p<0.05$) improved soil pH, organic matter, soil nitrogen, available phosphorous and potassium when compared with the control. The result showed that application of organic manure from different source improved soil chemical properties as well as growth parameters considered. The extent of influence on the chemical properties was found to be dependent on the organic manure source.

Key words: organic manure, soil chemical properties, sweetpotato

INTRODUTION

Agricultural soils in the humid tropics are marginal, fragile and infertile especially those that fall under Oxisols and acidic Ultisols (Ikpe *et al*, 2014). Apart from the economic cost, the use of chemical fertilizers under continuous cultivation in the tropics have been found to be unable to sustain crop yield (Makinde and Ayoola, 2012). Continuous application of inorganic ferttilizer has been found to deplete soil organic matter and reduction in crop yield and serious environmental degradation and decline in soil productivity (Adeniran *et al*., 2004). Numerous studies have shown that organic manure including livestock manure, plant biomass and sewage sludge can be used to improve soil fertility and productivity (Ikpe *et al.*, 2003). Animal (cattle, sheep, goats, poultry, and pig) manures have been shown to contain large amounts of organic matter (OM), Nitrogen (N), phosphorus (P), Potassium (K) which are essential for soil fertility and crop growth. Poultry manure, cow dung, goat droppings and swine waste are generated in large quantities from livestock farms and are commonly used by farmers across Nigeria. There is a need to compare the effectiveness of these organic manure on soil chemical properties and growth parameters of sweetpotato. Therefore, the objective of this study was to evaluate effect of different organic manures on selected soil chemical properties and growth parameters of sweetpotato at Umudike.

MATERIALS AND METHODS

The study was carried out in Umudike, Ikwuano LGA of Abia State Southeastern Nigeria. Umudike is located on latitude 05°29' N, longitude 07°33' E and 122m above sea level. The climate is essentially humid tropical with an average annual precipitation of 2164mm. There are two distinct seasons; the rainy season which starts in March/April and ends in October. Then the dry season which starts in November and ends in March subsequent year (NRCRI Meteorology Centre, 2021).The site of the experiment was cleared, ploughed, harrowed and ridged mechanically with tractor before planting. Treatments, poultry manure, Cow dung, Goat droppings, Swine waste, and Oil Palm bunch were applied at 8t/ha and laid in Randomized Complete Block Design (RCBD) on 3m x 3m beds, replicated 3 times. Sweet potato vines obtained from National Root Crops Research Institute Umudike, were planted at 30cm x 30cm.

Plant (growth) parameters were determined at 4, 8 and 12 weeks after planting (WAP); using the standard methods. Soil samples were collected after 12 weeks, air-dried and sieved with 2mm sieve and stored for lab. Analysis. Soil pH was determined in H_2O using glass electrode pH meter at a soil liquid ratio of 1:2.5 as explained by Udo *et al.* (2009). Soil Organic Carbon was determined by Walkley *and* Black wet oxidation method as modified by Udo *et al*., (2009). Organic Matter was obtained by multiplying organic carbon values by conventional Van Bellema factor (1.724). Total Nitrogen was determined by Kjeldhal digestion method (Bremmer and Mulvaney 1996). Available Phosphorus was determined by Bray 2 method as described by Bray and Kurtz (1945). Exchangeable potassium (K) was determined by Flame Photometer using ammonium acetate extraction (NH_4AOC) method according to Udo *et al*. (2009).

Soil and plant data were subjected to analysis of variance for CRBD experiment, significant treatment means were separated using the least significant difference at 5% probability level

RESULT AND DISUSSION

Result of Pre-Cropping Soil Sample of the Study Area

Result of the pre-cropping soil (table 1) showed that soil texture of the study area is sandy loam with pH of 4.9, (acidic) and low in most of the basic nutrient (Ca= 3.6 cmol/kg, N = 0.093%, K = 0.211 cmol/kg, p = 14.5 mg/kg, OM = 1.95 %) required by sweetpotato for good growth and yield.

Soil Chemical properties

The result (table 2) showed that soil pH ranged from 4.7 to 6.7, with poultry manure given highest value (6.7) followed by 6.5 and 6.0 from swine and cow dung. While palm bunch and goat droppings gave 5.9 and 5.7 respectively. Though higher than control 4.7. The ability of the organic manure to positively influence soil pH is in the following order; poultry manure > Swine waste > Cow dung > Palm bunch > Goat droppings > Control. Organic matter significantly ($p<0.05$) increased as a result of applying different organic manure. Cow dung gave highest value of 4.88% followed by goat droppings (4.39%) and poultry manure (4.37%) while the lowest value among the manures was 3.96% from palm bunch. Total nitrogen ranged from 0.070 to 0.394%. The result showed that application of organic manure significantly ($p<0.05$) improved total nitrogen over the control. Poultry manure gave highest value of nitrogen 0.394%, followed by swine waste and cow dung (0.386 and 0.294%). Goat droppings and palm bunch gave 0.244 and 0.215% while lowest value of nitrogen (0.072 %) was recorded on control. Available phosphorous ranged from 11.1 to 25.1 mg/kg, with highest value obtained from swine waste (25.1 mg/kg) followed by poultry and cow dung (24.6 and 20.8 mg/kg) while control gave lowest value of 11.1 mg/kg. potassium ranged from 0.090 to 0.410 cmol/kg with palm bunch manure given highest value of potassium (0.410 cmol/kg) followed by poultry manure and swine waste (0. 402 and 0.380 cmol/kg. while cow dung and goat droppings recorded lower values of potassium among manures tested. The result obtained from this study is in accordance with the findings of Makinde and Ayoola, 2012.

Plant Parameters

The result shows that vine length increased significantly ($p <0.05$) across the month of the experiment (figure 1). At 4 weeks after planting (WAP), poultry manure gave highest value (26.33 cm) followed by swine waste and cow dung (16.67 and 16.33cm) while lowest value of vine length was recorded on control (11 cm). At 8 WAP and 12 WAP, poultry manure gave highest values of 69.3 and 121 cm followed by 55.9 and 109.6 cm from swine waste. While lowest value of vine length was recorded on control (4 WAP=11, 8WAP= 39.7 and 12WAP= 57.3 cm). Number of leaves ranged from 11 to 16 at 4WAP, 29 to 66 at 8WAP and 54 to 134 at 12 WAP. Number of leaves were significantly ($p<0.05$) improved by the application of organic manures, poultry manure gave highest number of leaves at 4WAP (16), 8WAP (66) and 12 WAP (134) followed by swine waste 4 WAP = (15), 8 WAP= (60) while lowest number of leaves were recorded on control.

CONCLUSION

The result showed that application of organic manure from different source improved soil chemical properties as well as growth parameters considered. The extent of influence on the chemical properties was found to be dependent on the organic manure source.

Table 1: Result of Pre-Cropping Soil Sample of the Study Area

Soil properties	Value
Sand (g/kg)	700
Silt (g/kg)	140
Clay (g/kg)	160
Texture	Sandy loam
pH (H_2O)	4.9
Available phosphorus (mg/kg)	14.8

ABSTRACT

This study investigates the effects of industrial wastes on heavy metal deposit of composite soil in exide battery industry. The heavy metal content of composite soil from industrial wastes discharge were determined. This is done to give appropriate advice to industrialists on possible hazard of improper effluents treatments.

The samples for the study were collected at exide battery industry, located at Oluyole Industrial Area, Ibadan. The soil samples were collected by using soil auger. There werefour treatments, replicated five times. The treatment was represented by the distance of collection. The soil was collected at 0 metres point, 3 metres point, 6 metres point, and 50 metres as control. There were five points of soil collection at each of the four treatments. This was done at 20 cm distance. The measurements were on industrial waste discharge area. Each of the composite soil sample collected was sieved to 2 mm size and grounded to powdery form. Powdered soil samples were chemically homogenized in the laboratory, for heavy metal analysis. The digested composite soil samples were analyzed using atomic absorption spectrophotometer (AAS) (model ZA-3300), for the determination of the level of heavy metals present. All the values were subjected to analysis of variance (ANOVA), using statistical package for social science, and mean separated by Ducan multiple range test, with significant difference level of $p \leq 0.05$.

The finding of the study reveals that soil samples taken at Om had the highest Zn concentration of 2.63 mg/kg above the FAO permissible level and was significantly higher than the soil samples collected at 3m, 6m and 50m which had 1.29mg/kg, 1.42 mg/kg and 0.60 mg/kg respectively at $p \leq 0.05$. However, soil samples taken at 3m and 6m were not significantly different form each other at $p \leq 0.05$, while soil samples taken at 50m had the lowest significant value (0.60mg/kg).

INTRODUCTION

Environmental issues have become important to all mankind. Anthropogenic activities that releases pollutant to the planet earth include: industrialization, the use of atomic bomb, nuclear plants, improvements in agriculture, health, food processing, automobiles, jet and space travels, the plastics revolution, deforestation and desertification, information technology and many others.The compelling need for the awareness of these problems is imperative in the sense that environmental pollutionis trans-boundary in nature (Ahmed *et al.*, 2009; Oyelola*et al.*, 2013).Effects of industrial effluents is one of the most important problems around the world in which thousands of millions of world inhabitants suffer health problems (Martinez *et al.*, 2001). The recent years have witnessed significant attention being paid to the problems of environmental contamination by a wide variety of chemicals including the trace metals (Hisseien *et al.*, 2015). Trace metals enter into our environment from both natural and anthropogenic sources (Ahmed *et al.*, 2009). They contaminate food sources and accumulate in both agricultural products and sea foods through water, air and soil contamination (Bebson *et al.*, 2013). All trace metals are toxic at soil concentration above permissible levels (Ahmed *et al.*, 2009). The objective of this study is to determine the level of heavy metal content of composite soil from industrial waste discharge and to give appropriate advice to industrialists on possible hazard of improper effluents treatments.

MATERIALS AND METHODS

The study area was at the Exide battery located at Oluyole industrial Estate, Ibadan, Oyo State, Nigeria. Composite soil samples were collected at industrial waste discharge area of Exide battery, Ibadan. The soil samples were collected by using soil auger at 10 cm deep. The collected soil was put in an envelope and labeled accordingly. In soil samples collection, there were four treatments, replicated five times. The treatment was represented by the distance of collection. The soil was collected at 0 metres point, 3 metres point, 6 metres point, and 50 metres as control. The measurements were done on industrial waste discharge area. At 0 metres point, the soil was collected at 0 – 10 cm deep using soil auger. At 0 meters point, the soil was collected on the same line at 20 cm distance at five different points. This was treatment 1, at 0 cm point. The soil samples for treatments 2, 3, 4 and 5 were collected as done above. Each of the composite soil sample collected was sieved to 2 mm size and grounded to powdery form. Powdered soil samples were chemically homogenized in the laboratory, for heavy metal analysis. The digested composite soil samples were analyzed using atomic absorption spectrophotometer (AAS) (model ZA-3300), for determination of the level of heavy metals present.

Data was collection on the levels of heavy metals (Zn, Pb, Cd, Mn, and Fe) present in the composite soil samples. All the values were subjected to analysis of variance (ANOVA), using statistical package for social science, and mean separated by Duncan multiple range test, with significant different level of $p \leq 0.05$.

RESULTS AND DISCUSSION

Heavy Metal Contents in the Soil at the Industrial waste discharge of Exide battery industry, Ibadan.

There were significant differences in the Zn content/concentration amongst the treatments at 5% level of significance.

Soil samples taken at Om had the highest Zn concentration of 2.63 mg/kg which was significantly higher than the soil samples at 3m, 6m and 50m which had 1.29mg/kg, 1.42 mg/kg and 0.60 mg/kg respectively at $p \leq 0.05$. However, soil samples taken at 3m and 6m were not significantly different form each other at $p \leq 0.05$, while soil samples taken of 50m had the lowest significant value (0.60mg/kg).

There were significant differences in the Pb content/concentration amongst the treatments at 5% level of significance. Soil samples taken at 0m had the highest Pb concentration of 105.60mg/kg which was significantly higher than the soil samples taken at 3m, 6m and 50m which had 61.68mg/kg, 20.82mg/kg and 4.48mg/kg respectively at $p \leq 0.05$. However, soil samples taken at 3m and 6m were significantly different from each other at $p \leq 0.05$ while soil sample taken at 50m had the lowest significant value (4.48mg/kg).
There were significant differences in the Cd content/concentration amongst the treatments at 5% level of significance. Soil samples taken at cm had the highest cd concentration of 5.00 mg/kg which was significantly higher than the soil samples taken at 3m, 6m and 50m which had 0.15mg/kg, 0.02 mg/kg and 0.04mg/kg respectively at $p \leq 0.05$. However, soil samples taken at 3m, 6m and 50m were not significantly different from one another in Cd content.
There were significant differences in the Mn content amongst the treatments at 5% level of significance. Soil samples taken had the highest Mn concentration of 19.50 mg/kg which was significantly higher than the soil samples taken at 3m, 6m and 50m which had 14.05mg/kg, 13.22kg/mg and 8.10kg/mg respectively at $p \leq 0.05$. However, soil samples taken at 3m and 6m were not significantly different from each other at $p \leq 0.05$ while the soil sample taken at 50m had the lowest significant value 8.10 mg/kg.
There were significant differences in the Fe content/concentration amongst the treatments at 5% level of significance. Soil samples taken at 0cm had the highest Fe concentration of 9.40mg/kg which was significantly higher than soil samples taken at 3m, 6m and 50m which had 7.28mg/kg, 3.64mg/kg and 4.20mg/kg respectively at $p \leq 0.05$. However, soil samples taken at 3m and 6m were significantly different from each other at $p \leq 0.05$.These were has recorded in Table 1. From the point source, there was high concentration of industrial waste discharge containing heavy metals. As water carries the wastes from the point source, the concentration of waste discharge reduces. This gives the reason for the difference in the heavy metal contents recorded.

Table 1: Heavy Metal Contents in the Soil at the Industrial waste discharge of Exide battery industry, Ibadan.

TRT	Zn (mg/kg)	Pb(mg/kg)	Cd(mg/kg)	Mn(mg/kg)	Fe(mg/kg)
T1	2.63a	105.60a	5.00a	19.50a	9.40
T2	1.29b	61.68b	0.15b	14.08b	7.28
T3	1.42b	20.82c	0.02b	13.22b	3.64d
T4	0.60c	4.48d	0.04b	8.10c	4.20c

Means with the same letter are not significantly different at $p \leq 0.05$

T1: 0 m, T2: 3 m, T3: 6 m, T4: 50 m

CONCLUSIONS AND RECOMMENDATION

As shown by the progressive decrease in the content of heavy metals in the soil around the discharged area of the industry,it was concluded that there was no proper monitoring of the industrial discharge.It is therefore recommended that government must ensure strict compliance of all industries to proper treatments of their waste discharge. Equally, there must be public enlightenment to the people living around the industrial areas, to be sensitized of the possible health hazard that may likely be generated from the improper waste treatments from these industries around them.

ABSTRACT

Application of different organic manure in ginger production has various advantages such as improving soil microbial biomass which in turn increases soil fertility and crop yield. Therefore, the impact of four different organic materials (cow dung, saw dust, poultry manure and rice mill waste) on soil microbial biomass, dynamics in soil microorganisms and ginger yield were assessed. The different organic materials seemed to influence the behavior of the bacterial communities after six months as diverse microorganisms which can be considered as plant growth promoters were observed in different treatments such asBacterial species (*Pseudomonas* and *Bacillus spp,Proteus* spp ,*Clostridium spp and others*) and fungi species (*Rhizopus japanus*, *Aspergillus spp, Penicillium spp and others.)* These microorganisms show high versatility in their metabolic capacity and they areknown as intensive decomposers. The dynamics of microbial biomass of carbon was assessed, rice mill waste (RMW) showed significant increase (92.28 mg/kg) in microbial biomass-C at 6th month after planting among other treatments such as sawdust which decreased significantly than rice mill waste (RMW) with 28.23mg/kg at 6th month after planting. Ginger yield responded according to different organic amendments treated soils giving the highest yield on Rice mill waste (RMW) with 8.10kg followed by cow dung with 6.30kg and finally poultry manure (5.4kg) though not significantly different from each other. The least yield was found on saw dust organic amendment (2.07kg) which is significantly different from other treatments. This study shows that analysis of the activities and diversity of soil microorganisms, is necessary to assess the impacts of organic amendments in ginger yield and soil fertility. However, the application of Cow dung (CD) poultry manure(PM), rice mill waste (RMW) serve as the best farming option for improving ginger production and soil microbial activities and hence improve soil fertility.

Keywords: Microbial biomass -C, Ginger rhizomes, organic amendment, microorganisms and yield

INTRODUCTION

Ginger (*Zingiber officinale* Rosc) is among the important widely used spice crops worldwide (Archana *et al*., 2013).The economic part is the underground rhizome which ispungent and used for culinary purposes (Thankamani *etal.*, 2002).

Application of organicmanures has various advantages like improving soil physical properties, water holding capacity and organic carbon content, apart from supplying good quality nutrients (Singh *et al.*, 2009). The productivity of ginger, level of soil microorganisms and rate of soil fertility are declining day by day due to non-judicious and indiscriminate use of inorganic fertilizers.

Soil microorganisms are involved in many biochemical processes and particularly carbon turnover (Buckley and Schmidt, 2003). It is characterized by its rapid turnover compared to the other components of organic matter (Sparling *et al*., 1998). Thus, the microbial communities are an indicator of changes occurring in managed ecosystems. Different organic amendment that are rich in nitrogen and carbon accommodates a lot of microorganisms. These microbial communities produce and use different carbon pools in a dynamic process, release nutrients that are biologically available for plants, decompose toxic materials and also affect the dynamics of organic matter and soil structure. An example is the turnover rate of the microbial biomass and population which is faster than the turnover rate of total soil organic matter (Carter *et al.* 1999).
However, the aim of this study was to assess the impact of different organic amendments on soil microorganisms and their activities as well as the yield of ginger rhizomes.

MATERIALS AND METHODS

The study was carried out in the agricultural field of National Root Crops Research Institute (NRCRI), Umudike. The experiment was conducted in plots set-up as randomized complete block (RCBD) design. Ginger rhizomes were planted on 2cm by 2cm on each plot measured (2mx3m) and each plot was replicated 3 times making it a total of 12 plots. Before the planting, different amendment method were thoroughly mixed accordingly and incorporated in the soil before the planting of ginger.The experiment was designed for the evaluation of agronomic, microbiological and ecological effects of amendments with four different organic material such as Cow dung (CD),saw dust (SD), poultry manure (PM) and rice mill waste (RMW).

Soil sampling

This was done in accordance with the general methods for soil microbiological study (Alexander, 1977). Four top soil samples were collected from a depth of (0-10) cm from each plot (Saeki and Toyota, 2004). Soil samples for analysis were collected at 4th and 6th month after planting

Microbial enumeration

This was done according to the method described by Adarsh *et al.*,(2007) for the isolation of soil microorganisms. While microbial biomass-C was done according to the method described by Ladd and Amato (1989) and Ginger was harvested at the end of 12th month after planting and each treatment was harvested and weigh in kg to determine the ginger yield response.

RESULTS AND DISCUSSIONS

Microbial Enumeration

Bacterial species such as *Pseudomonas* and *Bacillus spp*. have a wide distribution among the treatments except in sawdust (Table 1) and it shows high versatility in their metabolic capacity as they are considered to be among plant growth promoters (Buckley and Schmidt, 2003). Among the fungi, *Rhizopusjapanus, Aspergillus sp, Penicillium sp*.and *Metharizium anosoplie* were also observed among the treatments and they are considered to be the most intensive decomposers (Laughlin and Steven, 2002).

Microbial Biomass-C

In Figure 1, the periodic time graph showed that there are changes during the months study, microbial biomass-C-content varied slightly between the 4th month and the 6th month of study seasons and between different treatments but the differences were not significant except for rice mill waste (RMW) which shows higher microbial biomass-C of 92.28mg/kg and 109.20mg/kg at 4th and 6th month after planting respectively, which is significantly different from other treatments such as sawdust which is significantly lower than rice mill waste (RMW) with 22.10mg/kg and 28.23mg/kg at 4th and 6th month after planting.

Enhancement of microbial biomass-C after organic amendment has been reported during long-term experiments (Garcia-Gil *et al*., 2000) as well as in short-term experiments (Saison *et al*., 2006). Our results showed that over a short length of time, (six months) with different levels of organic amendment microbial biomass-C was seen to increase significantly in RMW among other treatments.

Ginger Yield (Kg)

Ginger yield responded according to different organic amendments treated soils giving the highest yield on Rice mill waste (RMW) with 8.10kg followed by cow dung with 6.30kg and finally poultry manure (5.4kg) though not significantly different from each other. The least yield was observed on saw dust (SD) organic amendment (2.07kg) which is significantly different from other treatments (Fig2). This confirmed the findings of Olayinka and Adebayo (1985) which stated that sawdust has higher propensity to reduce microbial bioload which could be as a result of nitrogen immobilization caused by sawdust, resulting to reduced microbial respiration and hence reduction on yield. According to Amakiri (1982) and Beck *et al*. (2005), soil biochemical and biological processes are critical for ecosystems functioning, as microbes have key roles in organic matter transformations, nutrient cycling, degradation of organic pollutants, including pesticides which affect crop yield.

CONCLUSION

This study shows that analysis of the changes in activities and diversity of soil microorganisms is necessary to assess the impacts of organic amendments in ginger yield and soil fertility. Therefore organic amendments accessed improved the overall soil microbial dynamics which revealed a correlation between microbial biomass and ginger yield resulting in, the higher the microbial biomass, the higher the yield. It therefore concluded that application of Cow dung (CD), poultry manure (PM), rice mill waste (RMW) serve as the best farming option for improving ginger production and soil microbial activities and hence improve soil fertility.

24 - 28 Oct., 2022

ABSTRACT

Coastal ecosystems contribute significantly to marine primary productivity, and are responsibly a key player in the balance of the environment as they interrelate and interact dynamically. Mangroves are important ecosystem that functions ecologically and socio-economically at local to global scales. The concentration of internationally frightening five heavy metals (Cr, Cd, Pb, Ni, and Fe) was assessed the in surface sediment of Badagry creek in Lagos, Nigeria, during the dry and wet seasons from July 2017 to May 2019, Nine stations were established in the upper, middle and lower course of the creek, (upper; Ebute (Station 1), Gberefu (station 2), Topo (station 3), middle; Povita (station4), Ajido1 (station 5), Ajido2 (station 6), lower; Iworookun (station 7), Whispering palms1 (station 8) and Whispering palms2 (station 9). Heavy metals were analyzed by Atomic Absorption Spectrophotometer (AAS). The mean values of heavy metal concentration Chromium (Cr) 5.36±0.20, Lead (Pb) 6.24±0.3, Cadmium (Cd) 0.07±0.00, Nickel (Ni) 0.71±0.07, and Iron (Fe) 662±68.48, across the nine stations. varied significantly except Chromium, Nickel, and Iron which differed non-significantly. The concentration is in the following decreasing order FE>Pb>Cr>Ni>Cd. Seasonal variation of mean values differed non significantly, with higher values in the dry season than wet season registered for all the heavy metals. Total organic matter 7.06±0.42 (TOM) and Total organic carbon 4.10±0.44 (TOC) differed significantly across the stations. The correlation given values were Pb-Cr (r^2 =0.61), Cd-Cr (r^2 = 0.69), and TOC-Fe (r^2= 0.64), the results presented a moderate correlation between the heavy metal parameters suggesting similar non-point source pollution, such as domestic waste dumping, boat transportation activities,

sand dredging waste effluent and agriculture fertilizer runoff, while moderate correlation of Cd-Pb (r^2=0.43) suggested source origin from aquaculture industrial processing effluent. The principal component PC had 99.9% of the total variance of the heavy metal composition. The total variance of the PCs for heavy metal was 11.9%, 0%, and 0% for PC1, P,C2, and PC3 respectively. PC1 was only considered, the eigenvalues showed that there isa strong correlation with Fe (2.64), while Cr (-0.33), Pb (-0.33), Cd (-035), Ni (-0.34), TOM (-0.32) and TOC (-0.32) moderately correlated with PC1.

INTRODUCTION

Heavy metals among other hazardous chemicals have contributed large quantities of input globally into river due to exponential growth in human populaton, intensive domestic activities and through expansion of industry and agricultural production (Srebotnjak et al., 2021; Su et al., 2013; Islam et al., 2014; Islam ett al., 2015), Urban areas rivers usually have water quality problems because of the indiscriminate discharging of untreated domestic and industrial waste into the water bodies which gives entrance to the increase in the level of metals in river water (Khadse et al., 2008; Venugopal et al., 2009; Islam et al., 2015). Metals' behavior in the natural water form substrate sediment composition, the suspended sediment composition, and the water chemistry (Mohiuddin et al., 2012). In the process of water movement, heavy metals undergo several changes in speciation due to dissolution, precipitation, sorption, and complex procedure (Dassenakis et al., 1998; Akcay et al., 2003; Abdel-Ghani and Elchaghaby, 2007). Sediment is an important and unique part of the river and lagoon basin, with numerous diverse ecosystem. Mangrove aid the coastal food web, control the nutrient pollution, sequestrate carbon, form buffer zone against catastrophic emergent such as tsunamis, cyclone, hurricanes, can protect shoreline erosion, as habitat for terrestrial and marine fauna and flora (Sappal et al., 2016). The potential toxicity, accumulation and contamination of aquatic environment by heavy metal is matter of major concern (Jordan et al., 2014; Tscheikner-Gratl et al., 2019). Trace elements such as Uranium (U), arsenic (As), antimony (Sb), thorium (Th), beryllium (Be), radon (Rn), cadmium (Cd), selenium (Se), chlorine (Cl), phosphorus (P), chromium (Ch), Nickel (Ni), lead (Pb), mercury (Hg), manganese (Mn), and fluorine (F), and their compounds, are commonly found in coal and classified as potentially 'hazardous air pollutant' by the US Clean Air Act Amendments of 1990. The present study aims to evaluate the temporal seasonal variation of heavy metal in surface sediment samples of Badagry creek .

MATERIALS AND METHODS

The study focused on Badagry creek located south west, Lagos Nigeria. The creek is a long stretch of water body that runs parallel to the Atlantic Ocean in the south; it extends from Lake Nokue near Port-Novo, Benin republic to Apapa area of Lagos before opening up into the Atlantic Ocean via Lagos harbor. The creek (see Figure 3.1) is located in Lagos State, Nigeria between longitude 2º42ˈ and 3º23ˈE and latitude 6º23ˈand 6º 28ˈN. It is part of the 260km-long lagoon system stretching from Cotonou in the Republic of Benin to the Niger Delta in Nigeria. It is estimated to be more than 51km from Lagos. The creek is fed mainly by River Ajara in the Republic of Benin and the Yewa River in Nigeria while it also links Ologe Lagoon. Hundreds of villages, towns and commercial places like Marina jetty, coconut market, museum park, and point of no return jetty have been built on both side of the Badagry creek. Agriculture, aquaculture and fishing are the primary activities of the people living near the creek. This estuary creek receives domestic raw sewage, house hold waste, and industrial waste from surrounding habitat. Human activities over a period of have impacted the ecosystem of the creek.

Sample collection

Samples were collected from nine different stations (St1 – St 9; Ebute, Gberefu, Topo, Povita, Ajido1, Ajido2, Iworookun, Whisperingpalms1, and Whispering palms2) from upper, middle and downstream. The creek bed sediment samples were taken at a depth of 0 to 5cm using stainless steel VanVeen grab sampler. Sediment samples of mass approximately 250g were collected at each station. The collected sediments were air-dried at room temperature in the laboratory (Nigerian Institute for Oceanography and Marine Research). The dried samples were crushed to a fine texture in a ceramic mortar, re-packaged in labeled polythene bags. The sediment samples were analyzed for Cr, Cd, Pb, Ni, and Fe by the Atomic absorption spectrometry (AAS) (Model: is 3300,Thermo scientific).

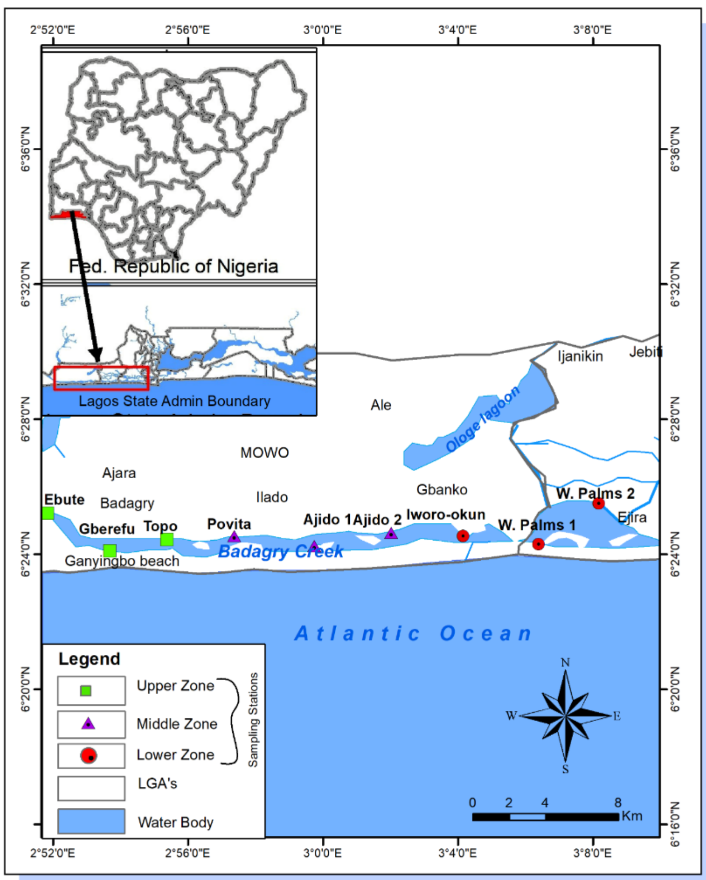

Fig 1: Map of Badagry Creek Showing Sampling Stations.

Data analysis

The data were statistically analyzed using the statistical package, SPSS 16.0 (SPSS, USA) and PAST v.3.2 (Hammar et al., 2001). The means and standard deviations of metal concentration were calculated. Pearson's correlation was applied to find the possible linear relationships among the different heavy metal in surface sediment samples. Agglomerative hierarchical clustering (AHC) was done by Ward's method with Euclidean distance as a measure of dissimilarity. Hierarchical clustering approach is generally used to found out the sequential clusters, grouping of similar objects and the step-by-step formation of the samples cluster (Maurya et al., 2019). Principal component analysis was performed on the data using correlation matrix.

RESULTS AND DISCUSSION

The mean values of heavy metal concentration (Table 1) Chromium (Cr) 5.36±0.20, Lead (Pb) 6.24±0.3, Cadmium (Cd) 0.07±0.00, Nickel (Ni) 0.71±0.07, and Iron (Fe) 662±68.48, across the nine stations (Ebute (station 1), Gberefu (station 2), Topo (station 3), Povita (station 4), Ajido1 (station 5), Ajido2 (station 6), Iworookun (station 7), Whispering Palms1 (station 8), Whispering Palms2 (station 9)) varied significantly except Chromium, Nickel and Iron that differed non significantly. The concentration is in the following decreasing order Fe>Pb>Cr>Ni>Cd. Seasonal variation of mean values presented in (Table 2) differed non significantly, with higher values in dry season than wet season registered for all the heavy metals. Total organic matter 7.06±0.42 (TOM) and Total organic carbon 4.10±0.44 (TOC) differed significantly across the stations. The mean range of Fe was between 26.40 and 4054mg/kg, this is similar to the value of Bhuyan et al., 2017 from Meghna river, Bangladesh. The highest Fe concentration was recorded in Ajido1(station 5) during the wet season in an impacted site of sand dredging and dredging waste discharge activities was present, this can be a reference to the dredging activities and runoff water from the neighboring location and the current mangrove vegetation at this station yield a enormous amount of litter that contribute to high Fe. The highest Pb concentration was (12.22mg/kg) in the aquaculture industrial zone during the dry season, the source of the discharge waste water of a shrimp processing plant and farm. This value is lower to Islam et al., 2015 reported range (36-83mg/kg) in Korotoa, Bangladesh, but Raphal et al., 2011 recorded a lower value of 0.45mg/kg from Okumeshi river, Nigeria. Cadmium concentration varied between (0.00 – 0.12), station 9 that is an aquaculture and shrimp processing plant, had the highest mean value during the wet season, this corroborates the result of Gupta et al., 2009 that reported (0.14-1.4) from river Ganges, India. Chromium maximum value was 9.12mg/kg registered at Povita (station 4) during the dry season, a station characterized under the activities of sand dredging, the value is lower to (55-183mg/kg) registered from Korotoa, Bangladesh, as stated from the findings of Islam et al., 2015. Nickel ranged between (0.17-3.80mg/kg), highest value in Ajido1 during the dry season, this result is similar to Raphal et al., 2011 that reiterated 1.21mg/kg from river Okumeshi , Nigeria. The station is impacted with non-point source of sand dredging and runoff of fertilizer from agriculture farm. TOM ranged between (0.10-33.37%) and TOC ranged (0.60-19.30%), highest percentage of TOM and TOC was recorded in Gberefu (station 2) during the wet season, with reference to domestic waste dumping, runoff water and transportation activities at this station.

Table 1: Heavy metal concentration variation across the nine stations

	St 1	St2	St 3	St 4	St 5	St 6	St 7	St 8	St 9	P value

TOC (%)	6.21±0.24	6.10±0.44	p>0.05

Correlation

The correlation matrix expressed the strength of relationship between the investigated heavy metal parameters (Gopinath et al., 2019). The given values were positively moderate correlated (Liu et al., 2020), Pb-Cr (r^2 =0.61), Cd-Cr (r^2 = 0.69), TOC-Fe (r^2= 0.64), suggest similar non point source pollution, such as domestic waste dumping, boat transportation activities, sand dredging waste effluent and agriculture fertilizer runoff, while moderate correlation of Cd-Pb (r^2=0.43) suggested source origin from aquaculture industrial processing effluent.

Table 3: Correlation matrix between the heavy metal parameters in the sediment sample

	Chromium	Lead	Cadmium	Nickel	Iron	TOM	TOC
Chromium							
Lead	.603*						
Cadmium	.691*	.433*					
Nickel	-0.368	-.941**	0.254				
Iron	-0.482	-.915**	0.300	.961**			
TOM	-.168	-0.305	-.029	-.461**	-.640*		
TOC	-.159	-0.314	-.016	-.472	.645*	.997**	

**. Correlation is significant at the 0.01 level (2-tailed).

*. Correlation is significant at the 0.05 level (2-tailed)

Multivariate Analysis

Cluster analysis

The hierarchical analysis of all the nine sampling stations clustered into two groups according to their similarities. Cluster 1 and 2 had 3 and 6 stations respectively. cluster 1(Ebute (station 1), Gberefu (station 2), Ajido 1(station 5)), while cluster 2 had (Topo (station 3), Povita (station 4), Ajido 2(station 6), Iworookun (station 7) Whispering palms1(station 8) and Whispering palms2 (station 9)). Each cluster represents a distinguish feature which shows the heavy metal chemical progression taking place in the surface sediment of the estuary and impact of the land use activities. Cluster 1 had stations grouped under domestic waste, boat transportation and sand dredging activities with high loadings of TOM,TOC, Fe and Ni. Cluster 2 comprising of major factors of Fe, Pb, Cd and Ni with sampling stations characterized with anthropogenic activities.

Principal Component Analysis

The extracted method, correlation matrix was executed, the components were taken as principal components whose eigen values were greater than 1 were taken into account. 3 PCs were extracted which reflects the process influencing the heavy metal composition having 99.9% of total variance (Table 4). The total variance of the PCs for heavy metal was 11.9%, 0%, and 0% for PC1,PC2 and

PC3 respectively. PC1 was only considered, the eigen values showed that there is strong correlation with Fe (2.64), while Cr (-0.33), Pb (-0.33), Cd (-035), Ni (-0.34), TOM (-0.32) and TOC (-0.32) moderately correlated with PC1. The source of PC1 can be reference to the same source from anthropogenic inputs. The PC1, PC2, and PC3 extracted for the sampling months had 86% composition of the total variance of the sampling months of total variance of PCs were 48.13%, 21.20% and 17.38% for PC1, PC2, and PC3 respectively. Principal components whose eigen values were higher than 0.6. PC1 strongly correlated with March ’18, March’19, May ’19, May ’19, July ’18, September ’18, November ’18 and January ’19. The strong correlation of the wet season months indicated massive input of runoff water from agriculture fertilizer farm, domestic dumping, and aquaculture waste effluent. The sampling stations had PC total composition variance of 96.13%, PC1 was considered with variance 70.13%, eigen values higher than 0.5 were considered. The eigen values presented (Table 4), Ebute (1.17), Gberefu (1.97), and Ajido1(0.54) strongly associated with PC1, while Topo (-0.62), Ajido2 (-0.54), Whispering palms1(-0.82) and Whispering palms2(-0.86) negatively associated with PC1. Station 4 and 7 (-0.36 and -0.48) weakly correlated with PC1.

Table 4: Component matrix of three factors model with strong to moderate loadings in sediment

Canonical Correspondence Analysis

The first two axes explained that 100% of the variance of heavy metal concentration in surface sediment can be explained by the sampling months (period of collection). The CCA ordination bi-plot diagram (figure 6) indicated the eigen values of Cr (0.28), Pb (0.77), Cd (0.52), Ni (0.1), Fe (-0.03), TOM (0.78) and TOC (0.71) were strongly associated with the sampling months, except Iron and Nickel that had weak correlation. Secondly, figure 7 , explained that 100% of the first two axes of the variance of heavy metal concentration can be related to the sampling stations, (station 1 – Station 9). The eigen scores were Cd (0.32), Ni (0.00), Fe (0.0), TOM (0.49), TOC (0.5), Cr (-0.4) and Pb (0.58), it showed that all parameters had moderate association with the stations, while Ni and Fe had weak correlation. All the parameters had moderate influence in all the stations except in Ebute (station 1), this is an indication of different sources of pollution input from the human activities, runoff water of agriculture fertilizer, domestic waste dumping, sewage, sand dredging waste water, and aquaculture shrimp processing plant in all the stations. Ebute (station 1) is located at the upper course of the creek received direct waste and sewage dumping from the municipal.

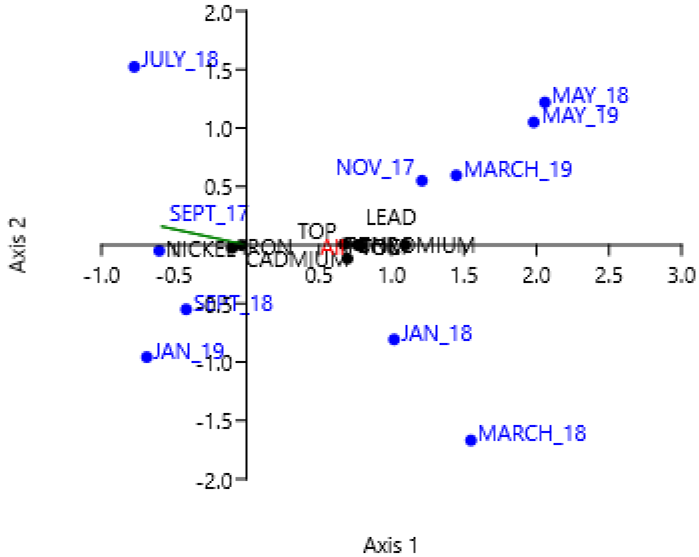

Figure 6: Canonical Correspondence Analysis of loadings of heavy metal among the sampling months

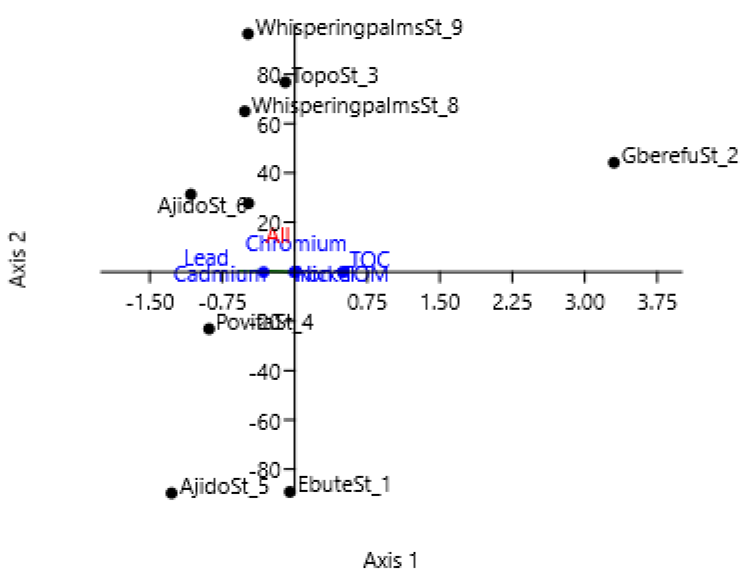

Figure 7: Canonical Correspondence Analysis of the loading plots of heavy metals across the sampling stations

CONCLUSION

The present study summarizes the variation in heavy metal concentration in Badagry creek. The canonical correspondence analysis, Algometric hierarchical cluster and Principal component present the sampling locations with similar characteristics evolved in the same group reflecting on the source and origin. The high concentration of Fe is reference to the dominance of inherent biological productivity and redox processes at the sediment surface water. Agricultural runoff, sand dredging waste water , aquaculture waste, domestic waste dumping and shrimp processing plant waste were the major source of Pb, Cd, Cr, and Ni.

ABSTRACT:

Yield decline is an issue that has plagued sugarcane production in Nigeria. The objective of the study was to evaluate the effects of sugarcane trash mulch and weed management practices on soil fertility and sugarcane production. Field experiment was conducted in 2016 and 2017 at National Cereals Research Institute, Badeggi in the Southern Guinea Savanna ecology of Nigeria. The treatments consisted of factorial combination of two sugarcane genotypes (Bida local and NCS 001), four sugarcane trash mulching levels (0, 3, 6, 9 t/ha) and four weed management practices (weedy check, 5 monthly hoe weeding (5MHW), pre-emergence (PE) application of diuron at 2 kg a.i/ha + Post-Emergence (POE) of 3-Maize force at 179.2 g/ha + Two hoe weeding (2HW)] and PE Diuron + POE 3-Maize force arranged in a split plot design and replicated three times. Weed management practices and mulching constitute the main plot while sugarcane genotypes constitute the subplot. The results showed that application of 9 t ha^{-1} trash mulch significantly ($P<0.05$) produced the highest organic carbon, N, P and K, which in turn enhanced sugarcane yield. Similarly, the application of 9 t ha^{-1} trash mulch plus PE+POE+ 2HW produced the highest NCS 001 sugarcane yield. In conclusion, application of trash mulching at 9 t ha^{-1} plus P.E+PO.E+ 2HW effectively boast soil fertility and sustained the productivity of NCS 001 sugarcane in the study area and related ecologies.

Keywords: Sugarcane, Trash mulch, Soil properties, Genotypes, Weed management

INTRODUCTION:

Sugarcane (*Saccharum officinarum* L.) is a significant commercial cash crop widely grown by farmers in most tropical countries grown for the production of sugar, molasses, livestock feeds, alcohol, bagasses for fuel (Alvaris, 2008; Junejo *et al.*, 2010), and trash for mulching and as organic fertilizer (Gana, 2008). Sugarcane contributes 60 % of the total world sugar requirement, while the remaining 40 % comes from sugar beet (Busari and Misari, 2007). Weeds constitute a significant component of the pest complex in African farms and form an important constraint in agricultural production system in most farmers' fields (Takim and Amodu, 2013). Apart from the quantitative damages caused by weeds to crops due to competition for water, light and nutrients, weeds can cause a reduction in crop yield (Takim *et al*., 2012). Previous studies have shown a reduction in sugarcane yield due to weed infestation by 40 - 67% (Ndarubu *et al*., 2006; Kadam *et al*., 2011). There is an urgent need to integrate these weed management options with trash mulching for weed control and boost the production of these sugarcane genotypes in order to meet the needs of increasing population. Hence, the objective of the study was to evaluate the effect of varying trash mulch and weed management practices on soil properties sugarcane genotypes production in this study area.

MATERIALS AND METHODS:

Field trial was conducted at the upland sugarcane experimental field of the National Cereals Research Institute, Badeggi (lat. 9^0 45^1 N, long. 0.6^0 07^1 E) in the Southern Guinea savanna agro-ecological zone of Nigeria in 2016 and 2017 rainy season. At the commencement of the experiment, a composite sample from ten random points was collected, using a soil auger at 0 - 15 cm depth for both years. The initial soil properties of the experimental site are shown in Table 1. The total rainfall during the experimental period was 1504.1 mm in 2016 and 1045.4 mm in 2017, respectively. The mean air temperature during the sugarcane plant cropping season was 35 to 38 ^oC in 2016 and 34 to 36 ^oC in 2017 plant cropping seasons. Prior to cultivation, the vegetative cover of the experimental site was manually cleared, ploughed and harrowed with a tractor. Tender healthy young stalks of six months old sugarcane were used as planting material. The stalks were cut into setts each containing three eye buds. The PE diuron was applied a day after planting at the rate of 2.0 kg a.i/ha while the POE 3-Maize force was applied at five weeks after planting (WAP) at rate of 179.2g a.i/ha. The weeds were identified using the hand book of West African Weeds (Akobundu *et al*., 2016). NPK fertilizer was applied at 150 kg N, 60 Kg P and 90 Kg K in equal halves at planting and 8 – 10 WAP. The treatments consists of factorial combination of two sugarcane genotypes, Bida local and NCS 001, four cane trash mulching levels, (0, 3, 6, 9 t ha^{-1}) and four weed management practices (weedy check, 5 monthly hoe weeding (5MHW), Pre-emergence of diuron at 2 kg a.i/ha (PE) + Post-Emergence(POE) 3-Maize force at 179.2 g/ha + Two hoe weeding (2HW)] and PE diuron + POE 3-Maize force arranged as a split plot and replicated three times. Herbicides were applied with knapsack (CP3) sprayer at a spray volume of 4l/ha. Weed management practices and mulching were allocated in the main plot while sugarcane genotypes in the subplot. The gross plot size was 35 m^2 (7 m x 5 m), while the net plot size was 17.5 m^2 (3.5 m x 5 m). Each net plot consists of four rows of 5 m long. All data collected were subjected to analysis of variance (ANOVA). The means were separated using Duncan multiple range test at 5 % level of probability using SAS version 9.0 statistical package.

RESULTS AND DISCUSSIONS:

Sugarcane genotypes was significantly (P<0.05) influenced by organic carbon and total nitrogen at harvest (Table 2). Industrial sugarcane recorded the highest organic carbon and nitrogen than the local chewing cane. The application of 9 t ha^{-1} trash mulch significantly (P<0.05) produced the highest organic carbon, N, P and K which was closely similar to 6 and 3 t ha^{-1}. The result shows the ability of trash mulch in increasing soil organic matter, N (Graham and Haynes 2005; Robertson and Thorburn 2007; Yadav *et al*. 2009; Fortes *et al*. 2012) and improved physico-chemical properties. Similarly, organic carbon, N, P and K, were significantly (P<0.05) influenced by weed management practices (Table 2). The application of Pre-emergence + Post-emergence herbicide produced the highest organic carbon, N, P and K.

LSD- least significant difference, MHW-Monthly hoe weeding, PE- Pre-emergence (Diuron at 2 kg a.i/ha) herbicide, POE- Post-Emergence (3-Maize force at 179.2 g/ha) herbicide, NS-Not significant, MAP- Months after planting

Sugarcane genotypes was significantly (P<0.05) influenced by stalk height at 11 MAP (Table 3). Industrial sugarcane recorded the highest stalk height than the local chewing cane. The advantage that industrial sugarcane has over local chewing cane in stalk height can be attributed to the ability of industrial sugarcane to withstand drought more than the chewing sugarcane. This result confirms the findings of Ishaq and Olaoye (2007) which states that industrial sugarcane establishes faster because of its ability to withstand drought than the chewing cane. Similarly, stalk height at 11 MAP was significantly influenced by different rates of trash mulch application. The application of 9 t ha^{-1} trash mulch significantly (P<0.05) produced the highest stalk height which was closely similar to 6 and 3 t ha^{-1}. The result shows the ability of trash mulch in enhancing growth parameter, which may be attributed to increased soil organic matter (Graham and Haynes 2005; Robertson and Thorburn 2007; Yadav *et al*. 2009; Fortes *et al*. 2012), improved physico-chemical properties and soil water regimes. Cheong and Teeluck (2015) indicated that unburned trash remaining as surface mulch resulted in annual recycling of 105 kg N ha^{-1} therefore complement fertilizer needs. Stalk height at 11 MAP was significantly (P<0.05) affected by weed management practices (Table

3). Stalk height was highest with the application of Monthly hoe weeding which was similar to Pre-emergence + Post-emergence herbicide + 2 hoe weeding and application of Pre-emergence + Post-emergence herbicide only. The result of this study demonstrates the effectiveness of manual weeding, Pre-emergence + Post-emergence herbicide application in influencing growth parameter. Our results are consistent with previous studies of Smith *et al*.(2008) and Zafar *et al*. (2010) which indicates that growth parameters in sugarcane can be achieved by mechanical, chemical and chemical + mechanical and trash mulching.

Sugarcane genotypes significantly influenced stalk girth at 10 MAP (Table 3). The local chewing cane recorded the highest stalk girth than the industrial sugarcane. The superiority of the local chewing cane in having higher stalk girth than the industrial can be attributed to more robust, soft stem with high water and less sucrose content. This confirms the finding of Busari *et al*. (2005) which states that local chewing canes has more robust, soft stem with high water and less sucross than the industrial canes. Similarly, stalk girth at 10 MAP was influenced by different rates of trash mulch applied. The application of 9 t ha^{-1} trash mulch produced significant ($P<0.05$) higher stalk girth which was similar 6 and 3 t ha^{-1}. This may be attributed to high moisture retention, increased soil organic matter and improved physico-chemical properties like N and S (Robertson and Thorburn 2007; Yadav *et al*. 2009 and Gana (2008). Stalk girth at 10 MAP was also affected by weed management practices (Table 2). Stalk girth was highest with the application of monthly hoe weeding which was similar to Pre-emergence + Post-emergence herbicide + 2 hoe weeding and application of Pre-emergence + Post-emergence herbicide only. Our result was consistent with previous studies conducted by Smith *et al*.,(2008) and Zafar *et al*.(2010) which reported that the application of monthly hoe weeding followed by Pre-emergence + Post-emergence herbicide + 2 hoe weeding recorded an increase in sugarcane girth compared to the check plot.

Sugarcane genotypes significantly influenced brix at 11 MAP (Table 3). Industrial sugarcane recorded the highest brix than the local chewing cane. This may be due to the fact that industrial sugarcane has relatively thin and hard stem, thick ring (nodes) and usually contains more sucrose and less water content. This confirms the findings of Busari *et al*.(2005) and Shah *et al*. (2008) which states that improved sugarcane (industrial canes) variety usually have thin stems with high sucrose content and less water due to their varied genetic potential of sugarcane genotypes. Similarly, sugarcane brix at 11 MAP was significantly ($P<0.05$) influenced by different rates of trash mulch application. The application of 9 t ha^{-1} trash mulch produced significant ($P<0.05$) higher brix which was closely similar to 6 and 3 t ha^{-1}. This result may be attributed to the response of improved variety to higher moisture conservation, weed suppression potentials and increased N availability of trash mulch. This is in agreement with the finding of Thompson (2005); Uwah and Iwo, 2011). Brix at 11MAP was significantly affected by weed management practices (Table 3). Brix was highest with the application of monthly hoe weeding which was similar to Pre-emergence + Post-emergence herbicide + 2 hoe weeding and application of Pre-emergence + Post-emergence herbicide only. This may be attributed to effective weed control which resulted in increasing yield promoting attributes. Our result is in agreement with the previous findings of Smith *et al*., (2008) and Singh *et al*. (2011) which reported that all the weed control treatments favourably influenced the yield contributing characters such as stalk height, stalk girth and brix. Sugarcane genotypes significantly influenced sugarcane yield at harvest (Table 3). Industrial sugarcane recorded the highest yield than the local chewing cane. The difference in cane yield of sugarcane genotypes was due to their varied genetic potential which exploit edaphic and aerial factors of crop production. These results are in accordance with those of Bashir *et al*. (2012), Ongin *et al.* (2011) and Shah *et. al.* (2008) who reported significant difference among the sugarcane genotypes for cane tonnage. Similarly, sugarcane yield at harvest was significantly influenced by different rates of trash mulch application. The application of 9 t ha^{-1} trash mulch produced significantly ($P<0.05$) highest yield which was statistically similar to 6 and 3 t ha^{-1} in 2016. However, in 2017, application of 3 t ha^{-1} of sugarcane trash produced the highest yield; statistically similar results were obtained in 6 and 9 t ha^{-1} while the lowest yield was obtained in the control plot. The result is similar to the findings of Srivastava and Chauhan (2006) and Gana (2008) which states that the higher the quantity of organic mulch applied, the more the productivity of the crop on the field. Sugarcane yield at harvest was significantly ($P<0.05$) affected by weed management practices (Table 3). Yield was highest with the application of monthly hoe weeding which was similar to Pre-emergence + Post-emergence herbicide + 2 hoe weeding and application of Pre-emergence + Post-emergence herbicide only in 2016. But in 2017, application of Pre-emergence + Post-emergence herbicide gave the highest yield which was in turn similar to the application of monthly hoe weeding and Pre-emergence + Post-emergence herbicide + 2 hoe weeding .This may be attributed to effective weed control which resulted in increasing yield. The result is in agreement with the findings of Singh *et al*. (2011) who observed that increased number of stalk height, stalk girth and cane yield was observed with weed free situations. Sugarcane genotypes responded positively to trash mulching and weed management practices. Industrial cane (NCS 001) performed better than Bida local in terms of growth establishment, yield and weed suppression. Response to trash mulching from 6- 9 t ha^{-1} contributed significantly in high yield of sugarcane.

Table 3: Effects of sugarcane genotypes and weed management practices on stalk height, Girth, Brix content, Number of Stool per plot , Millable stalks and Came yield at 12 MAP

in 2016 and 2017 seasons

LSD - least significant difference, MHW-Monthly hoe weeding, PE- Pre-emergence (Diuron at 2 kg a.i/ha) herbicide, POE- Post-Emergence (3-Maize force at 179.2 g/ha) herbicide, NS-Not significant

CONCLUSION:

The application of 9 t ha^{-1} trash mulch produced the highest organic carbon, N, P and K. Increased trash mulching of 9 t ha^{-1} with application of P.E+PO.E+ Two hoe weeding was promising in managing weeds thus, sustaining the productivity of sugarcane.

Agricultural Society of Nigeria
24 - 28 Oct., 2022

ABSTRACT

In the present study, correlation analyses of data collected on agronomic characters were used to determine the relationship of these characters with cane yield; and ascertain their contribution in obtaining high cane yield. Field experiment was conducted in 2016 and 2017 at National Cereals Research Institute, Badeggi in the Southern Guinea Savanna ecology of Nigeria. The treatments consisted of factorial combination of two sugarcane genotypes (Bida local and NCS 001), four sugarcane trash mulching levels (0, 3, 6, 9 t/ha) and four weed management practices (weedy check, 5 monthly hoe weeding (5MHW), pre-emergence (PE) application of diuron at 2 kg a.i/ha + Post-Emergence (POE) of 3-Maize force at 179.2 g/ha + Two hoe weeding (2HW)] and PE Diuron + POE 3-Maize force arranged in a split plot design and replicated three times. Weed management practices and mulching constitute the main plot while sugarcane genotypes constitute the subplot. The cane yield, considered as the most important character of sugarcane, was positively and significantly correlated with sprouting percentage (r=0.531**), number of tillers (r=0.574**), number of millable canes (r=0.716**), sugarcane stalk girth (r=0.595**) and height (r=0.677**), sugarcane brix (r=0.595**), organic carbon (r=0.568**), nitrogen (r=0.532**) and soil moisture content (r=0.531**) while Phosphorus (r=0.445), Potassium (r=0.397), showed positive but non-significant correlation with cane yield. Cane yield was negatively correlated with evapotranspiration (r= -0.500) and weed dry matter (r= -0.556) at all the stages. Results from the analysis indicated that selection programme for high yielding sugarcane genotypes should be based on sprouting percentage, number of tillers, number of millable canes, sugarcane stalk girth and height, sugarcane brix, organic carbon, nitrogen and soil moisture content.

Keywords: Sugarcane, Correlation, Growth, Yield, Attributes

INTRODUCTION

Sugarcane (*Saccharum* spp.) belongs to the family Poaceae, which are large tropical or subtropical grasses that are grown widely within the zone of 30^{o} C on either side of the equator (Wada *et al.*, 2017). Approximately, 75 % of world's sucrose production is from sugarcane (Bassey *et al.*, 2020). Besides the production of raw sugar, of which sugarcane is mainly produced for, sugarcane also represents an important source of renewable energy which has recently gained attention because of ethanol production. The national average yield of sugarcane is less than 65 t ha $^{-1}$ which is much lower than the world average of 175.1 t ha $^{-1}$ (NSDC, 2014). The correlation between growth and yield components of sugarcane has been studied and reported by several authors. Sanjay and Devendra (2014) reported that, sugarcane yield was significantly and positively correlated with germination percentage, number of shoots, number of millable canes, stalk diameter, stalk length, number of internodes, length of internodes, stalk weight, number of green leaves, while with the top weight, it showed positive but non-significant correlation. Cane yield was negatively correlated with brix at all the stages. In the present study, correlation analyses of data collected on agronomic, soil and weed parameters on sugarcane genotypes were used to determine the relationship of these characters with cane yield and ascertain their contribution in obtaining high cane yield at Badeggi, Nigeria.

MATERIALS AND METHODS

A field experiment was conducted at the upland sugarcane experimental field of National Cereals Research Institute, Badeggi (Lat. 9^{0} 45' N, Long. 6^{0} 07' E and 89 m above sea level) in the southern Guinea savanna agro-ecological zone of Nigeria in 2016 and 2017 wet and dry season. The average annual rainfall during the experimental was 1504.1mm in 2016 and 1045.4 mm in 2017 while the mean air temperature was 35 to 38 ^{0}C in 2016 and 34 to 36 ^{0}C in 2017.

Composite soil samples were taken before field establishment from ten spots along a diagonal and at harvest from each treatment plot from 0 to 15 cm depth, and subjected to routine analyses. Particle size analysis was done by the Bouyoucos hydrometer method (Gee and Or 2002). Soil organic carbon was determined by the procedure of Walkley and Black using the dichromate wet oxidation method (Nelson *et al*. 1996). Total N was determined by the micro—Kjeldahl digestion method (Bremner and Mulvaney 1982). The Olsen method was used to determine available phosphorus, and flame photometry for exchangeable potassium (Okalebo *et al*. 2002).
Soil pH was determined in 1:2 soil–water ratio using digital electronic pH meter.

Before cultivation, the vegetative cover of the experimental site was manually cleared, ploughed and harrowed with a tractor in the first week of February 2016 and 2017. The land was fully irrigated before planting by pumping water from a stream using a 3.5 HP water pump with a 12.5 cm diameter hose. Thereafter, the land was marked out into plots with bunds at the edges for water retention. Gross plot size was 5 m x 4 m (20 m^{2}) consisting of 4 sugarcane rows, and net plot size was 5 m x 2 m (10 m^{2}) consisting of 2 sugarcane rows. Each row was spaced at 1 m apart. Tender healthy young stalks of six months old sugarcane were used as planting material. The stalks were cut into setts each containing three eye buds, planted continuously end-to-end without intra-row spacing in shallow sunken bed. The application of pre-emergence (PE) diuron was done immediately after planting at 2.0 kg a.i ha-^{1}. The trash mulch was applied at a thickness of 1, 3 and

5 cm (Henrique *et al*. 2013) for 3, 6 and 9 t ha respectively, with a small opening left of the setts which were closed up after sprouting. The application of postemergence (POE) 3—maize force at 179.2 g ha [metolachlor 375 g L^{-1} plus terbuthylazine 125 g L plus mesotrione 37.5 g L^{-1}] was applied at 5 weeks after planting (WAP). The NPK fertilizer was applied at 150 kg N, 60 kg P_2O_5 and 90 kg K_2O in equal halves at planting and 10 WAP. Irrigation water was applied at 41.3 L per plot once per week from February to April. Rainfall was supplemented with irrigation in May which was the establishment of the rainy season.

The treatments consisted of a factorial combination of two sugarcane genotypes [Chewing cane (Bida local and Industrial cane (NCS 001)], four rates of sugarcane trash mulch rates (0, 3, 6, 9 t ha^{-1}) and four weed management practices [weedy check, five monthly hoe weeding (5 MHW), pre-emergence (PE) application of diuron at 2 kg a.i ha^{-1} + post-emergence (POE) application of 3 – maize force at 179.2 g ha^{-1} + 2 MHW, and PE diuron + POE 3-maize force] making a total of 32 treatments arranged as a split- plot in a Randomized Complete Block Design and replicated three times. Weed management practices and trash mulching were allocated to the main plot, while sugarcane genotypes were the subplot. The gross plot size was 5 m x 4 m (20 m^2), while the net plot size was 5 m x 2 m (10 m^2). Each net plot consisted of four rows of 5 m length.

RESULTS AND DISCUSSIONS

In 2016 plant crop, with the exception of all the weed parameters and evapotranspiration that negatively correlated with cane yield, all the growth and yield characters as well as nitrogen content measured, correlated significantly and positively with cane yield (Table 1). The strongest relationship between the growth parameters and the yield in 2016 plant crop was found between millable stalk and cane yield (r=0.716**), followed by the relationship between stalk height and yield (0.677**). In 2017 plant crop, all the growth and yield characters as well as phosphorus and potassium content measured, correlated positively but not significant with cane yield with the exception of all the weed parameters and evapotranspiration that negatively correlated with cane yield. Organic matter, nitrogen and moisture content correlated positively and significantly with cane yield. The strongest relationship between the growth parameters and the yield in 2017 plant crop was recorded between organic matter and cane yield (r=0.537**), which was in turn the strongest relationship between any two growth parameter in this year (Table 1).

Similarly, in the ratoon crop of 2017, sprouting (%), tiller per plot, stalk height, brix, millable stalks and nitrogen content positively and highly significantly correlated with cane yield, while weed parameters and evapotranspiration were negatively correlated with cane yield (Table 1). The strongest relationship between the growth parameters and the yield in 2017 ratoon crop was recorded between brix and cane yield (r=0.590**), followed by the relationship between stalk height and yield (0.585**). Also, in 2018 ratoon crop, stalk girth, brix, organic matter, nitrogen and moisture content positively and significantly correlated with cane yield while weed parameters and evapotranspiration were negatively correlated with cane yield (Table 1).

Moisture content	0.264*(0.02)	0.526*(0.05)	0.380**(0.01)	0.531**(0.01)

*Significant at 0.05, ** highly significant at 0.01, ns-not significant, P-value in parenthesis

The strongest relationship between the growth parameters and the yield in 2018 ratoon crop was recorded between stalk girth and cane yield (r=0.595**), which was in turn the strongest relationship between any two growth parameter in this year

The significant and positive correlations observed between some growth and yield parameters particularly sprouting %, number of tillers, stalk height, stalk girth, brix, millable stalks with yield suggest that these characters are important cane yield contributing determinants. This finding agreed with that of Takim *et al*. (2014) who reported significant and positive correlation between number of tillers and cane yield. Flavio *et al*. (2013) reported similar results between number of tillers, stalk girth, brix, millable cane and cane yield. It implies that sugarcane breeders need to consider these characters in breeding for yield. Similarly, N and P were significant and positively correlated with cane yield. These indicate that these soil nutrients are essential yield contributing factors. This finding agreed with the work of Vitti *et al*. (2010) and Fortes *et al*. (2012) who reported significant and positive correlation between organic matter, N and P with cane yield. The importance of soil amendment in sugarcane cannot be overemphasized. Soil moisture content (SMC) was significant and positively correlated with cane yield. This is because the more the availability of water for plant use, the better the nutrient translocation which in turn affected growth and yield of sugarcane. This finding agreed with the work of Ball-Coelho *et al*. (2009); Peres *et* *al*. (2010) and Cheong and Teeluck (2015) who reported similar results between soil moisture content and cane yield.

CONCLUSION:

The selection programme for high yielding sugarcane would be effective if it was based on sprouting percentage, number of tillers, number of millable canes, sugarcane stalk girth and height, sugarcane brix, organic carbon, nitrogen and soil moisture content.

ABSTRACT

A field experiment was carried out at the Department of Agricultural Technology, School Farm Federal Polytechnic Nekede to determine the effect of different watering regimes on dry season of cucumber (cucumis sativus L) using irrigation methods, The experiment was laid out in a Randomized complete Block Design (RCBD) using 3 different replicates. The treatments were four different watering regimes, the parameter collected include plant height, Numbers of leaves, fruit length, fruit girth, fruit weight, number of days of flowering, number of days of emergence, reading were taken at 2, 4and 6 weeks after planting. All the data collected were subjected to analysis of variance. From the result obtained, it was observed that some of the parameters were not significantly different while some were significantly different. DAYS TO 50% emergence of cucumber was significantly increased by the treatment 3 which is (watering using manual watering can aided with grass mulching material) however, plant that received furrow irrigation alone T2 took shorter time to emerge when compared with other treatments. Significantly taller cucumber plants were observed in treatment 1 and treatment 4 this could be attributed to evenly distributed water application following the method used as well as the mulching material used in treatment 4 (use of ultraviolent ray tarpaulin with the drip irrigation). The number of leaves also follow similar trend as plant higher above. The yield of cucumber were not significantly affected by different watering regime. However, yield was more enhanced in treatment 4(use of ultraviolent ray tarpaulin with the drip irrigation).
Keywords: Cucumber, Dry Season, Water Regime

INTRODUCTION

Background Of The Study

Cucumber (*Cucumis sativus*) is one of the most popular and widely grown vegetable crops in the world and it belongs to the family cucurbilaceae. It is a typical vegetable that grows in warm. temperate and cool tropical regions. It is a vegetable that have little tolerance for water stress. (*Huai-Fu Fan et al*., 2014). Due to it increased demand, it is considered as one of the most important economic vegetables. From the various researches carried out on the crop, it was established that it requires more water than grain crops (*Li and Wang. 2000: Mao, 2003*).

It was discovered that fresh fruit yields of cucumber were highly affected by total volume of irrigation water at all growth stages (*Mao, 2003*).

The production of cucumber during dry season is encouraged for availability of fresh vegetables, despite the fact that traditional farmers rely on their experience to irrigate cucumber such as furrow and basin irrigation, it does not in most cases actually result into expected high yield with it attendant drudgery. The production of cucumber can be enhanced with adequate knowledge of crop water use and the application of the irrigation technique such as sprinkler is inevitable for vegetable production in the near future because of the salinity problem caused by traditional irrigation methods.

Researchers have found out that excess in watering and improper irrigation techniques leads to non-uniform distribution of water in crop field with reduced yield (*Motilvaet et al., 2000*).

Being aware of the water sensitivity of plant species and their responses to water, there is need to choose the most suitable irrigation method and scheduling for them based on the source and availability of water (Meiri,1992)(Gao,1994) reported that cucumber plants posses moderate deep root and shallow fibrous root system which make them efficient user of available moisture within the top 60cm of soil layer. Timely and adequate application of irrigation water is necessary for good yield. Hence, it is important to determine the growth period when the plants are susceptible to water usage to avoid water stress and optimize the yield from irrigated area (Pandey *et al., 2000*).

Previous studies have shown that fairly good knowledge of crop water use have resulted into proper irrigation scheduling to save water and increase yield (Zhang *et al*, 201I: Oweis *et al*., 2000).

Statement Of Problem

The seasonal cucumber production ranges from 1 50-290 ton/ha with a mean daily production of approximately l,500kg/ha/day excluding those from 2018 because of it short growth period and the influence of root rots disease, there is need to find a sustainable system of production all year round due to the health benefit of the vegetable.**1**

Objectives

The major objective of the study is to evaluate the effect of different watering regime/irrigation on dry season cucumber.

i) To compare the growth cucumber under the various water regime.

ii) To determine the yield of cucumber affected by the different water regime used

iii) To determine the best affordable water regime for dry season production of cucumber

The significance of this study is to determine the impact of variation on water availability on plant growth and crop yield using various irrigation systems. This is aimed to determine the quantity of water needed and how it affect crop yield during the dry season period.

MATERIAL AND METHODS

Treatment 1= water regime using drip irrigation.
Treatment 2 = use of furrow irrigation system.
Treatment 3 watering using manual watering can aided with grass mulching material.
Treatment 4 = use of Tarpaulin with the drip system.
The treatments were replicated in three blocks to reduce error. The experiment produced 12 treatments in combination.

The experiment was laid out in a Randomized Complete Block Design (RCBD) and treatments was randomly administered. A plot size measuring (15m x 9m) was cleared and bed made at 3m x 2m each with lm spacing in-between blocks, The seeds were planted at 3 seeds per hole and later thinned down to one seed per hole after 3 weeks, in the month of December. **T**he recommended NPK fertilizer application of NPK 15 15 15 at 150kg/ha was used. The improved seed variety was sourced from Thia-agro farm and was used for the experiment. Weeding was carried out periodically using the convention weeding method of hoeing and hand weeding.

Data Collection

Data was taken at 2 weeks interval on the following parameters

Days to 50% Emergence of Cucumber Seed: The number of days to 50 days emergence was counted as the number of days it took 50% of all planted seed to germinate above soil level. This was calculated by counting calender days.

Flowering: This is the number of days of flowering, this was recorded as the number of days it took 50% of the plant to produce visible flowers.

Plant Height (cm): The plant height was measured in 2 weeks, 4weeks, and 6weeks after planting with a meter rule. The meter rule was placed at the base of the plant and measured to the tip of the plant

Number of Leaves: The number of leaves were counted and recorded in 2weeks, 4weeks and 6weeks from each plot. This was calculated by counting the number of fully developed leaves on each tagged plant and recorded per plot

Fruit Length (cm): The length of the fruit was measured with a meter rule after harvesting from each plot. This was measured using a meter rule from the base of the fruit to the tip

Fruit Girth (circumference) cm: The Girth of the fruit was measured with thread and meter rule from each treatment.

Fruit weight (g): The cucumber were measured using electronic weighing balance.

Statistical Analysis: Data collected were subjected to analysis of variance (ANOVA) and treatment means were separated by fishers least significant difference (F-LSD) at 5% level of probability using R desktop version 1.4.1717 (R core Team, 2021).

RESULTS AND DISCUSSION

Table 1 Effect Of Different Watering Regimes On The Number Of Days To 50% Emergence

Treatment	Days To 50% Emergence

T1 water regime using drip irrigation	6.00
T2 use of furrow irrigation system	5.08
T3 watering using manual watering can aided with grass mulching material	6.16
T4 use of ultraviolet ray tarpaulin with the drip system	4.0
LSD (0.05)	0.98

The table above showed that the number of days to 50% emergence of cucumber was significantly affected by the different watering regime. Treatment 4, significantly emerged at about four days after planting, while the other treatments emerged at about the same time of 5-6 days after planting.

Table 2 Effect Of Diferent Watering Regime On The Numbering Of Days To 50 % Flowering In Dry Season Cucumber Production

Treatment	Number Of Days Of Flowering
T1 water regime using drip irrigation	29.33
T2 use of furrow irrigation system	33.00
T3 watering using manual watering can aided with grass mulching material	35.00
T4 use of ultraviolet ray tarpaulin with the drip system	34.33
LSD (0.05)	2.35

The number of days to 50 % flowering of cucumber plants were significantly affected by the different watering regime. T1 (29.33) flowered significantly earlier when compared with the other treatments. These was followed by T2 which flowered at (33.00), T4 (34.33) and (35.00) respectively.

Effect Of Different Watering Regime On Cucumber Plant Height

At 2WAP, the plant height of the cucumber was significantly affected by the different watering regime. T1 use of trip tape irrigation gave significantly taller plants (17.16) when compared with T2 (7.08) with the shortest recorded plant height. Plant height recorded for T3 (13.83) and T4 (14.00) were not significantly different.

At 4WAP, similar result was also obtained, the use of trip tape irrigation gave significantly taller plant when compared with the other treatments. The use of furrow irrigation alone affected plant height at all the sampling time, as the treatment produced significantly shorter plant.

At 6WAP Plant height was not significantly affected by the different treatments

Table 3 Effect of Different Watering Regime on Cucumber Plant Height (Cm)

Treatment	Weeks after Planting (WAP)		
	2	4	6
T1 water regime using drip irrigation	17.16	50.66	114.08
T2 use of furrow irrigation system	7.08	37.58	110.08
T3 watering using manual watering can` aided with grass mulching material	13.83	48.33	113.75
T4 use of ultraviolet ray tarpaulin with	14.00	38.41	101.08

the drip system			
LSD (0.05)	5.41	3.45	NS

Effect Of Different Watering Regime On Number Of Leaves

At 2WAP, The number of leaves per Plant of cucumber was not significantly affected by the different watering regimes, Though T1 (19.25) produce plants with the highest number of leaves followed by T3 (13.16) and T4 (10.41) and T2 (12.41) respectively.

Table 4. Effect Of Different Watering Regime On Number Of Leaves

TREATMENT	Weeks after Planting (WAP)		
	2	4	6
T1 water regime using drip irrigation	19.25	25.33	78.50
T2 use of furrow irrigation system	12.41	22.50	50.58
T3 watering using manual watering can aided with grass mulching material	13.16	19.33	68.91
T4 use of tarpaulin with the drip system	10.41	17.50	46.25
LSD (0.05)	NS	NS	NS

At 4WAP, The table reveal that the number of leaves per plant of cucumber were not significantly affected by the different watering regime, T1 (22.50) again produces plant with the highest number of leaves when compared with the other treatments T3 (19.33), T4 (17.50) and T2 (15.33) respectively.

At 6WAP, The table show that the number of leaves per plant of cucumber were not significantly affected by the different watering regimes, though T1 (78.50) produces plant with highest number of leaves followed by T3 (68.91) and T2 (50.58) and T4 (46.25).

Table 5 Effect Of Different Watering Regime On Fruit Length (Fl) Of Cucumber

Treatment	Fruit Length (Cm)
T1 water regime using drip irrigation	14.18
T2 use of furrow irrigation system	13.50
T3 watering using manual watering can aided with grass mulching material	12.58
T4 use of ultraviolet ray tarpaulin with the drip system	15.08
LSD (0.05)	\NS

The Table shows that the Fruit Length of cucumber were not significantly affected by the different watering regimes. It was observed however that T4 Use of tarpaulin with the drip system recorded the highest fruit length value (15.08) when compared with the other treatments T1 (14.18) T2 (13.50) and T3 (12.58) respectively. The least value frecorded in cucumber fruit length was observed in the plots treated with watering can alone.

Table 6 Effect Of Different Watering Regime On Fruit Girth (g).

Treatment		Fruit Girth (Cm)
T1	water regime using drip irrigation	40.56
T2	use of furrow irrigation system	39.80
T3	watering using manual watering can aided with grass mulching material	37.56
T4	use of ultraviolet ray tarpaulin with the drip system	40.56
LSD (0.05)		NS

The table reveal that the Fruit Girth of cucumber were not significantly affected by the different watering regimes. The highest girdth values were recorded in T1 (40.56) and T4 (40.56) have same Girth, T2 (39.80) and T3 (37.56) had the least recorded girth value

Table 7 Effect Of Different Watering Regime On Fruit Weight of Cucumber

Treatment		Fruit Weight (Kg)
T1	water regime using drip irrigation	383.33
T2	use of furrow irrigation system	333.33
T3	watering using manual watering can aided with grass mulching material	353.30
T4	use of ultraviolet ray tarpaulin with the drip system	483.33
LSD (0.05		NS

The fruit weight of cucumber were not significantly affected by the different watering regime. T4 (483.33) had the highest recorded fruit weight when compared with the other treatments. The fruit weight includes T3 (353.30), T1 (383.00) and T2 (333.33) respectively. The result revealed that although different treatments were applied in dry season production of cucumber, none of these treatments significantly affected the growth and yield of cucumber, Although one could categorically say that the plants in treatment 3 watering using manual watering can aided with grass mulching material produced better fruit yield when compared with other treatments.

CONCLUSION

Water application to the field during dry season farming is very essential especially in vegetable production. The different watering regime for irrigating cucumber during dry season has proved to be worthwhile from this study. However, optimal use of water to meet crop requirement at any stage of growth has also resulted into appreciable level of yield as demonstrated in different yield obtained from different watering regime applied to the crop. Therefore, cucumber grown in irrigated condition showed good production responses. From the result of the experiment carried out so far, it can be inferred that yield is considerably appreciable when cucumber receives adequate water or moisture below which there are noticeable decrease in yield. Even though, the experiment has not established the optimum water use for irrigating cucumber that will give the optimum yield during dry season farming, the result has shown that the different watering regime has an effect on cucumber yield. This simply showed that moderate irrigation is essential. The analysis of water applied in each of crop's growth stages made it possible to classify their effects on the development of the yield. The Production of cucumber during dry season with planned watering regime is profitable. Having carried out this experiment on the effect of different watering regime on dry season Cucumber Production, the following are recommended Irrigation, irrespective of the method used, is recommended for optimum production of cucumber during dry season. More work should be done in different regions to confirm the best water regime for cucumber plant.

24 - 28 Oct., 2022

ABSTRACT

A survey of brown leaf spot on Fonio (*Digitaria iburua and D. exilis*) was carried out in major Fonio growing areas of Nigeria in 2014 and 2015. The surveyed areas were Bauchi, Kaduna, Plateau and Nassarawa States. Two visits were made to each state in each of the years. In each LGA, three towns were selected and three farms were sampled in each town with a farm representing a replicate. With the help of a quadrat five sampling plots were assessed for disease incidence and severity in all the farms visited. In 2014, there were significant ($P \leq 0.05$) differences in incidence of brown leaf spot in all areas visited, however the highest incidence of brown leaf spot was recorded in Zawang (Plateau) which was not significantly different from all other locations except, Nahuta and Bogoro (Bauchi) which had the least incidence. In 2015, the incidence of brown leaf spot was also highest in Zawang and Kwaturu (Kaduna). Angware, Bogoro, Demank, Mbar, Nahuta, Munguna, Nyeleng and Gyara had the least incidence. There were no significant ($P \leq 0.05$) differences in brown leaf spot severity in all the locations in both years. The disease was more prevalent in Plateau and Kaduna States.

INTRODUCTION

Fonio (Acha) or hungry rice (*Digitaria exilis* and *Digitaria iburua* Family Poaceae) originated in West Africa and as a grain crop cultivated for centuries across fifteen countries in the Northwest Africa from Cape Verde Island to Chad, Ivory Coast and Cameroon (Jideani, 1999). Fonio is the most ecologically adapted and economically useful. species of the monocotyledons (Anon. 1996, Cruz, 2004) due to its ability to grow under marginal rainfall and low inputs However, it is underutilized and neglected also considered one of the lost crops in Africa (Anon. 1996). It has the potential to improve nutrition, boost food security, foster rural development and support sustainable use of the land. It is grown mostly in the central and northern states of Nigeria such as Bauchi, Kaduna, Kebbi, Nassarawa and Plateau states where it is locally called 'Acha' (Aliero and

Morakinyo, 2001). The three largest producers are Guinea, Nigeria and Cote d' Ivoire with production of 500 986, 82 750 and 19 263 tons from 466 622, 190 315 and 33 983 ha respectively (FAO, 2016). Both *Digitaria* species have shown to be susceptible to insect pests and diseases (Vietmeyer *et al.*, 1996; Kwon-Ndung and Misari, 1999) thus a contributing factor to low yield. However, despite its economic importance, very little is known about the diseases of fonio in Nigeria (Auta, 1983). The first case was reported in Samaru, Zaria, where the incidence of leaf blast caused by *Pyricularia* sp and *Helminthosporium* leaf spot were identified on fonio plants (Auta, 1983). Therefore, the objective of this study is to determine the occurrence and distribution of brown leaf spot on Fonio in major growing areas in Nigeria.

MATERIALS AND METHODS

A survey of brown leaf spot of Fonio (*Digitaria iburua and exilis*) was carried out in Fonio growing areas of Nigeria between the second week of July and last week of August, 2014 and 2015. The Fonio growing states surveyed were Bauchi, Kaduna, Plateau and Nassarawa states. Two visits were made to each state for each of the year. The reason for the visits at such periods was it is expected that fonio plants have attained these ages since individual locations have different planting date. Two Local Government Areas (LGA) were surveyed in Bauchi (Bogoro and Tafawa Balewa), three LGAs in Kaduna (Jabba, Kachia Kagarko), ten LGAs in Plateau (Barkin ladi, Bassa, Bokkos, Jos East, Jos South, Kanke, Mangu, Pankshin, Quanpan and Riyom) and one LGA in Nassarwa State (Wamba) were surveyed. For each LGA, three selected towns and three farms were sampled with a farm taken as a replicate. Using a quadrat of 30x 30 cm five sampling plots in farms that were up to a hectare and three for farms less than a hectare were assessed for infection visually

Disease incidence was estimated by counting the number of infected plants in each sampling plot and expressing this as a percentage of the total Fonio plants per plot (Tarr, 1981). This was carried out with the help of a quadrant of 30 cm x 30 cm.

$$DI=\frac{Number\ od\ individual\ diseased\ plants}{Total\ number\ of\ plants}\ X\ 100$$

For disease severity assessment individual plants within the sampling plot were scored in numerical disease rating scale of 1 – 5 where; 1=No spots on leaves, 2= 1-25 % of leaves with spots, 3= 26-50 % of leaves with spots, 4= 51-75 % of leaves with spots and 5= 76% and above leaves with spots (Tarr, 1981).The disease severity was calculated using the formula below as expressed in percentage:

$$DS=\sum\frac{Nx}{N(5)}$$

where; $\sum$ = Sum total, x = disease rating grade, n = number of plants per given grade, N= total number of plants examined per plot and 5= the maximum disease grade. Data collected were subjected to statistical analysis of variance (ANOVA) using SAS (2013) and means compared using the Student Newman Keuls (SNK) test at 5 % level of significance.

RESULTS

Acha growing locations in major producing states and the level of brown leaf spot infection is presented in Figure 1. Geographically the study area stretches between latitude $9^{0}0^{1}0^{11}$ N - $11^{0}0^{1}0^{11}$ N of the equator and between Longitude $8^{0}0^{1}0^{11}$E – 10^{0} 0^{1} 0^{11} E of the Greenwich Meridian covering Bauchi, Kaduna, Nassarawa and Plateau States (Fig 1). Areas with 20- 30 % severity were grouped as low severity, 30.1-40 % moderate severity while above 40 % high severity (Figure 1.)

The result of the various locations visited is presented in Table 1. In 2014, the highest incidence of brown leaf spot was recorded in Zawang which was not significantly ($P \leq 0.05$) different from all other locations except Nahuta and Bogoro which had the least incidence. In 2015, the incidence of brown leaf spot disease was also highest in Zawang and Kwaturu, however, this significantly ($P \leq 0.05$) varied with only Angware, Bogoro, Demank, Mbar, Nahuta, Munguna, Nyeleng and Gyara which had the least incidence that was not significantly different from other locations. There were no significant ($P \leq 0.05$) differences in brown leaf spot severity in all the locations visited.

The results according to states shows in 2014, the incidence of brown leaf spot was highest in Plateau state but it was not significantly ($P \leq 0.05$) different from locations in Kaduna state. Meanwhile the least incidence was recorded in Bauchi state and they were at par with Nassarawa and Plateau states. However, in 2015 Kaduna state had the highest incidence and it did not vary from locations in Plateau state while Bauchi had the least incidence Figure 2. For severity of brown leaf spot, Nassarawa state recorded the highest severity and it did not differ from other locations in Plateau state while the least severity was observed in Kaduna state during 2014 cropping season. In 2015, Kaduna state recorded the highest severity Figure 3.

DISCUSSION

The disease was more prevalent in all the locations in Kaduna and Plateau states than Bogoro and Nahuta in Bauchi State. The reason could be due to differences in agro ecological zones and variation in weather parameters which in some case might not have been favourable for the pathogen. Weather factors play a major role in the initiation of disease and each pathogen has its own optimum requirement for infection (Hardwick 2002). The presence of high temperature and frequent rainfall has been attributed to the incidence of Curvularia blight of Zoysia grass caused by *Curvularia inaequalis* in China (Kim *et al.*, 2000). The average rainfall in Kaduna state is 284 mm (August) while temperature is 24.5 -29 ^{0} C and Plateau has 308.6 mm in August and temperature 24.5- 27 ^{0} C (Weather records from State Agricultural Development Project). This could be the reason why the disease is more prevalent in Plateau and Kaduna states than Bauchi (rainfall -252 mm and Temperature 29 ^{0} C). Bauchi has drier days than Plateau and Kaduna states. Bawa (1992) reported the influence of weather on the spread and development of midrib disease of millet. In the report, it was discovered that Jibia in far north had lower disease incidence than Sokoto and Katsina, and this was attributed to the effect of hot dry weather which slows the rate of disease development. The differences in disease spread observed on the fonio fields could also be attributed to differences in time of planting, while some fields were planted at the onset of rains others were planted later in the season therefore making infection period to vary in different locations during the survey.

CONCLUSIONS

From the above results Brown leaf spot is found in all the fonio growing areas visited with higher incidences and severity in Kaduna and Plateau states.

ABSTRACT
Four cassava varieties (NR87/184, TMS 07/0539, TME 419 and 01/1368) harvested (12 MAP) were carefully uprooted and stored at ambient temperature on shelves for a period ranging from 0 to 14 days. High quality cassava flour (HQCF) was processed from the stored roots at 0; 7 and 14 days after storage. The effects of variety on the chemical and functional properties of the flour were investigated. There were significant differences observed in the bulk density, water absorption capacity and swelling Index among the HQCF varieties and the days of processing. The hydrogen cyanide (HCN) content of the flour samples among the varieties decreased as the storage period progressed. There was significant difference among moisture, crude fibre and ash content values of HQCF samples within the storage days. The study shows that HQCF from different varieties of cassava roots tolerant to Postharvest Physiological Deterioration (PPD) can be stored up to 14 days and result in acceptable product in terms of moisture, crude fibre, ash and HCN contents.

Keywords: Cassava, HQCF, Postharvest Physiological deterioration and functional properties

INTRODUCTION
Cassava (*Manihot esculenta* Crantz) is cultivated in many regions of the developing world. It is important to the livelihoods of many millions of poor people who consume it as a staple in these regions (Alamu, Maziya-Dixon et al. 2017). Cassava thrives well in soils where many other crops perform poorly and thus plays an important role in food security (Iyer, Mattinson et al. 2010). Cassava roots are bulky and perishable and require appropriate strategies and technology for postharvest processing and utilization. Processing of fresh cassava roots provide a means of producing shelf-stable products (thereby reducing losses), adding value and reducing the bulk to be marketed (Ukpabi and Ndimele 1990). Cassava can be processed into different products such as chips, grits, flour, starch and syrup. High Quality Cassava Flour (HQCF) is one of the

intermediate products of cassava processing. It can be used as a substitute for wheat flour in the food industry as partial replacement for many baked and pasta products. Its special properties of clear appearance, low off-flavor and ideal viscosity makes it a vital ingredient in the food industry (Maziya-Dixon, Alamu et al. 2017). Postharvest Physiological Deterioration (PPD) is one major limitation of cassava roots utilization that causes a significant loss of storage roots, reducing the food, feed, and market value of the crop (Beyene, Solomon et al. 2018). Ideal operating conditions demand that the roots be processed on the day of harvesting or one or two days later. Studies have shown that some cassava varieties are tolerant to Postharvest Physiological deterioration (PPD) at ambient temperature for a period of 14 days. There is scanty information on the chemical and functional properties of high quality cassava flour (HQCF) from stored cassava roots (Manihot esculenta Crantz) tolerant to postharvest physiological deterioration (PPD). Availability of such information would guide in selection of cassava varieties that are suitable for marketing and utilization in enterprises requiring fresh cassava roots such as those that process snacks and other products.

MATERIALS AND METHODS

Four experimental cassava varieties was used for this study NR87/184 and TMS 07/0539 (white and yellow fleshed) tolerant to PPD and TME 419 white fleshed and 01/1368 yellow fleshed was used as check. Root samples were obtained from plants grown at the multiplication farm of Cassava Programme of the National Root Crops Research Institute Umudike, Umuahia, Abia State, Nigeria. The roots were harvested 12 months after planting and care was taken during harvesting to avoid injuries to the roots since root injury accelerates the onset of PPD. Cassava roots (ten kilograms each) of the four varieties NR87/184, TME 419, TMS 07/0539 and TMS 01/1368 without mechanical damage or pre-harvest rot were selected. Each of the ten kilograms harvested cassava roots were labelled day 0, day 7 and day 14. The sample of day 0 was immediately processed into HQCF while the remaining were stored at ambient temperature on shelves under a roof without walls for air to circulate freely and were equally processed into high quality cassava flour (HQCF) on days 7 and 14.

Preparation of high quality cassava flour (HQCF)

Ten (10) kg of cassava roots were manually peeled with stainless steel knife, the peeled roots were washed and re-weighed, grated, dewatered, and sieved. The resulting sieved mash was oven-dried at 40℃ and milled and sieved (sieve size, 0.5 mm).

Chemical and Functional Analyses of HQCF

The chemical (moisture, ash, crude fibre and ash contents) were determined using AOAC (2000) standard methods. The hydrogen cyanide content of flour samples were determined by the method described by Onwuka, (2005). Functional properties (water absorption capacity and bulk density) of the flour samples were determined by the methods described by Onwuka, (2005), while the swelling index of the flour samples was determined following the methods described by (Abbey and Ibeh 1988).

Statistical analysis

Data generated was analyzed statistically using R- Statistics, (R- programming language version 3.4.4). Statistical significance was established using analysis of variance (ANOVA) and means were separated using least significant difference (LSD) at $p \leq 0.05$.

.

RESULTS AND DISCUSSIONS

The results of chemical properties high quality cassava flour (HQCF) from stored cassava varieties are shown in Table 1. The moisture, crude fibre, ash, and hydrogen cyanide contents ranged from 8.02 to 9.09%; 1.60 to 2.38 %, 1.31% to 1.42% and 1.60 to 3.72 % respectively. There was significant differences ($p<0.05$) in all the parameters and they all fell within the acceptable standard for HQCF. Moisture content is one of the factors that determine the shelf life of HQCF and low moisture observed for all the varieties confers higher shelf life on the flour. The concentrations of hydrogen cyanide in all the samples were within the maximum value (10 mg/kg) considered as National Standard Specifications for HQCF.

Typical functional properties examined in this study include; bulk density (BD), water absorption capacity (WAC) and swelling power or swelling index (SI). The results of the functional properties of high quality cassava flour cassava (HQCF) from stored cassava varieties are shown in table 2. Water absorption capacity of HQCF from the cassava varieties stored at different days significantly differed in this study and it ranged from 1.18 mL/g (TME 419) to 1.23 mL/g (NR 87/184) for day 0, 1.31 mL/g (TMS 07/ 0539 to 1.34 mL/g (NR 87/184) for day 7 and 1.20 mL/g (TMS 07/0539) to 1.27 mL/g (TME 419) for day 14. Water absorption capacity (WAC) is the ability of flour to absorb water and swell for improved consistency in food and it's desirable in food system to improve yield and, consistency and give body to the food (Offia-Olua ,2014). Flours processed at day 7 had highest WAC (1.31 mL/g- 1.34mL/g). High water biding ability of flours limits the amount of water available such that during mixing free water can migrate towards water biding sites and thus increase the viscosity of the products (Ajani, *et. al*., 2016).

CONCLUSION

At the end of this study, we made the following conclusions on HQCF processed from cassava varieties tolerant to Postharvest physiological deterioration (PPD); that all the flour samples contained residual hydrogen cyanide within the recommended National Standard Specifications for edible flours, and the flour samples had moisture contents within safe level limit. Flours processed at day 7 with higher WAC will be desirable in food system that needs improved yield and higher consistency. Finally, HQCF from different varieties of cassava roots tolerant to Postharvest Physiological Deterioration (PPD) can be stored up to 14 days and result in acceptable product in terms of moisture, crude fibre, ash and HCN contents.

Table 1: Effect of variety and processing days on the chemical properties of High Quality Cassava Flour (HQCF)

ABSTRACT

The study was conducted to evaluate the quality and suitability of the soil at Idi – Iya area of Yewa North Local Government Area in Ayetoro for possible cocoa production. The stratified random technique at depths of 0–15 cm, 15–30 cm, and 30-45 cm was employed for soil sampling. The samples were analyzed for pH, organic carbon (OC), nitrogen (N), available phosphorus (P), etc. The analytical results revealed that the mean value of soil pH falls within the allowable limits of between 4.5- 7.00 considered for cocoa production. The soil texture was generally sandy loam in nature. The soil organic contents (total nitrogen, available P, exchangeable cations (K+, Ca, Mg) were low compared to the critical value required for cocoa production in Nigeria. Hence, there would be a need for fertilizer applications for sustainable cocoa production to augment the deficiencies.

Keywords: Cocoa, Evaluation, Random techniques, Soil and Stratified

1.0: INTRODUCTION

The roles of soil in agricultural production and sustainability are quite enormous and cannot be overemphasized; hence, they must be properly catered for at the planning stages. Soil takes care of both micro and macronutrient elements, water, oxygen, and root support required by our crops to grow and produce bountiful yields. They also serve as a buffer to protect delicate plant roots from drastic fluctuations in temperature. However, soils that are primarily sand or heavy clay represent the extremes in soil types and may be more difficult to improve and grow certain crops at the desired or sustainable production level needed to support the farm.

In view of the very important and strategic roles played by soil in sustainable food security and production, site selection and its subsequent fertility evaluation prior to planting becomes imperative. Soil fertility evaluation of a selected site for agricultural purposes is the single most important factor in the fruit production process, which can make a very significant difference in how luxuriant and abundant the fruit will grow. This is because soil fertility examination has significant effects on the potential production of a given crop. The main objective of this study was therefore to assess the fertility status of soils at a farm site at Idi-Iya, located in the Ayetoro village area of Yewa North local government area of Ogun State, Nigeria for sustainable cocoa cultivation.

2.0: METHODOLOGY

The site was demarcated into two blocks based on the types of vegetation cover, topography and current land use. Soil samples were collected based on these identifiable features on the field. Soil samples were collected on the demarcated blocks in a stratified manner. Three soil samples were collected per augering point at 0 – 15; 15 – 30 and 30 – 45cm soil depths respectively with the use of soil auger. A total of 40 augering points were collected at three levels making a total of one hundred and twenty soil samples altogether across the site, these were later partitioned and composited to form sixty composite samples, the samples were well labeled, air dried and sieved to pass through a 2mm sieve. Samples were partitioned for different activities such as particle size analysis, pH determination, macro and micro nutrients determination etc. The particle size distributions of the soil across the augering points were determined in the laboratory using the hydrometer method as described by **(Gee and Bauder, 1996)**. The organic carbon (OC) content was determined using wet digestion method **(Carmo, and Silva. 2012)** while the pH of the soil in soil to water ratio of 1:2 was by the use of electrical pH meter. The soil total N content was determined by **Franzluebbers, et al., (2018)** while the available Phosphorus (P) was by the Bray 1 method **(Juo, 1996)**. Potassium is extracted from the soil by mixing 10 milliliters of 1 normal ammonium acetate, pH 7 with a 1 gram scoop of air-dried soil and shaken for 5 minutes. The available potassium is measured by analyzing the filtered extract on an atomic absorption spectrometer set on emission mode at 776 nm (**University of Minnesota, 2022)**.The exchangeable cations of Ca and Mg were extracted by leaching the soil with 1NNH4 OAC at pH 7 and the contents were determined by the use of flame photometer. Ca and Mg contents were determined by the use of atomic spectrophotometer (AAS). The soil micro nutrients (Fe, Mn and Cu) were also determined using AAS.

3. 0: RESULTS

3. 1: The Particle Size Analysis Results

The results of the mechanical analysis revealed that at the top soil (0–15 cm) depths, the sand contents ranged between 64.40% and 86.80% with an overall mean value of 79.58% sand; the clay particles ranged from 5.20 to 16.20% with an average value of 9.95% clay. The silt, however, ranged between 5.40 and 20.40% with a mean value of 10.93% silt content (Table 1). However, the mean average percentage of sand, silt, and clay contents at 15–30 cm depths, respectively, were 70.26; 15.73; and 11.76%, whereas at 30-45 cm depths, the values recorded were 73.85; 16.55; and 9.95%. The plot had a textural classification of sandy loam (**SL**) soil. The average Clay + Silt contents of 20.88% (0 - 15 cm) are less than the critical value of 32% (Egbe et al., 1989); however, this observation may not pose a threat to sustainable cocoa production in this area if good agricultural practices (e.g. sufficient mulching with dry grass or plastic mulch and planting of shade crops such as Plantain prior the establishment of cocoa seedlings) are implemented in conjunction with adequate daily water supply. This is necessary because the area lacks forest trees, which can cast necessary shade during the dry spell of the year.

3.3: The Soil Reaction (pH) Situation of the Site

The soil pH values within the 0–15 cm depths ranged from 5.83 to 6.52 with an average mean value of 6.13; at 15–30 cm depths, the pH ranged between 5.77 and 6.90 with a mean value of 6.00. However, at the deeper depths of between 30 and 45 cm, the soil acidity ranged between 5.89 and 6.50, with an average value of 6.11. Generally, the pH values across the field were found to be slightly acidic to slightly basic. This pH range falls within the pH that can be considered suitable for sustainable cocoa cultivation. However, efforts must be put in place to avoid practices that could further lower the pH of the plot. The degree of the acidity of the soil falls within the permissible limits of between 4.5 and 7.0, considered appropriate for better cocoa growth and establishment (Table 1).

3.7: The exchangeable cations (K, Ca, Mg) contents of the sites:

(i): Calcium (Ca):
The soil Ca contents at 0–15 cm depth ranged from 1.68–3.42 cmol/kg soil, with a mean value of 2.38 cmol/kg soil. The values ranged from 0.01 to 0.05 cmol/kg soil, with a mean value of 0.06 cmol/kg soil Ca at 15 to 30 cm depth. At the depths of 30 to 45 cm, the Ca values ranged from 1.68 to 3.46 cmol/kg soil Ca, with an average of 2.35 cmol/kg soil (Table 2).

(ii): Magnesium (Mg):
At the top soil layer of 0–15 cm, magnesium contents in the soil ranged from 0.31–1.03 cmol/kg soil with the mean average magnesium contents in the soil being 0.67 cmol/kg soil, while at 15–30 cm depth, the magnesium contents ranged from 0.42–0.90 with a mean of 0.65 cmol/kg soil. The mean soil Mg contents at 30 to 45 cm depths were 0.57cmol/kg soil respectively. Generally, the mean values of 0.67; 0.65 and 0.57 cmol/kg soil respectively were far below the critical level of 0.8cmol/kg soil (Table 2).

(iii): Potassium (K):
The soil exchangeable K at 0 - 15cm soil depths varied from 0.02 – 0.09 cmol/kg soil K with a mean value of 0.04 cmol/kg soil K, The K at 15–30cm depths ranged between 0.01 – 0.05 cmol/kg soil K with a mean value of 0.04 cmol/kg soil whereas, at 30 – 45cm depths, the K values range between 0.02 – 0.09 with an average value of 0.03 cmol/kg soil (Table 2)

3.4: The Total Nitrogen (N)

The total N contents at the first 0–15 cm depths ranged from 0.03–0.09% with a mean value of 0.06% (Table 3). The N values at 15–30 cm and 30-45 cm depths varied with depth, with average values of 0.04 and 0.06%, respectively. The mean N values across the plots were very low and below the critical level of 0.09%, but with good agricultural practices such as intercropping with leguminous crops like Cajanus – Cajan, Egusi – melon and Cowpeas coupled with application of organic fertilizer for better soil fertility management, the plot can be used for cocoa establishment. Due to the shallow nature of the soil, efforts must be made to provide adequate shade, water, and committed labour that will work all year round on the farm.

3.5: The Soil Available Phosphorus (P):

The soil available P contents varied from 0.37 to 1.91 mg/kg-1 soil with a mean of 1.19 mg/kg-1 soil at the depths of 0–15 cm soil; the average P values at 15–30 and 30-45 cm depths were 0.03 and 0.04 mg/kg-1 soil, respectively (Table 3). The available P contents were generally far below the critical value of 10.00 mg kg1 soil needed for good cocoa performance; hence, there will be a need for phosphorus-based fertilizer during the second growing season of cultivation.

3.6: The Soil Organic Carbon (OC):

The soil organic carbon (OC) at 0–15 cm soil depths ranged from 0.39–1.27% with a mean value of 0.74%. Similarly, at 15 cm and 30-45 cm depths, the organic matter contents varied respectively; they ranged between 0.51 and 0.91% with an average value of 0.66% and from 0.44 to 1.03% with a mean value of 0.66, which were also found to be far below the critical value of 3.00%, an amount that is required for coca production in Nigeria (Table 3). The low OC nature of the soil could be a result of previous usage by the local farmers. Although the OC was low, it can be improved with organic-based fertilizer, a good cropping system, good agricultural practices, and well-planned and regulated soil nutrient management systems. However, the generally low level of OC content in soils is an indication that the soil N will need some amendments in terms of fertilizer (organic and inorganic) for sustainable cocoa production in the long run to support cocoa growth.

3.8: Micronutrient Contents:

The average micronutrients (Mn, Fe, and Zn) contents of the site varied between locations within the site. The mean values of Mn contents at 0–15; 15–30; and 30-45 cm depths were 9.99; 5.17; and 5.40 mg/kg, respectively (Table 4). For Fe, the mean values were 2.19, 1.84, and 2.42 mg/kg soil, while Zn recorded average values of 2.86 at 0-15 cm, 0.33 mg/kg at 15- to 30-cm depths, and 0.95 mg/kg at 30- to 45-cm depths, respectively. The micronutrients are needed in a small quantities by the proposed choice crop; hence, micronutrients may not pose any threat to the proposed crop.

Table 4: Soil micronutrients contents across the different points and depths

Locations	Micronutrients								
	0 – 15 cm			15 – 30cm			30 – 45cm		
	Mn (cmol /kg)	Fe (cmol /kg)	Zn (cmol /kg)	Mn (cmol /kg)	Fe (cmol /kg)	Zn (cmol /kg)	Mn (cmol /kg)	Fe (cmol/ kg)	Zn (cmol /kg)

4.0: Discussion

The site's textural classification was generally sandy loam soil (SL) throughout the soil profile. The mean clay and silt content of the site at 0–15 cm depths was far below the critical level required for cocoa cultivation. So, there should be sufficient water supply through irrigation during the first three years of establishment throughout the dry season periods of three to four months as the case maybe. Plantains could also be planted as shade crops although not sufficient during these periods because most of the plantain stands die off. This is because the soil may not be able to hold sufficient amounts of soil moisture (water) for a long time because of the sandy nature of the soil. Therefore, sufficient arrangements must be made during these periods of the year to supply water in adequate and sustainable quantities. The non-existence of a naturally flowing source of river water in the location suggest an alternative water supply hence, the need for a deep well (s) or borehole(s) is/are highly essential to supply water for irrigation purposes during the dry season of the year, especially during the first three years of field establishment (if it could be afforded by the farmer). The borehole can be piped and connected to a gasoline-powered pumping machine for effective water delivery during the periods for even distribution and delivery of irrigation water to the various sections and parts of the field. During the dry periods of the year, the presence of a few standing forest trees would provide natural shade for the young, growing cocoa seedlings on the farm land. The soil organic carbon (OC), although low, can be improved with good agricultural practices and a good cropping system. As a result, fertilizer application regimes (organic or inorganic) that take into account both macro and micronutrient needs of the plot within the first three years of growth of cocoa seedlings on the field would be required to enhance good establishment. The soil exchangeable cation of magnesium (Mg) was observed to be inadequate and lower than the critical level of 0.8 mg/kg soil in most of the points where soil samples were collected within the plots. The soil reaction and pH values were within the range ideal for cocoa crop performance.

4.1: RECOMMENDATIONS:

Based on the observations and results of the study, the proposed site will be suitable for the purpose for which it was intended if:

1. Provision of all-year-round water supply, especially during the dry season of the year, through the sinking of deep wells or boreholes at reasonable distances to cover the entire farm
2. Provision of trickle irrigation to optimize water usage and minimize waste. This could be improvised by using Eva water bottles with a needle perforated cap, filled with water, and placed very close to the base of cocoa seedlings. It should be noted that the distal end of

the water-filled bottle must be raised and supported with a stone or small piece of wood for ease of water delivery in trickle form to the base of cacao.

3. Adequate mulching can be provided during the dry season around the young cocoa seedlings to guard against high rates of water loss through evaporation of surface water.
4. Sufficient shade is provided to provide a needed microclimate for the survival of the proposed crops.
5. Adequate use of the right choice of recommended fertilizer that can supply a sufficient amount of the needed nutrients is provided.
6. Good access roads could be provided to link the farm to the nearby towns and villages for ease of transportation of the cocoa products to buyers within the state.
7. Planting materials, especially cocoa seeds, are sourced from (C.R.I.N.), Ibadan.
8. Other alternative crops like Oil palm trees, Cashew etc can be planted as companion crops.

4.2: CONCLUSION:

Based on the results obtained from the routine laboratory analysis of both physical and chemical properties of the soil collected from the proposed site at Idi-Iya, in Aiyetoro village, Yewa North Local Government Area of Ogun State, It is therefore concluded that the proposed site chosen for the establishment of cocoa seedlings will support the purpose for which it was meant if the above-itemized recommendations and suggestions are followed.

PROCEEDINGS
56th Annual Conference
Agricultural Society of Nigeria
24 - 28 Oct., 2022

ABSTRACT

Field experiments were conducted in National Cereals Research Institute low land research field Gwadangaji area, Birnin Kebbi (lat. 12°12.99' N; long. 4° 21.90'E; 197m above sea level) during 2020 and 2021 rainy seasons which is located in the Sudan Savanna ecological zone of Nigeria. The aim was to study the response of rice varieties to age of seedling at transplanting. The treatments consisted of factorial combination of three rice varieties (Faro44, Faro52 and Faro57) and five (5) seedlings age; 10, 20, 30, 40 and 50 days, laid out in a randomized complete block design (RCBD), with three replications. The size of each plot was 3 m x 2 m (6 m^2). Results revealed that plant height, number of tillers, leaf area index, crop growth rate (CGR), relative growth rates were higher with Faro 57 and Faro 52 in conjunction with seedling age of 30 days old. Interaction showed that all the three varieties (Faro 44, Faro52 and Faro57) attained maximum growth with seedling age of 30 days. It could be concluded that Faro 57 and Faro 52 out yielded Faro 44. Also, seedling age of 30 days resulted in the higher growth attributes of rice.

Keywords: Rice, Variety, Seedling age, Growth

INTRODUCTION

Rice belongs to the grass family Poaceae and the genus Oryza. The *Oryza genus* contains about 20 different species of which only two are currently cultivated*; Oryza sativa* and the *Oryza glaberrima* with origin from Asia and Africa, respectively. The species varied in statute, life cycle and adaptation (Maji *et al*., 2014). Substantial amount of water is required for its production (Padhi, 2004). Rice is a staple food for over 50% of the global population making it the most important food crop (More *et al*., 2007). Rice yield in Nigeria is relatively low (1.81t/ha) despite abundant area put to rice production and availability of suitable ecologies, suitable climatic conditions and the availability of improved high yielding varieties farmers still record low yields. This low yield is attributed to poor agronomic practices, particularly the nursery and transplanting procedures. Considering the water requirement for rice production and the cost of pumping water during the dry season it is pertinent to relate age of seedling at transplanting with days to maturity, as delay in transplanting affects growth and yield (Muhammed *et al*. 2017). Late transplanting delays maturity compared to early transplanting which results to longer days of irrigation, thereby increasing the cost of production. Transplanting rice too late affects root establishment and tillering ability and grain formation which reduces productivity of rice (Sarker *et al*., 2012). Varieties vary in their days to maturity so it is very important to determine appropriate age of seedling at transplanting for each variety. For effective extension package on rice production in Sudan Savana region like Kebbi State, a scientific knowledge on the most appropriate age of seedling at transplanting for various varieties of rice is necessary. The main aim of this paper is to determine the growth performance of some selected rice varieties as influence by seedling ages in the study area.

MATERIALS AND METHODS

The experiment was conducted at the research field of the National Cereals Research Institute (NCRI) Sub-station, Gwadangaji in Kebbi State (Sudan savanna agro ecological zone), during the 2020 and 2021 rainy seasons. The average annual rainfall of the area ranges from 650 mm-750 mm per annum and the relative humidity ranges from 21-40% and 51-79% during the rainy and dry seasons, respectively. The temperature varied from 18 to 31^{o}C in the dry season and 27-41^{o}C in the wet season (NIMet 2021). The treatment consisted of three rice varieties (FARO 44, FARO 52 and FARO 57) and five seedling ages (10, 20 30 40 and 50 days old), making a total of fifteen treatment combinations, laid out in a Randomized Complete Block Design (RCBD) with three replications. All the three varieties were sourced from the breeding unit of NCRI, Badeggi, Niger State.

Nursery was established at the experimental field of NCRI sub-station. Raised beds of 2 x 5 m (10 m^2) were constructed and the seeds were broadcasted on the bed and lightly covered with thin layer of soil, the beds were regularly irrigated to keep them wet but not flooded. The seedlings were transplanted starting at 10, 20, 30, 40 and 50 days after sowing according to the treatments at spacing of 20 x 20 cm. Prior to transplanting, the nursery beds were irrigated to facilitate easy lifting of seedlings. After transplanting, the plots were flooded to a depth of 2cm which was increased to 3-5 cm up to physiological maturity stage. Data were collected on number of tillers, leaf area index, crop growth rate and relative growth rate. Data generated were analyzed using analysis of variance procedure, and treatment means were separated using Duncan's Multiple Range Test (DMRT).

RESULTS AND DISCUSSION

Number of Tillers

Results on number of tillers of rice varieties as affected by seedlings age for both years is presented in Table 1. Tillering influences grain yield of rice as it is closely linked to the final panicle number produced per unit area of cultivated land (Quyen *et al.*, 2004). In 2020, at 6 WAT, more tillers were significantly produced with 30 days old seedlings, followed by 50 and 40 days old ($P \leq 0.05$)

which were statistically similar; while few number of tillers were produced from 10 days old seedlings. Similar trend was observed at both 8 and 10 WAT in 2021. At 6 WAT in 2021, more tillers were recorded by the 30 days old seedlings, followed by 50 days and 40 days, while the few number of tillers were recorded with the seedlings age of 10 days. At 10 WAT, seedlings age of 30 days significantly produced more tillers than by the seedling age of 20 days, 50 days and 40 days. Fewest tillers ware by the seedling age of 10 days.

Variety on the other hand, showed significant effect with respect to number of tillers in both 2020 and 2021rainy season. In 2020, at 6 WAT, Faro 44 recorded the highest number of tillers followed by Faro 57; while fewest tillers were by variety Faro 52. Similar trend was obtained at both 8 and 10 WAT. In 2021, at 6 WAT, Faro 44 recorded significantly more tillers than both Faro 57 and Faro 52 which were statistically similar. Similar trend was obtained at both 8 and 10 WAT. The age of seedling at transplanting significantly affect the number of productive tillers, this also is inconsistent with the report of Li *eta al*., 2011 this may be ascribed to the ability of the older seedling to recover fast and compete intensively for resources under normal growth conditions,

Leaf Area Index (LAI)

LAI of rice varieties as influenced by seedlings age at transplanting is presented in Table 2. Leaf area is an important plant trait which is directly linked with the rate of photosynthesis and crop yield. Total leaf area present at flowering greatly affects the amount of assimilates available to the panicles (De Datta, 2019). In 2020, at 6 WAT, higher LAI was obtained from the seedlings transplanted at 30 days, than the other seedling ages, while the lowest LAI was by the seedling age of 10 days. Similar trend was observed at 8 and 10 WAT for 2020 and at 6 and 10 WAT in 2021. At 8 WAT in 2021, higher LAI was recorded from seedling age of 30 days, followed by seedling age of 20 days and 40 days, which in turn were higher than the seedling age of 50 days. The lowest LAI was by seedling age of 10 days. Variety showed significant effect with respect to LAI. In 2020 trial, Faro 52 and Faro 44 recorded significantly similar and the highest LAI while Faro 57 recorded the lowest. Similar trend was obtained at 8 and 10 WAT. In 2021 trial, at 6 WAT, Faro 44 had ($P \leq 0.05$) highest LAI, while Faro 52 and Faro 57 recorded similar but lower LAI. A similar trend was obtained at 10 WAT. At 8 WAT, Faro 44 recorded higher ($P \leq 0.05$) LAI, followed by Faro 52, while the lowest LAI was obtained by Faro 57. The interaction of seedling age and variety on LAI was not significant in all the sampling periods at in both years.

Crop Growth Rate ($gm^{-2}wk^{-1}$)

Crop growth rate (CGR) of rice varieties as affected by seedling age is presented in Table 3. In 2020, at 6 WAT, greater CGR was obtained from the seedling age of 30 days, followed by the seedling age of 10, 20 and 40 days which were in turn higher than by seedling age of 50 days. A similar trend was observed in 9 WAT in both 2020 and 2021 trial. But at 6 WAT, in 2021 trial, higher CGR was obtained by the 30 days aged seedlings followed by the other treatments, which were statistically similar.

There was significant difference in CGR among the varieties in both seasons throughout the sampling periods. In 2020 trial, at 6 WAT, higher CGR was recorded by Faro 52 followed by Faro 44, while Faro 57 recorded the lowest CGR. Similar trend was obtained in 9 WAT in both 2020 and 2021 trial. At 6 WAT in 2021 similar and greater CGR was obtained from Faro 52 and Faro 44, while the lowest CGR was recorded with variety Faro 57.

The interaction between the seedling age and variety (Table 8) shows that, the highest CGR was recorded by Faro 52 when transplanted at 30 days, while the lowest CGR was recorded by Faro 44 when transplanted with the seedlings aged 10 days.

Relative Growth Rate ($gg^{-1}m^{-2}wk^{-1}$)

Relative growth rate (RGR) of rice varieties as influenced by seedling age at transplanting is presented in Table 4. In 2020, at 6 WAT, the treatments had no significant effect on RGR. At 9 WAT, higher RGR was recorded by the 30 days old seedling which was at par with those transplanted at 20 and 50 days, and were in turn higher than seedlings transplanted at 10 and 0 days. A similar trend was observed at 9 WAT, in 2020, and throughout the sampling periods in 2021 trial. There was significant difference in RGR due to variety in both 2020 and 2021 throughout the sampling periods. In both 2020 and 2021, at 6 WAT variety did not significantly affect the RGR. At 9 WAT, variety Faro 52 and Faro 57 were similar and significantly higher than Faro 44 in RGR. Similar trend was observed 2021 trial at 9 WAT. But at 6 WAT in 2021, Faro 52 recorded the highest RGR compared with Faro 44 and Faro 57 which were statistically similar. The interaction of seedling age and variety on relative growth rate was not significant throughout the sampling periods in both years.

CONCLUSION

Based on the results of this study, it could be concluded that Faro 57 and Faro 52 out yielded Faro 44. Also, the seedling age of 30 days resulted in the high growth attributes of rice which resulted in higher grain yield.

24 - 28 Oct., 2022

ABSTRACT

Field experiments were conducted at the National Cereals Research Institute low land research field Gwadangaji area Birnin Kebbi, kebbbi State (lat. 12°12.99' N; long. 4° 21.90'E; 197m above sea level) during the 2020 and 2021 rainy seasons located in Sudan Savanna ecological zone of Nigeria. The aim of the experiments was to study the response of rice varieties to Seedling age. The treatments consisted of a factorial combination of three rice varieties (Faro44, Faro52 and Faro57) and five (5) seedling age; 10, 20, 30, 40 and 50 days which were laid out in a randomized complete block design (RCBD), replicated three times. The size of each plot was 3 m x 2 m (6m^2). The study reveals that correlation between the grain yield, establishment count (r = 0.382) and panicle lenght (r = 0.394) were positive and weak; that with plant height 6 WAT (r = 0.491), number of panicles (r = 0.511) and 1000-grain weight (r = 0.407) were positive and moderate. On the other hand, correlation between grain yield and LAI 8 WAT (r = -0.576) was moderately negative while that with CGR 9 WAT (r = - 0.209) was negative and weak. In 2021 location, correlation between yield and Plant Height 6WAT (r = 0.341), NP (r = 0.367), panicle lenght (r = 0.375), and 1000-grain weight (r = 0.311) were positive and weak; while that with tiller number (r = -0.789) and LAI 8WAT (r = -0.694) were strongly negative.

Keywords: Rice, Variety, Seedling age, Growth and Yield

INTRODUCTION

Rice belongs to the grass family Poaceae and the genus Oryza. The *Oryza genus* contains about 20 different species of which only two are currently cultivated*; Oryza sativa* and the *Oryza glaberrima* with origin from Asia and Africa, respectively. The species varied in statute, life cycle and adaptation (Maji *et al*., 2014). The plant is not aquatic but substantial amount of water is required for its production, hence it is considered to be semi-aquatic annual (Padhi, 2004). Rice is a staple food for over 50% of the global population making it the most important food crop (More *et al*., 2007). In Nigeria, rice is the highest cherished fastest growing food and cash crop. Its demand is growing faster than any other food crop, and it remains one crop in which Nigeria can easily become food self-sufficient given the potentials that abound in the country in terms of ecology and favourable agro-ecological conditions (Ibrahim *et al.*, 2015). Rice can be utilized as food in many forms, it is mostly served at a social gathering and in performing some traditional rites, the forms includes rice cake, *Masa,* rice dough *Fura* in Hausa, infant food, beverages and snacks. The bye-product has so many uses, rice straw if incorporated into the soil enhances aeration, used as livestock bedding, animal feed and even in mushroom production (Gao *et al.*, 2004). Rice yield in Nigeria is relatively low (1.81t/ha) despite abundant area put to rice production and availability of suitable ecologies and climatic conditions. Despite the availability of improved high yielding varieties farmers still record low yields. This low yield is attributed to poor agronomic practices, particularly the nursery and transplanting procedures. Considering the water requirement for rice production and the cost of pumping water during the dry season, it is pertinent to relate age of seedling at transplanting with days to maturity, as delay in transplanting affects growth and yield. (Mohammed *et al*. 2017). Late transplanting delays maturity compared to early transplanting which results to longer days of irrigation thereby increasing the cost of production. Transplanting rice too late affects root establishment and tillering ability and grain formation which reduces the productivity of rice. (Sarker *et al*., 2012). Varieties vary in their days to maturity so it is very important to determine the appropriate age of seedling at transplanting for each variety. For an effective extension package on rice production in Sudan Savana region like Kebbi State, a scientific knowledge on the most appropriate age of seedling at transplanting for various varieties of rice is necessary.

MATERIAL AND METHOD

Experimental site: The experiment was conducted at fadama field of the National Cereals Research Institute (NCRI) Sub-station, Gwadangaji in Birnin Kebbi Local Government Area of kebbi State, located in the Sudan savanna agro ecological zone of Nigeria. The average annual rainfall of the area ranges from 660 mm – 750 mm per annum. The temperature varied from 22 to 31^{o}C in the rainy season (NiMet, 2019).

Experimental Design: The treatments consisted of three rice varieties (FARO 44, FARO 52 and FARO 57) and five seedling ages (10, 20 30 40 and 50 days old), making a total of fifteen treatment combinations. These were laid out in a Randomized Complete Block Design (RCBD) with three replications. All the rice varieties were collected from the National Cereals Research Institute (NCRI) Badeggi..

Data collection and analysis: Agronomic data were taken from plants in two middle rows of each plot to reduce border effect. Data collected includes; establishment count, plant height, tiller number, crop growth rate, leaf area index, net assimilation rate, and yield parameters (number of panicle per (m^2), panicle length, number of grains per panicle, days to 50% flowering, 1000-grain and grain yield), all data were collected using the standard evaluation system (SES 2013) and were subjected to Analysis of Variance (ANOVA) procedure and means were separated using Duncan's New Multiple Range Test (DNMRT) at 5% level of probability. Pearson's correlation coefficient analysis was carried out to study the relationship among growth and yield parameters.

RESULTS AND DISCUSSION

Result shows correlation coefficient between growth and yield parameters at NCRI Research field Birnin Kebbi during 2020 rainy season.

In 2020, the correlation between the grain yield and establishment count (r = 0.382) and panicle length (r = 0.394) were positive and weak; that with plant height 6 WAT (r = 0.491), number of panicles (r = 0.511) and 1000-grain weight (r = 0.407) were positive and moderate. On the other hand, correlation between grain yield and LAI 8 WAT (r = -0.576) was moderately negative while that with CGR 9 WAT (r = - 0.209) was negative and weak.

In 2021, correlation between yield and Plant Height 6 WAT (r = 0.341), NP (r = 0.367), Panicle Length (r = 0.375), ssand 1000-Grain Weight (r = 0.311) were positive and weak; while that with Tiller Number (r = -0.789) and LAI 8 WAT (r = -0.694) were strongly negative.

CONCLUSION

From this study it was concluded that growth and yield parameters recorded positive correlation among each other, which indicate strong relationship between and within growth parameters. However, the magnitude of growth parameters correlation coefficient was higher than their corresponding yield parameters correlation coefficients, suggesting the importance of age of seedling at transplanting on yield. Generally, traits such as grain yield, tiller number,1000-grain weight are important traits for grain yield in rice.

56th Annual Conference
Agricultural Society of Nigeria
24 - 28 Oct., 2022

ABSTRACT
A survey of brown leaf spot on fonio (*Digitaria iburua and D. exilis*) was carried out in the major growing areas of Nigeria in 2014 and 2015. The states surveyed were Bauchi, Kaduna, Plateau and Nasarawa. Two visits were made to each state in each of the years (2014 and 2015). In each LGA, three towns were randomly selected and three farms were sampled. With a quadrat, five plots were assessed for disease incidence and severity in all the farms visited. In 2014, there were significant ($P \leq 0.05$) differences in incidence of brown leaf spot in all areas visited. The highest incidence (48.06%) of brown leaf spot was recorded in Zawang in Plateau state which was not significantly different from all other locations except, Nahuta and Bogoro (Bauchi) which had the least incidence (22.0 and 20.30 %). In 2015, the incidence of brown leaf spot was also highest (55.13%) in Zawang (Plateau state) and Kwaturu, in Kaduna state. Angware, Demank, Mbar, Munguna, Nyeleng (Plateau state) and Bogoro, Nahuta Gyara (Bauchi state) had the least incidence. There was no significant ($P \leq 0.05$) difference in brown leaf spot severity in all the locations in both years. The disease was more prevalent in Plateau and Kaduna States.

INTRODUCTION
Fonio (*Acha*) or hungry rice (*Digitaria exilis* and *Digitaria iburua*) originated in West Africa and is a grain crop cultivated for centuries across fifteen countries in the Northwest Africa from Cape Verde Island to Chad, Ivory Coast and Cameroon (Jideani, 1999). Fonio is the most ecologically adapted and economically useful species of the monocotyledons (Anon. 1996; Cruz, 2004) due to its ability to grow under marginal rainfall and low inputs. However, it is underutilized and neglected in Africa (Anon. 1996). It has the potential to improve nutrition, boost food security, foster rural development and support sustainable use of land. It is grown in the central and northern

states of Nigeria, particularly in Bauchi, Kaduna, Kebbi, Nasarawa and Plateau states where it is locally called 'Acha' (Aliero and Morakinyo, 2001). The three largest producers are Guinea, Nigeria and Cote d' Ivoire with production of 500, 986, 82, 750 and 19, 263 tons from 466, 622, 190, 315 and 33, 983 ha, respectively (FAO, 2016).

Both *Digitaria* species have been reported to be susceptible to insect pests and diseases (Vietmeyer *et al.*, 1996; Kwon-Ndung and Misari, 1999), thus, contributing to low yield. There is a paucity of information on the diseases of fonio in Nigeria (Auta, 1983). The first incidence was reported in Samaru, Zaria, where leaf blast (*Pyricularia* sp) and leaf spot (*Helminthosporium* sp) were identified on fonio plants (Auta, 1983). Therefore, the objective of this study is to determine the occurrence and distribution of brown leaf spot on fonio in the major growing areas in Nigeria.

MATERIALS AND METHODS

A survey of brown leaf spot of fonio (*Digitaria iburua and exilis*) was carried out in the growing areas of Nigeria between the second week of July and last week of August, 2014 and 2015. The producing states surveyed were Bauchi, Kaduna, Plateau and Nasarawa states. Two visits each were made to each state in 2014 and 2015. Two Local Government Areas (LGAs) were surveyed in Bauchi (Bogoro and Tafawa Balewa), three in Kaduna (Jabba, Kachia and Kagarko), ten in Plateau (Barkin Ladi, Bassa, Bokkos, Jos East, Jos South, Kanke, Mangu, Pankshin, Quanpan and Riyom) and one in Nasarwa State (Wamba). In each LGA, three selected towns and three farms were sampled with a farm taken as a replicate. Using a quadrat of 30x 30 cm, five plots of about a hectare and three farms of less than a hectare were surveyed/. Disease assessment was based on macroscopic symptoms characteristic of fonia brown leaf infection which are usually brown pin sized lesions of less than 0.1mm in diameter around the lower leaves which later enlarges becomes dark red and form numerous spots of about 0.1-0.3 mm. In advanced cases lesions coalesced to form blight along leaf margin and towards the leaf tip leading to wilting of leaves.

Disease incidence was estimated by counting the number of infected plants in each plot and expressing this as a percentage of the total number of plants in the plot (Tarr, 1981).

$$DI=\frac{Number\ od\ individual\ diseased\ plants}{Total\ number\ of\ plants}\ X\ 100$$

For disease severity assessment, individual plants within the sampling plot were scored on a rating scale of 1 – 5, according to Tarr, 1981, where; 1=No spots on leaves, 2= 1-25 % of leaves with spots, 3= 26-50 % of leaves with spots, 4= 51-75 % of leaves with spots and 5= 76% and above leaves with spots. The disease severity was calculated using the formula below as expressed in percentage:

$$DS=\sum\frac{Nx}{N(5)}$$

where; $\sum$ = Sum total, x = disease rating grade, n = number of plants per given grade, N= total number of plants examined per plot and 5= the maximum disease grade. Data collected were subjected to analysis of variance using SAS (2013) and means compared using the Student Newman Keuls (SNK) test at 5 % level of significance.

RESULTS

Acha growing locations in the major producing states and the level of brown leaf spot infection is presented in Figure 1. Geographically, the study area stretches between latitude $9^{0}0^{1}0^{11}$ N - $11^{0}0^{1}0^{11}$ N of the equator and between Longitude $8^{0}0^{1}0^{11}$E – $10^{0}\ 0^{1}\ 0^{11}$ E of the Greenwich Meridian covering Bauchi, Kaduna, Nasarawa and Plateau States (Fig 1). Areas with 20-30 % severity were grouped as low severity, 30.1-40 % moderate severity while above 40 % high severity (Figure 1.)

The result of the various locations visited is presented in Table 1. In 2014, the highest incidence of brown leaf spot was recorded in Zawang (48.06%) which was not significantly ($P \leq 0.05$) different from all other locations except Nahuta and Bogoro (22.30 and 20.36%) which had the least incidence. In 2015, the incidence of brown leaf spot disease was also highest in Zawang (55.13%) in Plateau state and Kwaturu (54.33%) in Bauchi state, however, this significantly ($P \leq 0.05$) varied with only Angware, Bogoro, Demank, Mbar, Nahuta, Munguna, Nyeleng and Gyara which had the least incidence that was not significantly different from other locations. There were no significant ($P \leq 0.05$) differences in brown leaf spot severity in all the locations visited.

In 2014, the incidence of brown leaf spot was highest in Plateau state (33.20 %) but was not significantly ($P \leq 0.05$) different from locations in Kaduna state. The least incidence was recorded in Bauchi state (27.5) and this was at par with Nasarawa and Plateau states. However, in 2015 Kaduna state (42.7) had the highest incidence which did not vary from locations in Plateau state while Bauchi (28.1 %) had the least incidence (Figure 2). For severity of brown leaf spot, Nasarawa state (31.0%) recorded the highest severity which did not differ from other locations in Plateau state while the least severity was observed in Kaduna state (29.2%) during 2014 cropping season. In 2015, Kaduna state recorded the highest severity (28.5 %) (Figure 3).

DISCUSSION

The disease was more prevalent in all the locations in Kaduna and Plateau states than Bogoro and Nahuta in Bauchi State. The reason could be due to differences in agro ecological zones and variation in weather parameters which in some case might not have been favourable for the pathogen. Weather factors play a major role in the initiation of disease and each pathogen has its own optimum requirement for infection (Hardwick, 2002). High temperature and frequent rainfall have been reported to favour blight of Zoysia grass (*Curvularia inaequalis*) in China (Kim *et al.*, 2000). The average rainfall recorded in Kaduna state during the survey (August 2015) was 284 mm while the temperature ranged from 24.5-29 ^{0}C. Plateau state had an average rainfall 308.6 mm in August and temperature of 24.5-27 ^{0}C These could have accounted for the prevalence of the disease in Plateau and Kaduna states compared to Bauchi state with an average rainfall of -252 mm and temperature of 29 ^{0}C. Bauchi has drier days than Plateau and Kaduna states. Bawa (1992) reported the influence of weather on the spread and development of midrib disease of millet. In the report, it was discovered that Jibia in far north had lower disease incidence than Sokoto and

Katsina, and this was attributed to the effect of hot dry weather which slows the rate of disease development. The differences in disease spread observed on the fonio fields could also be attributed to differences in the time of planting; while some fields were planted at the onset of rains, others were planted later in the season, thereby making infection period to vary in different locations during the survey.

CONCLUSION

Brown leaf spot was found in all the fonio growing areas visited with higher incidences and severity recorded in Kaduna and Plateau states.

ABSTRACT

A field experiment was conducted to evaluate the response of soil microorganisms (bacteria and fungi), to some soil amendments (organic and inorganic). The experiments were laid out in randomize complete block design (RCBD). The treatments applied were compost (3.4t/ha), poultry manure (4.2t/ha), *Tithonia diversifolia* (4.8t/ha), NPK (15:15:15) (0.8t/ha) at 120kg N/ ha and the control. Treatments were replicated three times. Soil microbiome (Fungi and Bacteria were estimated using standard laboratory methods. Data collected were subjected to statistical analysis. Compost improved both the total number and diversity of fungi than other amendments while diversity of bacteria was increased more by poultry manure and *Tithonia diversifolia* than the other amendments studied. Compost had the highest percentage (25.8%) of bacteria suppressed than other amendment studied. *Tithonia diversifolia* enhanced the growth of bacteria the most (16.7%) while NPK had the highest reduction of bacteria growth (31.6%). *Tithonia diversifolia* had the highest percentage of proliferation of allochtonus bacteria (27.7%). Percentage of suppressed fungi was the highest in *Tithonia diversifolia* (28.2%). Fungi growth was more enhanced in un-amended plot (66.7%) while poultry manure had the highest percentage of fungi growth reduction (26.1%). Poultry manure and *Tithonia diversifolia* had the highest percentage of proliferation of allochtonus fungi (25.5%). application of compost, poultry manure and *Tithonia diversifolia* are recommended for the improvement of soil microbial properties.

Keywords: Tomato, Soil fungi, Soil bacteria, organic amendment Allochtonous and Soil microbial properties.

INTRODUCTION

Over the years, the idea of practicing intensive agriculture is to achieve high productivity however; this practice had adversely affected soil health and biodiversity despite the remarkable increases in overall food production (Tuğrul, 2019). Long-term usage of inorganic fertilizers causes soil, water and environmental pollution, food insecurity, development of pathogen/pest resistance, residual toxicity towards micro and macro organisms and loss of biodiversity (Ruano-Rosa and Mercado-Blanco, 2015). This therefore necessitated the need for eco and human health friendly, sustainable and alternative farming practice.

Organic farming is a sustainable and affordable system which strictly prohibits the use of synthetic fertilizers thereby reducing the negative effect of chemical fertilization (Chaney and Ramsubhag, 2017; Ye et al, 2020). It's one of the oldest ways of practicing sustainability in agriculture (Faissal et al., 2017). Application of organic amendments such as compost, plant debris, animal manure, peat moss and organic mulch increase the organic matter content of the soil. It's also a major substrate in management of soil and plant health as well as suppression of diseases resulted from soil borne pathogens. The organic matter content of soil is use to determine soil health as it governs the physical, chemical and biological properties of soil (Gómez-Sagasti et al., 2018). It has been reported that presence of soil organic matter can reduce bulk density and increase water holding capacity and soil aggregate stability (Gómez-Sagasti et al., 2018). Organic matter supply microorganisms with essential nutrients (Reeve et al. 2016) therefore increase the microbial population, catalyze their activity (Larkin, 2015), allows high biodiversity (Turmel et al., 2015). As stated by Chandrashekara and Bhatt (2014) and Scotti et al. (2015) organic matter aids natural disease suppression and soil fertility thereby improving soil health.

Compost as a type of organic amendment has been known to improve the growth and yield of plant by improving the physio-chemical properties of soil hence enhance nutrient availability (Chaney and Ramsubhag, 2017).

Soil can be enriched through the incorporation of green manures (Larkin, 2013) which is an important alternative source of organic fertilizers (Hafifah et al., 2016). Green manure has lot of benefit in the soil, which ranges from soil organic carbon enhancement, soil health improvement, high agronomic productivity (Hafifah et al. 2016), soil microbial biomass and activity enhancement (Larkin, 2013).

Tithonia (*Tithonia diversifolia*) from Asteraceae family used as green manure due to its high nutritional composition, has proved effective in improving soil fertility (Hafifah et al., 2016), physical properties of soil (Hafifah et al., 2016; Dayo-Olagbende et al., 2020) and crop yield (Babajide et al., 2012).

The role of microorganisms is vital in the ecosystem; however, the method of intensive agricultural does not support their healthy population which could result in low productivity (Christopher Johns, 2017). Soil microorganisms are involved in many biogeochemical processes of the soil. Soil microbes are important to life as they play a pivotal role in nutrient cycling and responsible for the biological fertility of the soil (Christopher Johns, 2017). They are great determinant for soil performance through decomposition of plant materials and residues to increase the organic matter content of soil, thereby improving the soil quality (Faissal et al., 2017).

There has been well documented information on how organic amendments improve soil fertility and productivity. More also, research results shows that the use of synthetic chemicals (fertilizers, pesticides, herbicides) results in toxic residues in food; enhance environmental pollution and eliminate non-target organisms from the ecosystem. There is need to study the response of soil microorganisms to some soil organic amendments since soil microorganisms are important energy transformers and nutrient regulator in agro-ecosystems.

This research therefore aimed at assessing the response of the soil microbial community (bacteria and fungi) to some soil organic and inorganic soil amendments in an alfisol cropped with tomato.

MATERIALS AND METHODS

Experimental Site:

The experiment was conducted at the staff quarters of Landmark University, Omu-Aran, Kwara State, Nigeria with coordinates Latitude 08^o 12107' N and Longitude 05^o 08915' E. The area's annual rainfall ranges from 600 - 1,500mm. The chemical characteristics of the soil is as indicated in table 1.

Table 1: Initial properties of study sites prior to planting

SOIL PARAMETERS	SITE A	SITE B
pH in H_20	5.3b	7.3a

Silt (%)	7.0	4.0
Clay (%)	11.88	5.4
Textural class	Sandy loam	Sandy

Experimental layout and design

The study adopted randomized complete block design (RCBD) with three replications. The five soil amendments include compost, poultry manure, *Tithonia diversifolia,* inorganic fertilizer (NPK: 15:15:15) and control. The experimental site consists of 15 plots with each measuring 1 × 1m and 0.5 m alley separating each of the plots.

Sources of organic amendments

The compost used was purchased from Institute of Agricultural Research and Training (IART) in Ibadan, poultry manure was collected from the poultry section of Landmark University Teaching and Research Farm, *Tithonia diversifolia* was collected from Landmark University Teaching and Research Farm and inorganic fertilizer (NPK: 15:15:15) was purchased from agro-allied store Omu-Aran, Kwara state.

Land preparation, manure incorporation, seed sowing and fertilizer application

Beds were prepared using hoe. Experimental sites were laid out in 1 × 1 m plot sizes. Organic amendments were incorporated at rate of 120kg N/ha using a hoe to a depth of 20 cm approximately. The weight of each amendment applied were compost (3.4t/ha), poultry manure (4.2t/ha), *Tithonia diversifolia* (4.8t/ha) and NPK (0.8t/ha). Before land preparation the tomato seeds were raised in the nursery at a temperature of about 23 ^{0}C and watered daily. The plots were permitted for mineralization of amendments before seedlings were transplanted. Transplanting was carried out at cool hours of the day and each seedling was transplanted with some soil beneath to reduce damage on the seedling roots (Adekiya, 2019). Each seedling were transplanted at a spacing of 50 × 50 cm. NPK fertilizer was applied 10cm away from the seedlings a week after transplanting employing the side placement method. Manual weeding was done at interval of 3 weeks after transplanting and the tomato plants were staked at fifth week after transplanting.

Tomato Seed Variety: The variety used for the experiment was Roman

Soil sampling and laboratory analysis

Soil sample was obtained from the study site at o-15cm depth before and after the experiment. Soil pH was determined with an electronic soil pH meter (Model 215, Colorado, U.S.A.); soil particle size was analysed using the hydrometer method (Gee and Or 2002); organic matter content was determined using the wet oxidation method (Shamshuddin et al. 1994); exchangeable bases (K, Mg, Na, and Ca), were determined by ammonium acetate method (Chapman 1965).

Organic amendment analysis

Samples of organic amendments (compost manure, poultry manure and green manure) were taken for laboratory analysis. Chemical properties of amendments used are as stated in table 2

Table 2: Chemical component of the organic amendments used for the study

PARAMETERS	COMPOST	POULTRY MANURE	*TITHONIA DIVERSIFOLIA*
Organic carbon (%)	52.0a	26.4b	17.4c
Nitrogen (%)	3.5a	2.9b	2.5c
Calcium (cmol/kg)	2.7a	1.5c	1.7b
Magnesium (cmol/kg)	4.9c	5.7b	11.3a
Sodium (cmol/kg)	0.01a	0.01a	0.01a

Potassium (cmol/kg)	0.4a	0.3b	0.3b

Microbial analysis

Samples collected after the experiment into polythene bag at random using soil auger and transported to the laboratory for microbial count. The standard plate count agar method was employed. Isolation of bacteria and fungi were done using Potato Dextrose Agar (PDA) and Nutrient Agar (NA) respectively. Fungi and bacteria population were estimated using the 6-fold serial dilution method. The pour plate technique was used to culture fungi and bacteria from 10^{-3} and 10^{-5}soil dilutions respectively. Incubation of PDA and NA were done at 37^{0}c for 3-5 days and 24 hours at 28^{0}c respectively. Thereafter; colony-forming units were counted. The frequencies of occurrence of isolates were then calculated.

RESULTS AND DISCUSSION

Response of soil microbial diversity and total number (bacteria and fungi) to organic and inorganic amendments

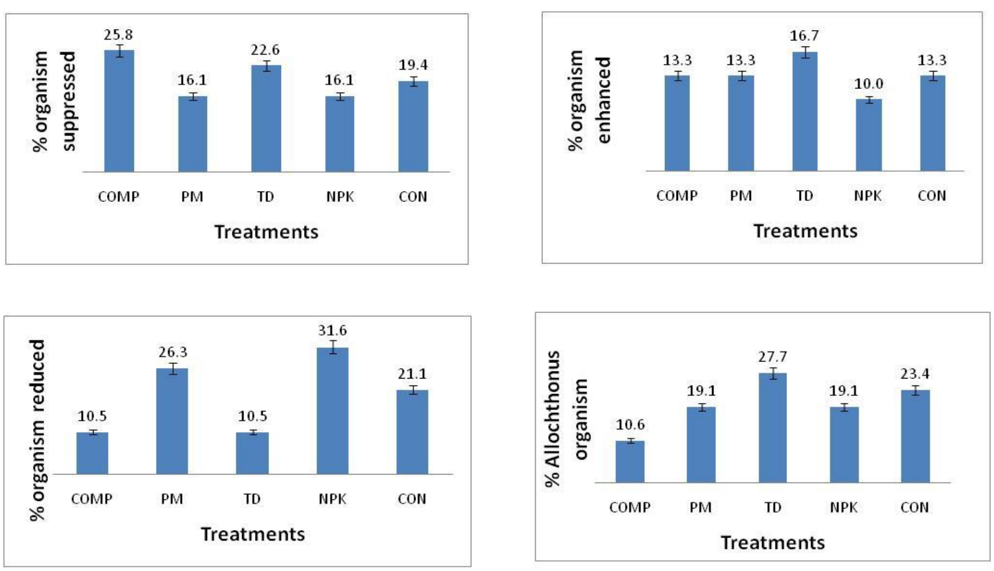
Table 3 shows that all the treatments had greater diversity of bacteria and fungi (ranges from 18-20 and 17-21) than initial (14 and 16) except compost and control that were 11 and 16 respectively. All treatments also had greater total number of bacteria (ranging from 368-1406) than initial (316) except *Tithonia diversifolia* (228) and fungi ranges from 101 – 215 while the total number of the initial was 76. *Tithonia diversifolia* had the highest diversity of bacteria (20), followed by control (19), followed by poultry manure (18) and followed by compost which had the lowest diversity (11) while NPK had the highest diversity of fungi (21), followed by compost (19), followed by poultry manure (18), followed by *Tithonia diversifolia* (17) and control had the least (16). The total number of fungi is in the order of compost (215) > NPK (165) > poultry manure (146) >*Tithonia diversifolia* (125) > control (101) and the total number of bacteria is in the order of poultry

Table 3: Response of soil microbial diversity and total number (bacteria and fungi) to organic and inorganic amendments in the two study sites

TREATMENTS	DIVERSITY OF BACTERIA	TOTAL NUMBER OF BACTERIA	DIVERSITY OF FUNGI	TOTAL NUMBER OF FUNGI
Compost	11	368	19	215
Poultry manure	18	1406	18	146
Tithonia diversifolia	20	228	17	125
NPK	18	868	21	165
Control	19	991	16	101
Initial	14	319	16	76

Response of soil bacteria to the organic and inorganic amendments

Compost (25.8%) had the highest suppression of bacteria site B followed by *Tithonia diversifolia* (22.6%), followed by control (19.4%) and followed by poultry manure and NPK (16.1%). Compost, poultry manure and control enhanced the percentage of bacteria by 13.3% while *Tithonia diversifolia* and control enhanced the percentage of bacteria by 16.7% and 10%. Compost and *Tithonia diversifolia* reduced the percentage of bacteria present initially in the soil by 10.5%, control by 21.1%, poultry manure by 26.3% and NPK by 31.6%. *Tithonia diversifolia* (27.7%) had the highest percentage of bacteria Allochthonus to the soil followed by control (23.4%), followed by poultry manure and NPK (19.1%) and compost (10.6%).

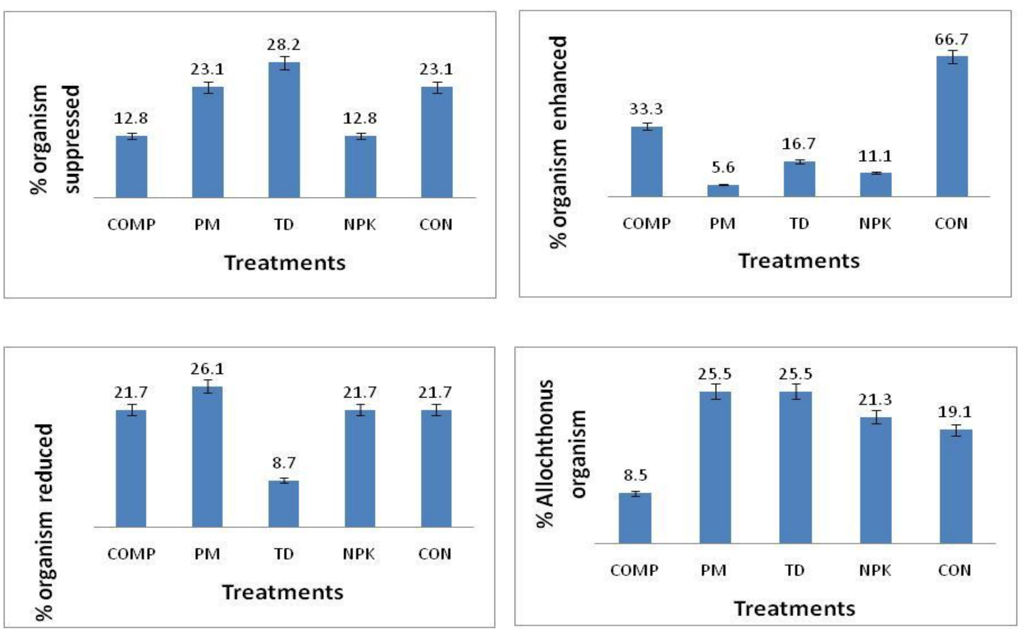


COMP- compost, PM- poultry manure, TD- *Tithonia divesifolia*, CON- control

Fig 3: Response of soil bacteria to the organic and inorganic amendments

Response of soil fungi to the organic and inorganic amendments

The increasing order of fungi suppressed in site B is compost and NPK (12.8%), poultry manure and control (23.1%), and *Tithonia diversifolia* (28.2%). The decreasing order of fungi enhanced is poultry manure (5.6%), NPK (11.7%), *Tithonia diversifolia* (16.7%), compost (33.3%) and control (66.7%). The percentage of fungi reduced by poultry manure was 26.1% while, compost, NPK and control were 21.7% and *Tithonia diversifolia* had the lowest reduction 8.7%. The increasing orders of Allochthonus fungi are compost (8.5%), control (19.1%), NPK (21.3%), poultry manure (25.5%) and *Tithonia diversifolia* (25.5%).



COMP- compost, PM- poultry manure, TD- *Tithonia divesifolia*, CON- control

Fig 4: Response of soil bacteria to the organic and inorganic amendments

DISCUSSION

All treatments increased both diversity of organisms and total numbers of organisms compare to initial, as well as control. Organic amendments enhance organic matter of soil thereby providing nutrients and energy to soil which make the soil a favorable environment for crops growth and microorganism proliferation (Ansari et al., 2019). Poultry litters are important for functional and structural diversity of microbial populations (Mierzwa-Hersztek et al., 2018). Application of poultry manure increased the microbial biomass and significantly influences the activity of nitrifying bacterial in the soil (Mierzwa-Hersztek et al., 2018). Control despite not amended the number of bacteria and its diversity increased which shows that the crop planted had beneficial effect on the bacterial community through root exudates. Nazir et al., (2016) further stressed that root exudates is an important factor which serves as food source for soil microbes and play pivotal role in the interaction of plant and soil microbe.

The amendments affected the diversity and number of fungi presents in study site. The biotic and abiotic characteristic of compost in soil is an indicator for high soil quality (Luo et al., 2021). According to Luo et al., (2021) study, most bacteria and fungi were detected after the incorporation of compost. High fungi diversity in poultry manure and *Tithonia diversifolia* treated plot is as a result of organic matter richness. In addition, changes in fungi was noticed when soil was amended with poultry manure (Abdullahi et al., 2013). Fungi diversity in NPK treated plots is higher and this shows that fungi are sensitive to mineral fertilizer because it has highest diversity in study site. This result correlates with Zhong et al., (2009) who found higher amounts of fungal PLFA in NPK treated soil. Soil microbes are involved in many biogeochemical processes of the soil (Christopher Johns, 2017). Soil microbial biomass and different community structures in soil will increase with organic fertilization (Francioli et al., 2016). Higher nutritional component of compost has been reported by various researches which can be supporting the growth of the encountered organisms (Antoniou et al., 2017). Some treatments suppressed the growth of some organisms which could be associated to antagonistic effect of the treatment or the treatments and tomato plant do not support the growth and proliferation of these organisms. Antoniou et al. (2017) indicated that microorganisms that grow from compost are either characterized with disease suppressing organisms or beneficial organisms. Growth of some pathogenic fungi can be reduced in the soil during mineralization of fresh poultry manure in the soil which results in high heat production through ammonia (Shaji et al., 2021). Some organisms were enhanced in the treated and control plots which were not present in the initial sample. This could be due to microbial and plant exudates or they were either slow growing organisms whose growths were only enhanced by treatment and root exudates or they were foreign organisms introduced by the treatments. According to Bahramisharif and Rose, (2019), organic amendments release organic matter into the soil thereby increasing the microbial biomass, microbial activity and production of polysaccharides in the soil. Plant root exudates are crucial for plant growth by releasing nutrients, changing of soil pH and enhancement of some microbial diversity and activities (Antoniou et al., 2017). Some organism occurred only in the initial samples. This could be as a result of nutrient consumption by the plant in control and/or as a result of microbial and plant exudates. This could also imply that all the treatments and tomato plant do not support the growth and proliferation of these organisms. Some organisms occurred only in a treatment. The occurrence of different organism in these treatments could be as a result of chemical composition difference of the treatments. For instance, it was stated in Zhong et al., (2009) that fungi are sensitive to mineral fertilizers. Some organism occurred only in control and this shows that root exudates supports the growth of microorganisms in the soil. According to Antoniou et al., (2017) plant root exudates are important for plant growth and improving soil quality by releasing nutrients, changing of soil pH and enhancement of some microbial diversity and activities. Moreover, correlating this observation to disease incidence and severity, this shows why compost as well as poultry manure has the lowest disease incidence and severity.

Compost significantly increased the organic carbon of soil and this could high organic matter value of compost as recorded in table 2. Soil organic carbon promotes soil biological properties like nutrient cycling and microbial enhancement as well as soil structure, aeration, water drainage and retention there by reducing soil risk to erosion and nutrient leaching (Corning et al., 2016). This also explains why compost had the highest significant value of total fungi in study site.

Conclusion

Compost improves both the total number and diversity of fungi than other amendments while diversity of bacteria was improved more by poultry manure and *Tithonia diversifolia* and other amendments studied. To improve microbial properties of soil, compost, poultry manure and *Tithonia diversifolia* are recommended.

ABSTRACT
Breeding of cassava had focused on the use of agro chemical and commercialization. But the needs of resource-poor farms, marginal areas and organic products cannot be over looked. Currently a breeding Programme was carried out focusing on development and selection of cassava varieties that will yield their potential with little application of external input and those varieties that can give appreciable yield without the application of any external input (agro-chemicals), and improve our degraded soils. An experiment was carried out in NRCRI.UMUDIKE using the combination of organic manure and inorganic fertilizer tested on nine newly developed cassava genotypes and one control to select at less one or two genotypes capable of meeting the above aims. Three treatments consisted of 200kg/h of NPK fertilizer, combination of 5tons of poultry manure and half rate 200kg/h NPK fertilize and 0kg/h application as control were used. This result revealed that genotype V5T1(37t) gave the highest yield and can be recommended for resource poor farmers, followed by V4T2(36t/h)followed can be recommended for poor soils and resource farmers, whileV3T3 and V7T3 are selected for farmers who can afford external input.

INTRODUCTION
Cassava (manihot esculenta crantz) is an important food and industrial crop worldwide, it has a less production cost per unit output than other major staples such as yam, cocoyam etc and capable of growing and giving reasonable yields in low fertile and poor soils (Adeji et al 2005 and stones,2002). Still to get higher yield and greater economic benefits, the crop requires good management and addition of some external inputs. Ekeoro et al (2009) , however observed increase in cassava yield with the use of improved varieties and the addition of external inputs such as agro-chemicals including organic fertilizer comprising macro and micro nutrients, herbicides and pesticides. According to FAO,(2013), Nigeria is the largest producer of cassava in the world with production yield of 52.4 metric tons annually, but with a wide gap between farmers yield of (12h/ha) and actual yield of (50t/ha).The increasing demand for cassava as a staple food for millions of people is increasing at (2%) for food and 1.6% for industrial and animal feed (1.6%) (Dixon, 2003and Nweke, 2004;), and the use of cassavas for ethanol production, (Olumide, 2004), cannot be met with this low yield rate of farmers since more than 90% of cassava producers in Nigeria and Africa belong to the low income class who cannot afford the high cost of these external inputs -agro-chemicals (Mailumo et al, 2012). More so increasing marginal soils caused by degradation, deforestation and reduced fallow system period which have reduced the inherit soil fertility needed for production without the addition of external input has affected

cassava yield and productivity adversely .In Nigeria, different rates of inorganic fertilizer are used by farmers not really adopting fully the recommended rate due to financial constraint and non avaliabity of those inputs. While the facts remains that the recommended rate of NPk fertilizer is 400 kg per hectare for increase yield and 10 tons of organic manure to ameliorate the degradation of soil for enhanced crop yield. This study therefore aims at developing cassava genotypes which will use the soil inherent nutrients or the addition l of minimal input to give optimal yield.

MATERIALS AND METHODS:

The experiment was conducted at NRCRI umudike in the 2019 cropping season. The site is located at 7^o32^e, 50^o29^n and 122m above sea level. The soil is characterized by sandy loamy and medium fertility. Nine newly developed cassava genotypes and three levels of treatments: (half rate of NPK fertilizer 200kg, combination of half level of NPK 200kg/ha and half level of organic manure –poultry manure 5ha and zero level additional input) as against the recommended rates (400kg NPK and 10tons of poultry) respectively. A control which is additional of no external input was used for comparism. The experiment was laid out in 4mX5m factorial randomized complete block design, replicated 3 times. The cassava genotypes were planted at a spacing of 1m X 1m in a plot size of 20m. The treatment was applied 8 weeks after planting. The field was kept weed free by manual weeding and under brushing. Primary data were collected on growth and yield parameters such as harvest index, biomass, number of large roots and total fresh root weight at 12 months after planting. The data collected were analyzed using spss statistical tool version and significant difference was determined and separated by using Duncan multiple range

RESULT AND DISCUSSION:

result of analysis of variance on the fresh root yield, plant height and harvest index of the cassava genotypes evaluated showed high significant differences. Table1 showed that Variety performed differently with treatments. Varieties 6 and 7yielded higher without the addition of external input,variety4 with the combination of organic and inorganic, while variety 3 ranked same with half level of NPK . Table 2 showed that control maintained best harvest index due the variety capacity where varieties 3(0.7cm) and (0.6cm)5 respectively. Other treatments did not influence harvest index much. Table3 shows that the combination of organic manure and inorganic fertilizer gave higher plant height (v1-150,a6-140andv3 137).This was followed by half level 2ookg of NPK fertilizer. Lack of additional input affected plant height negatively as seen in v1. With regards to the objectives of the study varieties 5 treatment 1 (V_5T_1) and variety 6 treatment 1(V_6T_1) shows high potential for high yield without the addition of external input, so should be selected for organic farming and poor resource farmers. Varieties 3 treatment 3, (V3T3) and variety 7 treatment$_{3\ (V7T3)}$ performed will with the combination of organic and inorganic fertilizer,

CONCLUSION:

Breeding cassava varieties which require low or no additional input to give reasonable yield is very important to meet the need of low income farmers who incidentally are the major producers of cassava and the result obtained from this work revealed that genotype 5,6 and 7 are promising genotypes which can alleviate farmers of the burden of additional input in cassava production,

ABSTRACT
A 35-day feeding trial was conducted to determine the serological estimates of grower pigs fed sun-dried pineapple wine sediment (PWS).A total of sixty-four (64) grower pigs of 3-4 months old with similar live weights averaging between 21±0.7kg were randomly assigned to four dietary treatments replicated four times in a Completely Randomized Design (CRD) experiment with 4 grower pigs per replicate. Four experimental diets were formulated such that PWSM replaced maize at 0%, 10%. 20% and 30% dietary levels coded as T_1, T_2, T_3 and T_4 respectively. Results shows that glucose, total protein, albumin and globulin values increased as dietary PWSM increased in the diets, an indication of optimum metabolism of energy and the synthesis of blood forming metabolites. It is recommended that PWS be included up to 30% replacement level for optimum biochemical stability and production efficiency.

INTRODUCTION
Animal agriculture sought to fulfill two mandates of United Nations Sustainable Development Goals notably poverty reduction(SDG 1) and optimum food supply (SDG 2). In the wake of dwindling oil prices in the world market, climate change challenges, population explosion and post COVID-19 pandemic, diversification of the economy of sub Saharan African (SSA) countries notably Nigeria through crop and animal agriculture is a step in the right direction (Nkwocha *et al.*, 2021). According to world population prospects (2019) meat consumption will continue to increase in developing countries to march with alarming projected rate of 9.7 billion in the next 30-50 years. The rising pig production globally is therefore to accommodate rising demand in animal protein intake (Nkwocha *et al.*, 2014).

Pig production is a viable and profitable enterprise despite its association with social and religious taboos (FAO, 2011).On good health perspective, pork which is the meat obtained from pig is the most concentrated and easily assimilated nitrogenous food and a good source of first class protein very stimulating to metabolism (Nkwocha and Anukam, 2012). The world trend today is towards the consumption of more white than red meat because white meat yields less cholesterol than red meat (Holness, 2005).

On the corridor of upward spiral trend in pork consumption, intensification of pig production therefore will require adequate supply of feed throughout the year. Conventional feedstuffs are very expensive and since swine competes with humans for food, looking into some unconventional feed raw materials like pineapple (Ananas comosus) wine sediment, a by-product of pineapple wine production will reduce the cost of feeding in the livestock industry and boosts economic prosperity.

Pineapple wine sediment meal (PWSM) is a viscous residue deposited at the bottom of stock-fermenting vessels over a period of time after filtering out the pure wine. The lees or sediment are made up of precipitated solids and dead yeast cells that accumulate at the bottom of the fermentation vessel in wine making (Jacobs, 2001).

The residue is extracted from mixture of raw materials such as pineapple pulp, Brewer’s yeast slurry, peptic enzymes, residual sugar, bentonite, glycerin, vitamins and mineral components, stabilizers, caramel, acetic acid, tannin and alcohol.
Serum biochemical assay on PWS will provides information about the organs and tissues in the body, as well as the animal's metabolic state subjected to this potential ingredient vis-à-vis, guaranteeing its wholesome acceptability as a feed raw material.

MATERIALS AND METHODS

Location of study:
The study was carried out at the Teaching and Research Farm of the Imo State University, Owerri which lies within the humid tropical rainforest zone of South Eastern Nigeria. The climatic data of Owerri obtained from NIMET (2015) Official Website (nimet.gov.ng/content/nimet-weather) showed that Owerri lies within latitudes 5°45'N and 7°15'N, and longitude 6°50'E and 7°25'E with an annual rainfall range of 2400-2500mm and annual temperature range of 26°C- 29°C while relative humidity is between 70-78% annually.

Experimental Animals and Design
Sixty-four (64) grower pigs of 3-4 months old with similar live weights averaging between 21±0.7kg were used for the study. The pigs were housed in pens measuring 48m^2 divided into 16 compartments with each floor measuring 4.0 x3.0 m. The 64 grower pigs used for the study were randomly divided into 4 treatment groups of sixteen pigs and fed the experimental diets as specified in Table 2. Each treatment was replicated four times in a Completely Randomized Design (CRD) experiment with 4 grower pigs per replicate.

Grower pigs were acclimatized/adapted in the study area by feeding them the control diets and supplying them water *ad libitum* for one week physiological adjustment period. Routine management practices notably deworming and the administration of antibiotics (Oxytetracycline Long Acting injection) were observed accordingly. After adaptation, pigs were weighed using small ruminant weighing scale (0-50kg) at the commencement of the experiment and weekly thereafter for a period of 35 days.

Feed preparation and feeding

The wet pineapple wine sediment (PWS) used for this experiment was obtained from a popular winery at Imo State. The product, on collection, was stored in air-tight containers to avoid oxidation and reduction reaction which if allowed, would reduce the nutritional quality of this ingredient. After collection and storage, the sediment was air-dried for seven days and then pulverized before incorporation into the experimental diets.

Four experimental diets were formulated such that pineapple wine sediment meal (PWSM) replaced maize at 0%, 10%. 20% and 30% dietary levels coded as T_1, T_2, T_3 and T_4 respectively. Other ingredients apart from PWSM in the diets were included at equal ratios. Table 1 shows the ingredient composition of the experimental diets. The experimental diets were subjected to proximate analysis using AOAC, (2000) method and resulting proximate composition is shown in Tables 2 respectively.

Table 1: Proximate composition of sun-dried Pineapple Wine Sediment Meal.

Parameters	Concentration (%)
Crude Protein	22.88
Ether extract	4.43
Nitrogen free extract	53.76
Crude fibre	7.28
Ash	11.65
Moisture content	14.19
Metabolizable Energy(kcal/kg)	2778.24 kcal/kg.

ME = Metabolizable energy calculated; ME (kcal/kg) = 37 x %CP+81 x %EE + 35.5 x %NFE (Pauzenga, 1985)

Blood sample collection

At the end of the five weeks feeding trial, two pigs were randomly selected from each replicate, and 5ml blood sample was collected through the vein at the ham section for serum biochemical analysis. The blood collected was used for the analysis of serum parameters (albumin, total protein, glucose, cholesterol, urea, etc).

Data analysis

All data obtained were statistically analyzed using the General Linear Model (GLM) procedure of SAS, (2001) for the analysis of variance, while differences in treatment means were separated using Duncan's Multiple Range Test from the same software package.

Table 2: Percentage composition of the grower pigs ration containing graded levels of PWSM.

Ingredients	Dietary treatments			
	T_1	T_2	T_3	T_4

* Composition per 2.5kg: Vitamin A 10000000IU, Vit.D 2000000IU, Vit E 20000IU, Vit K 2250mg, Thiamine 1750mg, Riboflavin 5000mg, Pyridoxine 2750 mg, Niacin 27500mg, Vit B12 15mg, Pantothenic acid 7500mg, Folic acid 7500mg, Biotin 50mg, Choline chloride 400gm, Antioxidant 125g, Manganese 80g, Zinc 50g, Iron 20g, Copper 5g, Iodine 1.2g Selenium 200mg, Cobalt 200mg.

RESULTS AND DISCUSSION

The proximate composition of PWS is shown in Table 1.The ingredient composition of experimental diets is on Table 2, while the serum biochemical estimates are summarized on Table 3 respectively.

The glucose values of pigs fed T_2 (10%), T_3 (20%) and T_4 (30%) are significantly the same (P<0.05) which shows positive energy level contribution of the treatment. Glucose values increased as dietary PWSM increased in the

Table 3: Serum biochemistry of grower pigs on graded level of dietary PWSM

^{abc} Means along the row having different superscript differ significantly at P<0.05 level of (LSD).

diets, an indication of optimum metabolism of energy in the body.

The urea level of grower pigs fed on T_3 (20%) and T_4 (30%) are significantly the same (P<0.05) while grower pigs fed on T_1 (0%) and T_2 (10%) differed significantly (P<0.05). Creatinine values decreased with increase in the level of PWSM in the diets of grower pigs. Creatinine is a waste product of endogenous protein found in muscle and blood and is excreted in the normal urine. T_4 (30%) was the least (1.70mg/dl), however, the normal value of creatinine in grower pigs is (0.8-2.3mg/dl). T_1 recorded the highest 2.70 mg/dl which differs significantly (P<0.05) from T_3 (20%) and T_4 (30%) respectively. Comparing the normal level from T_1, it appears that T_1 (the control) is slightly higher than the normal range which is an indication of slight muscle wastage. (Udoyong *et al*., 2010).

The cholesterol values of pigs fed on T_4 (PWSM 30%) differed significantly (P<0.05%) from T_1, T_2 and T_3. T_4 recorded the least value of 112.50mg/dl followed by T_3 while T_1 recorded the highest value of 128.00mg/dl buttressing the fact that the dietary increase in PWSM based diets inversely reduces the level of cholesterol in the body of grower pigs which is an indent of good pork quality (Amarson, 2019). The serum protein, albumin and globulin concentrations increased proportionally as dietary PWSM increased in the treatment diets (P<0.05). Serum albumins and serum globulins are soluble proteins abundant in animals (Merck Manuals, 2016). Their optimal levels in the blood determine the level of immunoglobulins responsible for immune responses in the body (Coffey and Cromwell, 2001; Merck Manuals, 2016). The significant increase (P<0.05) in the concentration of the serum parameters indicates that PWSM contains significant amounts of functional protein, including immunoglobulin gamma (IgG), transferrins, haptoglobulin and several hormones and growth factors which positively influences the synthesis of blood forming metabolites.

CONCLUSION AND RECOMMENDATIONS

From all indications, PWS based diets promoted highest values in glucose, total protein, albumin and globulin parameters. In view of the above results, PWS should be included in the ration of growers as partial replacement for maize at 30% level for optimum production efficiency.

24 - 28 Oct., 2022

ABSTRACT
Lactating women are among the most nutritionally vulnerable groups of a population due to their higher nutritional physiological requirements, which are often not met. This could induce detrimental effects of metabolic disturbances and irreversible physiological alternations on their health. This paper points out the required nutritional intakes to enhance adequate lactation which improves gestation health, prevents maternal death, child mobidity and enhance growth from birth.

Key Words: Lactation; Nutrition; Physiological Requirements and Health.

INTRODUCTION
Nutrition is a vital indicator of the complete health of a population and pillar of development (Picciano, 2018). A balanced amount of nutrients is necessary for the proper functioning of the body system. However, the nutritional requirements of everyone differ according to age, gender, physical activity levels and physiological states such as pregnancy, infancy, lactation, etc. Lactation is the process of synthesizing and secreting milk from the breasts to feed young ones. It is an integral part in the physiologic completion of the reproductive cycle of mammals. (Demissie, 2003).

Lactating women and children are among the most nutritionally vulnerable groups of a population due to their higher nutritional physiological requirements, which are often not met, could induce detrimental effects of metabolic disturbances and irreversible physiological alternations on their health (Marcos, 2017). Consequentially, low quality and quantity of milk is secreted and this has a long-term impact on the child's health (Allen, 2012). The diet consumed by the mother will not only fulfil her own nutritional needs but will also enable her to produce enough milk for her infant (Valinda 2018). Breast milk is an ideal food for infants which provides multiple nutrients, including energy, for up to a year and a major source of calories and protein in a diet for two years or more (Sanusi, 2019). Also, it offers protection against diseases. It is regarded as the most precious gift a mother can give to her infant.

Human Milk
Human milk provided by healthy, well-nourished mothers represents the best food available for infants born at term to healthy mothers (Olivia et al., 2013).Exclusive breastfeeding is recommended for the first 6 months of life, with continued breastfeeding along with appropriate complementary food up to 2 years or beyond (Olivia et a..,; 2013).

Unlike infant formula, which has a standardized composition, human-milk composition changes dynamically within a feeding, with time of day, over lactation, and between mothers and populations (Olivia et al., 2013). It is influenced by genetic and environmental factors, by infant sex and infective status, as well as by maternal lifestyle, including dietary habits. For example, colostrum, the milk produced in the first few days after birth, is reported to be higher in protein, vitamin A, vitamin $B_{12,}$ and vitamin K. Over the following 4 weeks milk composition changes gradually and is only considered “mature” from the sixth week after birth. However, subtle changes in milk composition do occur over the course of lactation (Olivia et a; 2013).

Maternal nutrition

Nutrition plays a major role in maternal and child health and it is widely recognized that optimum nutrition in early life is the foundation of long-term health (Irene and Arianna 2015). A healthy maternal dietary pattern, along with adequate maternal body composition, metabolism, and placenta nutrient supply, reduces the risks of maternal and foetal death and long-term effects in children (Irene and Arianna 2015). Maternal malnutrition in current years has turned out to be an integral theme of public challenge (Prince, 2020) as it is associated with upward push in maternal-child morbidity and mortality and known to accentuate the risk of poor pregnancy outcomes such as obstructed labour, premature birth or low-birth-weight (LBW) babies and postpartum hemorrhage (Gebre 2008). In many low-income countries, women spend a large portion of their reproductive years under nutritional stress because of chronically low dietary energy intakes, high energy expenditure related to work, and high energy and nutrient demands of pregnancy and lactation .(Aiperi et al, 2022)

In Africa and Asia, where chronic energy deficiency is more prevalent, most women are pregnant or lactating between age 35-48 of their reproductive years (Michelle , 2016). Typically, women are pregnant or lactating for 23% (Costa Rica) to 61% (Pakistan) of the time between the ages of 15 and 45 years respectively. New evidence indicates the importance of maternal nutrition for the first 2 years of child life for prevention of stunting and subsequent obesity and non-communicable diseases in adulthood. Similarly, poor maternal nutrition prior to and during pregnancy is strongly linked with increased risk of maternal anaemia, mortality, and adverse birth outcomes such as Low Birth Weight (LBW) and Preterm Birth (Shweta et al., 2019).

Determinants of Maternal Nutrition

Malnutrition manifests itself as a function of many and complex factor. It is directly linked to the inadequacy of diet and diseases under severe living factors which include crisis in *families, food insecurity, inappropriate child care* and feeding practice, unhealthy place of residence (Masresha *et al.,* 2019), etc. The following are the prevalent factors causing malnutrition associated with pregnancy, lactating mothers, and children in many African countries:

Marital Condition

Studies have shown that bad marital condition from a wife perspective was found to be a vital predictor of mothers’ nutritional status. Therefore, bad marital condition affects the support and care the mother should get from her partner and can directly affect her nutritional condition. (Abel et al, 2019).

Maternal age

Maternal age according to a study showed a statistically significant association with maternal under nutrition among mothers (Mohammed et al, 2020). Based on a recent study, it was evidenced that the age of the mother significantly influences her nutritional status (Mohammed et al, 2020).

As the age of a mother increased by one year, her risk of under nutrition decreases. In the case of young mothers, asides from inadequate development of their reproductive system and their need of nutrition for their growing body, they are often suddenly confronted by uncomplimentary nutritional conditions (Mohammed et al, 2020). Other factors include; Household food insecurity and Family size.

Nutritional requirements during lactation

The nutrient intake of lactating women is one of most important determinants of women's health, well-being and the ability for long-term successful breastfeeding. Many essential nutrients are secreted into breast milk and they represent a significant proportion of nutrient intake in the maternal diet, including docosahexaenoic acid (DHA), and most vitamins, vitamin B2, vitamin A, etc. Therefore, nutritional requirements for lactating women are higher compared to women who do not breastfeed. Table 1.0 shows the requirements in their different proportions.

TABLE 1.0

MINIMUM NUTRIENT REQUIREMENTS FOR HEALTHY WOMEN AS WELL AS PREGNANT AND LACTATING WOMEN

Nutrient	Recommended daily allowance (RDA)(healthy adults	Pregnancy (add to RDA)	Lactation (add to RDA)	Tolerable upper intake level (UL)
Intake				
Proteins	50 g	+10 g	15 g (0---6 months) +12 g (6---12 months)	ND (do not exceed tolerable upper intake levels during lactation)
Fat-soluble vitamins				
Vitamin A	700 micrograms	+70 micrograms	+600 micrograms	3000 micrograms
Vitamin D	+5 micrograms	0 micrograms	0 micrograms	50 micrograms
Vitamin E	15 mg	0 micrograms	+4 mg	1000mg

Selenium	55 micrograms	+5 micrograms	+15 micrograms	400 micrograms
Zinc	8mg	+3mg	+4 mg	40mg

ND, not determined due to a lack of studies in these population studies in these population subsets; RDA, recommended dietary allowance. The intake must come from food sources to avoid potential overdoses

Source: Susana Ares Segura et al. 2015. The Importance of maternal nutrition during breastfeeding: Do breastfeeding mothers need nutritional supplements?

CONCLUSION

The general wellbeing of a woman during gestation (pregnancy) and lactation depends greatly on her nutrition and so also the wellbeing of the fetus and subsequent development of the child after being born as this prevents maternal death and child mobidity.

MONOGASTRIC ANIMAL NUTRITION

Evaluation Of Baker's Yeast (*Saccharomyces Cerevisiae)* Supplemetnation On Growth Performance And Cost Benefit Of Feeding Weaner Rabbits (O*oryctolagus Cunniculus)*

Ibrahim, h.
Department of animal production, faculty of agriculture, ibrahim badamasi babangida university, lapai, niger state, nigeria. Correspondence: ihadiza080@gmail.com. Tel.: +2348036101761

PROCEEDINGS
56th Annual Conference
Agricultural Society of Nigeria
24 - 28 Oct., 2022

ABSTRACT

The study was conducted to evaluate the effect of baker's yeast (Saccharomyces cerevisiae) supplement in four experimental diets at different levels of inclusion in the diet, Thirty-six (36) weaned rabbits of mixed sex at 2:1 (2 Females: 1male) were randomly allotted to four treatment groups in a complete randomized design. Each treatment was replicated three times with three rabbits per replicate. The trial lasted for a period of 8 weeks. Data were collected on growth parameters (feed intake, weight gain and feed conversion ratio) and cost benefit rabbit supplemented with Baker's yeast at different inclusion levels. The result obtained revealed no significant (p>0.05) difference among the growth performance parameters measured except feed intake that was significant and cost benefit of the experimental animals also revealed feed cost increased with an increased level of baker's yeast supplement, from the result obtained, it can be reported that best weight gained was recorded in treatment three diet having less level of yeast inclusion and therefore could be recommended

Key words: baker's yeast, supplementation, growth, performance, cost

INTRODUCTION

The human population growth in developed countries is stabilizing while that of developing countries including Nigeria is still increasing rapidly. Thus, the search for alternative sources of protein to meet up the population challenges is imperative. Economic indices indicate that as this population trend continues, more people are to be fed. Agricultural outputs needs to be increased rather than through food importation into such countries. In order to maximize food production and meet protein requirements in Nigeria, viable options need to be explored and evaluated (Owen *et al.,* 2008). Among such alternatives is the use of livestock species that are yet to play a major role in animal production within these countries. Fast growing micro livestock such as rabbits possess a number of features that might be of advantage. The yeast is a probiotic and a possible strategy alternative because of its availability, safety and cheapness. It is a valuable and qualitative growth promoter for feeding livestock (Shareef and Al-Dabbagh, 2009)

Aim of the study

The aim of the trial is to evaluate the effect of baker's yeast on the growth performance and cost benefit of feeding the weaned rabbit supplemented with baker yeast ***(Saccharomyces cerevisiae)***

The objectives of the study are:

i. to determine the growth performance of weaned rabbits fed with different level of baker's yeast (*Saccharomyces cerevisiae)* supplement
ii. to evaluate the cost benefit of weaned rabbits fed different level of baker's yeast (*Saccharomyces cerevisiae)* supplement

MATERIALS AND METHODS

Location of experimental site:

The experiment was conducted at the Rabbitry unit of the Teaching and Research Farm, Department of Animal Production, Faculty of Agriculture, Ibrahim Badamasi Babangida University Lapai, Niger State, Nigeria. Lapai lies between latitude 9^{o}31 and 9^{o}45, each of the equators. Savannah Vegetation Zone of Nigeria with mean rainfall ranges between 1100-1600mm and mean temperature 21^{o}C and 36.5^{o}C (6). 21^{o}C and 36.5^{o}C (Usman 2011).

Experimental animals and their management

Thirty-six (36) weaned rabbit aged 5-6 weeks were used and of both sexes (twenty-four females and twelve males), were randomly allotted to four treatment groups. Each treatment had three replicates with three rabbits per replicate (one males two females). The rabbits were housed intensively in a well-constructed hutches that were made of wire and woods with trays to collect the faeces as well as for easy cleaning of the hutches. The hutches were equipped with feeders and drinkers. The hutches were cleaned twice daily throughout the study period. lasted 8 weeks The rabbits on all the treatments were kept under close observation for proper monitoring indication of ill-health. The rabbits were dewormed against endoparasite using ivermecin, coccidiosis was treated once using sulphadimidine and multivitamin soluble powder (vitalyte) were given as an anti-stress

Source of Feed Ingredients, rabbits and Test ingredients / Experiment diets

Groundnut cake (GNC), Bone meal (BM), Limestone, premix wereobtained from Fauziya farm adjacent Gidan Matasa feed Ingredients milling Factory, Minna, while Maize and Salt were obtained from Lapai Market. Thirty-six weaned rabbits of mixed sexes were sourced from rabbitry section Niger state veterinary clinic Minna. A commercial baker's yeast (*Saccharomyces cerevisiae)* was used as the (test ingredients) dietary supplement. Four experimental diets were formulated. Diet 1 (basal diet), which was design as TRT_1 and without supplementation of *Saccharomyces cerevisiae*, serve as control diet. Diet 2, 3, and 4 were design as $TRT_{2,}$ TRT_3 and TRT_4 respectively.

Table 1: Composition of Experimental Diet

Ingredients (%)	T1	T2	T3	T4
Maize	76.00	75.80	75.60	75.40
Groundnut cake	20.00	20.00	20.00	20.00
Fish meal	1.50	1.50	1.50	1.50
Lime stone	1.00	1.00	1.00	1.00
Bone meal	1.00	1.00	1.00	1.00
Premix	0.25	0.25	0.25	0.25

Salt	0.25	0.25	0.25	0.25
Baker's yeast (kg)	-	0.20	0.40	0.60
Total	100	100	100	100
Calculated values				
Crude protein(%)	17	17	17	17
Metabolizable energy(Kcal/kg)	**2,799.128**	**2,799.128**	**2,799.128**	**2,799.128**

Key: T_1= Treatment one (Concentrate +0kg Baker's yeast*)* T_2= Treatment Two (Concentrate + 0.20kg Baker's yeast) T_3= Treatment Three (Concentrate + 0.40kg Baker's yeast) T_4=Treatment Four (Concentrate + 0.60kg Baker's yeast) into three replicates, each comprising 3 rabbits.

Data collection

Data on growth were generated on the Initial weight = weight taken at the beginning of the experiment

Final weight gain = weight taken at the end of experiment

Total weight gain = final weight – initial weight (g)

$$\text{Daily weight gain} = \frac{\text{final weight – initial weigh}}{\text{Number of days}} \text{ (g)}$$

$$\text{Feed conversion ratio} = \frac{\text{Quantity of Feed Consumed}}{\text{Weight gain}} \text{ (g)}$$

Cost Benefit Analysis

All the feed ingredients acquired and processing activities involved were monetized and price per kg of each ingredient were determined for economic analysis. Veterinary care and miscellaneous (variable cost); this were calculated as the total amount of money spent on vaccines, drugs and other expenses divide by the number of rabbits. Average body weight (kg); this was the final body weight of rabbits before slaughtering. Price per feed; this was calculated by taking into consideration of individual ingredients to be used in compounding the diet. This was calculated by price per (kg) feed= cost per kg of diet.

Data Analysis

Data collected were subjected to analysis of variance (ANOVA) according to the procedures of Steel and Torrie (1980) and significant means were separated using Duncan Multiple Range Test (Duncan 1955).

RESULTS AND DISCUSSION

Table 2: Proximate Analysis of the experimental diets

Treatments	T_1	T_2	T_3	T_4
Parameters	0g/kg	20g/kg	40g/kg	60g/kg
Moisture	6.20	6.20	7.60	6.60
Crude protein	13.65	13.60	13.86	13.00
Crude fibre	10.50	10.22	7.24	6.00
Ether extract	7.48	6.38	6.74	7.00
Ash	7.21	8.33	7.34	7.63
Nitrogen free extract	54.96	55.27	57.22	59.77

Table 3: Growth Performance of Weaned Rabbits Fed Different Levels of Baker's Yeast as Supplement

Parameters	T_1	T_2	T_3	T_4		
Inclusion level (g)	0g/kg	20g/kg	40g/kg	60g/kg	SEM±	LSD

Initial weight	633.33	611.11	633.33	633.33	39.89	NS
Final weight	868.67	873.67	923.00	859.00	97.39	NS
Total body weight gain	235.33	262.55	289.67	225.67	69.91	NS
Total Feed intake	3450.73^{b}	4069.00^{a}	4221.00^{a}	4221.00^{a}	246.69	*
Weekly body weight gain	29.42	32.82	36.21	28.21	8.76	NS
Weekly feed intake	431.34^{a}	508.63^{ab}	527.63^{b}	527.63^{ab}	39.28	*
Feed conversion ratio	14.66	15.50	14.57	18.70	6.04	NS

a, b, c: Means with different superscripts on the same row differ significantly (P<0.05), NS=not significant, * = significant, S.E.M=Standard error of mean, LS= level of significance, T_1=treatment one (0g/kg yeast), T_2=treatment two (20g/kg yeast), T_3=treatment three (40g/kg yeast), T_4=treatment four (60g/kg yeast).

The results of the growth performance of rabbits fed different level of baker's yeast as supplement. The results no reveals that significant (P<0.05) variation were observed across the treatment groups in the value of feed intake and weekly feed intake parameters with treatment three recording the highest value of (4221.00 g) and (527 .63 g) respectively. Enhancement in feed intake may be attributed to dietary live yeast addition increases the population of total rumen bacteria and which in turn helps increase feed intake as well as feed stuff digestibility, therefore, more nutrients are available to growth operations (Habeeb *et al.*, 2017). This finding is in line with Shanmuganathan *et al.* (2004) who stated a favorable leverage of yeast on weight gain for fattening rabbits which was aided by feed intake increament. Habeeb *et al.* (2006) found that average daily gain improved by 12.6 %, when yeast added to rabbit's diet. No significance (P>0.05) differences were observed in the value of initial weight gain, final weight gained, total body weight gained and feed conversion ratio. However, the highest final weight gain(923.00g), Total body weight gain (289.67) and the best feed conversion ratio (14.57) were all recorded in treatment three rabbits fed with 40g/kg of baker's yeast in the diet. This results coincided with the observation of Belhassen *et al.* (2016) who recorded that body weight gain was not significantly affected by yeast supplementation to rabbit's diet after weaning (5-11 wk). The results of the feed conversion ratio recorded from this experiment are similar to that of Kustos *et al.* (2004); Matusevičius *et al.* (2006) who noticed non-significant difference in FCR by using a commercial probiotic in rabbit diet. However, Shanmuganathan *et al.* (2004) recorded a favorable impact of yeast on feed conversion in fattening rabbits.

Table 4: Cost benefit of rabbit fed with different dietary levels of baker yeast

Parameters	T1	T2	T3	T4	LSD	SEM
Cost of feed (₦/kg)	146.40^{d}	178.40^{c}	210.4^{b}	242.2^{a}	0.50	0.00
Cost of feed consumed/rabbit (₦)	505.19^{d}	725.91^{c}	888.09^{b}	1023.17^{a}	1.00	0.00

Feed cost /weight gain(₦ /kg)	580.68^{d}	830.87^{c}	962.18^{b}	1,191.12^{a}	0.80	0.00

a, b, c: Means with different superscripts on the same row differ significantly (P<0.05), NS=not significant, * = significant, S.E.M=Standard error of mean, LS= level of significance, T_1=treatment one (0g/kg yeast), T_2=treatment two (20g/kg yeast), T_3=treatment three (40g/kg yeast), T_4=treatment four (60g/kg yeast).

The result for the cost benefit of rabbits fed baker's yeast supplement revealed the values for cost of feed, cost of feed consume per rabbit and feed cost per weight gained differs significantly (P<0.05) across the dietary treatment level. Cost of feed increased with an increased level of baker's yeast supplement, highest cost of feed produced (₦ 242.2) was obtained in Treatment four while the least cost of feed produced was obtained in treatment one (₦ 146.40). Cost of feed consume per rabbit is costlier (₦ 1,023.17) in treatment four while least expensive (₦505.19) in treatment one. Best feed cost /kg weight gained (580.68 ₦/kg) was recorded in treatment one while the poorest (₦ 1,191.12kg) was obtained in treatment two. The cost of the experimental diet and the feed cost per weight gain were higher in treatment four because treatment four contained high inclusion level of the yeast. However, the best weight gained was recorded in treatment three diet having less level of yeast inclusion when compare to treatment four. This finding strengthen the evaluation of Ezema and Eze (2015) they recorded high cost of experimental diet/kg in group C because group C had the highest probiotic inclusion of 0.16 g/kg of diet but did not gain as much weight as group B (0.12 g/kg of diet). This might be explained by the fact that probiotics are not dose dependent but are threshold dependent (Ortwin,2005).

CONCLUSION:

From the results obtained from this study it can be deduced that rabbits diet supplemented 40g/kg performed better in the parameters considered. Thus, rabbits diet can be supplemented with baker's yeast without having any adverse effect on the growth performance and cost benefit of rabbits diets.

RECOMMENDATION:

Based on the above results, 40g probiotic baker's yeast /kg of diet was thus recommended for maximum weight gain and optimum economic benefit in rabbit production

ABSTRACT

A 21 days feed trial on processed cassava root meals using oven-dry and sun-dry techniques were substituted at varying inclusion levels in broiler starter chicken diets. Data were collected on the proximate composition of CRMs and performance characteristics of the broiler starter chickens. The results of the proximate composition revealed that moisture, dry matter, crude protein, crude fibre, ash, ether extract and Nitrogen free extract were 8.79, 27.47, 4.25, 3.68, 3.48, 0.60 and 47.73% respectively for oven-dry CRM, and 7.39, 29.10, 3.85, 4.08, 2.63, 0.44 and 48.51% respectively for sun-dry CRM. The results showed that the final weight and weight gain of birds on Treatment 4 had superior values 1242.70g and 1242.25g respectively compared to birds on other treatments. The feed intakes of the birds ranged from 1695.81 – 1785.03g. Also, birds on T4 showed better FCR compared to the other treatments. It is recommended that processed CRM could be fed to broiler starter chickens up to 50%CRM inclusion either as sun-dry or oven-dry for improved growth performance.

Keywords: Broiler starter chickens, cassava root meal (CRM), performance characteristics and proximate composition

INTRODUCTION

The effects of covid-19 and climate change recently have negative impact on agricultural production globally. There has been a closure of several farms within Nigeria and some low-income countries due to a hike in the prices of feed resources and its unavailability for use in animal production had been challenging. The usage of non-conventional feed resources hascontinued to be widely appreciated in the livestock industry due to their availability and cheaper compared to conventional feed resources (Okpara *et al.*, 2022).
Cassava (*Manihot esculenta*) is a plant that has been widely used both for humans and animals. Its leaves are an excellent meal for ruminants. It is among the most cultivated plant globally. It grows all year round and can thrive in most soils in Nigeria. There are several varieties which are most predominant in the tropics. Its root tuber can be processed (sun-drying, boiling, oven-drying) into various products consumed by man, and animals and its by-product for industries.

This research was designed to evaluate the effects of these processing techniques on cassava root meal as partial or whole substitution in broiler starter chickens on their performance characteristics.

MATERIAL AND METHODS.

Experimental Location and Site

The experiment was carried out in the teaching and research poultry unit at Dennis Osadebay University, Asaba, Delta State. The poultry unit had a deep litter system which is partitioned into pens with netting materials. Each pen had a space of 1x2x2.5.

Processing of test ingredient and experimental diets.

The cassava variety used was UMUCASS 36 (vitamin A) and was harvested 9 months after planting. The tubers were peeled, washed with water to remove impurities and sliced before being sun-dried for (5days) and oven-dried at 60^{o} C for 6hrs respectively. The dried samples were ground into meals and kept in sacks before usage. These meal samples were supplemented as partial and whole into six diets as a substitute for maize in the birds' diets. T1 serves as the control, T2 had 25% each of oven-dry and sun-dry CRM, T3 had 25% maize and 25% oven-dry CRM, T4 had 25% maize and 25% sun-dry CRM while T5 had only 50% oven-dry CRM and T6 also had only 50% sun-dry CRM respectively.

Table 1: Percentage composition of broiler starter chicken diets

Feedstuff	T1	T2	T3	T4	T5	T6
Maize	50.00	---	25.00	25.00	---	---
Oven-dried cassava	---	25.00	25.00	---	50.00	---
Sun-dried cassava	---	25.00	---	25.00	---	50.00
Soyabean meal	20.00	20.00	20.00	20.00	20.00	20.00
Groundnut cake	14.00	14.00	14.00	14.00	14.00	14.00
Wheat bran	8.50	8.50	8.50	8.50	8.50	8.50
Palm Oil	2.00	2.00	2.00	2.00	2.00	2.00
Bone meal	3.00	3.00	3.00	3.00	3.00	3.00
Limestone	1.00	1.00	1.00	1.00	1.00	1.00
Methionine	0.50	0.50	0.50	0.50	0.50	0.50
Lysine	0.50	0.50	0.50	0.50	0.50	0.50
Salt	0.25	0.25	0.25	0.25	0.25	0.25
Premix	0.25	0.25	0.25	0.25	0.25	0.25
Total	**100.00**	**100.00**	**100.00**	**100.00**	**100.00**	**100.00**
Calculated values						
Crude protein%	23.08	22.44	22.84	22.96	23.06	22.92
ME(Kcal/kg)	2872.11	2852.27	2882.50	2896.70	2876.44	2882.56

Experimental animals and design.

A total of 108 Arbor acre day-old chicks were used. The birds were randomly distributed in a completely randomized design into the various treatments. Each treatment was replicated thrice with 6 birds per replicate respectively. Feed and water were administered *adlibitum* for 3 weeks. One-way ANOVA was used to analyze and their means were separated using Duncan Multiple Range Test.

Proximate composition

Proximate compositions of the samples were carried out according to the AOAC 2015 procedures. Hydrogen cyanide (HCN) content was determined using Chisenga *et al.*, (2020) procedures

Data collection

Performance characteristics

Live body weight (BW) was registered at the beginning and termination of the experimental period, whereas feed intake and weight of birds were determined once a week. The weight gain of birds was recorded by subtracting the initial weight from the final weight, while the feed conversion ratio was calculated as the feed intake divided by weight gain.

Statistical analysis

All data collected were analyzed using SPSS version 23

RESULTS AND DISCUSSIONS

Table 2: Proximate composition of cassava root tuber (Vitamin A variety)

Parameters	Oven-dry	Sun-dry
Moisture (%)	8.79	7.39
Dry matter (%)	27.47	29.10
Crude protein (%)	4.25	3.85
Crude fibre (%)	3.68	4.08
Ash (%)	3.48	2.63
Ether extract (%)	0.60	0.44
Nitrogen free extract (%)	47.73	48.51
HCN (mg/100g)	3.15	2.84
Energy (kcal/kg)	2,942	2,958

The results of the proximate composition revealed that moisture, dry matter, crude protein, crude fibre, ash, ether extract and Nitrogen free extract were 8.79, 27.47, 4.25, 3.68, 3.48, 0.60 and 47.73% respectively for oven-dry CRM, and 7.39, 29.10, 3.85, 4.08, 2.63, 0.44 and 48.51% respectively for sun-dry CRM These results were inconsistence with an earlier report by Okpara et al. (2022) that also documented similar values on processed cassava on broiler chickens performance. The CP, CF and NFE results were at variance with reports of Yadav et al.(2019); Chisenga et al. (2020). Moreover, the reports of some authors on CP, CF, NFE showed discrepancies with the present results which can be aligned to the age of harvest, processing methods, cassava variety and some ecological factors (Bhuiyan and Iji 2015).

Table 3: Performance characteristics of birds fed experimental diets

Parameters	T1	T2	T3	T4	T5	T6	SEM	p-value
Initial weight/bird (g)	0.45	0.45	0.45±0.00	0.45	0.45	0.45	0.00	0.00
Final weight / bird (g)	1206.14^{ab}	1145.52^{d}	1069.42^{c}	1242.70^{a}	1051.34^{d}	1102.62^{b}	15.32	0.03
Weight gain/ bird (g)	1205.69^{ab}	1145.07^{d}	1168.97^{c}	1242.25^{a}	1050.89^{d}	1182.17^{b}	14.55	0.01
Feed intake/ bird (g)	1785.03	1712.56	1735.8l^{b}	1745.03	1695.8l^{a}	1721.28	12.06	0.04
Feed conversion ratio	1.48^{b}	1.50^{b}	1.48^{b}	1.40^{c}	1.61^{a}	1.46^{b}	0.55	0.02

a-b-c: Means within the row with different superscripts are different at $p< 0.05$. SEM: Standard Error of the Mean

The result on performance characteristics of birds showed significant ($p<0.05$) influence of the diets (Table 3). The final weight and weight gain of birds on T4 had superior values 1242.70g and 1242.25g respectively compared to birds on T1 whose values 1206.14g and 1205.69g was better than T6 < T3< T2 respectively. The feed intakes of the birds range from 1695.81 – 1785.03g, where T5 and T1 recorded the least and highest values respectively. It was observed that T4 birds had better FCR against the birds on other treatments. These results are similar with Bhuiyan and Iji (2015) but differ from Okpara et al., (2022), who reported a reduced feed intake on birds fed oven-dried CRM. Earlier reports have documented that up to 50%CRM had greater weight gain in birds (Etalem, 2013).This recommendation was consistent with this study's result.

CONCLUSION

The birds on T4 showed superior values in the final weight, and weight gain and had a better feed conversion ratio. It was also observed that broiler starter chickens could be fed processed CRM up to 50% inclusion for improved growth performance..

ABSTRACT

The composition of milk will determine its ability to meet with the requirement of an individual. The experiment was carried out at the Fulani settlement located behind Kabba College of Agriculture/ ABU. Twelve lactating cow, ewe and doe were used in a complete randomized design experiment. The animals were hand-milked and samples of milk were bulked separately and taken to the laboratory for analysis. The physical composition observed were; colour, density, pH and conductivity, while the chemical composition were total solid, protein, fat, ash and lactose using standard procedures. The colour of cow milk appeared yellow, while those of sheep and goat milk appeared white. The density of milk for cow, sheep and goats are 1.04mg/dl, 1.02mg/dl and 1.04mg/dl respectively. The pH of milk is 6.70 for cow and 6.62 for sheep and goat. Conductivity range of the milk samples was 6.14 Ms/cm for cow, 10.55 Ms/cm for sheep and 9.63Ms/cm for goat. The total solid was 14.25%, 20.70% and 15.32% for cow, sheep and goat respectively. The protein content was 4.32% in cow milk, 6.63% in goat milk and 4.63% in sheep milk. The fat content in sheep was (7.65%), cow (4.95%) and goat (5.30%). The lactose content of the milk varied between 4.47% - 5.29%. It was concluded that there were variations amidst the milk of ruminant animals considered in this study. Sheep and goat milk use can be recommended to farmers that are interested in butter production.

Key words: Assessment, Species, physicochemical ruminant and milk

INTRODUCTION

Milk is an important food for mankind and young ones of all mammals as a liquid food. Milk contains water, fat, protein, lactose, vitamins and minerals (Park, 2009). Unraveling the composition of milk and its constituents has been a challenging problem for scientists due to its complex nature. These constituents are present in three phases viz; true solution colloidal dispersion and fat-in-oil type emulsion. Knowledge of milk composition leads to understanding of physico-chemical nature of this complex biomolecule, it will also add to the knowledge needed for the preparation and manufacture of milk and its products (Haile *et al.*, 2018).

The milk composition not only reflects the dairy quality and health status of dairy animals but also affects the nutritional value of milk and dairy products (Auldist *et al*., 2007).Milk composition determines the nutritional value as well as its quality. The composition of milk will determine its ability to meet with the requirement of an individual at any given point in time. Each species of ruminant has peculiar composition which may lead to allergic reactions when consumed.

Therefore, it is necessary to investigate differences in milk composition of ruminants as occasioned by species.

MATERIALS AND METHODS

Experimental site

The experimental site was at the Fulani settlement located behind the Division of Agricultural Colleges, Ahmadu Bello University Kabba Campus, Kogi State, Nigeria, which is located within the Guinea Savanna Agro-ecological zone of Nigeria. The area experiences a tropical climate with marked wet and dry seasons, high temperature and high humidity. The rainy season spans over seven month from mid-march or early April to October. The mean annual rainfall is 750mm per annum. The dry season spans from November to early March. The average mean annual temperature of the area ranges between 32°C and 35°C.

Source of experimental materials

Milk that was used for the experiment was sourced from the Fulani settlement located behind the Division of Agricultural Colleges, Ahmadu Bello University Kabba Campus, Kogi State
Animal management and feeding
Twelve lactating animals were sourced within the Fulani settlement raised under the extensive management systems. Routine grazing was carried out twice daily (morning and evening). They were fed on natural pasture.
Experimental Design and Procedure
Milk samples were collected from the cows, goats and sheep in a completely randomized design. Twelve lactating does, ewes and cow free from disease and other infections were selected randomly to eliminate bias in the experiment. The animals were hand-milked before morning grazing. Representative samples of milk obtained from the does (West African Dwarf), ewe (The Bororo) and cow (white Fulani) respectively were bulked separately and collected into clean, white plastic containers. The samples were taken in a cold ice packed container to the laboratory for analysis.

Samples analysis.

The density of the milk was calculated by dividing the weight of the milk sample by the volume (Selvaggi *et al.*, 2014). The pH value of milk was determined by using a pH meter as described by Li *et al.* (2019). The conductivity was determined by a calibrated conductometer (AOAC, 2000). Standard procedures adopted by AOAC (2000) were followed in the determination of the percentages of total solids (TS), fat (Gerber's method) and protein (Kjeldahl's method). The lactose percentage was calculated as TS – (protein + fat + ash).

Statistical analysis

All data obtained were statistically analyzed using the Analysis of Variance (ANOVA) procedure of SAS (2002) while the significant differences in means were separated using pair wise-difference.

RESULTS AND DISCUSSION

Physical composition of milk from different ruminant's species

The results of the physical composition of milk from different ruminant species during the study period are shown in Table 1.The colour of cow milk appeared yellow, while those of sheep and goat milk appeared white. This agreed with the findings of Balthazar *et al.* (2017) and Saini and Gill, 1991, they reported that goat and sheep milk is white in colour compared with cow milk, which is yellowish because of the presence of carotene. In this study the density of milk for cow, sheep and goats are1.04mg/dl, 1.02mg/dl and 1.04mg/dl respectively. This agreed with the findings of Park *et al*. (2007) they reported the range value of 029–1.039mg/dl, 1.0347–1.0384mg/dl and 1.0231–1.0398mg/dl for goat, sheep and cow respectively. The variation may be as a result of differences in volume and weight of individual milk.

The pH of milk is 6.70 for cow and 6.62 for sheep and goat. The slight acidity of milk is due to the presence of lactic acid, citric acid and phosphoric acid (Balthazar *et al.*, 2017). However, their values fell within the range value of 6. 65 – 6.71, 6.61 – 6.51 and 6.62 – 6.71 for cow, goat and sheep respectively as reported by Park *et al*. (2007). The conductivity range of the milk samples was (6.14 Ms/cm) for cow, (10.55 Ms/cm) for sheep and (9.63Ms/cm) for goat. The variation in conductivity may be due to the different levels of the electrolytes present in the milk samples.(Rehman and Salaria, 2005).

Table 1: Physical composition of milk from different ruminant's species

Composition	Species		
	Cow	Sheep	Goats
Colour	Yellow	white	White
Density (mg/dl)	1.04	1.02	1.04
pH	6.70	6.62	6.62
Conductivity(Ms/cm)	6.14	10.55	9.63

Chemical composition of milks from breeds of ruminant animals

The results for the chemical composition of milks from different species of ruminant animals are shown in Table 2.

The total solid composition of milk was 14.25%, 20.70% and 15.32% for cow, sheep and goat respectively. The significant effect of species on total solid in the present findings is in line with the reports of Imran *et al.* (2017); they reported that sheep milk contains higher total solids and major nutrient contents than goat and cow milk. This may be as a result of higher proportion of nutrient constituent in sheep milk compared to goat and cow milk. According to the present result, the protein content was 4.32% in cow milk, 6.63% in goat milk and 4.63% in sheep milk. The amount of protein content in sheep milk was significantly ($p<0.05$) higher compared to goat and cow milks. This may be as a result of higher essential and non-essential amino acids as well as more whey protein fractions in sheep milk compared to the rest species (Belloni *et al.*, 1999).

The amount of fat content in milk was significantly ($p<0.05$) higher in sheep (7.65g) compared to cow (4.95g) which is similar ($p > 0.05$) to goat (5.30g). This observation is similar to those reported by Enb *et al.* (2009). This may be as a result of higher saturated, mono -unsaturated and poly –unsaturated fatty acids in sheep milk compared to cow and goat milk (Renner, 1982). The ash content of milk was significantly ($p<0.05$) higher in sheep (0.83g), although similar ($p>0.05$) to the milk content of goat (0.70g) while cow had the least ash content (0.51g).This is similar to the report of Saini and Gill (1991). This may be as a result of higher concentration of both water-soluble and fat- soluble vitamins and minerals being more in sheep and goat milk compared to cow's milk (Alichanidis and Polychronia, 1996). There was a non-significant ($p > 0.05$) difference between the percentage composition of lactose in cow, sheep and goat milk; however, their mean composition was 4.47%, 5.29% and 4.69% respectively. The values obtained in this present study is within the range of 4.10-5.24% in cow milk, 3.89-4.73% in goat and 4.42-5.31% in sheep milk reported by Enb *et al*.(2009).

Table 2: Chemical composition of milk from different ruminant's species

Species

Composition (g)	Cow	Sheep	Goat	SEM
Total solid	14.25[b]	20.70[a]	15.32[b]	0.02
Total protein	4.32[b]	6.63[a]	4.63[b]	0.03
Fat	4.95[b]	7.95[a]	5.30[b]	0.03
Ash	0.51[b]	0.83[a]	0.70[a]	0.04
Lactose	4.47	5.29	4.69	0.04

[ab]: means with different superscript in the same row are significantly ($p<0.05$) different

CONCLUSION AND RECOMMENDATION

The physical and chemical composition of various ruminant animals (cow, sheep and goat) varied amidst species and they can all serve as nutritional source of milk.

Goat, sheep and cow milk can be taken, as they will adequately serve as nutritional source of protein for human consumption, however, sheep milk seems the richest

Sheep milk is recommended for farmers interested in butter production because they contain the highest fat percentage.

ABSTRACT

The study was conducted at the Research Unit of Delta State University, Asaba Campus to evaluate the haematological and serum biochemical parameters of broiler chickens fed Vernonia amygdalina (bitter leaf) and Ocimum gratissimum (scent leaf) meals. Two hundred (200) one-day-old broiler chicks were randomly assigned to five experimental diets consisting of 0% bitter leaf (BL) and 0% scent leaf (SL), 0% BL and 0%SL with antibiotic, 75% BL and 25% SL, 50% BL and 50% SL, and 25% BL and 75% SL, in a Completely Randomized Design. Results obtained showed that crude protein intake was similar among the treatment groups. The white blood cell (WBC), red blood cell (RBC), haemoglobin (Hb), mean cell haemoglobin concentration (MCHC), glucose, albumin, globulin and total protein were similar among the treatment groups. Cholesterol was significantly ($P<0.05$) highest in 25% BL and 75% SL, and lowest in 0%BL and 0%SL, in the birds fed the control diet. Since 2 – 200 mg/dl daily intake of cholesterol is recommended, it is concluded that bitter leaf and scent leaf meal can be added to the broiler diet, even at a combined level of 25% BL and 75% SL, without adverse effects on the haematological and biochemical status of broiler chickens.

Keywords: Haematology, serum biochemistry, bitter leaf, scent leaf.

INTRODUCTION

Poultry production is a necessity in the supply of animal protein, especially to developing countries in the globe, which have been disadvantaged over the centuries. Various feed additives are used in poultry production to maximize profit, performance, carcass quality, health status, and to mitigate the attendant problems of antibiotic usage. Consequently, phytochemicals, which are plants' secondary metabolites, are now included in poultry diets. This is due to their inherent antioxidant and anti-microbial activities (Ali et al, 2021). *Ocimum gratissimum* (scent leaf) and *Vernonia amygdalina* (bitter leaf) are some of the plants of interest in the quest for a panacea to the above-mentioned problems.

Consequently, nutrition is being more widely used as a practical solution for maintaining animal health. Feed components and nutrients influence health in many different ways. By manipulating or selecting them, feed quality may be maintained and the risk of mycotoxin contamination may be reduced.

Haematology is the specific study, with the responsibility of diagnosing and managing of a plethora of benign and malignant diseases of red and white blood cells, platelets, and coagulation system in living organisms (Newman, 2022). Phytochemical investigation of bitter leaf and scent leaf yielded quite different compounds such as alkaloids, tannins, flavonoids and steroids. Ugoze, *et al*. 2020, emphasized the usefulness of these phytonutrients in reducing diseases and death. This study is designed to evaluate the haematological and serum biochemical parameters of broiler chickens fed bitter leaf and scent leaf meals at varying proportions.

MATERIALS AND METHODS

The experiment was carried out at the Training and Poultry Research Unit of Delta State University, Asaba Campus. Bitter leaf (BL) and scent leaf (SL) which were procured from Asaba and the neighbourhood were air-dried separately and milled and samples were sent to the Animal Science Laboratory of Delta State University Asaba Campus for analysis of proximate composition and phytochemical substances. Five dietary treatments were formulated to contain approximately 3000 kcal/ME and 20% crude protein. The first group is the control which had 0% BL and 0% SL, the second group had 0% BL and 0%SL, with antibiotic, the third group had 75% BL and 25% SL, the fourth group had 50%BL and 50%SL, and the fifth group had 25%BL and 75% SL. The compositions of the experimental diets are presented in Table 1.

Two hundred (200) 28-days old Marshal broiler chicks were procured for this experiment. The chicks were randomly allotted to five treatment groups of 40 chicks, with each treatment group further subdivided into four replicate sub-groups of 10 chicks in a completely randomized design. Each treatment group was assigned one of the dietary treatments. Feed and clean drinking water were provided *ad libitum.*

At the end of the nine weeks of age, one bird from each of the replicates was selected at random for bleeding, through the vein. Blood samples were then analysed for packed cell volume (PCV), Haemoglobin (Hb), white blood cells (WBC) count, red blood cells (RBC) count, mean corpuscular haemoglobin (MCH), mean corpuscular volume (MCV), mean corpuscular haemoglobin concentration (MCHC), serum total protein, albumin, globulin, glucose and cholesterol.

RESULTS AND DISCUSSION

The proximate composition and phytochemical constituents of bitter leaf (BL) and scent leaf (SL) in Table 1, showed BL to be slightly higher than SL in dry matter, Ash, Alkaloid, Tannin, Flavonoid, and Steroid. On the other hand, SL was slightly higher than BL in crude protein, ether extract and Saponins.

Table 1: Proximate Composition and Phytochemical Constituents of Bitter Leaf (BL) and Scent Leaf (SL)

Parameters	BL	SL

BL: Bitter leaf SL: Scent leaf

Table 3 shows the results of the haematological and serological indices of the broiler chickens. The haematological parameters of broiler chickens fed varying levels of bitter leaf and scent leaf meals indicated that PCV values (%) of 37.50 and 37.25, fell within the range of 27.50-37.50% cited by Onwumelu (2009) for broilers. Generally, dietary treatments had no significant (P>0.05) effect on the haematological indices measured except MCV and MCH. The similarity in the Hb levels means the oxygen transportation within the bird's physiological system was not affected by the diets. MCH and MCV of treatment 2 were significantly (P<0.05) higher than treatments 1 and 4, but similar (P>0.05) to treatments 3 and 5.

****Antibiotic: (Tylo-dox extra wsp: Tylosin Tartrate 20g, Doxycycline Hyclate15g).***
SEM = Standard error of the means
BL: Bitter leaf **SL: Scent leaf**

The glucose, total protein, albumin and globulin of birds in all treatment groups were similar (P>0.05). This is an indication that the contents of phytochemicals in bitter leaf and scent leaf meals in the diets did not precipitate inadequacy of nutrients which could create an anaemic condition. Cholesterol levels were significantly (P<0.05) higher in birds fed diets containing 50%BL and 50%SL; and 25%BL and 75%SL. This cannot be explained in this study, as it is contrary to reports on the cholesterol-lowering effect of phytochemicals as reported by Tchouan *et al*, (2020), whereby a decrease in serum LDL- cholesterol content, and an increase in HDL-cholesterol, with the addition of enzymes in cassava fibre-based broiler diets. More so, Adeloye *et al* (2021), observed that dough meals from unripe plantain, water yam and bitter leaf, have the potential to be used as functional foods to alleviate postprandial hyperglycemia. This could be an indication of hypoglycemic effect of bitter leaf on broilers.

CONCLUSION

It can be concluded from this study that both bitter leaf and scent leaf meals can be used at various levels of combination, without adverse effects on the haematological and serum biochemical parameters of broiler chickens.

ABSTRACT

Given the hike in price of some feed stuffs like cereals there is need to focus attention on alternative feed stuff which could either directly substitute conventional feed stuffs or could be included at certain levels to attain a comparable production quality without deleterious effect on the animal health, reduce the cost of production and readily available. This paper reviewed research efforts on the potentials of cassava leaf meal in pig feeding. This review shows that cassava leaf meal is readily accepted as a component of livestock feed. Cassava leaf meal is a potential source of protein supplementation for livestock. There is no competition between man and pigs for cassava leaf meal, it is readily available and cheap. Cassava leaf meal have been found to improve performance of carcass quality, growth performance; and blood serum and biochemistry in pigs when fed at different levels

INTRODUCTION

The major aim of every farm enterprise is to maximize profit. Majority of the cost in livestock productions is incurred from feed stuffs and feeding which can take up to about 70-80% of the total cost of production (Tewe *et al*., 2002).

Cassava foliage is a very good feed stuff that will help to conquer this high cost of feed in the livestock industry (Ukachukwu, 2008). Recently, emphasis has been placed on the increase utilization of cassava foliage. This opens up the possibility of including foliage and tender stems of cassava which is rich in protein in diets containing increased amount of cassava roots (Garbati *et al.*, 2001), since this material has been successfully used in pig feeding (Trompiz *et al*., 2000). Cassava leaf yields as much as 4 tones dry matter per hectare and may be produced as a by-product at root harvest (Preston 2002).

Improved productivity of pigs using Cassava foliage meal will reduce the pressure on other sources of dietary nutrients. This will invariably have a positive impact on the economy because the huge amount of the money spent annually by government in importing other sources of animal protein will be channeled to other uses.

POTENTIALS OF CASSAVA LEAF ON PERFORMANCE OF PIGLETS

Growth: Based on research carried out by Tram, Nguyen & Preston, Thomas. (2004), they observed that as the proportion of fresh cassava leaf was increased in the ration of growing/finishing pigs, growth performance was lowered. This adverse effect was suspected to be due to high levels s of hydrocyanide acid present in the fresh leaves, which affected the palatability. In another experiment to use cassava leaf meal as a substitute for other protein supplement in swine diets was not encouraging Ravindran (1990), in his work substituted 10, 20 and 30 percent leaf meal of cassava in a maize/soyabean meal based diet for pigs that are growing and discovered that the mean daily gains and feed efficiency reduced linearly with increasing levels of leaf meal. In a diet of pigs containing 10% cassava leave meal, performance was improved by addition of methionine and energy supplement. Based on research carried out by Siaka (2017), reduced gains and poorer feed intake was reported when leaf meal of cassava was added at above 30% in pigs.

Carcass: In an experiment carried out by Jiménez *et al*., (2005), they finalized that swine fed *ad libitum* with diets compounded to contain 40 percent of cassava root meal and 20 percent from mixture of cassava foliage and leaves of trichanthera had similar weight performance and carcass qualities in comparism with those fed a conventional diet. Jimenez *et al*., (2005) who fed cassava root and mixed foliage meal of cassava and trichantera leaves did not observe any significant difference in all carcass parameters analyzed. This may be an indication that the pigs in all the treatments optimally utilized the nutrients contained in the diets.

The abdominal fat value of pigs shows that as the level of Cassava foilage meal increased in the diet of pigs, the abdominal fat reduced. This might suggest that higher level of CFM led to reduction in energy density of feed, hence reduced fat deposit in the animal. It could also be due to higher crude fiber content of the foliage, which may have reduced the digestible energy content of the diet.

Haematology: Haematological profile in any farm animal is a very important indicator of health and disease condition in an animal and cannot be done without in the diagnosis, prognosis or treatment of a lot diseases (Mbanasor *et al*., 2003). Evaluation of the haematological indices shows the animal's physiological responsiveness to its external and internal surrounding haematological indices avails the opportunity to do a clinical study of many metabolites, as well as other constituents in the animal's body. A study carried out by Iyayi (2001), feeding swine with cassava leaf supplement significantly improved total protein of serum and reduced serum glutamic oxaloacetic transaminase and serum glutamic pyruvic transaminase. The value of WBC and blood coagulation time increased with increasing level of leaf meal of cassava which implies that the leaf has substance that interferes with clotting.

Nutrient Composition of Cassava Leaves: Cassava leaves contain about 21% crude protein, even though values ranging from 16.7-39.9% have been reported. This wide variation can be attributed to cultivars variations, maturity stage, procedure of sampling, fertility of the soil and climate (Hue *et al*, 2012).

Optimization of cultural activities such as fertilizer application may give another means of raising the protein value of cassava leaves. Even though cassava leaves are rich in protein, some factors such as high level of crude fire may reduce its nutritive value for monogastric animals. Maturity Stage is an important factor contributing to the variation in fibre content, but cultivar effects and environmental factors are also responsible. Cassava leaves are very nice sources of minerals. They are mainly rich in Fe,Ca, Mn, Mg, and Zn.

Cassava leaves also are rich in vitamin A and ascorbic acid, and contain reasonable amounts of riboflavin. But considerable losses of vitamins, particularly of ascorbic acid, occur during processing.

Amino Acid Composition: The protein contained in Cassava leaf is low in methionine, possibly marginal in tryptophan, but high in lysine (Chhay Ty and Preston T R 2005). Some reports have been made about differences in the amino acid profile of leaves and may be attributed to variation in procedures of sampling, stage of leaf maturity, ecological conditions and analytical methods. During leaf maturation, the obvious pattern was for the amino acid level to decrease. Among the essential amino acids, histidine and lysine appeared to decrease the greatest.

Table 1: Amino Acid Composition of Cassava Roots and Leaves (g/16g n).

ABSTRACT

The high cost of conventional sources of energy like maize and sorghum for monogastric animal production has led to search for alternative low cost energy sources. This assessment was carried out to investigate the potential value of cassava products as feed ingredient for non-ruminant animals. The starchy roots produced in many tropical areas constitute an important energy source for human and animal feeding. Studiesshow that most of these cassava products are uncommonly used as feed for non-ruminant animals; this could be as a result of low protein content and high anti-nutritional factors. However, processing methods like sun-drying, boiling, ensiling, soaking and fermentation are engaged to improve their utilization in non-ruminant feed. Thoroughly processed cassava products could replace maize in non-ruminant diet at certain levels provided adequate protein supplement is used.

INTRODUCTION

In Nigeria today, concern of the rather low level of animal protein consumption has been generally occasioned mainly by low production level due to high cost of inputs. This low production is further aggravated by the outrageous demand for even the limited livestock products, leading to escalated costs. In monogastric animals like poultry, rabbits and pigs, feedstuff represents 65 to 70% of the total cost in an intensive production system in developing countries (Ekwe *et ai., 2021*). Energy source constitutes between 45 to 60% of finished feeds for these animals. The increasing pressure on the use of maize and other grains by man, livestock and industries makes it scarce and costly. The high cost has led to the need to explore alternative feed ingredients that are cheap and readily available which can also meet the nutrient requirements of livestock. Cassava products like foliage/leaves, stem and root are recognized as cheaper carbohydrate and protein sources than grains. They have high caloric yield and low production cost per hectare (Hahn, 1990). Their by-products such as peels, leaves and foliage are non-competitive feed materials that can be developed as components of feeds (Apata and Babalola, 2012).

Potentials of Cassava Products as Non-Ruminant Animal Feed

Cassava Peel: There is a great deal of interest in supplementing feeding of animals with cassava in Africa (Hahn, 1990). Cassava peel which is slightly richer in protein (2-3%) than the edible portion of cassava (1-2%) (Aina, 1990) could partially replace maize grains if adequately furnished with protein sources. The cassava peel will require a conscious supplementation of both methionine and dietary fat. About 5% palm oil will be useful for dietary cassava peel beyond the 30% level in the ration. According to Esonu and Udedibie (1993) cassava peel meal significantly depressed feed intake of rabbits at 100% replacement level for maize which could be as a result of high fibre and low energy content of the diet. They concluded that the optimal replacement level of maize with dried cassava peel meal from the trial is 50% for weaned rabbits. Cassava peel meal could make up to 40% of ration of fryer rabbits without any deleterious effects on live performance, especially when fish meal was used (Ijaiya, 2001). Preliminary studies have so far shown satisfactory performances in finisher cockerels with up to 45 percent inclusion of cassava peel as a replacement for maize in their rations. Growing pigs fed on a diet containing 40 percent cassava peel and discarded small tubers have been observed to perform satisfactorily (Tewe and Oke; 1983). Indeed, pigs fed such rations produced leaner carcasses and showed and economy of feed conversion. Cassava peel has been used to replace maize as an energy source in the diets of growing pigs.

Composite Cassava Meal: This is a cassava based diet that comprises the roots, leaves and stems fed to livestock at certain ratio (Akinfala *et al*., 2003). According to Tewe et al, (2002) the nutrient composition, quality and digestibility of composite cassava meal could be used as a ration for monogastric animals. There was a significant increase in weight gain, feed efficiency and consumption when composite cassava meal-based diet replaced maize in the diets of broiler chickens (Akinfala, *et al.*, 2003).

Cassava Root Meal: Supplementation of cassava-based diets with methionine has yielded better result than maize based diet. It should be noted that besides methionine supplementation, careful control of energy-protein ratio is necessary for satisfactory results. Eshiet *et al.*, (1989) fed 0, 15, 30 and 45% cassava root meal, in isocaloric and isonitrogenous diets, to fryer rabbits. They observed that rabbits could tolerate up to 30% cassava root meal diet without adverse effects on feed intake and rate of growth. The 45% cassava root level, however, gave poor growth and utilization efficiency. Cassava root meal is also deficient in essential fatty acids (Raimondi *et al*., 1983). It has been demonstrated that satisfactory feed intake and live weight gain was achieved when pigs were fed ad-libitum on freshly chopped cassava and different protein supplements (Hector, 2000). Cassava can fully replace cereal in pig diet without any negative effect when the diets are properly balanced. Further studies with pigs by Hector (2000) showed that cassava-based diet were clearly superior to wheat, barley and corn in terms of live weight gain, feed efficiency and bio-economics of production. To overcome cyanide toxicity in pigs sun-dried cassava meal-based diet was confirmed to be better than fresh root tubers. However, cassava based ration presented in mash were generally disliked by pigs. Pelleted cassava diets were more readily accepted by pigs than the conventional corn based diets. However, due to low protein content of cassava root relative to that contained in maize grain, replacement of dietary maize with cassava usually results in wide protein deficits in such diets. Thus, the enhancement of cassava root meal protein allows its favourable comparison with maize grain on qualitative basis (Ikurior and Akem, 1998).

Cassava Leaf/Foliage: is another new emerging protein source for livestock. The green nature of cassava leaf suggests it for better source of protein, vitamins and minerals. It is possible to obtain from cassava leaves more than 6 tons of crude protein per hectare a year with the proper agronomic practices directed towards foliage harvesting (Huy et al., 1995). The total essential amino acid content of cassava leaf protein is similar to that found in hen’s egg and is greater than that in oat and rice grain, soybean seed, and spinarch leaf, while the vitamin content of the leaves is high. Cassava leaves are rich in protein. According to Rogers and Milner (1983) the amount of protein (dry basis) ranges from 17.8 to 34.8 percent. It is important to note that when cassava leaves are sun-cured or dehydrated, most of the HCN is liberated and no toxic effects are therefore found when the leaves are consumed by animals. Cassava leaves therefore could be used as a source of protein for livestock in the tropics. Gomez et al., (1986) showed that broiler can tolerate a level of 15% cassava leaf meal without negative effect on their growth. According to Ranvindran (1991) nitrogen balance in growing pigs fed a cassava root meal diet is unaffected when cassava leaf meal replaces up to 35% of the protein from soybean meal.

CONCLUSION

It has established that cassava products possesses enormous potentials for use in replacement of the scarce and high priced maize in production of livestock feeds. This fact promises increased production of livestock, and by extension increased availability and consumption of animal protein if employed into use. Through this, cassava products could also contribute significantly to the protein of Nigerians thereby enhancing both household and national food security.

ABSTRACT

Cocoyam tubers were selected from those harvested from the experimental fields of NRCRI (National Root Crops Research Institute), Umudike. The cocoyam was processed into flour. Then the three groups of cocoyam; The processed Tecto-40EC treated cocoyam, the processed Benomyl treated cocoyam and the processed non - treated cocoyam flour were used to compound feed according to the standard technique and a selected commercial feed was used to compare the outcome. 36 day-old broiler chicks were divided into four groups and used for the experiment. The packed cell volume of the birds of the two controls, CC (non treated cocoyam diet) and Com.F (commercial feed diet) present a comparable result statistically 36.3% and 34.7% respectively. Whereas the CC group gave a better result generally than the Com.F group. Although there is a slight significance across the packed cell volume 40.0% and 37.7% respectively and the red blood cell indices (Mean corpuscular value, MCV) of the Benomyl treated cocoyam-based diet (CB) and Tecto-40EC treated cocoyam-based diet (CT), the result (90.0fl and 90.7fl respectively) compared favourably for the two control groups. When compared across the groups, the red blood cell indices are normocytic normochromic. Pre-treatment of cocoyam before planting to avoid pest and diseases did not present any adverse effect on the haemogram and blood biochemistry of the chickens fed cocoyam-based diet. This could be due to the drying methods used. Hence, pre-treatment prior to planting of cocoyam should be practiced. Supplementation of cocoyam flour in chicken feed can reduce cost of feed and increase the profit of the farmers. This is especially valuable to explore further in the supplementation of chicken feed in the advent of rising cost of maize used for feed formulation. This findings further confirms that cocoyam is rich in nutrients and can be of value in small household and in poultry

Key words: chicken, haemogram, cocoyam and blood biochemistry.

INTRODUCTION

Colacasia esculenta (L). Schott (cocoyam) is a perennial tropical plant primarily grown as a root vegetable for its edible, starchy corms. The plant has rhizomes of different shapes/sizes and is widely naturalized. The tubers are peeled, dried and ground into floor for pastry that can be stuffed with meat or other fillings. Thus, some varieties of this tuber crops can provide a substantial contribution to nutritional requirements, not only for energy but also for protein and minerals (Adelekan, 2012).

Feed alone accounts for 70% in livestock production. In Nigeria today, the cost of maize which constitutes the bulk energy source for livestock feed continues to soar high, making the cost of feed in the market to as well rise hence, the need for other alternatives. Such alternatives therefore include cocoyam root, peel and leaf meal. Cocoyam is a tuberous root that serves primarily as a source of carbohydrate and can completely replace maize as an energy source in feeds for poultry and other livestock.

In the planting of this root crop, many times there are incidences of fungal attack on the crop. This affects the yield of this root crop hence, the use of various fungicides to improve the yield. The objectives of this study were; to ascertain if the pretreatment of the cocoyam with two types of fungicide will negatively affect the haematology of chicken fed such pretreated cocoyam-based diet, to ascertain if the pretreatment of the cocoyam with two types of fungicide will negatively affect the serum biochemistry of chicken fed such pretreated cocoyam-based diet, to compare the effect with non – treated cocoyam based diet vis a vis a selected commercial feed.

MATERIALS AND METHODS

Sample collection and Preparation: Cocoyam tubers were selected from those harvested from the experimental fields of NRCRI, Umudike at 9 months after planting. The tubers were hand peeled using stainless steel knife, washed thoroughly and sliced into tiny pieces. The sliced samples were placed on a stainless steel tray and sun-dried for 5 days. The dried chips were grinded using a Warren blender to convert into flour. Then the flour was placed in polythene bags, packed and kept in desiccators until analysed for contents of proximate, minerals and anti-nutritional factors.

Then the three groups of cocoyam; the processed Tecto-40EC treated cocoyam, the processed Benomyl treated cocoyam and the processed non - treated cocoyam flour were used to compound feed according to the standard technique. Then a selected commercial feed was procured to make it four groups. 36 day - old broiler chicks were procured, stabilized for three weeks and afterwards divided into four groups were subjected to the experiment.

Determination of Proximate and Mineral Composition: Proximate compositions (total moisture content, crude fat, crude protein, crude fibre, ash, total carbohydrate and gross energy values) as well as the mineral compositions were determined using the procedures described by the Association of Official Analytical Chemists (AOAC, 2005). Analyses of the anti-nutritional factors were carried out by the method described Fana et al, 2015.

Statistical Analysis: A comparative analysis was conducted to prevent the difference in proximate compositions, mineral contents and antinutritional factors of the Benomyl and Tecto-40 EC treated and non-treated samples. The analyses of the haematology and serum biochemistry were performed using SPSS Version 23. Difference in means at $P \leq 0.05$ was considered significant. The data obtained from the study were summarized and represented as means=±SD. Statistical analysis of the treatment groups were made using statistical package for social sciences (SPSS).

RESULT AND DISCUSSION

Table 1: HAEMATOLOGY OF BROILERS AT DAY 21

GROUP	RBCx10^6	PCV (%)	HB (g/dl)	WBCx10^3	PLATELET	MCV (fl)	MCH (pg)	MCHC (g/dl)

NS=Not significant, CB=Benomyl treated cocoyam based meal, CC= Non treated cocoyam based meal, CT= Tecto-40 EC treated cocoyam based meal, COM.F= commercial feed.

BLOOD BIOCHEMISTRY OF BROILERS AT DAY 21

Total cholesterol is similar among CB, CC and CT but significantly lower in Com.F. HDL is similar between CB and CT but significantly higher to CC. Groups CB, CC and CT were significantly higher to com.F. TAG is significantly difference across the groups. Total protein is significantly higher in CB than the rest of the groups which were similar. (Table 3). AST is similar among CB, CC and CT but were significantly lower to Com.F. ALT had no significant difference. In ALP, CB is similar to CT, CC is similar to CT but CB, CC and CT were significantly lower to Com.F. The LDL value of CB and CT are similar, CC is significantly lower to CB, CT and Com.F while Com.F is significantly higher to CB, CC and CT. In VLDL there is significant difference across the four groups. (Table 3).

Table 4: HAEMATOLOGY OF BROILERS AT DAY 42

GROUP	RBCx10^{6}	PCV (%)	HB (g/dl)	WBCx10^{3}	PLATELET	MCV (fl)	MCH (pg)	MCHC (g/dl)
CB	4.4±0.0^{a}	40.0±1.0^{a}	10.6±0.1^{a}	36.0±0.7^{NS}	116.7±1.5^{a}	90.7±0.0^{a}	24.1±0.0^{a}	26.5±0.0a

BLOOD BIOCHEMISTRY OF BROILERS AT DAY 42

Total cholesterol has significant difference across the groups. CC is highest followed by CB, CT and Com.F in that order. HDL has significant difference across the groups. CC is highest, CB, CT and Com.F in that order. In TAG, CB, CC and CT are similar and significantly higher to Com.F. Total protein of CC is significantly higher to CB and both are significantly higher to CT and Com.F. (Table 6). AST of CB, CC and Com.F are similar and are significantly higher to CT. ALT across the groups are similar. ALP of CB and CT are similar and significantly higher to CC and Com.F. CC is significantly higher than Com.F. LDL of CB, CC and CT were similar and significantly higher than Com.F. VLDL is significantly different across the groups. CC is the highest, followed by CB, CT and Com.F in that order. (Table 6).

RESULT AND DISCUSSION

The 21st day haematology of the birds of the two controls, CC (non treated cocoyam diet) and Com.F (commercial feed diet) present a comparable results. Whereas the CC group gave a better result generally than the Com.F group (Table 1). This is especially valuable to explore further in the supplementation of chicken feed in the advent of rising cost of maize used for feed formulation. This findings further confirms that cocoyam is rich in other nutrients not just energy source (given the result) and can be of value in small household and in poultry. This agrees with the findings of Nwankwo, (2021) but contrasted with Adelekan, (2012) who noted in his work that cocoyam is an energy rich food.

Although there is a slight significance across the haemogram and the red blood cell indices of the Benomyl treated cocoyam-based diet (CC) and Tecto-40EC treated cocoyam-based diet (CT), especially in the RBC, PCV, HB, MCV, MCH and MCHC, the result compared favourably to the two controlled groups. When compared across the groups, with the controls, the red blood cell indices are normocytic normochromic. (McGill, 2016., Sharma, 1990 and Bessman, et al 1983).

We therefore states that the pre-treatment of cocoyam before planting did not adversely affect the PCV and Hb of the chickens in this experiment (Onibi., 2011). The WBC across the groups did show leukocytosis. This is further confirmed in the WBC differential of the 21st day blood picture (Table 2). (Orawan and Aengwanich, 2007). The 21st day of age biochemical parameters across the groups significantly differed slightly. However, the total cholesterol of the three cocoyam-based diet (CB, CC and CT) gave a higher value that was significant compared to Com.F. This is of immerse health benefit in chicken feed and indirectly to human's health. Across the groups LDL, low density lipoprotein (bad fat) were similar indicating that the four diet were good in this area. The VLDL, very low density lipoprotein (very bad fat) was lowest in Com. F compared to the other groups. Although all values were within the normal range. This area may need further studies/ investigation by our breeders/ biotechnologists. Other parameters across the groups were similar. Lipoproteins are a combination of proteins and fats found in the blood of mammals. They are categorized based on their density. Very low-density lipoprotein is regarded as bad cholesterol. VLDL and LDL are generally considered more harmful than high density lipoprotein (HDL). (Jeffrey, W., 2021).

The 42nd day haemogram (Table 4), RBC indices were essentially similar and within the normal range hence were normocytic normochromic. CC group gave the lowest platelet counts compared to other groups. However, the value falls within the normal range. The WBC across the groups were not significantly different, indicating that there was a normal playing ground across the group. The RBC, PCV and HB across the groups were slightly different. (Onibi., 2011). In day 42nd day blood biochemistry (Table 6), the biochemical parameters showed significance in the TC across the four groups and com. F was the least. The HDL, high density lipoprotein (good fat) of the three cocoyam-based diets gave slightly higher value compared to Com.F diet. This is an advantage for the cocoyam-based diets. The VLDL, very low density lipoprotein (bad fat) had the CB, CC and CT groups slightly higher than Com. F. This trait need to be further investigated and genetically re-engineered to improve the make-up of the cocoyam based diets. Other biochemical parameters across the groups were similar.

CONCLUSION AND RECOMMENDATION

Pre-treatment of cocoyam before planting to avoid pest and diseases did not present any adverse effect on the haemogram and blood biochemistry of the chickens fed cocoyam-based diet. This could be due to the drying methods used. This agrees with earlier worker, (Fana, et al., 2015). Hence, pre-treatment prior to planting of cocoyam should be practiced. Supplementation of cocoyam flour in chicken feed can reduce cost of feed and increase the profit of the farmers

ABSTRACT

The concern of selective picking of non-conventional feedstuffs by goat has necessitated the need for pelleting the feedstuffs mixture for indiscriminate intake and performance. Hence, twelve growing goats of similar weight range from 5 to 6 g were used to determine the effect of pelleting graded level of rice bran n cassava peels based diet for goat performance and blood evaluation. Four diets were formulated; diet 1 contained 0% rice bran and 100% dried cassava peel, diet 2 contained 15% rice bran and 85% dried cassava peel, diet 3 contained 25% rice bran and 75% dried cassava peel, and diet 4 contained 35% rice bran and 65% dried cassava peel. A total of twelve (12) West African Dwarf goats were randomly allocated to the four diets, with three animals per diet, each serving as a replica. The parameters assessed were feed intake, water intake, weight gain, feed conversion efficiency, and blood hematology and serum biochemistry such as parked cell volume (PCV), white blood cell (WBC), red blood cell (RBC), Hemoglobin (HB), total protein (TP), albumin (ALB), globumin (GLOB), alanine aminotransferase (ALT), alaline phosphatase (ALT), aspartate aminotransferase (AST), cholesterol (CHOL), creatinine (CRET. The results showed that pelleting rice bran with cassava peel n goat diet generally enhance rice bran intake and utilization. The intake of rice bran increased (p.0.05) increased as rice bran inclusion increased from diet 1 to 4. Total feed intake reduced (p>0.05) with least value (15.17kg) obtained on diet diet 4. However, total weight gain, average weight gain increased (p>0.05) with increased rice bran inclusion in the det. The value ranges from 0.33 to 1.17 for weight gain and 0.005 t0 0.017kg for average weight gain respectively. The feed conversion ratio increased (p>0.05) with increased rice bran n pelleted diet. Animals on Diet 4 showed lowest value (12.98) that indicated highest efficiency. Animals on det 4 recorded highest PCV value (31.67) but similar to value from animal maintained on diet 3. RBC and HB were similar (p>0.05) for all treated groups and WBC values were comparable (p>0.05) but those on diet 1 had least value (9.23). Serum biochemistry responses of goat fed indicated comparable values (p>0.05) as rice bran inclusion increased. The values of TP and ALT indicated similarity for all treated animal groups and animals maintained on diets 3 and 4 that contained high grade levels of rice bran displayed similarity (p>0.05). Pelleting of rice bran with cassava peels improved consumption and

conversion ratio and thereby enhancing the performance of growing goats and thus proved its efficacy up to 35% inclusion.

Key words: Pelleting; Race bran; cassava peel; heamatology, serum; weight gain; growing WAD goat.

INTRODUCTION

Goats are among the relatively few ruminant species in the animal realm. They only have five (5) basic dietary requirements: crude protein, energy (in the form of fiber), fat, and water-soluble vitamins and minerals is required because concentrated ingredients like maize are food for humans (Morais et al., 2020). According to (Kalio et al., 2018), even while forage crops provide for superior ruminant feed, they are not always accessible. As a result, these NCFRs are fed to the animals in their place. In this environment, goats have a diverse diet that includes many non-conventional feedstuffs. Given that goats are very selective feeders and switch from a diet that consists mostly of forbs (8–64%) to browse (35–88%), it is thought that this may also apply to concentrates (Mellado., 2016). The eating habits of these dwarf goats are typical of the local husbandry method in which they scrounge for food to satisfy their daily nutritional needs (Daramola et al., 2005). But since there isn't nearly enough green vegetation for these natural browsers, particularly during the dry season, attempts s been undertaken to encourage goats in this ecozone to consume the abundant non-conventional feedstuffs such as rice bran that are always present. The shortage of good quality feeds to sustain ruminant animals during dry season has being a challenge to the ruminant production as reported by Ososanya, et al., 2013. On this note, a feeding strategy is required to gear up the consumption of inexpensive, unpalatable and readily available feed resources in the mixture without selection. Rice bran which stand better chance of effective and efficient utilization during feed scarcity because of the availably and storability. Hence, the focus of this study s to assess the effectiveness of pelleting technique on intake and performance of growing goats fed rice bran n pelleted cassava based det.

MATERIALS AND METHODS

Study location

The location of this study was the sheep and goat unit of Teaching and Research Farm, Landmark University, Omu –Aran, Kwara State, Nigeria. The coordinates of Omu-Aran are Latitude 8.9N and Longitude 50.61E and is on approximate altitude of 306above sea level. The temperature is uniformly high and range between 250^{0}C and 300^{0}C in the wet season and between 330^{0}C and 340^{0}Cin dry season. The relative humidity is 75 to 80% in the wet season and about 65% in dry season.

Experimental diet

Mechanical grinder was used to grind dry cassava peel to sizes. The four formulated diets used in this study were formed by replacing the proportion of grinded cassava peels with rice bran, mixed thoroughly with hand and pelleted using mechanical pelletizer of die 8mm size thus; Pelleted diet 1 contained 100% cassava peel and 0% Rice bran; The pelleted diets 2, 3 and 4 contained 15, 25 and 35% rice bran respectively that replace equivalent proportion of cassava peel. (Table 1) Equal measured quantity of feed additives were added to each of the 4 diets prior mixing and each diet had molasses that served as binding agent as well enhancer of the energy.

Table 1: The composition of pelleted diet

Ingredient	Diet 1	Diet 2	Diet 3	Diet 4
dried cassava peel(kg)	100	85	75	65
Rice bran(kg)	0	15	25	35
Total	**100**	**100**	**100**	**100**
Constant additives				
Molasses (kg)	5	5	5	5
bone meal (kg)	1	1	1	1
Salt (kg)	0.25	0.25	0.25	0.25
Vitamin premix	0.25	0.25	0.25	0.25

Experimental animals and management

A total of 12 growing WAD goats were used. The growing goat aged 5 to 6 with initial average weight of 6kg. Each treatment comprised three replicates. Animals were treated with ivermectin subcutaneously against both ecto and endo parasites. Long acting injectable oxytetraycline was intramuscularly administered against bacterial infections before the commencement of the trial. The weight of the animals were taken before the takeoff of the trial to established the initial body weight and thereafter they were weighed weekly through the trial period. Experimental diets were served once daily at 8.00 hours in cleaned feed trough at 5% body weight on dry matter basis through the seventy (70) days of the experiment that included first 7 day adjustment period. Clean water and salt licks were also made available throughout the study time. Parameters assessed include; body weight, feed intake and feed conversion efficiency. Feed efficiency was calculated by dividing the feed intake by weight gain

Haemmtology and serum biochemical indices analyses

The blood was evaluated at the end of the trial. Two animals per dietary treatment were randomly picked for blood sample collection. 10mls of blood sample was collected via jugular venipuncture using 20 gauge needle and syringe on the final day of a ten-week experimental study. Each blood collection was divided to 2 lots; one part was transferred to Ethylene Diamine Tetracetic Acid (EDTA) bottles that contained anticoagulant for haematological assay (jain 1986) and other part free bottles that contain no anticoagulant for serum assessment. The samples were taken to university of Ilorin Central Laboratory where it was analyzed according to available clinical methods. Packed cell volume (PCV), Haematoglobin (HB), RBC, WBC, Mean corpuscular volume (MCV), Mean corpuscular haemoglobin concentration (MCHC), Cholesterol, Albumin, Total protein, Globulin WBC differentials; Monocytes, Neutrophils among others were assessed. The PCV was determined with wintrobe haematocrit method, Wintrobe (1993). WBC and RBC were determined using haemocytometer after the necessary dilution (Dacie and Lewis, 1994). Haemoglobin, Mean corpuscular volume (Brown . 1976). Cholestero was measured (Roshlan SIGMA Kits (Feteris, 1965).

Statistical analysis

Dara obtained were subjected analysis of variance with SAS General model (2000) and means were separated at p>0.05 using New Duncam Multiple range test (Obi, 2002)

RESULTS

Table 2: Proximate composition of experimental diets

	0%rice bran (Diet1)	15% rice bran (Diet2)	25% rice bran (Diet3)	35% rice bran (Diet4)	SEM ±
DM (%)	92.50^{a}	91.33^{a}	92.43^{a}		0.56
MC (%)	7.50^{a}	8.67^{a}	7.57^{a}	7.89^{a}	0.02
CP (%)	0.27^{c}	4.41^{ab}	5.11^{a}	4.91^{b}	0.58
EE (%)	4.50^{b}	2.40^{c}	6.0^{a}	5.24^{ab}	0.43
CF (%)	7.50^{ab}	8.46^{b}	9.01^{a}	9.50^{a}	2.24
ASH (%)	5.30^{b}	6.93^{a}	4.44^{bc}	3.49^{c}	0.41
NFE (%)	61.37^{c}	69.38^{b}	71.47^{b}	78.39^{a}	1.90

a,b= Means in the same row having different superscript differs significantly (P< 0.05).
DM-Dry matter, MC-Moisture content, CP- Crude protein, EE-Ether extract, CF- Crude fibre, ASH- Ash, NFE- Nitrogen free extract.

The proximate composition of the feed utilized is shown in Table 2. The DM mean values of the feed was similar across treatments. The CP mean value of diet 3 is higher and different(P<0.05) among the treatment means, but comparable (p>0.05) to CP value of diet 4 while the MC mean value increased with the addition of rice bran in the pelleted diet compared to diet 1, which contained no rice bran but value were similar (p>0.05). The fat mean value of diet 3 was the highest among the treatments and significantly different (P<0.05s) but comparable (p>0.05) to the mean value of diet 4. However more fat was recorded as rice bran inclusion increased in the diets. The highest crude fibre was recorded in diet 4 (35% rice bran inclusion ration} but the values across the treatment were comparable (p>0.05)

Table 3: performance of growing WAD goats fed pelleted rice bran-dried cassava peel diet

Parameters	DIET1	DIET2	DIET3	DIE 4	SEM±
Total feed intake (kg)	19.93^{a}	20.55^{a}	14.93^{b}	15.17^{b}	0.86
Average daily feed intake	0.28^{a}	0.29^{a}	0.21^{b}	0.22^{b}	0.01
Total water intake(ml)	22516.7b	27066.65b	31850ab	31616.70a	118.60

Daily water intake (ml)	2251.67b	2706.67b	3185ab	3161.67a	10.60
total weight gain(kg)	0.33[a]	0.67[a]	0.67[a]	1.17[a]	0.17
Average daily weight gain (kg)	0.005[a]	0.010[a]	0.010[a]	0.017[a]	0
feed conversion ratio	60.39[a]	30.67[b]	22.28[bc]	12.98[b]	6.18

a,b= Means in the same row having different superscript differs significantly (P< 0.05)

Table 3 shows the performance of the growing WAD goats fed graded levels of rice bran in pelleted dried cassava diets. The total feed intake mean value followed the same trend with FCR. The values decreased as rice bran inclusion increased comparable (p>0.05) for diet 3 and 4 mean values were equally similar (p>0.05). The water intake mean value of diet 4 was significantly different (p<0.05) among the treatment means but comparable to the mean values of diet 3.Total water intake of diet 1 and 2 were similar (p>0.05) and were comparable to the mean value of diet 3 weekly water intake and daily water intake mean followed the same trend.

Table 4: **EFFECTS OF DIFFERENT LEVELS OF THE RICE BRAN IN THE CASSAVA-RICE BRAN PELLETED RATION ON THE BLOOD**

Parameters	DIET1	DIET2	DIET3	DIET4	SEM ±
PCV (%)	26[ab]	21.33[b]	30.33[a]	31.67[a]	1.60
WBC (X109/L)	9.23[b]	10.40[a]	9.37[b]	9.8[ab]	0.16
RBC (X1012/L)	2.7	2.33	2.6	2.74	0.69
HB (g/L)	29.33	24.40	24.77	27.30	1.40
PLAT (X109/L)	180.67	181	183.33	179.67	1.51
MCV (fl)	10.13	9.47	10.33	10.17	0.20
MCH (pg)	10.44[a]	7.79[b]	10.01[a]	10.57[a]	0.36
MCHC (g/dl)	10.63[a]	9.4[c]	10.06[b]	10.33[ab]	0.15
LYMPH(%)	44.67	43	43	40.67	0.93

MONOCY(%)	0	0	0	0	0
EOSIN(%)	0	0.33	0.33	0.33	0.13
BASO(%)	0.33	0	0	0.33	0.11

a,b= Means in the same row having different superscript differs significantly (P< 0.05)

Legend: PCV= Packed cell volume, HB= haemoglobin, MCH= mean corpuscular haemoglobin, MCHC= mean corpuscular haemoglobin concentration, MCV= mean corpuscular volume, RBC= red blood cell, WBC= white blood cell, NUET= Neutrophils, LYMPH=. Lymphocyte,PLAT=platelets

Table 4, it shows the haematology parameters evaluated, the PCV mean values of diets 4 and 3 are similar (P>0.05) while the means of diet 2 was significantly different (P<0.05) among the treatments. The PCV mean value increased with increased rice bran in the pelleted ration. However, the values obtained (21.3-31.7) fall within the range reported by (Charles Magi 2007). The RBC values for all treatments shows no significant difference (P>0.05) and the mean value increased as rice bran increased in the pelleted ration. However, the values that range between (2.33-2.7) obtained in this research were higher than value reported by Daramola *et al.,* 2005 for healthy goat. The Haemoglobin (Hb) result followed the same trend as RBC. The mean value increased as the rice bran increased in the pelleted ration. The Hb obtained values in this study (2.4-29.3) were higher than (11.88-12.20) reported by (Odoemelen, 2014) for healthy goats Concern the WBC, the mean values indicates reduction as the rice bran increased in the pelleted ration, However, there was observable similarity (P>0.05) means of diets 1, 2 and 3 without any observable harmful nutritional effect on the status of the animals treated animals. The MCV mean values increased as the rice bran increased in the diet, however, the mean values are similar (P>0.05). The MCH mean values increased as the rice bran increased in the pelleted ration but the mean value of diet 1 (dried cassava peel only), diet 3 and 4 were similar (P>0.05) .The MCHC also increased as the rice bran increased in the pelleted ration but diet 3 and 4 mean values were comparable.

Table 5: EFFECTS OF DIFFERENT LEVELS OF THE RICE BRAN IN THE CASSAVA-RICE BRAN PELLETED RATION ON THE BIOCHEMICAL INDICES

Parameters	DIET1	DIET2	DIET3	DIET4	SEM ±
TP (G/L)	33.67	34.33	40	40	1.38
Alb (G/L)	18.67^{b}	21.93^{ab}	24.33^{a}	22.43^{ab}	0.8
Glob (G/L)	16.33^{ab}	14.10^{ab}	17.70^{a}	13.83^{b}	0.68
Creat (µMOL/L)	27^{b}	31^{ab}	33.33^{a}	32.33^{a}	0.98
Chol (MMOL/L)	1.65^{a}	1.56^{ab}	1.38^{b}	1.45^{b}	0.39
ALP (IU/L)	235.67^{ab}	231.67^{b}	246.67^{a}	249.33^{a}	2.90
AST (IU/L)	67.87^{a}	58.87^{ab}	48.47^{b}	52.43^{b}	2.87
ALT (IU/L)	20.33	67.73	13.5	12.23	12.46

^{a,b}= Means in the same row having different superscript differs significantly (P< 0.05)

Legend: CHOL= Cholesterol, CRT= Creatine, TP= Total protein, GLOB= Globulin, ALB= Albumin ALP=Alkaline Phosphate, AST= Aspartate Aminotransferase ALT= Alanine Transaminase

Table 5, shows the result of biochemical indices of goat treated; the total protein mean values indicates no significant difference (P>0.05), but the value increased as rice bran increased in the pelleted ration. The result also shows that all animals responded equally. The Albumin means showed that diet 3 is significantly different (P<0.05) from the mean value of diet 1. However, diet

3 mean is comparable with diet 2 and 4.The result also shows increase in the mean values of the albumin as the rice bran in the diet increases in the pelleted ration. The Globulin mean values increased from diet 3 to 4 but indicates significantly different (P>0.05), however they are comparable (p>0.05) to mean values of diets 1 and 2. Creatinine mean values for diet 3 and 4 are similar (P> 0.05) but value of diet 1 is significantly different (P>0.05) from values of diet 3 and 4 and comparable to values from diet 2. As reported by (Rahardja *et al.*, 2000) Goats have a clear relationship between body weight and the total amount of creatinine in their blood and urine. The ALP mean values increased as the rice bran in the pelleted diet increased, however the mean values of diet 3 and 4 were similar(P>0.05), while diet 2 is significantly different (P>0.05) from diet 3 and 4, but diet 1 is comparable (p>0.05) to diets 2,3 and 4.

DISCUSSION

Tables 1 and 2 shows the composition and nutrient composition of the experimental diets respectively. Cassava peel could be taken to represent the array of low protein and low energy crop residues as reflected in the calculated NFE obtained value of 61.37% for diet 1(pelleted cassava peel only) and 78.39% for diet 4 (diet that contained 35% rice bran in pelleted dried cassava peels used-this study contained 0.27%CP and 4.50%EE with a calculated NFE of 61.37%). These values fall within earlier reported ranges (Asaolu and Odeyinka, 2006). However, Norton (1994) reported that feeds containing less than 8% CP could not provide the ammonia levels required by rumen microbes for optimum activity. (Yousef *et al.*, 2007) opined that relatively high ADF but low EE and CP content were suggestive of low nutritional quality. In this study ,the nutrient content of all the pelleted experimental diets (2-4) increased with the addition of rice bran in the pelleted ration, and these results were in agreement with earlier reports (Asaolu and Odeyinka, 2006; Asaolu *et al.*, 2010). The CP of pellet rations was lower than the 8% level required for optimum microbial activity (Norton, 1994). If the values are also lower than the 11% to 13% known to be capable of supplying adequate protein for maintenance and moderate growth in goats (NRC 1981). However, the results indicated improvement in the nutrient availability for the experimental as the rice bran increased in the ration, which in turn was reflected in the increased feed intake and moderate weight gains. (Fredric N. Owens and Robert B. Hicks, 2019) narrated in their book that if a growing animal is provided with insufficient protein, the efficiency with which the animal will utilize metabolizable energy will probably be altered. This is what was observed and noticed as the rice bran inclusion in the pelleted diet increased. The noticed improvement in the feed intake, water intake, and weight gain by the animal fed with these pelleted rice bran in dried cassava peel diet is suggestive of the suitability of pelleting of rice bran in a dried cassava peel based diet for growing goats. All the experimental animals had adequate total feed intake. There was also an observed variation in the total feed intake with increasing rice bran in the pelleted ration. The lowest level of intake (15.17kg) of the animal in diet 4 may be due to the fact that the feed value for ruminants lies in its palatability. The variation observed may also have been due to the CP level of the diet, as indicated in the report by Mtenga & Shoo, 1990), which states a positive correlation between crude protein intake and dry matter intake . The experimental goats in this study gained weight as rice bran increased in the pelleted diet. This observation was translated to an improvement in the final weight gain of the animal, probably as a result of the duration of the study (10 weeks). Although the values obtained in this study were lower compared to the values reported by authors like (Babayemi *et al.*, 2006, and Odeyinka, 2001). However, the observed difference in weight gain with earlier studies could have been due to differences in the basal components of the diet, voluntary dry matter intake, feed intake, efficiency of feed utilization and the physiological state of the animal with increasing rice bran inclusion. Animals in diet 4 (35% rice bran inclusion) were indicated to be more efficient in converting feed to weight gain than those on less bran inclusion (diet 1-3).An earlier similar observation was reported (Tripathi *et al.*, 2006) between growth and feed conversion. The observed increased weight gain as rice bran increased could further be attributed to the better quality protein available in the nutrition. The increase in PCV, RBC AND the Hb as the inclusion percentage of rice bran increased in the dried cassava pelleted diets, can be compared to the literature value showing the animals used for the study may not be prone to anemia. The high concentration of RBC and haemoglobin values obtained across these treatments, indicated the absence of toxic factors such as haemoglobin which has adverse effects on the blood formation as proved by (Akinmutimi 2004)for some exotic goats. The MCV and MCH values obtained in this study were comparable to 5-8pg for MCH and 16-25fl for MCV reported by (Charles Magi 2007). The mean value of RBC increased as the rice bran increased in the diets, this could be as a result of good ratio of haemoglobin to the PCV since both haemoglobin and PCV were higher than the PCV (21-38%) reported by (Charles Magi 2007), and 7-15g/dl and 11.88 – 12 g/dl for Haemoglobin reported by (Daramola,*et al*., 2005). The mean values of creatinine increased as the rice bran increased in the pelleted ration and which indicated similarity value statistically was a reflection of good protein quality resulted from the pelleted rations as reported by (Aletor *et al*., 1998). The reduction in creatinine values as the rice bran increased in the diets reflected the ration quality and proved that the tested animals were not prone to muscular wastage. (Aletor *et al.,* 1998).

CONCLUSION

The pelleting technique as undertaken in this study resulted in an adequate intake of rice bran without indiscriminate selective feeding of the feedstuff. The pelleting predicted the adequate utilization of the rice bran by the growing WAD goat through weight gain and no deterioration health effect on the animal fed. The observed feed conversion efficiency and increased CP level with increased rice bran shows that pelleting technique will be better employed when feeding feedstuff of lesser palatability to goats.

RECOMMENDATION

The ration did not show any negative impact on the goat's development. It is therefore recommended that further inclusion level of rice bran above 35% inclusion level in pelleted dried cassava peel should be carried out to establish an acceptable limit for growing WAD goat performance.

PROCEEDINGS
56th Annual Conference
Agricultural Society of Nigeria
24 - 28 Oct., 2022

ABSTRACT

Poultry production in the rural areas is faced with a number of constraints such as high prevalence of poultry diseases, inadequate supply of vaccines and medicines which on the long run result in low productivity and reduced profitability. This study examined poultry disease control among rural small holder poultry farmers. A total of 240 respondents were interviewed, and of these, 59.4% were female and 40.6% were male. The highest source of livelihood was 41%, poultry keeping accounts for 12%. The most observable symptoms of disease outbreak were bloody, greenish and whitish diarrhea (30.2%), coughing and sneezing was 14.9%, while nasal discharge took 11.4%. Swelling of head, comb and eyes was18.1%, 25.4% was reported for the twisting of head and neck. 60.2% of the respondents depend on the existence and usage of traditional medicines to treat outbreak and prevent spread of disease. A shift from the traditional ways of treating poultry diseases to use of vaccines and medicines will increase productivity and profitability.

INTRODUCTION

The early poultry production was rudimentary and characterized by small number of birds per household, usually kept for special occasions (Chaiban, 2021). None of such household poultry production units can be described as a commercial entity. Small-scale poultry production systems are mostly found in rural, resource-poor areas that often also experience food insecurity (Kelvin *et al*., 2021), such rudimentary rural production still accounts for over 90% of chickens produced in many developing countries (Mujyambere *et al.*, 2022). The extensive poultry production system is the most commonly found in rural areas, and usually involves indigenous chicken genotypes. Poultry production in the rural areas is faced with a number of constraints which on the long run result in low productivity and reduced profitability. Productivity of village chicken is low and is hampered by problems of feed shortage, low chick survival rate, transportation, weather change, poor extension services, high prevalence of poultry diseases, inadequate supply of vaccines and medicines and lack of good housing management (Ola-Fadunsin *et al*., 2019). Village chicken production is dominated by indigenous chickens that exhibit remarkable adaptation to local environment; rural poultry production plays a vital role in the growing economy of the rural populace. It provides livelihood security to households in addition to securing the availability of food (Andrette *et al*., 2021). However, Disease outbreak is a major concern in rural poultry production and has a negative effect on production. Hence, efforts are therefore needed from all rural poultry farmers for prompt and active treatment of chicken geared towards improving the rate of production of egg and meat of village chicken.

MATERIALS AND METHODS

Four villages from Kwara South Senatorial District were randomly selected with sixty (60) respondents per village, a total of two hundred and forty (240) respondents were used for this study and the names of the four villages selected are Edidi, Isanlu-Isin, Etan and Ajuba. Data were collected by a trained enumerator that could translate the structured questionnaires into local language for low level illiteracy respondents. Due to poor internet availability in the selected areas paper questionnaires were used. The data collected included household characteristics, source of livelihood, observable symptoms during disease outbreak and steps taken to prevent the spread of diseases. Data collected from the respondents were collated and analyzed for most frequently selected answers by the small holder poultry farmers. Frequencies and percentages were reported.

RESULTS AND DISCUSSION

Table 1: Distribution of households' heads and other household characteristics

Gender of household heads	Percentage	Frequency
Male	61.9	148.56
Female	38.1	91.44
Gender of respondents in the household		
Male	40.6	97.44
Female	59.4	142.56
Age of household head		
20-29	1.9	4.56
30-39	9.7	23.28
40-49	13.5	32.40
50-59	29.9	71.76
60-69	29.7	71.72
70+	15.4	35.96
Education of household head		
None	37.0	88.80
Primary	25.4	60.96
Secondary	26.4	63.36
Tertiary	11.2	26.88
Relationship of survey respondent with household head		
Household head	61.1	146.64
Spouse	35.5	85.20
Other family members	3.4	8.16
Other non-family members	0.0	0.0

The household head is chiefly accountable for the cultural, social, nutritional and economic well-being of the household, the study showed that the male household head is higher than the female, men as household heads in the rural areas relative to women are at an advantaged position in the accessibility of society's economic resources and privileges. Men have easier access to lands due to paternal inheritance than women in Nigeria. Women who are household heads may be more independent and have more control over resources by virtue of their position than women who are not household heads (Saleemi and Kofol, 2020). As expected, most of the interviewed respondents were women (59.4 percent of women and 40.6 percent of men) this shows that women could be more involving than men in poultry keeping. The percentage of the age of household heads range of 50- 59 is similar to that of 60-69 an indication of economic empowerment age range of catering for the household members. The level of education of household head is a vital personal quality to make firm and strong decision on challenges of poultry production, 37% of the household heads were illiterate. Higher literacy level of household heads enhances the ability for information usage which will improve application of the knowledge to challenging situation of any poultry disease outbreak and combating the outbreak with the right treatment which will increase production, profitability and thus improve the nutritional status of the households (Chota *et al*., 2021).

Table 2: Distribution of households by source of livelihood

	Percentage	Frequency
Crop farming	41	98.4
Sheep/goat farming	7	16.8
Poultry keeping	12	28.8
Livestock product trading	0	0.0
Trading in non-livestock products	5	12
Formal salaried employment	9	21.6
Self-employed – trade	12	28.8
Self-employed- services	12	28.8
Fisherman	0	0.0
Old/retired	1	2.4
Others	1	2.4

The highest source of livelihood in the selected community is crop farming as shown in Table 2, which was 41% compare with other sources of livelihood this is in consonance with Okon *et al*., (2021), that reported that crop farming takes approximately 94% of Nigeria's agricultural sector. However, poultry keeping accounts for 12% this could be due to the challenge of disease outbreak of poultry production in the rural community (Herrero-Encinas *et al*., 2021). The village chickens are really vaccinated against poultry diseases; hence during the period of outbreak, the keepers are at the risk of losing the birds to the outbreak. The frequency for self- employed either in trade or in services were similar this due be due to advantages accrued to self-employment where the owner determine the schedule and control the work environment.

Table 3: Distribution of symptoms observed during disease outbreak among flock

	Percentage	Frequency
Diarrhea	30.2	72.48
Bloody, green & white		
Coughing & sneezing	14.9	35.76
Nasal discharges	11.4	27.36
Swelling	18.1	43.44
Head, comb& eyes		

Twisting Head & neck	25.4	60.96
Others	0.0	0.0

Poor protective resistance against diseases, unavailability of veterinary workers and low production are among several factors that challenge the future growth of the poultry industry (Hafez and Attia, 2020). The appearance of poultry feaces provides lots of information about the health or general wellbeing status of chickens. Bloody, greenish and whitish diarrhea was the most observable symptoms of disease outbreak (30.2%) among the poultry farmers. Diarrhea is characterized by the passage of frequent and soft or watery faeces, it is also known as watery bowel movements (Rivero-Perez *et al*., 2019). Diarrhea is a sign of many diseases in poultry and can be as a result of parasitic, bacterial, fungal, and viral infections. A whitish, chalky paste seen in the poultry's fecal droppings could be due to pullorum disease is a disease of poultry caused by the bacterium *Salmonella pullorum* of which mortality rate can reach 100% if the problem is not treated on time (Borda-Molina *et al*., 2018), whitish diarrhea is among the symptoms of infectious bursal disease. The clinical symptoms of coccidiosis include bloody diarrhea. Newcastle disease can cause greenish feaces in chickens, furthermore, fowl cholera is a disease caused by a bacterium called *Pasteurella multocida* which can also cause greenish faeces in chickens. Coughing and sneezing was 14.9%, while nasal discharge took 11.4%. Different ages of chickens and be infected and come down with signs of listless, sneezing, coughing and nasal discharge. Swelling of head, comb and eyes was18.1%, infectious coryza is a known acute respiratory disease of chickens characterized by reduced activity, sneezing, nasal discharge and facial swelling. Twisting of head and neck sign may be due to infectious, non-infectious and nutritional causes. 25.4% is reported for the twisting of head and neck. Newcastle disease is one of the most important and worldwide manifestation signs for torticollis.

Table 4: Distribution of steps taken to control the spread of diseases

	Percentage	Frequency
Treated by self with modern medicine	26.8	64.32
Treated by self with traditional medicine	60.2	144.48
Treated by veterinary practitioner	1.3	3.12
Slaughtered, process and consumed	4.3	10.32
Slaughtered, processed and gifted	3.1	7.44
Culled and sold the bird	4.3	10.32

60.2% of the respondents depend on the existence and usage of traditional medicines to treat the outbreak and prevent spread of disease. This could be due to high cost of conventional medicines and vaccines coupled with the lack of knowledge on their uses, these drugs are usually out of reach of the small-scale farmers. Treatment of poultry diseases may a burden to the rural household economy (Rist et al., 2015).

CONCLUSION

Good protective resistance against diseases such as the usage of vaccines, medicines and availability of veterinary workers should be adopted by rural poultry farmer for increased profitability.

INTRODUCTION

Background of the study

Poultry refers to a group of birds of particular species that are domesticated and raised for the production of eggs (chickens, guinea fowl, duck, quail, and geese), meat (chicken, turkey, quail, duck, and guinea fowl), and other uses like feathers (ostriches, peacocks), leather (ostriches), as pets (pigeons), as guardians (geese) (pigeons). Their production is one of the livestock production with significant contribution to human food (Sibhatu and Qaim, 2018). The hormonal balance in the body affects their growth, development and reproduction, the release of these hormones are used to mark the developmental stage of puberty and the entrance into the age of maturity in animals. This reproductive hormones released have many roles, it operates in the body using the negative feedback system, part of its function is that it induces the development of the reproductive organs and controls other secondary development into maturity, these are responsible for the sexual and reproductive behaviour leading to reproduction. The hormones include **testosterone, progesterone, follicle stimulating hormone, Luteinizing hormone, prolactin** and **oestrogen**, these hormones are all working interdependently, each affecting the other to cause stimulation of chemicals in the body.

Leutinising Hormone (LH)

Leutinizing Hormone (LH), a glycoprotein that controls gonad activity, is another gonadotrophic hormone generated in the pituitary gland by gonadotroph cells. It controls how well the ovaries and tesetes work. In men, it stimulates the laydig cells in the testes to produce and secrete testosterone, while in females, it stimulates the interna cells and lutal cells of the ovaries to produce oestrogen and progesterone, respectively. Luteinizing hormone concentrations rise during the female ovulation phase along with progesterone release and corpora lutea development. Gonadotroph Releasing Hormone (GnRH) secretions control the release of Luteinizing Hormone (LH).

Prolactin (PRL)

Prolactin is produced from the lactotroph cells in the anterior pituitary gland. This hormone has shown some degree of gonadal function in domestic animals and rodents. The brooding behaviors in birds and the metabolic changes during that period of brooding is as a result of the increased concentrations of prolactin in birds. Hypothalamus produces several neuro hormones that regulates the secretion of prolactin, this in turn affects prolactin concentrations. Among the neuro hormones secreted by the hypothalamus dopamine (or prolactin inhibitory hormone (PRL-IH)) is the most important because it inhibits the action of prolactin synthesis (Rastrelli et al., 2015).

Oestrogen

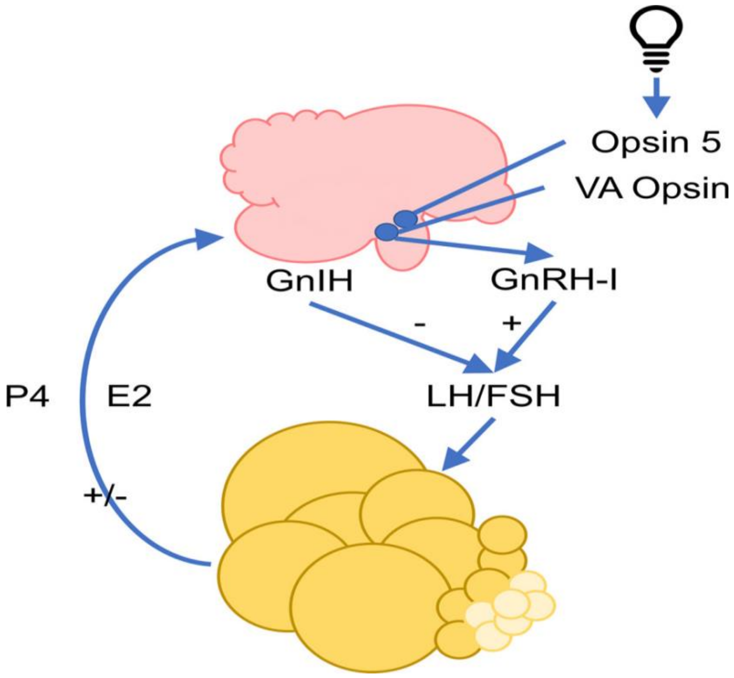
Oestrogen is a steroid hormone produced in the granulosa cells of the ovaries, it is also produced in males in the sertoli cells of the testes. This hormone is one of the main factors of reproductive development, is stimulates maturation and follicular growth, prepare the genitalia for copulation, induce Oestrus behaviour (heat) in females to help in mating processes, provide beneficial conditions to the development of fertilized egg cells, prepare the uterus for parturition and influences the growth of the mammary gland in mammals. Oestrogen have many roles on the influence of the female reproductive organs during maturation.

Progesterone (P_4)

The luteal cell in the ovaries produces the steroid hormone progesterone, which regulates body development and causes the female body to mature. The foundation molecule for it is a cholesterol molecule produced by the placenta and corpus luteum. This hormone gets the uterus ready to receive oozytes that have been fertilized. It inhibits female reproductive behaviour associated with oestrus. In the vagina, it causes exfoliation and secretion of mucus membrane. In the cervix it causes a blockage and closure by forming a mucous plug to prevent any infiltration into the uterus.

Testosterone

The male hormone known as testosterone, which is likewise a steroid hormone and is generated in the leydig cells of the testes, is responsible for spermatogenesis. The testicular tissue maintains a high concentration of testosterone, which is transported throughout the body through diffusion from the spermatic cord to the testicular arteries and veins. Testosterone has roles in spermatogenesis promotion, anabolic growth, and accessory sex gland secretion promotion. A negative feedback loop that occurs at different levels of the male sex hormone system controls the male sex hormones. (Gillies and McArthur, 2010).

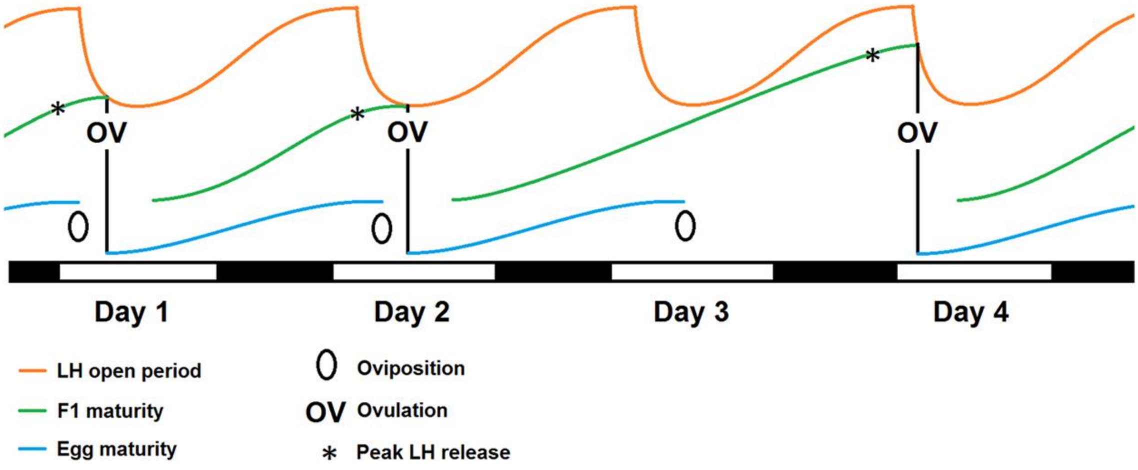


Effect of Season on Poultry Production

Changes in the weather variations affect the production of poultry birds and thus it is important to know and determine the effect that they have on the production of the birds so as to counter their adverse effects. In agricultural production, weather and climate changes are the most variable inputs affecting production, day by day it is managed. The main climatic factors affecting poultry reproduction are temperature and humidity (Nawab et al., 2018). In Nigeria most poultry farmers practice a low level or no level of technological input in their operation and management, it is mostly an extensive or semi-intensive system of management and if not, a dip-litter integrated system for most commercial poultry farmers (Heise et al., 2015).

Effect of Lighting schedule

With seasonal changes in the environment the behaviour and habits of the birds change slightly, like for instance how the increase or decrease in daylight affect the egg production, egg production in poultry is greatly affected and stimulated by daylight and length of day (Olanrewaju et al., 2010) this means that the longer the day the increase in production. Fig 2 shows how the photoperiod affects the release of hormones and thus reproductive development. As the season changes the length of day and night slightly changes, in the summer months (April-July) the length of day is longer while in the winter months (October-January) the length of day is shorter (Bradshaw and Holzapfel, 2007to 30 percent (van der Klein et al., 2020), this is done to ensure efficient and constant maximization of egg production.



Effect on the Reproductive Performance

As a result of seasonal fluctuation the production performance is decreased as well as significant decrease in egg weight, egg shell thickness and eggshell weight (Ahaotu., et al. 2019).

The dry season

This period is characterized with low amounts of rainfall, increase in solar radiation as a result of low cloud cover and low humidity. The dry season in Nigeria is divided into two main seasons: The Hot-dry season and The Harmattan. The major characteristic of dry season in the tropic regions such as Nigeria is dry heat and more windy conditions in the arid areas of the northern Nigerian areas, it is between the months of March to May. The harmattan is a season between the months of November and February, this period is accompanied by low temperatures, dusty-windy conditions and dryness.

Heat Stress

When chickens struggle to maintain a balance between the heat generated internally by the body and the heat lost to the environment, a condition known as heat stress results. (Igbokwe et al. 2018) The term "thermo neutral zone" refers to the range of ambient temperatures where an animal's normal productive and maintenance functions can be carried out without discomfort, balancing the heat lost to the environment without necessitating a higher rate of metabolic heat production.

The Reproductive hormones and Ovulation

Oestrogen and Progesterone are the two main hormones inducing the sexual maturity and reproduction in female animals. Ovulation, sexual maturity, and oviduct development are all influenced by estrogen. The pituitary gland responds to progesterone by releasing the hormones luteinizing hormone (LH) and folicle stimulating hormone (FSH), which start the formation of the yolk. Testosterone and Progesterone stimulates albumen formation (Lucas and Ostagno, 2013). Heat stress (acute and chronic) causes reduction in progesterone and testosterone levels because the increase in temperature causes a decrease in the concentration of ascorbic acid which is necessary for their synthesis. This in turn affects the concentration of Letuinizing Hormone (LH) and Follicle Stimulating Hormone (FSH) (Rozenboim et al., 2007).

Folliculogenesis

As a result of heat stress, the stimulation of Follicle Stimulating Hormone (FSH) is disrupted and the concentration of oestrogen, progesterone and testosterone are decreased. In mature hens, only the left ovary releases eggs, as the time of egg laying period approaches the ovary is activated and the follicles are released, because of the alteration of the normal stimulation and concentration of the reproductive hormones a few amount of follicles are stimulated and even still they do not grow well. (Igbokwe et al., 2018)

Ovulation

A sexually matured hen begin to ovulate when the yolk is released from a matured follicle, the initiation of ovulation is due to neurological and hormonal factors. Because of heat stress this initiation is delayed because the concentration of the reproductive hormone is decreased and the number of matured follicle is reduced. The next ovulation which is triggered by the egg lay is affected too because of the delay of egg lay (Rozenboim et al., 2007).

The Wet Season

This period, also called rainy season in Nigeria is mainly characterized by heavy rainfall it is mostly between the month of June to October. During this period there is high humidity as a result of frequent rainfall and as there increased cloud cover there is reduced intensity of solar radiation. The length of day is longer than the dry season meaning an increased rate of egg laying activities, also the feed intake will be more and the water intake will be lesser during this period. Because the overall environmental condition during the wet season is to a cooler temperature, the activity of the birds will be increased.

Management of Seasonal changes

In Nigeria, the effect of change in weather and season can be managed by taking proper measures though various techniques and methods such as the construction of the housing, the feeding and diet of the birds, the stocking density of birds and even the type of birds are all considered in determining the means of proper management of seasonal effect on poultry birds.

CONCLUSION

In poultry production, the reproductive-hormonal axis is more balanced during the wet season, the profile of the hormones are normal and this in turn favors reproduction thus, the reproductive performance of both male and female poultry is much better during the wet season. Poultry production in the tropics is more favourable during the wet season. At dry season, heat stress causes the rate of production to plummet and the quality of eggs and chicks is low this is because of the disruption of the hormone. Seeing this fact, poultry birds fare better during the wet season where the ambient temperature is cooler. Farmers should take measures to maintain comfort for the birds during the dry season and prevent heat stress, being that this alters the behaviour and production of the birds. With the knowledge of the effects of the seasons on the reproductive hormonal profile specific measures can be taken with target towards the balance and maintenance of these hormones in both the wet and dry season.

ABSTRACT

An experiment to assess the sensory and organoleptics characteristic of broilers chickens fed diets containing fermented cassava leaf- stump mix (FCLS) meal as replacements for maize. The cassava leaf and stump were fermented in solid state using Aspergillus niger ATCC 16404 for 96 and 192 hours respectively at room temperature. FCLS meal was prepared by mixing the fermented cassava stump and fermented cassava leaf at ratio of 19:1. The birds were allotted into four treatments with three replicates (n= 30). Treatment 1 contain 0% FCLS, while treatments 2 to 4 contain 20%, 40% and 60% FCLS meal respectively. There was a significant difference ($P < 0.05$) in the flavor, tenderness and texture. The overall acceptability was statistically similar ($p > 0.05$), however, the highest acceptability was obtained in Diet 3 (containing 40% FCLM). Therefore, inclusion of FCLS up to 60% inclusion level is acceptable to the consumers and may not have any negative effect on the palatability of broiler chicken meat.

Keywords: Cassava stump, Cassava leaf, Solid state fermentation, palatability, *Aspergillus niger*

INTRODUCTION

Broiler chicken has tremendous capacity to develop faster than any other meat sources (Kralik et al., 2018). The meat also has high quality nutrients, ease of preparation and delicious taste. The poultry feed industry is currently facing challenges of volatility in the cost of production due to soaring bills of conventional feedstuffs; thus, the search for alternative feed ingredients.

The by-products of cassava tuber are some of the alternatives being assessed by livestock scientists as a replacement for maize. However, these by-products as individual are low in crude protein and have high crude fiber (Latif and Müller, 2015). Leaf meals are known to be good sources of protein but the use is limited by the anti- nutrients and high fiber components. Morgan and Choct (2016) advocated fungal solid-state fermentation (SSF) as a veritable way of improving the nutritional quality of cassava by- products. Khempaka et al. (2014) observed increased level of protein of cassava and its by-products through fermentation by yeast. Sugiharto et al. (2019) also reported the use of enzymes and fermentation to solve the challenges of high fibre and anti – nutrient factors thereby enhancing the availability of the bioactive compound in the leaf meals.

The assessment of the quality of meat is vital, as it is view in relation to the quality of the meat component and the palatability factors. It is also a measurement of duration of meat freshness before deterioration commences (El Masry et al., 2012). The hydrogen index and nutrient composition affect the sensory/organoleptic traits of meat (Jayasena et al., 2013).

The study was therefore undertaken to determine the effect of feeding fermented cassava leaf-stump mix meal as replacements for maize on the sensory/organoleptics characteristics of broiler chickens.

MATERIALS AND METHODS

Experimental location: The experiment was conducted at the Poultry Unit of the Landmark University Research Farm, Omu Aran, Irepodun local Government, Kwara State, Nigeria. Coordinates 8°08′00″N5°06′00″E

Sources of materials: Cassava leaf and stumps were obtained from the Cassava processing Unit of Landmark University, Omu Aran while other feed ingredients were purchased from Ilorin, Kwara State.

Fermentation procedure: The dried cassava leaves and cassava stump were inoculated with *Aspergillus niger* (ATCC 16404) aseptically and fermented under room temperature for 96 hours and 192 hours for cassava leaf and stump respectively using the method described by Aro and Akinjokun (2012). The fermented cassava leaf and stump were then mix at the ratio of 1:19 to form the leaf-stump mix meal.

Proximate Components: The proximate analysis of the unfermented and fermented cassava leaf-stump mix meal were carried out using the method of AOAC, 2006.

Management of birds: Day old Ross broiler chicks were allocated based on their initial weight into four dietary treatments of 30 chicks per group, and 10 chicks per replicates. All vaccination and medication schedule, and standard management practices were adhered to. Portable water and feed were provided without restriction for the period of 56 days experimental period.

Experimental diets and design: FCLS mix meal was prepared by mixing the fermented cassava stump with fermented cassava leaf at ratio 19:1. Four experimental diets each were made for the starter and the finisher phases. The Diet 1 contained no FCLS, while treatments 2, 3 and 4 had maize replaced by 20, 40 and 60% FFCS. The diets' compositions are presented in table 2.

Sensory evaluation: Ten semi-professional panelists were selected for this evaluation using boiled meat samples from the breast muscle. Samples were rinsed, put in a clear double nylon bags and labeled. These were then cooked until tissue internal temperature reached 75^{o}C. The cooled boiled meat was thereafter given to the panelists. Each panelist chewed one sample per treatment and scored for appearance, taste, aroma, flavor, tenderness, texture and overall acceptability, using a Nine-Point Hedonic scale ranking.

Statistical analysis: All data produced were subjected to a One-Way Statistical Analysis of Variance (ANOVA) using SAS (2009). Duncan's New Multiple Range Test based on significant level of $P < 0.05$ was then used to evaluate the significance differences among the treatments.

RESULTS AND DISCUSSION

The Tables 1 and 2 show the proximate composition of the unfermented and fermented cassava leaf–stump mix meal and the diets composition respectively. The result of the sensory evaluation of the broiler meat is shown in Tables 3.

Proximate Analysis: The results showed that the SSF using Aspergillus niger 16404 enhanced the nutritive values of cassava leaf–stump mix meal, this is agreement with Olukomaiya et al. (2019) and Shi et al. (2021).

The organoleptic/sensory evaluation

The appearance, aroma, taste and overall acceptability values were not influenced ($P > 0.05$ by FCLS (table 3); Semjon et al. (2020) reported similar observation when broiler rations where supplemented with solid state fermented feed. This signifies that the inclusion of the FFCS in the diets did not hamper the sensory organoleptic characteristics of the broiler meat. Higher numerical values for aroma and tenderness were observed in the control diet. Melton (1990) has earlier posited that diets type affect the aroma of meat. Mottram (1991) also observed that meat aroma trait is because of complex interaction of precursors derived from both the lean and fat compositions of meat generating volatile flavor compounds during cooking. The better overall acceptance of the meat from chickens fed FFCS containing diets in this study is also in accord with that of Abu et al. (2015).

CONCLUSION

From this study, it can be deduced that solid state fermented FCLS can serve as a good energy resource in broiler production. For optimal result, up to 40% of FCLS mix meal could be incorporated in to the diet of broiler chickens with no fear of any detrimental consequence on the organoleptic indices. Further study may be carried out on the cassava stump using bacteria and other fungi or consortium of microorganisms to see if better result can be obtained.

ABSTRACT

A four-week feeding trial was conducted to determine the effect of Sweet potatoes peel meal (SPPM) on the growth performance of broiler finishers chicks. To achieve this, three hundred (375) four-week old broiler finisher chicks were randomly allocated to five experimental diets in a completely randomized design (CRD). Each treatment was replicated three times having twenty-five birds per pen. SPPM was prepared and fed at graded levels of 0.0, 7.5, 15.0, 22.5, and 30. The parameters measured and calculated include final weight, total weight gain, daily weight gain, total feed intake, daily feed intake, feed to gain ratio and feed cost per kilogram gain. The heamatological parameters were also measured. The results showed that dietary levels of inclusion of SPPM had significant (P<0.05) effect on these parameters. The final weight, the weight gain and feed intake of the birds fed 0,7.5% and 15.0%SPPM were statistically (P>0.05) similar and significantly (P<0.05) higher than those of other treatments. Cost of feed per birds and feed cost per kilogram gain were lower for all SPPM diets. The cost of feed decreased as the level of SPPM increased in the diet.There were no significant differences (P>0.05) between the treatment means for packed cell volume (PCV), heamoglobin (Hb) and Total protein (Tp). It was concluded that inclusion of SPPM in the diets of broiler finisher at 15% level has beneficial effects. Therefore, 15.0% level of inclusion is recommended in the diets of broiler finishers,

INTRODUCTION

Livestock Agriculture is very important in every economy of the world, including Nigeria. Poultry farming is an essential part of the agricultural industry and plays a vital role on the national economy. In many developing countries, like Nigeria. The major constraint of poultry production has always been high cost of quality feeds. Feed cost was estimated to be about 74% of the total cost of production [1, 2]. Livestock accounts for 40% of the Gross Domestic Products (GDP) and employs 1.3 billion people while supporting the livelihoods of one billion of the world's poor [3]. Poultry products are always at short supply because the population is increasing geometrically while the poultry production is increasing arithmetically. So, there is always pressure on the products available making the available poultry products to be costly. The population was estimated at one hundred and forty million (4). This high cost has been attributed to the over-dependence on the expensive conventional feed stuffs such as maize which mainly used in poultry feed formulation as a major source of energy. This high cost of feed necessitates research into non-conventional feed stuffs (NCF) that are readily available, cheap and nutritionally safe for the consumption of poultry.Utilization of SPPM which has crude protein of about 3.45%, Dry matter of about 91.20% and Metabolizable energy of 3089.9 Kcal/kg in poultry feed may lower feed cost because they are not consumed as food by humans. Thisstudywasdesignedtoevaluatethegrowthperformanceandhaematologicalparametersof broiler starter fed graded dietary levels of sweet potatoes peel meals.

MATERIALS AND METHODS

The experiment was conducted at the poultry section Department of Livestock, Ministry of Agriculture, Mariri, in Kumbotso Local Government Area of Kano State. Five experimental diets of SPPM at 0.7.5, 15.0, 22.5 and 30.0% levels for T1, T2, T3, T4 and T5 were formulated respectively. The feed composition for the chicks is shown in Table 1. The birds were randomly assigned to pens in a completely randomized design (CRD). There were five treatments and three replications of the five treatments each with 25 birds per pen. The management of the birds was carried out according to the standard procedures for brooding, vaccination and medication. The birds and feeds were weighed weekly. The performance characteristics were measured in terms of total weight gain, daily weight gain, total feed intake, daily feed intake, and feed to gain ratio. Haematological samples were collected into a sterile,

SPPM: Sweet Potatoes Peel Meals

RESULTS AND DISCUSSIONS

Table 2 shows the performance of broiler starter finisher fed Sweet potatoes peed meal. The final weight, total weight gain, daily weight gain and feed to gain ratio, of birds fed 0, 7.5% and 15% SPPM were similar, higher and better than those on other treatments, this could be an indication that chicks were able to efficiently utilize SPPM at 7.5% and 15% better than other levels. This result of better feed to gain ratio observed for birds fed 7.5.0 and 15% SPPM could also be due to the fact that there were sufficient metabolizable energy that were better utilized at this level.

Table 3 shows the result of the effect of SPPM in broiler diets on some haematological parameters of broiler finisher chicks There were no significant differences (P>0.05) between the treatment means for Packed cell volume (PCV), haemoglobin (Hb) and total protein (Tp).The non-significant (P>0.05)difference shown in the PCV, Hb and Tp showed that any of the diets was good enough to supply sufficient nutrients for birds.

CONCLUSION

From the results of the experiment, it was concluded that up to 7.5% of SPPM may be included in the diets of broiler chicks without any significant negative effect on growth performance.

ABSTRACT
The potential use of white lead tree (Leucaena leucocephala Lam.) leaf meal to replace soyabean meal in diets for Clarias gariepinus (Burchell, 1822) fingerlings was assessed in a feeding trial. A total of 150 fingerlings (mean initial weight = 6.35±0.02 g) were randomly assigned to fifteen plastic bowls. Five iso-nitrogenous diets were formulated by replacing 25% (Diet 2), 50% (Diet 3), 75% (Diet 4) and 100% (Diet 5) of soyabean meal by white lead tree leaf meal. The diet without soyabean meal replacement served as control treatment (Diet 1). The fingerlings were fed the experimental diets for 56 days. Results revealed that fingerlings fed with Diet 2 exhibited the highest mean weight gain (MWG) (15.62±0.01 g) and specific growth rate (SGR) (2.21±0.22 %/day) followed by Diets 1 and 3. There was significant difference ($p < 0.05$) in SGR values among fingerlings fed with Diets 1, 2 and 3. Fingerlings fed with Diets 5 showed lower MWG (9.88±0.02 g) and SGR (0.80±0.02 %/day) values than those fed with the other diets. Results of this present study indicate that white lead tree leaf meal could replace soyabean meal up to 25% in diets for Clarias gariepinus fingerlings.

Keywords: White lead tree leaf meal, soyabean replacement, *Clarias gariepinus*

INTRODUCTION
Fish feed plays a major role in aquaculture viability and profitability, because it accounts for at least 40 - 60% of the total production cost (Eyo, 2001; Agbugui *et al*., 2011). The major nutrients in fish feeds are protein and carbohydrate. However, conventional feedstuffs for animal feed

formulation are dwindling in supply and their prices very high (Tiamiyu *et al*., 2015). Non-conventional feed resources (NCFRs) are non-competitive in terms of human consumption, very cheap to get, readily available in large quantities (Nandeesha *et al*., 1991; Gabriel *et al*., 2007; Agbugui *et a*l., 2010) and may constitute nuisance as waste. The search for suitable NCFRs had focused on agricultural by-products of agro-processing industries (Hoffman *et al*., 1997; Madu *et al*., 2003). One of such plant resources is white lead tree, *Leucacena leucocephala*.

L. leucocephala is one of the fastest-growing trees in arid and semi-arid areas. It is a long-lived perennial legume tree. It is a multipurpose tree, valuable for its wood, which is used to make good quality charcoal, small furniture and paper pulps. Its young shoots, young leaves and seeds may be used as vegetable in human nutrition. Seeds can also be used as a substitute or as piece of jewellery (Brewbaker, 1987). In this context, the formulation of fish feed using a cheap, locally available and highly nutritious terrestrial resource such as *L. leucocephala* leaf meals is needed because the percentage crude protein is more than 20 percent. Crude protein levels of *L. leucocephala* seeds and leaf meals are comparable to high protein-containing seeds and legumes such as soybeans and cowpea; while lipid content of *Leucacena leucocephala* leaf meal is comparable to sunflower, soyabeans and cotton seeds (Srbinoska *et al.*, 2012). *Leucaena leucocephala* leaves also show high potential to be incorporated in fish feed due to their high protein content especially lysine (Kim, 2012).

African mud catfish (*Clarias gariepinus*) is a common cultured fish species in Nigeria and sub-Sarahra Africa (Olaifa and Bello, 2011). The species is widely accepted by fish farmers and consumers because of its high growth rate, high and very efficient feed conversion ratio, excellent adaptation to ambient climate and environmental stress, disease resistance and ability to adapt to intensive culture, ease of artificial propagation, acceptance of relatively cheap feeds, high fecundity, unquestionable market demand and high customers’ acceptance (Huisman and Richter, 1987; Fagbenro *et al.*, 1999). The experiment is designed to determine the growth performance and survival rate of *C. gariepinus* fingerlings fed with varying percentages of white lead tree (*Leucacena leucocephala*) leaf meal-based diets reared in plastic bowls.

MATERIALS AND METHODS

Experimental site

The experiment was conducted at the Feed mill unit of the Federal College of Freshwater Fisheries Technology (FCFFT) New Bussa, Niger State, Nigeria.Latitude 9° 53″N and Longitude 4° 33" E.

Experimental Fish

Live one hundred and fifty (150) *Clarias gariepinus* fingerlings of average weight of 2.83±0.02 g were purchased from A and B fish farm, Koro, New Bussa, Niger State. They were transported to the experimental site. The experimental fish were acclimatized to experimental condition in a plastic bowl in the College Feed mill for 3 days in the bowls during which they were fed on 40% crude protein Blue Crown feed before the commencement of the experiment.

Feed Preparation

The white lead tree (*Leucaena leucocephala*) leaves was harvested within the premises of Federal College of Freshwater Fisheries Technology, New Bussa. The other ingredients used to formulate the experimental diets which include soyabean, groundnut cake, fish meal, yellow maize and the fixed ingredients (vitamin and mineral premix, vegetable oil, methionine, lysine, DCP and salt) were purchased from local markets in New Bussa (Table 1). The ingredients were separately processed and milled to a fine powder form using 2 mm diameter dice in the flat die pelletizer of 40 - 60 kg/hr capacity and then sun-dried for 12hours. The milled ingredients were kept in air tight containers until required.

Experimental Design

Soyabean (SBM) was replaced with white lead tree leaf meal (WLLM) at 0% (DT1), 25% (DT2), 50% (DT3), 75% (DT4) and 100% (DT5) respectively. The formulation was done using the Pearson square method. The WLLM based diets were randomly allocated to triplicate 10fish/bowl in a completely randomised design (CRD) for 56 days. The fish were weighed with an electronic sensitive weighing balance (OHAUS-LS-200 model). The plastic bowls (30L capacity) were washed, thoroughly rinsed and filled with water to 16cm high.

RESULTS AND DISCUSSION

The results of proximate analysis of white lead tree (*Leucaena leucocephala*) leaf meal (WLLM) are presented in Table 1.

Table 1: Proximate analysis of white lead tree (*Leucaena leucocephala*) leaf meal

Parameter	Percentage dry weight
Moisture content	6.43
Crude protein	23.85
Crude fat	7.68
Crude fibre	8.70
Crude ash	5.13
NFE	48.55

Nitrogen Free Extract (NFE) is calculated by difference = 100 – (protein + lipid + fibre + ash)

The Percentage composition of the experimental diets is presented in Table 2.

Table 2: Percentage composition of the experimental diets (dry matter basis)

	White lead tree leaf meal inclusion levels (%)				
Feed ingredients (%)	**0**	**25**	**50**	**75**	**100**
WLLM	0.00	11.88	23.75	35.63	47.50
Soyabean meal	47.50	35.63	23.75	11.88	0.00
Groundnut cake	47.50	47.50	47.50	47.50	47.50
Yellow maize	1.00	1.00	1.00	1.00	1.00
Vitamin premix	1.00	1.00	1.00	1.00	1.00
Vegetable oil	1.00	1.00	1.00	1.00	1.00
Methionine	0.50	0.50	0.50	0.50	0.50
Lysine	0.50	0.50	0.50	0.50	0.50
Bone meal	0.50	0.50	0.50	0.50	0.50
Salt	0.50	0.50	0.50	0.50	0.50
Total	**100.00**	**100.00**	**100.00**	**100.00**	**100.00**

WLLM = White lead tree leaf meal

The proximate composition of the white lead tree leaf meal-based diets is presented in Table 3.

Table 3: Proximate composition (%) of white lead tree leaf meal-based diets

Parameters	DT 1 (0%WLLM)	DT 2 (25% WLLM)	DT 3 (50% WLLM)	DT 4 (75% WLLM)	DT 5 (100%WLLM)
Moisture content (%)	9.85	7.31	8.06	8.12	7.97
Crude protein (%)	40.65	40.81	39.25	39.02	39.00
Crude fat (%)	5.05	3.97	4.74	4.61	4.47
Crude fibre (%)	3.97	4.97	4.84	5.05	5.37
Crude ash (%)	4.97	4.84	5.05	5.37	5.70
NFE	35.31	36.65	36.65	35.91	35.15

Values with the same superscripts across the rows are not significantly different (p<0.05)

The result is similar to others, Sotolu and Faturoti, (2009), Mary *et al.* (2010) and Falaye *et al.* (2016).

The growth performance and survival rate of *C. gariepinus* fed white lead tree leaf meal based diets are presented in Table 4.

Table 4: Growth performance and survival rate of *C. gariepinus* fed white lead tree leaf meal based diets

Parameters	DT 1 (0%WLLM)	DT 2 (25% WLLM)	DT 3 (50% WLLM)	DT 4 (75% WLLM)	DT 5 (100%WLLM)
Mean Initial weight (g)	6.32 ± 0.03^a	6.36 ± 0.01^a	6.38 ± 0.02^a	6.36 ± 0.02^a	6.32 ± 0.02^a
Mean Final weight (g)	26.88 ± 2.00^a	21.98 ± 1.00^b	17.56 ± 1.00^c	11.97 ± 0.20^d	9.88 ± 0.34^e
Mean weight gain (g)	20.56 ± 2.00^a	15.62 ± 0.95^b	11.18 ± 0.94^c	5.61 ± 0.20^d	1.56 ± 0.32^e
Specific growth rate	2.59 ± 0.12^a	2.21 ± 0.22^b	1.81 ± 0.09^c	1.13 ± 0.12^d	0.80 ± 0.05^e
Total feed intake (g)	16.30 ± 2.11	10.56 ± 1.00	7.77 ± 1.12	4.65 ± 1.12	2.10 ± 0.40
Food conversion ratio	0.79 ± 0.10^e	0.68 ± 0.12^d	0.69 ± 0.05^c	0.83 ± 0.06^b	1.35 ± 0.06^a
Survival rate (%)	97.78^a	84.44^b	77.33^c	75.55^c	66.67^d
Culture period (days)	56	56	56	56	56

Mean values in the same row with different superscripts are significantly different (p < 0.05)

It was revealed that fish fed with control (Diet 1) gave the best results in terms of growth and survival rates. Fish fed diets containing 25% white lead tree leaf meal along with 75% soyabean meal were observed to have the better result among the treatments, with final weight gain of 21.98 g, specific growth rate of 2.21%/day and food conversion ratio (FCR) of 0.68±0.12; these results were closed to the control diets. The survival rate of control diet (Diet 1) was 97.78% which was significantly different from that of the Diet 2. The result is in line with those of other workers such as Falaye *et al* (1998), Nawwar *et al* (2017) for *Oreochromis niloticus* fries fed *Leucaena luecocephala* leaf meal-based diets. However, this is contrary to the result obtained by Oladele *et al.* (2010) who recorded the best performance in *Clarias gariepinus* fed tigernut at 100% substitution of maize meal with tigernut meal.

CONCLUSION

Partial inclusion of the plant meal might have significant effect on the growth of the fish and reduction of feeding cost in an aquaculture farm. The outcomes of this study are useful in better understanding of the production of new alternative solution for soyabean meal replacement. White lead tree leaf meal could partially replace soyabean meal up to 25% inclusion level in the diet of *C. gariepinus* fingerlings without compromising growth, nutrient utilization and health. This is therefore an added advantage to fish farmers providing a cheap alternative to substitute for soyabean meal.

RECOMMENDATION

The use of *L. leucocephala* meal in diets for *C. gariepinus* fingerlings should be considered as potential protein ingredient regardless of the anti-nutritional effect.

ABSTRACT

Fish is an important source of food all over the world and the assessment of the proximate composition of fish is vital. In this study, investigations were made on the nutritive composition of five cartilaginous fish species (Raja miraletus, Dasyatis magarita, Rhinobatos albomaculatus, Sphyrna couardi, Squalus megalops) from Lagos lagoon and its coast. The analysis of the nutritive composition was done using the methods of the association of analytical chemists and was revealed that Raja miraletus had the highest value of crude protein content of 25.85% while Squalus megalops has the least value of 24.83%. The carbohydrate content was highest in Squalus megalops (4.88 %) with the least value of carbohydrate evident in Dasyatis magarita (4.19%). The proportion of moisture content (66.17%) was highest in Rhinobatos albomaculatus while the least moisture content (61.94%) was found in Raja miraletus. The highest ether extract value (3.08%) was found in Sphyrna couardi while the least was found in Dasyatis magarita (1.69%). The highest ash content value (2.35%) was seen in Sphyrna couardi while the least value (0.36%) was seen in Raja miraletus. The crude fiber content value (4.76%) was highest in Raja miraletus while Sphyrna couardi had the least value of 1.78%. There was significant difference ($p<0.05$) in the nutritive value obtained for these fishes. However, the fishes belong to the high protein – low fat category and can be recommended in human diets to prevent protein deficiencies and excessive consumption of saturated fats.

Keywords: Proximate composition, Raja miraletus, Dasyatis magarita, Rhinobatos albomaculatus, Sphyrna couardi, Squalus megalops.

INTRODUCTION

Fish is a vital source of food which contributes to human health and digestible due to the long muscle fibres it contains (Kaur,Chugh &Gupta 2012) .It is a protein of animal origin that is found available to many Nigerians with an estimated annual per capita fish consumption of 13.3 kg in 2013 (Food and Agricultural Organisation FAO, 2017). It contains some significant amount of fatty acids ,amino acids and some major vitamins which provides energy for healthy life and at times called rich food that is available for the poor (Balami ,Sharma &Karn,2019;Bezbaruah &Deka,2021) . Fish contains four basic ingredients in varying proportions: water, protein, fat, and minerals. Flesh from healthy fish contains 60–84% water, 15– 24% protein, and 0.1–22% fat, mineral usually constitutes 1–2% (Clucas &Ward, 1996). The consumption of fish assists in maintaining a healthy status and prevent ailments such as blood pressure, cancer and coronary heart disease because of the amino acids, omega-3 highly unsaturated fatty acids (HUFA), eicosapentaenoic (EPA), docosahexaenoic (DHA) acids it is made up of (Abraha *et al*., 2018)

Proximate composition generally comprises the estimation of moisture, protein, fat and ash contents of the fresh fish body. The percentage composition of these constituent's accounts for about 96-98% of the total tissue constituents in fish (Nowsad, 2007). The chemical composition of fish flesh is regarded as a dependable predictor of the quality ,Physiological state ,habitat and nutritional value of the fish (Ravichandran, Kumaravel &Florence,2011). It is important to provide data on the proximate composition of fish since it serves as one of the major protein sources in human nutrition (Mohanty *et al.*, 2014). The Chondrichthyes are cartilaginous fishes represented by sharks, skates, and rays and most primitive living jawed aquatic vertebrates (Bouchaala ,Bouali,Ali, Benmiled , Gargouri & Fendri 2015). They are not as abundant and available as bony fishes and the available ones can be a good source of protein for human consumption (Last &Stevens ,1994). This study aims at evaluating the proximate composition and nutritive value of five cartilaginous fishes from Lagos lagoon and its coast.

MATERIALS AND METHODS

Study Area

The Lagos Lagoon is one of the several lagoons in West Africa, a brackish coastal lagoon, which lies within latitude 6° 26'–6° 37' N and longitude 3° 23'-4° 20' E and it stretches for 257km from the Benin Republic to the West and Niger Delta to the East and consists of nine lagoons namely, Badagry, Ologe, Yewa, Iyagbe, Lagos, Kuramo ,Mahin, Lekki and Epe Lagoon. Lagos Lagoon empties into the Atlantic Ocean through Lagos harbour (Nwankwo, 2004 ; Isebor, Awosika &Smith ,2006)

Fish sample collection

The cartilaginous fish species were collected based on the species available from three commercial landing sites namely Makoko fish market, Liverpool fish market, and Ijora fish market all in Lagos, Southwest Nigeria. The sampling was done during the rainy season. A total of 54 fish samples were obtained during this period which consisted of five different species of cartilaginous fishes. The species were *Dasyatis margarita* (sting ray), *Raja miraletus* (brown ray), Squalus *megalops* (dogfish shark), *Sphyrna couardi* (hammer head shark) and *Rhinobatos albomaculatus* (White spotted guitar fish). The fish species were collected randomly to represent the population. The fish samples were labelled for easy identification and kept in the freezer at a temperature of -20^{o}C prior to analysis.

Morphometric measurement

The fish specimen was removed from the freezer and thawed. Standard and Total length measurements were recorded using a measuring board and the weight taken using a weighing scale.

Proximate analysis

The proximate composition of the fish samples was done using the procedure of AOAC (1995). This method was used to evaluate the crude protein, ash, ether extract, crude fibre and moisture content of the samples.

Statistical analysis
Data obtained were analyzed using one way analysis of variance test (ANOVA) and the Duncan multiple range test was used to separate the means value using the statistical analysis system package (SAS,2005)

RESULT AND DISCUSSION

Table 1 shows the morphometric measurement of five cartilaginous fish species from Lagos lagoon and off its coast. The total length of *Raja miraletus* ranged from 12.1 cm – 43.4 cm, disc length ranged from 6.0 cm- 21.6cm and the weight ranged from 50g - 400g. The total length for *Dasyatis margarita* ranged from 38cm – 86.5cm, disc length ranged from 13.5cm -27.7 cm and the weight ranged from 101.7g -876g. For *Rhinobatos albomaculatus* , the total length ranged from 64.5cm - 64.8cm, disc length ranged from 24.4cm – 24.7cm while the weight ranged from 900g -1000g.the total length for *Sphyrna couardi* ranged from 48cm -59.5 cm, the standard length ranged from 47.5cm – 58cm while the weight ranged from 610g -1000g.The range of the total length for squalus megalops ranged from 33.5cm – 85.3cm, standard length ranged from 32.4cm- 84.5cm while the weight ranged from 100g - 3200g. The proximate composition for the five cartilaginous fishes and the SEM are given in Table 2. *Raja miraletus* had the highest protein content (25.85%) among the five cartilaginous fishes examined in this study while *Rhinobatos albomaculatus* had the least protein content (24.33%). *Squalus megalops* had the highest carbohydrate content (4.88%) with *Rhinobatos albomaculatus* having the least carbohydrate content (3.92%). For ether extract *Sphyrna couardi* had the highest value of 3.08% with *Rhinobatos albomaculatus* having the least value of 1.45%.*Sphyrna couardi* had the highest ash content of 2.35% amongst the five fish species with *Raja miraletus* having the least value of 0.36%. The crude fibre content was highest in *Raja miraletus* (4.76%) while *Sphyrna couardi* had the least value of 1.78%.The highest moisture content was found in *Rhinobatos albomaculatus* (66.17%) and the least moisture content was found in *Raja miraletus* with the value of 61.94% . Fish are usually categorized as lean, moderately fat, and fat according to its fat content, which is less than 5 percent, from 5 to 10 percent, and greater than 10 percent, respectively (Dean, 1990). Fishes are normally grouped as lean (< 5 percent), moderately fat (5 -10 percent), and fat (> 10 percent) depending on the fat contained in it (Dean, 1990) and according to Kari, Ahmad and Ayub (2022) , the standard proximate composition of fish protein is between 15-23%. The cartilaginous fishes examined in this study belong to the high protein (24-26%) –low-fat category (<5%) and based on fat content according to Dean (1990), they can be classified as lean fish. Emmanuel, Oshionebo and Aladetohun (2011), reported that *Clarias gariepinus* and *Tarpon atlanticus* belonged to the high protein -low-fat category which is in line with the protein–fat content range of the fishes used in this study. Their high protein content may be due to the high protein content in the fishes' diet The carbohydrate content in this study was found to be less than 5% and is in agreement with the carbohydrate values (1.48-4.54%) which is less than 5% obtained by Babalola, *et al.*, (2011) for five commercial fish species (*Trachurus trachurus, Sardinella aurita*, *Micropoonias furniereri, Scomber scombrus*, *Clarias gariepinus*) in Nigeria. Moisture content values of fishes obtained in this study (61.93- 66.17%) were lower than the values obtained by Olagunju, Muhammed, Mada, Mohammed and Mahmout (2012) which was (65- 74.9%) on the nutrient composition of *Tilapia* *zilli*, *Hemisynodontis membranacea*, *Clupea herengus* and *Scomber scombrus*. The observed range of ash content (0.36-2.35%) is higher than the ones obtained by Olagunju Muhammed, Mada, Mohammed &Mahmout (2012). This indicates that these fish species are good sources of mineral content.

Table 1: Morphometric measurement of five cartilaginous fish species from Lagos lagoon and off its coast

Fish species	Weight (g)	Total length (cm)	Standard length (cm)	Disc length (cm)
Raja miraletus	50-400	12.1-43.4	-	6.0-21.6
Dasyatis margarita	101.7-876	38-86.5	-	13.5-27.7
Sphyrna couardi	610-1000	48-59.5	47.5-58	-
Squalus megalops	610-1000	48-59.5	32.4-84.5	-
Rhinobatos albomaculatus	900-1000	64.5-64.8	-	24.4-24.7

Table 2. Proximate composition of five cartilaginous fishes from Lagos lagoon and its coast

FISH SPECIE	CHO	CP	EE	MOI	ASH	CF
Raja miraletus	4.75^{b}	25.85^{a}	2.34^{b}	61.94^{e}	0.36^{c}	4.76^{a}
Dasyatis magarita	4.19^{d}	25.13^{b}	1.69^{d}	64.36^{d}	1.17^{b}	4.10^{b}
Sphyrna couardi	4.64^{c}	25.13^{b}	3 .08^{a}	63.06^{d}	2.35^{a}	1.78^{d}
Squalus megalops	4.88^{a}	24.33^{d}	1.75^{c}	64.75^{b}	1.56^{b}	2.71^{c}
Rhinobatos albomaculatus	3.92e	24.83c	1.45e	66.17a	1.29b	2.34cd
SEM	0.10	0.13	0.16	0.39	0.19	0.39

Means on the same column with different superscripts are significantly different ($p< 0.05$) from each other. SEM – Standard error of means, CHO- carbohydrate -crude protein, EE-ether extract, MOI- moisture, CF- crude fibre.

CONCLUSION

The marine fish species examined in this study revealed high protein, low-fat content, and a good source of ash content and can be recommended as a rich source of nutrients in the human diet. These fish species can be used in human diets to avoid excessive consumption of saturated fats and help prevent protein deficiencies.

ABSTRACT

A growth study was carried out to investigate the effects of dietary moringa leaf meal, ginger, garlic powder and their mixture on growth performance and nutrient utilization of Clarias gariepinus fingerlings. In a 70-day feeding trial, C. gariepinus fingerlings (N = 300; 6.90 ± 0.31 g initial weight) were fed with a basal diet (control diet CT; free of moringa, ginger and garlic); treatment "A" (2% moringa); treatment "B" (2% ginger); treatment "C" (2% garlic) and treatment "D" (2% mixture of moringa, ginger and garlic). After the feeding trial, total weight gain of fish in treatment "C" were significantly higher ($p<0.05$) than those in treatment "A" and "D" but not significantly higher ($p>0.05$) than fish in treatment "CT" and "B". Specific growth rate and relative growth rate show a similar trend with weight gain. Feed conversion ratio was highest in treatment "D" and "A" and significantly different ($p<0.05$) from treatment "CT" "B" and "C". This study suggests that, 2% supplementation of ginger and garlic powder in the diet of C. gariepinus fingerlings could improve growth performance and nutrient utilization. However, 2% dietary inclusion levels each of dry moringa leaf meal and a mixture of dry moringa leaf meal, ginger and garlic powder in the diet of same fish species could reduce palatability and consequently reduce feed intake, nutrient utilization and overall growth performance of cultured fish.

Key word: Moringa, Ginger, Garlic, Catfish, Growth performance

INTRODUCTION

The use of plant products in aquaculture have been studied in different forms of extract (aqueous, ethanol and dried powder) and reported to be medicinal (Naylor *et al*., 2021). Most common are

Garlic (*Allium sativum*) and Ginger (*Zingiber officinale*) which are both perennial crops and have been a subject of considerable interest for centuries. They are natural and readily available additives which have been reported to promote various activities like anti-stress, immunostimulation, appetite stimulant, physical and mental health enhancers and growth promoters in fish (Wahab *et al.*, 2022).

Nutritional and phytochemical analyses revealed that garlic contains about 17 amino acids, 33 sulphur compounds, several enzymes, minerals and vitamins. Studies have also revealed its antiviral, antibacterial, antifungal, antioxidant, antiprotozoal and an effective immuno-stimulant, growth promoter and improves flesh quality owing to the presence of various sulphur compounds (Nyadjeu *et al.*, 2021). Ginger (*Z. officinale*), belongs to the family Zingiberaceae. It's a flowering plant whose rhizome is commonly used as spice and flavouring agent (Britannica, 2022). Ginger is medicinal and considered a safe herbal treatment for common cold, flu and nasal congestion. It contains compound such as alkaloids, flavonoids, polyphenols, saponin, steroids, tannin, fiber, carbohydrate, vitamins, carotenoids, minerals, natural antioxidants as gingerols, shogaols and zingerone (Nyadjeu *et al.*, 2021). Moringa (*Moringa oleifera*) is also proven to be medicinal. Its leaf contains crude protein with about 26g/100g of leaf, of which about 87% is true protein (Adel and Majid, 2021). Essential amino acids found in raw moringa leaf are methionine, cysteine, typtophan and lysine which is similar in composition with those found in soybean (Ya''ara *et al.*, 2022). Although it has been reported in previous studies that moringa, ginger or garlic have been found to strengthen immunity and uplift health status, enhance growth and flesh quality in freshwater fish like carp (C*yprinus carpio*), tilapia (*Oreochromis niloticus*) and the African catfish (*Clarias gariepinus*) (Naylor *et al.*, 2021). Studies in respect to their efficacy and combined effect in the diet of the African catfish are inadequate. Thus, the aim of this study was to evaluate the effect of dry moringa leaf meal, ginger powder, garlic powder and their mixture as feed additive on growth criteria and nutrient utilization of the African catfish *Clarias gariepinus* fingerlings.

MATERIALS AND METHOD

The study was carried out from February to April, 2022 at the hatchery wet-laboratory unit of the Nigerian Institute for Oceanography and Marine Research (NIOMR), Lagos Nigeria.

Processing of Additives

Freshly harvested moringa leaves (*Moringa oleifera*), ginger roots (*Zingiber officinale*) and garlic bulbs (*Allium sativum*) were washed under a running clean tap water and wiped with a clean kitchen towel. Garlic and ginger were individually peeled to remove fore-skin before being diced with a kitchen knife. Additives were sundried for a period of 72hours, then milled to powder using a laboratory milling machine (Model: HK - 860) and sieved with a hand sieve to obtain 2kg each of the powders which were then stored in an airtight cellophane bag and refrigerated at 4^oC for further analysis.

Nutritional and Anti-nutritional Composition of Additives

The nutritional and anti-nutritional composition of all three additives were carried out based on the recommendation of the Association of Official Analytical Chemist (A. O. A. C, 2005). This includes; Nutritional (moisture contents, crude protein, crude fibre, carbohydrate, crude fat, ash and mineral content) and anti-nutritional (phytic acid, oxalate content and tannin content).

Experimental Diets and Acclimatization of experimental fish

Five iso-nitrogenous diets were formulated to contain 35% crude protein with each additive powder added at 2g/100g. Diet "A" (2% dry moringa leaf meal inclusion), Diet "B" (2% dry ginger powder inclusion), Diet "C" (2% dry garlic powder inclusion), Diet "D" (mixture of all three additives: 2% inclusion) and Diet "CT" (0% additives).

Three hundred (300) catfish juveniles of average weight of 6.7 ± 0.4g were sourced from the fish hatchery unit of the Nigerian Institute for Oceanography and Marine Research for the experiment.

Experimental Design

They were distributed in an equal number of 20 pieces into a fifteen 80L plastic tanks. Each treatment was replicated thrice in a completely randomized design and fed thrice daily at 5% body weight between (10:00h, 13:00h and 16:00h). The feeding trial was carried out for a period of 10 weeks during which the corresponding weight of fish was recorded on a biweekly basis. The experiment was conducted in a water recirculatory system (WRS) plastic tank with a water exchange rate of 70L flow per minute.

At the end of the feeding trial, the weight gain, mean weight gain, total weight gain, relative growth rate (RGR), specific growth rate (SGR) and feed conversion ratio (FCR) were estimated from fortnightly measurements.

STATISTICAL ANALYSIS

All data resulting from the experiment were presented as means ± SD and analyzed by one way analysis of variance (ANOVA) using the SPSS (statistical Package Computer, Software 2004 version Chicago Illinois, USA). Duncan's multiple range tests was deployed to compare differences among individual means. Differences were regarded as significant at $P < 0.05$ (Zar, 1999).

RESULTS AND DISCUSSION

In this study, percentage proximate composition, anti-nutritional factor, growth performance and nutrient utilization indices of *Clarias gariepinus* fingerlings fed five different diets are shown in Table 1, 2, 3 and 4.

Results of proximate composition are presented in Table 1.

Table 1: Percentage Proximate composition of Moringa leaf, Ginger and Garlic

PARAMETER	Moringa Leaf	Ginger	Garlic
Moisture %	7.8	10.6	9
Crude Protein %	25.0	10.26	18.58

Crude Fat %	4.64	4.64	0.54
Fibre %	2.97	2.97	0.88
Ash %	9.5	9.5	4.33
CHO %	50.12	50.12	66.67

Mineral composition

Results of mineral composition is presented in Table 2.

Table 2: Mineral composition of Moringa leaf, Ginger and Garlic

PARAMETER	Moringa Leaf	Ginger	Garlic
Calcium Mg/100g	110.43	158.32	67.81
Magnesium Mg/100g	185.01	181.91	97.55
Potassium Mg/100g	855.96	707.87	784.3
Sodium Mg/100g	235.1	171.12	208.9
Manganese Mg/100g	1.02	22.99	0.6
Iron Mg/100g	9.9	17.14	3.52
Copper Mg/100g	0.77	2.15	0.67
Zinc Mg/100g	1.44	2.01	1.68
Phosphorus Mg/100g	175.46	162.29	282.57

Results of anti-nutritional factors are presented in Table 3.

Table 3: Anti-Nutritional Factor Analysis of Moringa leaf, Ginger and Garlic

PARAMETER	Moringa Leaf	Ginger	Garlic
Phytic Acid g/kg	0.031	0.025	0.054
Tannins mgTAE/kg	48.73	50.28	56.15
Oxalate Mg/100g	1.97	3.28	4.17

Growth Performance and Nutrient Utilization of Experimental Fish

In this study, the growth performance and nutrient utilization indices as well as bi-weekly growth curve of *Clarias gariepinus* fingerlings fed dry moringa leaf meal, ginger and garlic powder basal diets are presented in Table 4.

Table 4: Growth Performance and Nutrient Utilization of Experimental Fishes

Parameters	CT	A	B	C	D
Initial Weight of Fish/tank (g)	128.7	133.7	132	130	138
No Stocked	20	20	20	20	20
Total Weight of Feed/tank (g)	992.41	635.67	1019.88	1010.71	552.93

Final weight of Fish/tank (g)	481.6	222	477.4	511.2	171
Weight Gain of Fish/tank (g)	352.96 ± 28.3^b	88.61 ± 21.3^a	345.4 ± 134^b	381.6 ± 71^b	32.8 ± 26.8^a
FCR	2.8 ± 0.14^a	7.2 ± 1.54^b	3 ± 0.84^a	2.7 ± 0.39^a	8.2 ± 0.63^b
SGR	0.819 ± 1.33^b	0.315 ± 0.62^a	0.798 ± 0.25^b	0.849 ± 1.72^b	0.133 ± 0.41^c
RGR	2.742 ± 1.52^b	0.66 ± 0.37^a	2.617 ± 1.95^b	2.932 ± 0.23^c	0.239 ± 1.03^a

Treatment A = Fish fed moringa leaf-based diet; Treatment B = Fish fed ginger-based diet; Treatment C = Fish fed garlic-based diet; Treatment D = Fish fed combination of moringa, ginger and garlic-based diet; Treatment CT = Fish fed Control-based diet. Values are mean ± standard deviation of three replicates of 20 fish each. Mean within the same row with different superscripts are significantly different from each other at $p < 0.05$. FCR, feed conversion ratio; SGR, Specific growth rate; RGR, Relative growth rate.

Growth performance indices reveal that, cultured fish in treatment “D” had the lowest total weight gain (32.8 ± 26.8g) while fish in treatment “C” had the highest total weight gain (381.6 ± 71g). SGR and RGR were both highest in treatment “C” with values of 0.849 ± 1.72 and 2.932 ± 0.23 respectively. These values are significantly different ($p<0.05$) from other treatments.
FCR values of *C. gariepinus* fed with different dietary inclusions of moringa, ginger and garlic basal diets are presented in Table 4. It was noted that feed consumption translated in flesh increase for most of the treatments. In general, fish fed on diet “C”, “B” and “CT” each containing 2% of garlic, ginger and control diet inclusion had the best FCR with values of 2.7 ± 0.39, 3 ± 0.84 and 2.8 ± 0.14 respectively and are significantly different ($p < 0.05$) when compared to treatments “A” and “D”. Results obtained from fish fed ginger based diet is in agreement with that reported by Oh *et al*., (2022), who reported that the incorporation of Ginger (*Z. officinale*) residue from juice extraction improves juvenile black rockfish (*Sebastes schlegelii*) growth performance, antioxidant enzyme activity, and resistance to *Streptococcus iniae* infection. Chepkirui *et al.*, (2022) also reported that, the incorporation of garlic in diets for growing Nile tilapia significantly improved weight gain and specific growth rate. Elton *et al.* (2021) also reported a significant increase in weight gain, feed efficiency, protein efficiency ratio and specific growth rate of Nile tilapia fed diet containing 3% garlic powder. The findings of this study revealed that *C. gariepinus* fingerlings fed basal diet supplemented with ginger powder or garlic powder showed better growth and feed utilization in term of weight gain, feed conversion ratio, specific growth rate as well as relative growth rate when compared to fish fed diet containing moringa or combination of dry moringa leaf meal, ginger powder and garlic powder.

In this study however, group of fish fed 2% moringa leaf meal based diet “A” and group of fish fed 2 % mixture of dry moringa leaf meal, ginger and garlic powder based diet “D” revealed that the final body weight and weight gain were significantly ($p < 0.05$) lower resulting in a reduced average daily weight gain, specific growth rate and a high feed conversion ratio as observed in

Table 4. Feeding rate of affected fish reduced and consequently a reduction in weight gain. This observation may suggests a high dose of moringa in the experimental fish diet which may reduce palatability of diet and consequently reduced feed intake. This observation is similar to the findings of Dongmeza *et al.* (2006) who reported a considerable reduction in feed intake, nutrient utilization, and growth performance of *Oreochromis mykiss* when fed with dietary *Moringa oleifera* leaf extracts. The findings of this study are also similar to the report of Puycha *et al.*, (2017) who worked on effect of moringa (*Moringa oleifera*) leaf supplementation on growth performance and feed utilization of Bocourti's catfish (*Pangasius bocourti*) and reported that dietary moringa leaf could be included in the Bocourti's catfish diet at possibly not over 10g/kg fish without a negative effect on the growth, feed utilization, digestibility and serum biochemistry. In conclusion, this study showed that dietary supplementation of ginger and garlic powder in the diet of *Clarias gariepinus* fingerlings at 2% inclusion level could improve growth performance and nutrient utilization. The study also demonstrated that, 2% dietary inclusion level of dry moringa leaf meal and a mixture of dry moringa leaf meal, ginger and garlic powder in the diet of *Clarias gariepinus* fingerlings reduces feed palatability and overall growth performance.

ABSTRACT

Length-weight relationship and condition factor of 500 specimens of the Giant African River Prawn (Macrobrachium vollenhovenii) were cultured for 120 days in two different culture systems, 300 specimen were cultured in the pond and 200 specimens were cultured in the tank in the present study. Regression lines differed among the culture systems. The "b values" for the two culture systems were 2.415 and 2.651 respectively. The morphometric analysis revealed negative allometric growth patterns at $p < 0.05$. The parameters "a" and "b" of the morphometric analysis were estimated using the formular $W = aL^b$ while the condition factor were calculated from the equation $K = 100WL^{-3}$. The mean "K" value for the pond and tank culture systems were 0.7813 ± 0.254 and 0.8015 ± 0.475 respectively. There is no significance difference in the mean condition factor for the pond and tank culture at $p > 0.05$. Hence, further studies are required on the aspect of the water quality management of the two culture systems, which could also be a factor that must have contributed to their growth

Keywords: Length-weight Relationship, condition factor, Giant African River Prawn, Tank, Pond.

INTRODUCTION

The freshwater prawns of the genus Macrobrachium consist of over two hundred species that are distributed throughout the world, especially in the tropical and subtropical regions (Jimoh et al., 2011) vollenhovenii and macrobrachion are particularly of high economic importance in the diversification of both aquaculture and artisanal fisheries in the West African region (Bello-Olusoji, (2004).

Macrobrachium vollenhovenii which are found in both brackish and fresh waters environments in West African as a suitable choice for aquaculture in Nigeria due to its large size (Bello-Olusoji, 2004). However, its post larvae and brood stocks were usually obtained from the wild due to the constraints of getting hatchery-raised prawns (Anetekhai et al., 2007). Since, morphometric parameters such as length and weight were generally used as criteria for selecting brood stocks. It is therefore essential to ascertain the well-being of the brood stocks and post-larvae before been raised for consumption. Hence, knowledge about their growth pattern and state of health is important.

Length-weight relationship has vital importance in fisheries science. It helps in establishing mathematical relationship between the two variables, enabling conversion of one variable to the other (Le Cren, 1951), to describe growth in the wild (Enin, 1994; Abohweyere and Williams, 2008; Deekae and Abowee, 2010), to determine possible differences among different stocks of the same species (Petrakis and Stergiou, 1995; King, 2007), delineate the stocks and comparative growth studies (Sampaio and Valenti, 1996; Primavera et al., 1998; Peixoto et al., 2004). Although shrimp body weight is commonly recorded for culture management purposes (e.g. estimations of growth rate, feed conversion ratio, harvest weight, and productivity), the application of morphometric relationships could be a simple alternative to estimate body weight from length measurements that are less variable and more easily measured in the field (Cheng and Chen, 1990; Primavera et al., 1998).

Most recent works on the length-weight relationship and condition factor of Macrobrachium species includes Lagos lagoon (Abohweyere and Wilhams, 2008; Abohweyere, 2008b), Cross River estuary, Nigeria (Enin, 1994), Bello Olusoji (2005) on species from Rivers, Osun, Ogun and Osse. Yakub and Ansa (2007) used Length-Weight relationship as a tool to assess the general wellbeing of the pink shrimps- Penaeus notialis and giant tiger shrimps- P. monodon of Buguma creek in the Niger Delta. The observed condition factor suggested the ecological suitability of the brackish water of Buguma creek to be suitable for co-habitation of indigenous pink shrimp and exotic giant shrimp.

A study on the Length-weight relationship of M. vollenhovenii in Asejire Lake provides base line data for management decision on the species in the area and similar water bodies. The information on growth- length-weight relationship forms the basis for estimating mortality, recruitment and other parameters of populations.

MATERIALS AND METHOD

Area of Collection: juveniles of M. vollenhovenii were collected from Ogun River at Isheri Olofin area of Okunmanya River in Ogun State. They were caught with mosquito net trap.

Acclimatization: the prawns were transported in 50-liter plastic containers with or without water in an air-conditioned car to Badore NIOMR out station in Lagos State. On arrival at the Station, the prawns were treated with 5-ppm formalin for disinfection before they were transferred to quarantine tanks and acclimatized to the new environment.

The study area is Nigerian Institute of Oceanography and Marine Research, Badore Station. 500 specimens of Giant African River Prawn cultured in pond (300 specimens) and tank (200 specimens) were measured. The study period was from April to August 2019 (120 days). The culture shrimps were fed with 0.8-1.2mm imported extruded COPPENS feed twice daily at 3% body weight throughout the culture period. The specimens for the length-weight relationship (LWR) were collected after harvest using scoop net.

Total length (TL) was measured to the nearest 0.1 cm using 30cm ruler from the distance of the tip of the rostrum to the tip of the telson. The body weight was measured to the nearest 0.01g using sensitive weighing balance. The (LWR) was calculated using the conventional formula $W = aL^b$ where W = body weight, L = total length in centimeters while "a" and "b" are regression constant and regression coefficient respectively (Ricker, 1973). Log transformed as log W = a + b log L, a is the intercept in y-axis and the regression coefficient b is an exponent indicating isometric growth when close to three. The ANOVA was carried out carried out using spss. The statistical significance level was estimated. The condition factor (K) of the shrimps was calculated using the K = 100 WL-3 (Pauly, 1983). Where K = condition factor, W = body weight of shrimp (g) and L = Total length of shrimp (cm). The analysis was carried out using Microsoft Excel version of 2010.

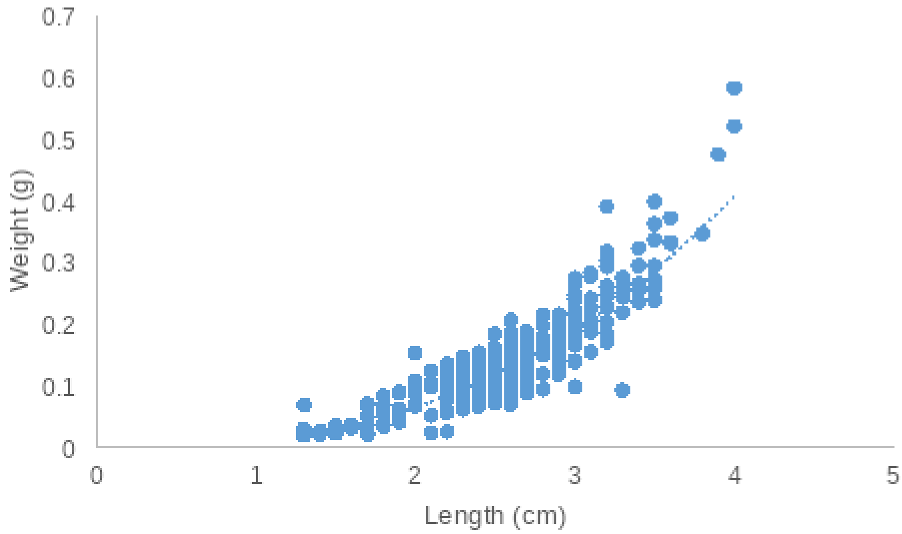
RESULTS

The values for elevation (a) and slope (b) together with their corresponding regression coefficient (r^2) for the length–weight relationships in M. vollenhovenii of the two culture systems are presented in the Table.

M. vollenhovenii cultured in tank has significantly lower value of b (Table 1), indicating lower weight gain relative to increase in length compared to the pond culture. The growth in the tank culture showed isometry where as it is positive allometry in the pond culture. Although the slope in tank culture was found higher than pond culture, no significant difference was observed between the tank and pond culture system. Scatter diagrams of length and weight for the two-culture system exhibited curvilinear relationship were shown in Figure 1 and 2 below.

Table: Regression analysis of *Macrobrahium vollenhovenii* cultured in tank and pond.

	Regression constant (a)	Regression coefficient (b)	Correlation coefficient (r)	Mean ISD	K	
					Range Min	Max
Tank	0.0140	2.4149	0.7441	0.80150± 0.475	0.4418	1.7384
Pond	0.0103	2.6514	0.8086	0.78131± 0.254	0.2348	3.0951



.

Fig. 1: Length-weight relationship of *Macrobrahium vollehovenii* cultured in pond.

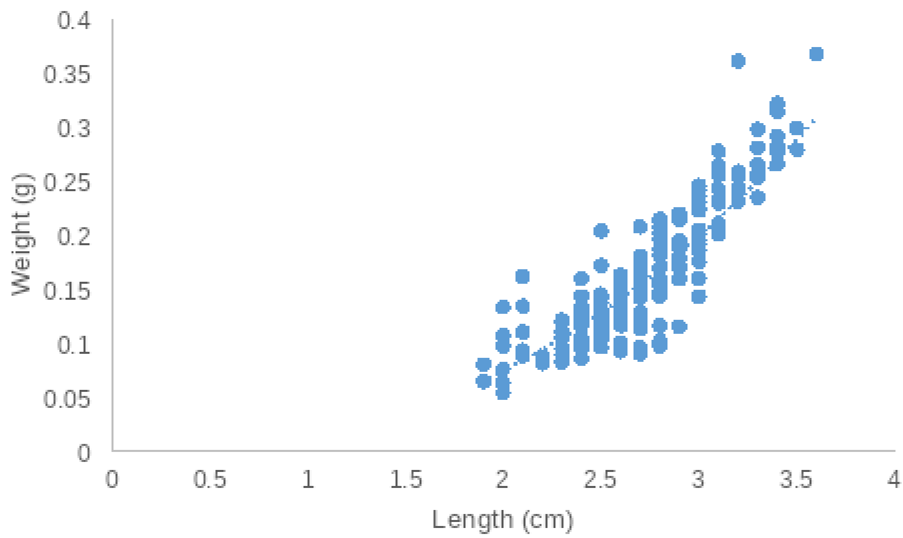


Fig. 2: Length-weight relationship of *Macrobrahium vollehovenii* cultured in tank.

The condition factor obtained in the present study show mean standard deviation, which is from 0.80± 0.47 in the tank culture to 0.78± 0.25 in the pond culture (Table 1). The table also show the ranges of the condition factor to be No significant variation was observed in K in the two culture systems with the pond culture showing the higher followed by the tank culture.

DISCUSSION

Lalrinsanga et al. (2012) reported that shellfish maintains dimensional equality; the weight increase will be proportional to the cube of length increment while the slope value less than 3 indicates that the animal becomes slender as it increases in length whereas slope greater than 3 denotes stoutness indicating allometric growth. Kunda et al. (2008) reported isometric growth (b= 3.075) of M. rosenbergii in Rice Field with coefficient of determination (r^2) of 0.99 which in contrast to the present study with negative allometric growth (b= 2.6514 and 2.4149) with coefficient of determination (r^2) of 0.88 and 0.74 which is similar to the work of Kunda et al. 2008. The values obtained indicating negative allometric growth. These values are similar to those obtained in the work of Gopalakhrishnan et al. (2013) Length-weight Relationship and Condition Factor of Wild, Grow-out and "Loose Shell Affected" Giant Tiger Shrimp, *Penaeus monodon* and Matanmi, M.A. (2014) Length-weight Relationship, Condition Factor and Sex Ratio of Black Tiger Shrimp (Penaeus monodon) Reared in NIOMR Shrimp Grow-out Concrete tank.

Information on condition factor (K) can be vital to culture system management because they provide the producer with information of the specific condition under which organisms are developing (Araneda et al., 2009). It reflects recent physical and biological circumstances, and fluctuates by interaction among feeding conditions, parasitic infections and physiological factors (Le Cren, 1951) and it is an indicator of the changes in food reserves and therefore an indicator of the general fish condition.

The K observed in the present study ranges from 0.44 to 1.73 in tank culture and 0.23 to 3.09 for the pond culture, indicating that the prawns are in good condition. Kunda et al. (2008) reported a condition factor and relative condition factor (Kn) of 1.09 and 1.00, respectively in M. rosenbergii under rice fields suggesting good condition of the prawn. P.L. Lalrinsanga et al. (2012) also reported a condition factor of 0.79 and 1.41, respectively in length-weight relationship and condition factor of giant freshwater prawn M. rosenbergii (De Man, 1879) based on developmental stages, culture stages and sex similar ranges of condition has also been reported in other species of Macrobrachium (Arimoro and Meye, 2007; Enin, 1994).

CONCLUSION

Prawn fishing in Nigeria is facing challenges of over fishing and pollution caused by industries like oil and gas, bottling industries and Nigeria breweries. Hence, the knowledge about Prawn Aquaculture, their growth pattern and state of health is important. This present study indicates that *M. vollenhovenii* cultured in tank has a higher value of condition factor with a slightly lower growth value compared to the one cultured in the pond. This can be as result of water changing in tank and availability of natural nutrient, live feeds and poor water condition in the pond. Further research work is required to be carried out on this study especially the water Quality Management aspects.

ABSTRACT
This eight-week fish nutritional experiment was carried out to appraise the effect of supplementing soaked pawpaw (Carica papaya) seed meal (SPSM) in the diet on growth and feed utilization of 360 Clarias gariepinus juveniles (initial mean weight = 8.5±0.37 g) inside 18 plastic aquaria (50 × 40 × 40 cm^3). SPSM was incorporated at six increasing graded levels (0, 10, 20, 30, 40 and 50%) labeled as Diet 1 (control diet), Diet 2, Diet 3, Diet 4, Diet 5 and Diet 6 respectively. The SPSM-supplemented diets (40% crude protein) and fish carcass were proximately analyzed via standard procedures. Indices such as Mean Weight Gain (MWG), Specific Growth Rate (SGR) and Feed Conversion Ratio (FCR) were assessed. Data generated were analyzed using one-way analysis of variance (ANOVA) at $P \leq 0.05$. Final carcass crude protein (62.2 – 64.5%) significantly ($p < 0.05$) superseded 56.31% in the pre-experimental fish. Juveniles fed with Diet 2 (10% SPSM supplementation) had significantly ($p < 0.05$) superior values of MWG (16.2 g), SGR (1.9%/day) and FCR (1.86). Higher SPSM supplementation (20 – 50%) caused progressively depressed pattern of growth and feed utilization indices. This study has revealed that up to 10% soaked pawpaw seed meal supplementation produced the best growth and feed utilization in C. gariepinus juveniles.
Key words: Soaked pawpaw seed meal, *Clarias gariepinus*, Survival, Proximate analysis, Protein intake

INTRODUCTION

Aquaculture development has often been regarded as an indispensable remedy to the lingering shortage of animal protein intake in developing countries which is largely due to rapid human population growth. In routine aquaculture operations, feed supply alone constitutes a major operational cost for most fish farmers as it accounts for about 40 – 70% of the total operational cost of sustainable fish farming (Dossou *et al*., 2021). The scarcity and escalating cost of most conventional feed ingredients have necessitated the use of unconventional alternative feed resources for reducing feed cost and maximizing profit from aquaculture practices. The search for such unconventional feed ingredients and evaluation of their nutritional suitability have become major determinants for improving aquaculture feed industry (Watanabe, 2002). Feed formulation based on cheap locally available domestic, agricultural and agro-industrial by-products plays a vital role in aquaculture feed industry (Tacon, 2002). Vegetable and fruit processing wastes or by-products constitute potential sources of energy and protein which should be harnessed as alternative ingredients in fish feed to reduce feed cost and thereby facilitate sustainable aquaculture (Jimenez-Yan *et al*., 2006). In addition to various reports on the nutritional relevance of legumes, oilseed cakes, cereal grains, rice bran and several other by-products as ingredients in aqua diets, vegetable and fruit wastes are equally nutritive and abundant (Daniels, 2006). There have been many useful reports regarding the use of vegetable and fruit wastes as unconventional feed ingredients in fish feed (Basker *et al*., 2011; Rebecca and Bhavan, 2011; Sajitha *et al*., 2011; Foramarzi *et al*., 2012; Bhavan *et al*., 2013).

One of such plants is pawpaw (*Carica papaya*) whose seeds have been used in various studies. Chemical analysis of pawpaw seed powder has been reported to contain 22.56 - 30.08% crude protein, 22.2 - 34.80% crude lipid, 1.67% crude fiber, 7.11 - 7.97% total ash and 23.67 - 47.27% nitrogen-free extract (Bolu *et al.*, 2009; Farrag *et al*., 2013). Several studies have been conducted on the utilization of processed pawpaw seeds in the diets of fish and other monogastric animals such as langur monkey (Lohiya *et al*., 2002), wistar rats (Naggayi *et al*., 2015), albino rats (Raji *et al*., 2005), broiler chickens (Bolu *et al*., 2009), *Oreochromis niloticus* (Farrag *et al*., 2013; Khalil *et al*., 2014) and *C. gariepinus* (Ayotunde *et al*., 2010). In view of the afore-mentioned studies, it is obvious that, regardless of available literature reports on the nutrient composition and dietary potential of pawpaw seed meal, there is still scanty information about its incorporation as a supplement in the diets for *C. gariepinus* juveniles. Therefore, this study was conducted to assess the suitability and influence of supplementing diet with graded increasing levels of soaked pawpaw seed meal on growth performance, feed utilization and survival of *C. gariepinus* juveniles.

MATERIALS AND METHODS

Formulation and preparation of experimental diets

Large quantities of ripe pawpaw (*C. papaya*) fruits were purchased from Iba market, Lagos State, Nigeria. The fruits were sliced open to extract the fresh mature seeds (6 kg) used in this study which were cleaned and soaked for 24 hours in a 20-litre plastic bucket containing clean water. The soaked seeds were removed, sieved, sufficiently sundried for 3 days to constant weight after which they were milled to a fine powder using a locally fabricated domestic food blender and kept in a dry air-tight polyethylene bag at room temperature pending its inclusion in the diets. Other ingredients were procured from a standard feed mill and ground separately into a powdery form. Six iso-nitrogenous (40% crude protein) experimental diets were formulated from various ingredients as presented in Table 1. Soaked pawpaw seed meal (SPSM) was incorporated as a supplement at increasing graded levels of 0 (control diet without SPSM), 10, 20, 30, 40 and 50% in the diets which were respectively coded as 0% SPSM (Diet 1), 10% SPSM (Diet 2), 20% SPSM (Diet 3), 30% SPSM (Diet 4), 40% SPSM (Diet 5) and 50% SPSM (Diet 6). Each diet was individually prepared by thoroughly mixing the dry ingredients inside a mixer after which groundnut oil and warm water were added to homogenize the dry mixture into a uniform paste. Each diet paste was steam-pelleted using a 2-mm die Hobart pelletizer. The resultant pellets were collected, sufficiently sundried for three days, cooled to room temperature and wrapped in separate air-tight containers prior to fish feeding.

Experimental design and fish husbandry

This eight-week feeding experiment was conducted in the fish nutrition research laboratory of the Department of Fisheries and Aquaculture Technology, Olusegun Agagu University of Science and Technology, Okitipupa, Nigeria. A total of 400 *C. gariepinus* juveniles were procured from a reputable commercial hatchery in Okitipupa, Ondo State. The juveniles were acclimatized to the experimental conditions inside four fiberglass tanks (1 m × 1 m× 0.5 m) for 7 days and fed twice daily with 2 mm Coppens feed. At the start of this study, 360 equal-sized fish (initial mean weight: 8.5±0.37 g) were batch-weighed on a sensitive balance and randomly allotted into 18 plastic aquaria (50 × 40 × 40 cm^3) at twenty juveniles per aquarium each containing 20 litres of borehole water. A completely randomized design was used to assign six dietary treatments in three replicates each to the fish aquaria to make up 18 treatment units. Fish were manually fed twice daily (07:00 - 08:00 and 17:00 - 18:00 hrs) at 5% of their body weight in two equal rations with constant aeration in the aquaria via air-stones connected to a central air pump. Temperature, dissolved oxygen concentration and pH of the culture water were monitored. Fish in each aquarium were batch-weighed weekly and weight gain recorded. Eight grams of each diet sample, six pre-treatment fish specimens and four post-treatment fish specimens per treatment were randomly collected, kept frozen and later used to determine the proximate composition of experimental diets and fish carcass. The proximate indices analyzed included crude protein, crude lipid, crude fibre, total ash, moisture content and nitrogen-free extract (AOAC, 2011).

SPSM: Soaked Pawpaw Seed Meal

Biological appraisal of fish growth performance and feed utilization indices

The following indices of growth and feed utilization were appraised:

i. $Mean\ weight\ gain\ (MWG) = (W_2 - W_1)\ g$

where: W_1 = initial mean weight (g); W_2 = final mean weight (g)

ii. $Percentage\ weight\ gain(\%) = \frac{Mean\ weight\ gain\ (g) \times 100}{Initial\ mean\ weight\ (g)}$ (Adesina and Agbatan, 2021)

iii. $Feed\ intake\ (g) = WFI_1 + WFI_2 + WFI_3 + WFI_4 + \ldots\ldots WFI_n$

where: WFI= weekly feed intake of fish per treatment (g);
1, 2, 3, 4,……..n= first week to the last week of the experimental duration

iv. $Feed\ conversion\ ratio\ (FCR) = \frac{Mean\ feed\ intake\ (g)}{Mean\ weight\ gain\ (g)}$ (Adesina and Agbatan, 2021)

v. $Specific\ growth\ rate(\%/\text{day}) = \frac{(\text{Ln Wf} - \text{Ln Wi}) \times 100}{t\ (days)}$ (Adesina and Agbatan, 2021)

where: Ln W_f = natural logarithm of fish final weight; Ln W_i= natural logarithm of fish initial weight; t= experimental duration in days.

vi. $Protein\ intake\ (g\ of\ protein\ in\ 100g\ diet/fish) = \frac{feed\ intake \times \%\ crude\ protein\ in\ diet}{100}$
(Adesina and Ikuyeju, 2019)

vii. $Protein\ efficiency\ ratio\ (PER) = \frac{Mean\ weight\ gain}{Mean\ protein\ intake\ (g\ of\ protein\ in\ 100g\ of\ diet/fish)}$
(Adesina and Ikuyeju, 2019)

viii. $Nitrogen\ metabolism\ (NM) = \frac{0.549 \times (Wi+Wf)t}{2}$

where: W_i= initial mean weight of fish; W_f= final mean weight of fish; t= experimental period in days; 0.549 = metabolism factor

ix. $Percentage\ survival,\ PS(\%) = \frac{Final\ number\ of\ fish\ harvested \times 100}{Initial\ number\ of\ fish\ stocked}$ (Adesina and Ikuyeju, 2019)

STATISTICAL ANALYSIS

Data obtained on the effect of supplementing diets with soaked pawpaw seed meal on proximate indices, growth, feed utilization and body composition of *C. gariepinus* juveniles were analyzed using one-way analysis of variance (ANOVA) based on the SPSS Statistics 22.0 version (IBM, USA). Differences among the six treatment groups were determined by means of Tukey's multiple range tests and were considered statistically significant at $p < 0.05$. All the data presented in this study were expressed as means of triplicate values (n = 3) ± standard deviation.

RESULTS AND DISCUSSION

Table 2 shows the proximate composition indices of the experimental diets which revealed an irregular pattern regardless of increasing levels of soaked pawpaw seed meal (SPSM) supplementation. Values of these indices conformed to the recommended range suitable to ensure ideal fish growth (Li *et al*., 2014). Crude protein values (38.94 – 41.01%) agreed with 32.35 – 40.65% earlier documented for oven-dried pawpaw seed meal and other seed meal-supplemented diets (Farrag *et al*., 2013; Bake *et al*., 2016, 2020; Michael and Mathias, 2020; Zulhisyam *et al*., 2021; Michael *et al*., 2021). Crude lipid values (5.12 – 9.99%) almost harmonized with 10 - 20% lipid in prepared fish diets which generally boosts ideal growth rate without producing unduly fatty carcass (Tibbetts and Lall, 2013). The present values tallied with 5.23 – 6.59% found in oven-dried pawpaw seed meal-supplemented diets (Farrag *et al*., 2013). Moreover, the present values of crude fibre and ash favorably complied with 10.75 – 11.12% recorded by Farrag *et al*. (2013) and 8 - 12% recommended for optimal fish growth (Condey, 2002) since higher crude fibre and ash contents usually reduce the digestibility of other dietary ingredients and cause high waste production which may lead to water pollution and poor growth. Values of nitrogen-free extract (NFE) (18.31 – 21.09%) were lower than 46.49 – 54.4% found in oven-dried pawpaw seed meal-supplemented diets (Farrag *et al*., 2013). The observed dissimilarities in the values of these proximate indices and earlier studies probably emanated from the influence of environmental factors on the seeds (Akajiaku *et al*., 2014), morphological differences in plant species, various processing techniques adopted and differences in ingredient mixtures.

Table 2: Proximate composition of graded levels of soaked pawpaw seed meal-supplemented diets fed to *C. gariepinus* juveniles

Mean values with different superscripts a, b, c, etc. along the same row are significantly different ($p < 0.05$). SPSM: Soaked Pawpaw Seed Meal

Table 3 presents carcass proximate composition indices of post-experimental fish. The appreciable elevation of carcass protein content in the post-fed *C. gariepinus* juveniles obviously validated enhanced protein synthesis and new tissue formation as earlier noted by Yusuf *et al*. (2016) for *C. gariepinus* juveniles. Appreciably elevated carcass crude protein values have also been reported for *C. gariepinus* fingerlings and juveniles fed variously processed seed meal-supplemented diets (Bake *et al*., 2016, 2020; Aliu and Osaro, 2018; Michael and Mathias, 2020; Jibrin *et al*., 2021; Michael *et al*., 2021; Zulhisyam *et al*., 2021). Final carcass crude lipid values (8.05 – 10.73%) displayed an irregular pattern of significant variations which possibly implied that increasing dietary inclusion levels of SPSM did not cause a corresponding increase in fat deposition in the fish. This finding, however, contradicted the progressively increasing fat accumulation detected in *O. niloticus* fingerlings fed pawpaw seed meal-supplemented diets (Farrag *et al*., 2013) and *C. gariepinus* fingerlings placed on toasted flamboyant seed meal-supplemented diets (Bake *et al*., 2016). These values superseded 1.5 – 6.68% documented by other authors (Bake *et al*., 2016, 2020; Jibrin *et al*., 2021) but fell below 13.47 – 15.12% noticed in *C. gariepinus* fingerlings fed toasted lablab bean meal (Aliu and Osaro, 2018). The dissimilarities observed in fish carcass composition between this study and other similar studies could be associated with variations in fish species' genetic make-ups, plant-based ingredients used, processing techniques adopted as well as influence of environmental factors or culture conditions.

Table 3: Carcass proximate composition of *C. gariepinus* juveniles fed graded levels of soaked pawpaw seed meal-supplemented diets

Proximate indices	Initial values	0% SPSM Diet 1 Control	10% SPSM Diet 2	20% SPSM Diet 3	30% SPSM Diet 4	40% SPSM Diet 5	50% SPSM Diet 6

Moisture (%)	10.51±1.59[a]	7.94±1.66[ab]	6.04±2.06[a]	7.01±1.19[a]	7.87±0.14[ab]	7.72±0.91[a]	6.22±1.83[a]

Mean values with different superscripts a, b, c, etc. along the same row are significantly different ($p < 0.05$). SPSM: Soaked Pawpaw Seed Meal

Table 4 shows the result of growth response, feed utilization and percentage survival indices which exhibited significant ($p < 0.05$) variations in the post-experimental *C. gariepinus* juveniles. Supplementing SPSM in the diets has caused appreciable increase in feed utilization and weight gain. Acceptance of diets vis-à-vis weight gain significantly ($p < 0.05$) increased in the fish placed on Diets 1 to 2 (0% - 10% SPSM) beyond which it progressively diminished with further increase in SPSM supplementation levels. Similar findings were reported on *C. gariepinus*, *O. niloticus* and *Heterobranchus bidorsalis* fingerlings fed with related seed meal-supplemented diets (Balogun *et al*., 2004; Bake *et al*., 2016; Oyegbile *et al*., 2017). The highest mean weight gain (MWG) and specific growth rate (SGR) (16.2 g and 1.9% day^{-1} respectively) attained by fish fed Diet 2 evidently attested to their optimal diet utilization and better conversion of dietary nutrients to flesh when compared with those fed with the other diets. The significantly lower growth indices manifested by fish placed on Diets 3 to 6 could be associated with low diet intake, diminishing palatability of the diets and presence of anti-nutrients in the diets. This finding corroborates the report of Akande and Fabiyi (2010) that most anti-nutrients inactivate some important dietary nutrients by obstructing the digestive process or metabolic utilization of feed which in turn impairs optimum nutrition. Comparable reducing growth responses were observed in *O. niloticus* and *C. gariepinus* fingerlings at higher inclusion levels of pawpaw seed meal and related seed meal-supplemented diets (Farrag *et al*., 2013; Bake *et al*., 2016). The current SGR values (1.3 – 1.9 %day^{-1}) harmonized with 1.85 – 2.57 %day^{-1} already documented for *O. niloticus, C. gariepinus* and Heteroclarias fingerlings fed pawpaw seed meal and other seed meal-supplemented diets (Farrag *et al*., 2013; Aliu and Osaro, 2018; Michael and Mathias, 2020; Michael *et al*., 2021; Jibrin *et al*., 2021; Zulhisyam *et al*., 2021). The low feed conversion ratio (FCR) values (1.86 – 2.32) were not significantly different ($p > 0.05$) across the six treatments and implied improved diet utilization by the fish since, according to De Silva (2001), ideal FCR values range between 1.2 and 1.8 for fish fed adequately formulated diets. Lower FCR depicts higher protein conversion efficiency and is inversely correlated with better feed utilization by fish which yields better growth (Olele *et al*., 2013). The numerically least FCR value (1.86) attained by fish fed Diet 2 suggested that they efficiently assimilated and converted dietary protein to more biomass at 10% SPSM supplementation level. Similar FCR values (1.91 – 2.73) have been documented for *O. niloticus* and *C. gariepinus* fingerlings raised on pawpaw seed meal and other seed meal-supplemented diets (Farrag *et al*., 2013; Michael *et al*., 2021; Zulhisyam *et al*., 2021). The values of protein intake (8.39 – 11.97 g 100g diet/fish) equally implied better dietary protein assimilation when juxtaposed with 0.18 – 0.29 and 0.84 - 1.33 g 100g diet/fish respectively observed in *Heteroclarias* and *C. gariepinus* fingerlings in related studies (Anyanwu *et al*., 2008; Adesina and Ikuyeju, 2019). The protein efficiency ratio (PER) values (1.09 – 1.35) marginally agreed with 1.63 – 2.58 found in *C. gariepinus* fingerlings in similar studies (Babale, 2016; Oyelere *et al*., 2016; Bake *et al*., 2016, 2020; Jibrin *et al*., 2021) and comparatively suggested better dietary protein utilization than 0.1 – 0.38 documented for *C. gariepinus* fingerlings fed locust bean seed meal-supplemented diets

(Michael and Mathias, 2020). PER indicates how effectively the protein ingredients in a particular diet can release the necessary essential amino acids in the fish nourished with such a diet (Davis, 2004). Fish survival rate (70 – 85.5%) recorded in this study concurred with 75.0 – 86.66% previously reported for *O. niloticus* fingerlings fed pawpaw seed meal-supplemented diets (Farrag *et al*., 2013) and 67.03 – 92.35% recorded for *C. gariepinus* fingerlings in related studies (Jimoh *et al*., 2014; Aliu and Osaro, 2018; Nwose *et al*., 2021) while it signified better survival in comparison with 48.0 - 86.0% achieved by *C. gariepinus* fingerlings (Anyanwu *et al*., 2015). This fairly high survival rate possibly implied that supplementing soaked pawpaw seed meal in the diet of *C. gariepinus* juveniles did not cause severe fish mortality. It further suggested adequate acceptability of the prepared diets by fish which could be associated with good handling, adequate water quality management, suitable feed processing and suitability of soaked pawpaw seed meal incorporation in *C. gariepinus* diet.

CONCLUSION

The results from this study have shown that soaked pawpaw seed meal can be used as an unconventional supplement in diet formulation for *C. gariepinus* juveniles. It was observed that 10% SPSM supplementation (Diet 2) yielded the best indices of growth performance, feed intake and utilization. Higher SPSM supplementation levels (20 - 50%) evidently caused progressively diminishing feed utilization and growth response. In view of this, other processing methods should be employed to broaden the scope of utilization of pawpaw seed meal in fish feed production for *C. gariepinus* and other cultivable species.

ACKNOWLEDGEMENT

The authors sincerely thank Mr. A. J. Adebayo (Assistant Chief Technologist) and his co-workers in the Department of Chemical Sciences, Olusegun Agagu University of Science and Technology, Okitipupa, Nigeria for technical support during chemical analyses of experimental fish and diet samples.

24 - 28 Oct., 2022

ABSTRACT

Grey Mullet is a member of the family Mugilidae, order Mugiliformes. Mullet are ray-finned fish found worldwide in coastal temperature and tropical waters. They are nektonic, usually in shallow inshore environments, such as coastal bays, reef flats, tide pools and round harbor pilings and in brackish water estuaries and mangroves. These species are diurnal and feeds on zooplankton, benthic organisms and detritus. Mullet are usually farmed in polyculture; it can be stocked along with other species. Stocking density depends on the site locations and the fish species to be stocked with mullet. The culture of grey mullet totally dependent on the physical, chemical and biological environmental requirement of fish. Mullet are cultured in so many part of the world, usually in extensive and semi-intensive ponds system. Aquaculture production by species in Africa show that Egypt alone produce grey mullet which comes second among the other species produced in Africa with tilapia topping the list while Africa catfish is the third on the list. Catfish is the most common to Nigeria aquaculture production. Nigeria is blessed with six species of grey mullet which are common landing of most artisanal fishermen in coastal area such as Lagos lagoon, Bonny River and Niger Delta. Adequate information on mullet culture will increase the number of culturable fish species in Nigeria.

Keywords: grey mullet, mugilidae, culture, Nigeria

INTRODUCTION

Global production of Grey mullet, increased from 25,600 tonnes in 1997 to 147,000 tonnes in 2003. Most of the reported increase was the result of the increased production from Egypt, which is the largest producer (92% in 2003). According to the Food and Agricultural Organization of the United Nation (FAO, 2015), there are no clear trends in production in the other countries rearing

Grey mullet. Aquaculture production by species in Africa show that Egypt alone produce grey mullet which comes second among the other species produced in Africa with Tilapia topping the list while Africa catfish is the 3rd on the list (FAO, 2011). Thus, grey mullet ranked second in production volume, but its production is confined to Egypt, therefore Tilapia and catfish are the most commonly farmed species in other parts of Africa except Egypt. Catfish is the most common to Nigeria aquaculture production (Bhujel, 2014). Aquaculture in Nigeria is limited to few species. Nigeria is blessed with six species of grey mullet which are common landing of most artisanal fishermen in coastal area such as Lagos lagoon, Bonny River and Niger Delta (Fagade and Olaniyan, 1973 and King, 1984). Adequate information on Mullet culture will increase the number of culturable fish species in Nigeria. FDF (2015), and Oziegbo *et al.,* (2014) Reported that out of over 1027, 058 MT of various freshwater, brackish and marine water fish species produced between 2008 to 2015 grey mullet is very negligible 11,967 compared to Clariidae catfish production. (Oziegbo *et al.,* 2014).

The choice of species to culture is very important for the success of any aquaculture production (Ugwumba and Ugwumba, 2003). Mullet are fish species with good market value, its seed is available from wild all year round and have very high potential yield mostly when poly-cultured with other species (Deekae *et al.,* 1994, Ugwumba and Ugwumba 2003)

Importance and value of grey mullet

Grey mullet is a very important aquaculture species in so many countries. Mullet are abundant in the wild. The species can grow up to a length of 120 cm (Saleh 2008). In Nigeria mullet are very important to commercial fishery as they form major constituent of the fish landings of artisanal fishermen in the Niger Delta region (Akpan and Ubak 2005). Saleh (2008), reported that mullet fetch the best price where marketed fresh. It is also processed into dried, salted product. Their roe which in some area such as Egypt and far East, has relatively highly valued if sold fresh, salted and dried or smoked.

Culture of Grey Mullet

Mullet are cultured in many countries of the world, usually in extensive and semi-intensive pond systems. Egypt has a long history of mullet aquaculture (Saleh 2008). Mullet are usually grown in extensive, semi- intensive and netted enclosures in shallow coastal waters. According to Pilly and Putty (2005), Mullet can be polycultured successfully with many other fish including common carp, grass carp, silver carp, Nile tilapia and milkfish and can be reared in freshwater, brackish and marine water Saleh (2008).

In Nigeria, several trial of polyculture of mullet was carried out e.g Ezenwa (1977) (polyculture trial of mullet) and (common carp) and Anyanwu and Awa (1988) (mullet, tilapia, hemichromis and elops spp respectively). In Nigeria mullets are very important to commercial fishery as they form major constituent of the fish landing of artisanal fishermen in the Niger Delta region (Akpan and Ubak, 2005, Abdullahi and Okonji 2018).

Identification and distribution

Mullet are member of the Order mugiliformes, family mugilidae. Mullet are ray-finned fish found worldwide in coastal temperate and tropical waters. Some species are also in freshwater. Taxonomically the family is usually treated as the sole member of the order mugiliformes (Saleh

2008). Mullet is an extremely important fish cultured in many countries particularly Mediterranean. It has a worldwide distribution and they feed at the lowest trophic level (i.e plants, detritus and algae) (Smith and Swart, 1998, Abdullahi and Okonji, 2018).

According to Edward *et al.,* (2001) many species of Mullet enter fresh water and they generally swim in large schools. There are 25 species in this genus Mugilidae. However, only 16 species are recognized with Liza species having the last number (Menezes *et al*; 2015). Mullet can be found in the western part of Africa from senegal to Angola. *Liza falcippinis* is probably the dominant mullet in West Africa coast and contribute significantly to the mullet fishery in Nigeria (King 1988 and Abdullahi and Okonji, 2018).

Habitat

Most mullets are found in coastal marine and brackish waters. They are nektonic, usually in shallow inshore environments, such as coastal bays, reef flats, tide pools, and around harbor pilings and in brackish water estuaries and mangroves. They usually swim over sandy-muddy bottoms and sea grass meadows, in relatively still waters. They commonly occur at water depths of 20 m but may be found offshore or in deeper waters. Many species are euryhaline and move between marine and freshwater environments of rivers and flooded rice fields. Some species occasionally swim far up river, while a few species spend their entire adult lives in rivers (Smith and Smith, 1986; Cardona, 2006). They are catadromous, frequently found in estuaries and freshwater environments. Adult mullet have been found in waters ranging from zero salinity to 75 ppt, while juveniles can only tolerate such wide salinity ranges after they reach lengths of 4–7 cm (Cardona, 2000). Adults form large schools near the surface over sandy or muddy bottoms and dense vegetation and migrate offshore to spawn in large aggregations (Eschmeyer, *et al*, 1983). The larvae move inshore to extremely shallow water, which provides protection from predators as well as a rich feeding ground. After reaching 5 cm in length, the young mullets move into slightly deeper waters (Saleh, 2006)

Feeding

The species is mainly diurnal and feeds on zooplankton, benthic organisms and detritus. Adult fish tend to feed mainly on algae. The success of mullet aquaculture is also a result of its feeding habits. Mullet are usually farmed in polyculture with other fish species in earthen ponds. Enhancing natural food production in the ponds through artificial fertilization is important as this reduces considerably the requirements for manufactured feed. In the Egyptian polyculture system, natural food covers 25–50 percent of the food requirement of the cultured fish (tilapia, carps) while the farmed mullet depend totally or to a very large extent on natural food. Cultured mullet are sometimes supplied with wheat or rice bran during the late nursery stage or when cultured as the main component of the fish stocks. Chicken manure is also used successfully as fertilizer to boast natural food for mullet in nursery and on-growing ponds.

Stocking Density

In countries where most cultured mullet are produced, pre-farming preparation of ponds is of great importance. Prior to stocking, culture ponds are prepared by drying, plowing and fertilization. Ponds are filled to depth of 25-30cm and kept at level, subsequently increased to 1.5 -1.75m and the fingerlings are stocked (Saleh 2008). In intensive polyculture of mullet in freshwater or slight

saline waters in Hong Kong, Israel, Egypt and India. Stocking is done at the rate of 10,000-15000 mullet/ha, along with 1000-2000 chinese carp fingerling/ha. In Taiwa, the stocking rate/ha is reported to be about 3000 Mullets, 2000 Milkfish, 3250 Chinese and 500 Common Carp (Pillay and Kutty, 2005).
According to Saleh, (2008) Acclimatization to the appropriate salinity and stocking about 10-15g individual at about 6200-7400/ha, a harvest of 4.3-5.6/tonnes/ha/crop can be obtained. In semi-intensive polyculture with tilapia and carp, mullet fingerlings are stocked at about 2500-3700/ha together with 1900-2500/ha of 100g size of common carp juveniles and about 62000-74000/ha of 10-15g Nile tilapia fingerlings. Total harvest are typically 20-30 tonnes/ha/crop of which 2-3 tonnes are mullets. After an on-growing season of 7-8 month. Grey mullet reach an individual weight of 0.74-1kg. The choice of rearing depend on market demand and economics (Saleh, 2008)

Environmental Requirement

The optimum fish production is totally dependent on the physical, chemical and biological environmental requirement of fish. Fish do not like any kind of sudden changes in their environment. Sudden changes may lead to stress (Bhatnager and Devi, 2013). All culturable freshwater/brackish water fish species has a wide range of tolerance to all the environmental changes (NAERLS 1996). The optimum ranges for various fresh water quality parameters for aquatic organism is shown in table 1.

Table 1. The optimum range of various fresh water quality parameter summary

Parameter	Acceptable Range	Desirable range	Stressful
Temperature ^{0}C	15-35	20-30	<12, >35
Transparency (cm)		30-80	<12, >80
Dissolve Oxygen (mg/l)	3-5	5	<5, >8
BOD (mg/l)	3-6	1-2	>10
CO_2 (mg/l)	0-10	<5 5-8	>12
PH	7-9.5	6.5-8.5	<4, >10
Alkalinity (mg/l)	50-200	25-100	<20,>300
Ammonia (mg/l)	0-0.05	0-0.025	> 0.3
Nitrite(mg/l)	0.02-2	<0.02	>0.2
Nitrate(mg/l)	0-100	0.1-4.5	>100<0.01
H_2S (mg/l)	0-0.02	0.002	Any detectable level
Plankton (No./L)	2000-6000	3000-4500	<3000>7000

Source (Bhatnagar and Devi 2013).
These above mentioned environmental guideline if taken into consideration will raise productivity and economic benefits in ponds environment required for suitable fish culture/aquaculture.

Suitable Culture System

Mullet are cultured in so many part of the world, usually in extensive and semi-intensive pond system (Eisawy and El-Bolok, 1975 and Crosetti, 2016). The traditional extensive culture of mullets together with other euryhaline species using brackish water still continues to be an important culture practice (Pillay and Kutty, 2005). In Italy, mullet farming is almost entirely based on extensive technique, with coastal lagoon and semi- intensive ponds being restocked with wild juveniles (Landoli 2000).

Saleh (2008) reported that, mullet are usually grown in extensive, semi- intensive and netted enclosures in shallow coastal waters. Mullet can be polycultured successfully with many other fish including common carp, grass carp, silver carp Nile tilapia and milkfish and can be reared in freshwater, brackish and marine water. Pillay and Kutty (2005), also reported that in Hong Kong and Taiwan, mullet are cultured in combination with Chinese carp, in Israel and Egypt with common carp and tilapia and in India with milkfish and pearspot and other estuarine species. The growing season is normally about 7-8 month under semi-intensive culture system. In Nigeria, several trial of polyculture of mullet was carried out e.g Ezenwa (1977) (polyculture trial of mullet) and (common carp) and Anyanwu and Awa (1988) (mullet, tilapia and elops spp respectively).

ABSTRACT

Cichlid species, Oreochromis niloticus and ecotype, Wesafu are of nutritional and economic importance with relevant aquaculture potential. They dominate tropical and sub-tropical fresh waters of Africa and have been successfully domesticated and hybridized reciprocally. However, differentiating them most times especially during culture is difficult. On this note, molecular characterization of pure stocks of cichlid especially ecotype cichlid, Wesafu that is unidentified and their reciprocal hybrids is necessary to determine their genetic variability for proper management in aquaculture production. This study utilized eight microsatellite loci to investigate and characterize two cichlid pure stocks (Oreochromis niloticus and ecotype, Wesafu) and their reciprocal hybrids. DNA was isolated from the clipped caudal fins of the cichlid species, amplified and further resolved on 6% polycarylamide gel electrophoresis (PAGE). The microsatellite analysis revealed that the hybrid from crossing between female O. niloticus and male ecotype, Wesafu (♀O. niloticus x ♂ Wesafu) had the highest genetic diversity as was evidenced by heterozygosity (He = 0.71) and shannon index (0.72) compared to others. Genetic relatedness was observed between O. niloticus pure stock and the female O. niloticus and male ecotype, Wesafu (♀O. niloticus x ♂ Wesafu) hybrid in the dendrogram. This finding provides genetic information for better breeding and management of these species in aquaculture production.

Key words: Molecular characterization, microsatellite analysis, Tilapia, pure stock, hybrid,

INTRODUCTION

Cichlid species (*Oreochromis niloticus* and ecotype, Wesafu) dominate tropical and sub-tropical fresh water of Africa and grow bigger than some other cichlid species particularly the ecotype, Wesafu which is unidentified and commonly found in Epe lagoon of Lagos State (Megbowon and

Fashina-Bombata, 2013). They have good nutritional, economic and aquaculture relevance which are all explored for food security in Nigeria. Furthermore, hybrids production has been of great importance to aquaculture production especially in Nigeria where different tilapia species have been cultivated. It is through hybridization that the desirable traits of selected species can be combined for fish growth enhancement and improved aquaculture production. Thus, aquaculture industry has increased through tilapia hybridization. Increased aquaculture production is greatly needed due to the global population expansion in order to meet the global demand.

According to Luo *et al*. (2015), understanding the genetic differentiation between wild and cultured populations will help inform proper management strategies and conserve wild genetic resources. Microsatellite markers have proven to have great discriminatory power as codominant for the evaluation of genetic diversity between wild and cultured aquaculture populations of cichlid species (Zhu *et al*., 2011). The present study is therefore focused on the investigation of the genetic variation of these cichlid species vis-à-vis their reciprocal hybrids which will form the basis for improved breeding programs of Tilapia aquaculture.

MATERIALS AND METHODS

Twenty specimens were taken from each of the cichlid species (*O. niloticus* and ecotype, Wesafu) and their reciprocal hybrids; female *O. niloticus* with male ecotype, Wesafu (♀*O. niloticus* x ♂ Wesafu) and female ecotype, Wesafu and male *O. niloticus* (♀Wesafu and ♂ *O. niloticus*) from fish hatchery of Nigerian Institute for Oceanography and Marine Research Lagos, Nigeria. Genomic DNA was extracted from the muscle tissue (1 cm^2) of the experimental fish using modified phenol-chloroform method. The purity check for the extracted DNA quality was done using a Nano-drop spectrophotometer at absorbance of 260/280nm and was further amplified in a thermocycler with eight microsatellite primers. The amplicons were separated on polyacrylamide gel electrophoresis (PAGE) at 6% concentration and 80 V for 2 h in a 1x TBE buffer.

Data Analysis

Genetic data generated was analyzed using POPGENE version 1.32 to obtain the number of alleles, effective number of alleles, Shannon information index, fixation index, observed heterozygosity and expected heterozygosity while the UPGMA dendrogram was used to determine the genetic relationship between the cichlid pure stocks and their reciprocal hybrid.

RESULTS AND DISCUSSIONS

DNA markers have been confirmed satisfactory to evaluate the genetic variability of two cultured strains of O. *niloticus* (Espindola de Souza, 2007). The microsatellite analysis revealed that the hybrid of female *O. niloticus* and male ecotype, Wesafu (♀*O. niloticus* x ♂ Wesafu) had the highest mean number of alleles (2.25), followed by the parents (*O. niloticus* and ecotype, Wesafu) with 2.00 mean number of allele respectively while the lowest was found in the hybrid of female ecotype, Wesafu and male *O. niloticus* (♀Wesafu and ♂ *O. niloticus*) (1.62).

The mean effective alleles varied from 1.37 to 1.98. In all, the mean effective number of allele was lower than the number of alleles. Shannon information index showed higher in ♀*O. niloticus* x ♂ Wesafu hybrid (0.72) followed by the parents reflecting high genetic diversity and the ♀Wesafu and ♂ *O. niloticus* hybrid had low index. The ♀*O. niloticus* x ♂ Wesafu hybrid was more variable

(He = 0.71) than the parents and ♀Wesafu and ♂ *O. niloticus* hybrid. Gene diversity was observed highest in ♀*O. niloticus* x ♂ Wesafu hybrid than others as shown in Table 1. The cross between the female *O. niloticus* and male ecotype, Wesafu (♀*O. niloticus* x ♂ Wesafu) hybrid was observed to have the most diversity as demonstrated by the number of alleles, Shannon's information index and heterozygosity which were higher in this hybrid when compared to the pure stocks that were observed to be less variable. Thus, ♀*O. niloticus* x ♂ Wesafu hybrid exhibits higher genetic diversity than the founder stock and might be attributed to poor selection and breeding management method observed by breeders. Therefore, adequate genetic monitoring should be considered for appropriate management of these genetic stocks.

Table 1: Summary of the genetic diversity level in the studied Cichlids and their Hybrids

Na: Number of alleles; Ne: Number of effective alleles; I: Shannon's Information Index; He: Observed heterozygosity; GD: Gene diversity or expected heterozygosity; F: Fixation index

OWhybrid: ♀*O. niloticus* x ♂ Wesafu, WO hybrid: ♀Wesafu and ♂ *O. niloticus*

The UPGMA dendrogram based on the genetic distance revealed two clusters: Cluster-1 consists of *O. niloticus* pure stock, female *O. niloticus* and male Wesafu (♀*O. niloticus* x ♂ Wesafu) hybrid and Wesafu pure stock suggesting genetic similarity between them while cluster-2 consists of female Wesafu and male *O. niloticus* (♀Wesafu and ♂ *O. niloticus*) hybid that clustered separately (Fig. 1) indicating a slight genetic divergence which might be due to hybridization. The genetic similarity between the *O. niloticus* pure stock and its hybrid might be attributed to single ancestry which is in line with the finding of Agbebi *et al*. (2016).

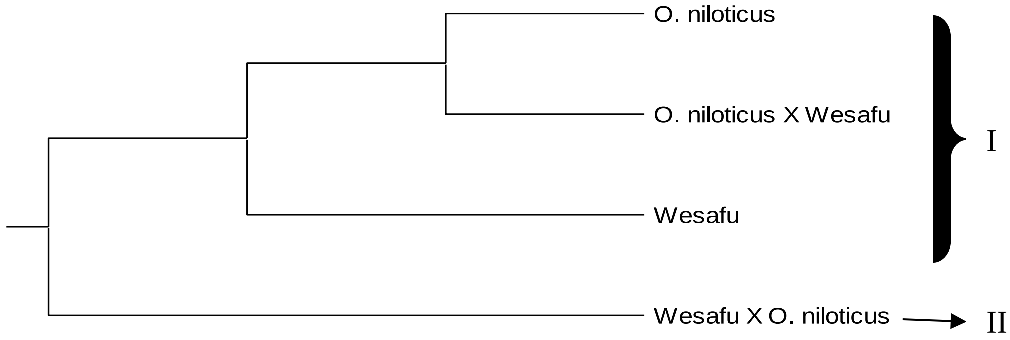

Figure 1: Dendrogram showing the Genetic Relationships among Cichlids Pure Stocks and their Hybrids

CONCLUSION

The female *O. niloticus* and male ecotype, Wesafu (♀*O. niloticus* x ♂ Wesafu) hybrid revealed high level of genetic variability with positive heterosis than the parents (pure stocks). This finding provides an insight for the proper management of these species and better breeding program.

ABSTRACT

Fish is a worldwide a good source of protein especially in the developing countries like Nigeria. It supplies the body with needed proteins necessary for growth, replacing worn out tissues and wellbeing of individuals. Spices are seeds, fruits, roots, barks, or other plant substance primarily used for flavoring, coloring food an as antimicrobial agents used in the preservation of food materials including fishes, they maybe bactericidal or bacteriostatic in action. The microbial quality of raw and smoked cat fish (with and without spices) was assessed to determine its wholesomeness and edibility and to determine the effectiveness of spices as an antimicrobial agent. Raw fish samples were purchased, divided into three parts namely raw, smoked without spices and smoked with spices after which they were all assessed for microbial contamination with regards to the effectiveness of spices. Smoked fish samples, the spiced and the unspiced were examined organoleptically, Potato Dextrose Agar (PDA) and Nutrient Agar (NA) were used to enumerate the mould/yeast and bacteria load of the raw and smoked fish respectively while appropriate selective media (*Salmonella-Shigella* Agar, Mannitol Salt Agar) were used for the isolation *Salmonella* spp., *Shigella* spp., and *Staphylococcus aureus*. The total bacteria count was 2.0 x10^4 cfu/g for raw, 2.0 x10^4 cfu/g for smoked unspiced fish, 1.0 x10^4 cfu/g for spiced smoked fish. There was no fungal growth in the raw fish sample, 5.0 x 10^4 cfu/g for smoked unspiced sample, 3.0 x 10^4 cfu/g for the smoked spiced fish sample. The result showed that no *Escherichia coli* or *Salmonella species* was found on the smoked fish. Generally, the total bacteria count was higher than the mould/yeast count in samples A (raw fish) while in samples B (smoked fish without spices) and C (smoked fish without spice) the mould growth exceeded that of the bacteria. The sensory evaluation of the smoked fish showed that the fish was generally acceptable in taste and flavour, most especially the spiced one. In conclusion, smoked *C. gariepinus* is of high

microbiological standard, the spices reduced microbial load which confirms the antimicrobial potential of the spices.

Keywords: Catfish, Spices, Smoking kiln, Bacteria, Mould.

INTRODUCTION

African catfish (*Clarias gariepinus*) is one of the most common aquaculture species in Africa water (Dauda *et al.,* 2018). It is widely distributed throughout Africa, inhabiting tropical swamps, lakes, and rivers, some of which are subjected to seasonal drying (FAO, 2016b). African catfish consumption is on the increase in both rural and urban centers of Nigeria (Emikpe *et al.*, 2011; Adedeji *et al*, 2012). Fish is an important food commodity in the international trade but deteriorate rapidly when storage facilities are lacking (Adedeji *et al.*, 2012). Catfish is highly perishable and therefore requires careful handling and preservation to extend its shelf life and maintain its desirable quality and nutritional content. Spices and herbs have been in use for long as far back as 19^{th} centuries where they were used mainly to improve flavor and aroma and of course for preserving foods and their medicinal value (antimicrobial properties), (Zaika, 1998, Khalaf *et al.*, 2008). Spoilage of raw fish is primarily bacterial in nature while fungi may be responsible for the spoilage of the smoked one, but other factors such as enzymatic break down of the tissue contribute to spoilage. About 30% of landed fish are lost through microbial activity alone (Ghaly *et al.,* 2010). The microbial flora associated with fish is sometimes a reflection of their aqueous environment (Arafat, 2013). Water being a natural habitat for a wide range of microorganisms including bacteria, protozoa and fungi (Sumer *et al.,* 2014), fish take in or harbour these organisms from its environment. These organisms may be pathogenic to fish including humans when ingested. Thus, the need to assess the microbial load of the catfish (raw, smoked with spice and smoked without spice) with a view to determining their edibility and to ascertain the potency of spices as an antimicrobial agent (Arafat, 2013).

MATERIALS AND METHODS

(i) Sample collection: 20kg of live catfish samples (*Clarias gariepinus*) were purchased from a reputable fish farm at Command Alimosho, Lagos, and transported in oxygen bag immediately to Sofunks Food Processing unit, Command Ajasa Alimosho, Lagos for smoking according to the method of Omojowo and Ibitoye (2005). 15kg (7.5kg each for spiced, made up of blended garlic and ginger, and unspiced) of the fish were smoked at 75^{o}c for 48hrs while the remaining raw sample (5kg) was transported in an ice box to the Microbiology Laboratory of Fish Technology Department, NIOMR within one hour of purchase for microbiological assessment.

(ii) Sensory evaluation: this was carried out according to the method of Afolabi *et al.*, (1984).

(iii) Preparation of Sample for Microbial Analysis: In an aseptic manner, portions of the samples were taken with a scalpel, homogenized in peptone water with a clean, sterile electric blender. An aliquot (5g), was introduced into 45ml of sterile distilled water, homogenized, and inoculated on Nutrient Agar, Salmonella-Shigella Agar, Mannitol Salt Agar and Potato Dextrose Agar using standard microbiological methods. The plates were incubated at 37^{o}C for 24hours for bacteria and at room temperature for fungi (Fawole and Oso, 2007).

(iv) Bacteria Colony Count: After incubation, colonies were enumerated, and the results were expressed as colony forming unit per gram (cfu/g) of the samples. Discreet colonies were sub-cultured into fresh agar plates aseptically to obtain pure culture of the isolates, (Fawole and Oso, 2007).

(v) Characterization and Identification of the Isolates: The isolates were identified in terms of their colony characteristics, microscopy and biochemical tests as described by Fawole and Oso, (2007).

(vi) Analysis of variance (ANOVA), Duncan F-Test was used as the statistical tool for the results

RESULTS

The results of the assessment of the bacteriological quality of cat fish are presented in tables below. The results obtained from the total heterotrophic mean count of bacteria in fresh, smoked spiced and unspiced smoked cat fish shows that raw fish recorded the highest mean count of 2.0 x10^4cfu/ml followed by the smoked unspiced with bacterial count of 2.0 x10^4cfu/ml while spiced smoked had the least count of 1.0 x10^4cfu/ml (Table 1).

Suspected bacteria from the catfish include *Bacillus subtilis, Pseudomonas* sp., *Bacillus cereus*, *Alcaligenes* sp., *Enterococcus* spp. While fungi include *A. niger*, *A. flavus*, *R. stolonifer* and *Penicillium* sp.

Based on fungal frequency of occurrence, *Aspergillus niger* had the highest followed closely by *A. flavus* and *Rhizopus stolonifer* and the least frequent was *Penicillium* sp. Enteric organisms were not detected and this made the samples to be safest for consumption

Effects of smoking and spices on the microbial load and sensory evaluation results follow thus

Table 1: Bacterial and fungal counts of the catfish samples

Samples	NA cfu/ml (10^4) for bacterial count	PDA cfu/ml (10^4) for fungal count
Raw	2.0	-
Smoked unspiced	2.0	5.0
Smoked spiced	1.0	3.0

table 2: fungal isolates occurrence from the catfish samples

Isolates	Number of appearances	% occurrence
Aspergillus niger	5	33
Aspergillus flavus	4	27
Rhizopus stolonifer	4	27
Penicillium sp.	2	13

DISCUSSION

From the results of this study, it was discovered that microbial loads of the raw catfish showed a slight difference from the spiced smoked and unspiced smoked fish samples and this could be attributed to the fish habitat which isn’t free from anthropogenic activities and human waste disposals. This can be compared with the work done by Adebayo-Tayo *et al.*, (2012) who also reported a slight varying load of isolates from raw and smoked catfish. Comparing the fresh and dry catfish, it was discovered that bacterial loads of the fresh catfish sample was more than that of the smoked owing to the water availability which is a condition for microbial attack and deterioration but fungal load in the smoked fish samples is more than that of the raw fish, this could be as a result of low water activity which favours fungal manifestation.

Organisms such as *Bacillus subtilis, Pseudomonas* sp., *Bacillus cereus, Alcaligenes* sp., *Enterococcus* spp., among others were suspected to be present in the fish samples. This was in agreement with the wok of Osuntokun *et al.*, (2020), who isolated similar organisms from catfishes from earthen and concrete tanks.

Smoking and spices, which maybe antimicrobial in nature, may also be a contributing factor in the reduction in the microbial load for the spiced fish sample. These spices do not only reduce water availability which is a condition for fungal growth but also impair microbial cell formation. As a result of this, spiced smoked fish sample had least microbial growth.

CONCLUSION AND RECOMMENDATION

From the results obtained, it could be concluded that raw fish harbour more of bacteria possibly because of the habitat and human handling while smoked fish samples had more of fungal growth. Spices being antimicrobial in nature affects both spoilage microorganisms and human pathogens by reducing the microbial load in the fish sample there by making it more suitable for consumption and wider acceptability amongst the consumers. Sensory evaluation also showed that the spiced fish sample is more acceptable by consumers because of its taste. It is therefore concluded that smoking at the appropriate temperature as well as the addition of spices reduce microbial load in both raw and smoked fish. It is therefore suggested that contamination and re-contamination can be minimized by avoiding fish exposure to harmful chemicals, increase in hygiene of the retailers and adequate measures should be taken while harvesting, preserving and processing the fish before consumption and the use of spices, which are sourced from natural herbs that are generally regarded as safe.

24 - 28 Oct., 2022

ABSTRACT

The study examined the effects of storage on the quality of a ready-to-eat shrimp cracker at two different temperatures. The proximate composition and sensory attributes of the ready-to-eat (RTE) shrimp cracker were evaluated during the storage of the product for 12 months. Results of Proximate analysis on the samples showed a reduction in protein, lipid, and moisture content and increases in ash and crude fiber at both storage conditions. Sensory evaluation of the shrimp cracker samples at both ambient and refrigerated temperature storage revealed a reduction in quality of the samples with respect to taste with increasing duration of storage, even as the best quality (texture, odor and color) was obtained at the start of the experiment. The ready-to-eat shrimp cracker should be consumed shortly after purchase to maximize freshness of the product. Thus, storage temperature and duration seemed to have unpleasant effects on the nutritional quality of ready-to-eat shrimp cracker.

Key words: Shrimp cracker, ambient storage, refrigerated storage, proximate composition, sensory, ready-to eat

INTRODUCTION

The desire and demand for healthy foods, snacks inclusive, that are made up of dietary fiber has grown tremendously (Idowu *et al*.,2019). This increased demand for healthy snack foods, which are quick sources of good nutrition, has resulted in the development of food products which combine convenience and nutrition (Ahmed and Abozed,2014; Sreelakshmi and Ninan,2018).These low cost foods seem to have gained wide popularity when compared with other processed foods based on their good nutritional quality and availability in various forms, their varied taste and longer self-life (Hussein *et al*.,2011). As ready to eat, convenient and inexpensive food products, they tend to possess digestive and dietary principles of vital importance(Idowu *et al*.,2019).

One of such important traditional fish-based snack food is the crackers, usually defined as biscuits that are more or less unsweetened, salty, thin and crispy with very low sugar and fat content (Uchegbu and Ishiwu, 2015). They are produced by gelatinization of starchy dough that is shaped into different forms before drying. Asides the two essential components of crackers which are starch and water, other ingredients, such as fish or other types of seafood, e.g shrimp, crab are usually added to produce different types of crackers (Vasanti *et al*.,1996).Crackers made from cassava starch and shellfish, properly formulated with adequate nutritional and sensory qualities, have the potential of being a source of essential nutrients for children and teenagers (Kolade *et al*.,2014).

Seafood products which include fish crackers, fish cakes, fish balls and fish burgers made from fish or other seafood are suitable ready-to-eat foods preferred by consumers around the world and numerous studies have been conducted on the production, quality, and stability of these food products(Cakli *et al*., 2005).However, seafood and their products can undergo undesirable changes during processing and storage of such food products, thus resulting in deterioration which may limit their shelf life. These undesirable changes emerge majorily from protein denaturation and lipid oxidation (Siddaiah *et al*., 2001; Benjakul *et al*., 2005).Previous works has conducted on the quality changes in seafood-based ready-to-eat products from different parts in the world, aiming especially at the microbial activity development and degree of safety (Oh *et al*., 2007; Meloni *et a*l., 2009; Miya *et al*., 2010; Kim *et a*l., 2011).

There seems to be paucity of information on quality changes that occur in shrimp crackers during storage with respect to temperature conditions. Based on this, the study sought to examine the nutritional and sensory changes that occur during storage of such ready-to-eat shrimp crackers for 12months under ambient and refrigerated conditions respectively.

MATERIALS AND METHODS

Sample Collection: Three (3) cartons of samples of ready-to-eat (RTE) shrimp crackers were obtained from a wholesale shop at Mushin, Lagos. Each carton was made up of twenty (24) vacuum packed samples with each sample containing 25g of the product. The carton of the shrimp crackers were transported to the Nigerian Institute for Oceanography and Marine Research, Victoria Island, Lagos for analysis. At the laboratory, 21 packs of the vacuum packed shrimp crackers were placed in a refrigerator (4°C) while another 21 packs of the products were left in the product carton and placed in a dry corner in the laboratory under ambient temperature (28^{o}C). The shelf life of the ready to-eat product under ambient conditions was indicated on the product pack and was indicated to be 10months. However, the present study was designed to reach such expiration date and surpass it. Thus, sampling of the product was carried out every other month for 7 times (month 0,2,4,6,8,10,12). Three packs of the vacuum packed products were taken from the refrigerated and ambient stored shrimp crackers respectively for proximate composition analysis and sensory evaluation at each sampling time. Each pack of the sample was opened, broken into smaller bits and then blended into powdery form. Five grams (5g) was taken from the blended the refrigerated and ambient stored shrimp cracker samples respectively and analyzed separately. In order to achieve the statistical analysis (n = 3) analyses were carried out in triplicates on the homogenized ready-to-eat shrimp cracker.

Proximate Composition Determination
Proximate composition of samples was determined using Association of Official Analytical Chemistry (A.O.A.C) methods (1994). All analyses were done in triplicates.

***Moisture Content**:*-This was estimated by drying samples to constant weight at 103 ± 20^{o}C using the oven dry method.

***Lipid Determination**:*-This was carried out using the modified Bligh and Dyer procedure (1959).

***Protein Content**:*-The protein content of the crackers was estimated by Kjedahl method as described by
(Vlieg,1984).This method involved the estimation of the amount of nitrogen in the sample and subsequent multiplication by a factor of 6.25.

Ash content :-The ash content of the shrimp cracker samples were determined by igniting the samples at 550^{0}C for about 5-6 hours until the samples was completely free of carbon particles in a carbolite Sheffield LMF3 muffle furnace. This was done based on Association of Official Analytical Chemistry(A.O.A.C) methods (1994).

Sensory Evaluation
Sensory Evaluation of the product was carried out using a 10-point Hedonic scale (Amerine *et al*.,1965) while assessing the samples for parameters such as taste, appearance, texture, color, odor and general acceptability. The organoleptic scoring for the shrimp cracker was rated as 1 for dislike extremely, 2 for dislike very much, 3 for dislike moderately, 4 for dislike slightly, 5 for neither like nor dislike, 6 for like slightly, 7 for like moderately, 8 for like very much, 9 for like extremely. Mean score 6 was considered as good and below 5 as poor or unacceptable. Panelists were given an opportunity to make additional comments.

Statistical Analysis
Samples were analyzed in triplicates even as mean values and standard deviations were calculated and results were expressed as mean ± SD. Analysis of variance (one-way ANOVA) was carried out using SPSS (IBM SPSS statistics version 16). Duncan multiple range test was employed to determine statistical differences of mean values at ($P \leq 0.05$).

RESULT
Mean nutrient compositions of the ready-to eat shrimp cracker stored under ambient temperature and refrigerated temperature are shown in tables 1&2.The results showed a gradual decline in the quantities of the nutrients of the ready-to eat shrimp cracker at both ambient and refrigerated temperature conditions. Percentage crude protein dropped from 5.22% to 5.07% during ambient storage while it dropped to 5.09% in refrigerated storage temperature(4^{0}C). Lipid content of the shrimp cracker which was 7.8% at the start of the experiment dropped to 7.45% at ambient temperature storage and to 7.47% at refrigerated temperature storage (Tables 1& 2).There was also a reduction in moisture content of the ambient stored shrimp cracker from 5.93% to 5.75% ,and from 5.93% to 5.80% for the refrigerated stored shrimp cracker. Furthermore, an increase was observed in the ash content of the shrimp crackers stored at ambient temperature and refrigerated temperature conditions respectively.

Table 1: Proximate composition of Ready-to-eat Shrimp Shrimp Cracker at Ambient Temperature condition (28^{0}C).

Storage Period (Month)	Protein (%)	Lipid (%)	Moisture (%)	Ash (%)
0	5.22 ± 0.06^{a}	7.8 ± 0.2^{a}	5.93 ± 0.23^{a}	4.70 ± 0.29^{a}
2	5.19 ± 0.12^{ab}	7.76 ± 0.7^{a}	5.9 ± 0.21^{ab}	4.78 ± 0.29^{a}
4	5.20 ± 0.12^{ab}	7.52 ± 0.29^{ab}	5.87 ± 0.5^{bc}	4.82 ± 0.12^{a}
6	5.15 ± 0.12^{c}	7.50 ± 0.5^{bc}	5.85 ± 0.25^{bc}	4.92 ± 0.12^{a}
8	5.13 ± 0.58^{c}	7.48 ± 0.29^{cd}	5.83 ± 0.29^{cd}	5.02 ± 0.5^{ab}
10	5.10 ± 0.5^{cd}	$7.42 \pm 0.^{14de}$	5.81 ± 0.29^{cd}	5.03 ± 0.29^{b}
12	5.07 ± 0.35^{d}	7.45 ± 0.35^{e}	5.75 ± 0.35^{d}	5.15 ± 0.35^{c}

Results are expressed as mean ± S.D. of 3 determinations.

Table 2: Proximate composition of Ready-to-eat Shrimp Cracker at Refrigerated Temperature Storage (4^{0}C).

Storage Period (Month)	Protein (%)	Lipid (%)	Moisture (%)	Ash (%)
0	5.22 ± 0.06^{a}	7.8 ± 0.25^{a}	5.93 ± 0.23^{a}	4.70 ± 0.29^{a}
2	5.21 ± 0.12^{a}	7.7 ± 0.17^{a}	5.90 ± 0.58^{a}	4.73 ± 0.12^{ab}
4	5.20 ± 0.5^{a}	7.72 ± 0.25^{b}	5.86 ± 0.5^{abc}	4.73 ± 0.29^{a}
6	5.18 ± 0.5^{ab}	7.67 ± 0.25^{c}	5.86 ± 0.12^{abc}	4.83 ± 0.29^{abc}
8	5.16 ± 0.50^{abc}	7.61 ± 0.29^{bc}	5.85 ± 0.29^{bac}	4.88 ± 0.29^{bc}
10	5.14 ± 0.29^{bc}	7.60 ± 0.29^{c}	5.82 ± 0.5^{cd}	5.09 ± 0.36^{c}
12	5.09 ± 0.12^{c}	7.47 ± 0.16^{d}	5.80 ± 0.58^{d}	5.17 ± 0.58^{c}

Results are expressed as mean ± S.D. of 3 determinations. Test values carrying different superscripts differ from one another across the rows ($P<0.05$).

Tables 3&4 show the organoleptic score ratings for the diverse parameters of the RTE shrimp cracker stored at ambient and refrigerated temperature conditions. The results showed a gradual decline in quality of the product based the ratings for the parameters of the ready to eat shrimp crackers stored at both ambient and refrigerated temperature conditions respectively.

A decline in the quality of product based on the organoleptic assessment seemed to be more apparent in the sample stored at ambient temperature as scoring for appearance, taste and texture dropped from 8.08 to 7.78, from 7.75 to 7.25 and from 7.67 to 7.40 respectively. Color and odor rating declined from 7.67 to 7.52 and from 7.67 to 7.45 respectively. The overall acceptability rating for the product at ambient storage dropped from 7.83 to 7.62.

For the shrimp cracker sample stored at refrigerated temperature, organoleptic score ratings for appearance, taste and texture reduced slightly from 8.08 to 7.80, 7.75 to 7.50 and 7.67 to 7.50 respectively. Color and odor score ratings dropped slightly from 7.67 to 7.53 and 7.67 to 7.56 respectively. The overall score rating for the refrigerated shrimp cracker declined from 7.83 to 7.66.

Table 3. Sensory Evaluation of RTE Shrimp Crackers at Stored At Ambient Temperature(28^{0}C).

Storage Period (Months)	Appearance	Taste	Texture	Color	Odor	Overall Acceptability

DISCUSSION

Proximate analysis of foods is used to estimate the components in food and such food components includes moisture, ash, lipid, protein and carbohydrate content. These food components could be useful in the food industry for the development of new products, quality control or regulatory purposes(Thangaraj, 2016).

Protein :-The protein content of a food is considered the most essential constituent of food (Jeyasanta *et al.*,2019). Most seafood have protein content that range between 18-20%, (Balachandran,2001). These variations tend to occur based on age, fat content, spawning, and starvation of the raw materials.

The protein content of the ready-to-eat shrimp cracker found to be 5.22%, later declined to 5.07% at ambient temperature storage and to 5.09% at refrigerated temperature storage (4^{0}C). This could be attributed to gradual breakdown of initial crude protein to more volatile products(Eyo,2001)..

Lipid:- Lipid content of the ready-to-eat shrimp cracker was found to be 7.8%. At the end of storage at ambient storage conditions, the lipid content of the shrimp cracker had dropped to 7.45% and to 7.47% at refrigerated temperature storage. This could be attributed to the occurrence of oxidation of the lipids of the shrimp meat. Lipid oxidation has been reported to be is a major factor that triggers spoilage in seafood (Shikha *et al.*,2017).

Moisture:- Moisture plays an important role in slowing down the occurrence of bacterial induced spoilage in foods (Stansby,1967 Jeyasanta *et al* 2019). As an indicator of the susceptibility of a product to spoilage, it has been found to vary considerably depending on the lipid content of such food (Balachandran,2001).

Results of this present study indicated that the moisture content of this ready-to-eat shrimp cracker was found to be 5.93%. Jeyasanta *et al.* (2019) reported that the moisture content of three ready-to-eat shrimp products (Dry Prawn Pepper fry, Dry Prawn Sambal and Dry Prawn Masala) to be 3.5%, 5.08% and 5.1% respectively. The moisture content of ready-to-eat shrimp cracker in this study was found to less than 10%. This low moisture value (5.93%) makes this shrimp cracker less prone to microbial spoilage(Umoh and Odaoba,1999; Jeyasanta *et al.*,2019).It however, decreased to 5.75% at ambient temperature storage and 5.80% at refrigerated temperature storage. This could be attributed to occurrence of evaporation of moisture from the product at both storage conditions.

Ash :- Ash content of a food is the portion that remains after complete combustion of the product. It is constituted by the minerals present in seafood and the content varies between 0.4 and 2% in seafood (Balachandran,2001). Result of this study revealed that ash content in ready-to-eat shrimp cracker stored in ambient and refrigeration temperatures, increased gradually throughout the storage period from 4.7% to 5.15% at ambient storage temperature and to 5.17% at refrigerated storage temperature.. This outcome is supported by the findings of Shikha *et al*.,2017 who reported an increase in ash content of fish condiment prepared from Thai Pangus (*Pangasianodon hypophthalmus*) during storage at low temperature for a long period (12 months). This observed increased levels of ash content in the RTE product could be due to moisture loss in the shrimp cracker through evaporation (Kocatepe *et al*.,2011). Reports have indicated that ash increase is related to reduction in moisture content during storage(Pawar *et al*.,2013), even as this study also portrayed an inverse relationship between moisture content and ash content of the RTE shrimp cracker.

Sensory Evaluation

This deals scientific procedures involved in evoking, measuring, analyzing and interpreting reaction characteristics of food as perceived through the senses of sight, smell, taste, touch and hearing (Joseph, 2003). The acceptability of fishery product is usually based on the consumer's perception of the overall appearance, color, odor, taste and texture of the product. There were changes in all the sensory parameters during both ambient temperature storage and refrigerated temperature storage.

The organoleptic attributes in the RTE shrimp cracker in this study showed higher mean values at the beginning of the experiment at both ambient and refrigerated temperature storage compared to the values obtained towards the end of the experiment. This could imply a gradual decline in the quality attributes of the shrimp crackers. It could also be an indication of the fact that the longer the shrimp cracker is stored at both ambient and refrigeration temperatures, the gradual the decline in the nutritional quality of the product.

Conclusion

Findings of the study showed that the RTE shrimp cracker is a good source of protein, lipid and ash with little moisture content. Significant nutritional changes seemed to occur during the storage of the product at ambient and refrigeration temperatures. However, more decline in the nutritional qualities and organoleptic parameters seemed to occur in the RTE shrimp cracker stored at ambient temperature. Therefore consumers are advised to avoid long storage of the RTE shrimp cracker at ambient temperature and refrigerated temperature before consumption so as to ensure maximum freshness of the product.

Agricultural Society of Nigeria
24 - 28 Oct., 2022

ABSTRACT

Streptococcus iniae is a significant fish pathogen of economic importance. Although, many studies have been done on Streptococcus iniae in other countries, no investigation has been carried out in Nigeria especially on Clarias gariepinus associated Streptococcus iniae infections. This study was aimed at identifying Streptococcus iniae from diseased pond-cultured Clarias gariepinus and to determine antibiotic resistance profile of the isolates. 150 diseased African Catfish were collected within a period of 12 weeks from eight consenting farms in Epe and Ikorodu farms, both in Lagos state of Nigeria. Samples were examined for signs of diseases at Aquaculture laboratory of Nigerian Institute for Oceanography and Marine Research, Victoria Island, Lagos. Catfish specimens were aseptically taken from the kidney, liver, gills, skin and intestine of the affected fish samples, and analyzed microbiologically using various media. The physico-chemical parameters and microbiological analysis of the water samples from the fish ponds were determined. Confirmatory identification of Streptococcus iniae was carried out with previously described primers using multiplex PCR. Standard Kirby-Bauer disc diffusion method was used for antibiotic susceptibility test. Out of the 150 fish screened, 30 were presumptively identified as Streptococcus iniae. The total bacterial load for the water samples ranged between 2.1×10^6 *to* 3.2×10^7 *cfu/ml on Blood Agar Base and* 4.1×10^5 *to* 4.0×10^6 *cfu/ml on Nutrient Agar. The isolates were sensitive to Cefoxitin, Ciprofloxacin, Streptomycin and Gentamycin. All the isolates were resistant to Oxytetracycline, Pefloxacin, Ceftriaxone and Oxacillin. The lactate oxidase (lctO) gene specific for identification of S. iniae was recognized in 16 (53.3%) of the 30 suspected isolates. The presence of this bacteria could be a function of the level of hygiene of the culture system. However, the indiscriminate use of drugs in fish farming portends a significant hazard to public health.*

Keyword: *Streptococcus iniae*, *Clarias gariepinus*, Antibiotics, Lactate oxidase (*lct*O) gene, Multiplex PCR.

INTRODUCTION

Clarias gariepinus (Burchell, 1822) is a species of great economic importance in Africa and South-East Asia, especially as a food fish and vital in the local sustainability of the aquaculture enterprise. According to FAO, the intensive aquaculture system, with a recognized high production capacity, is becoming an important food producing industry (Pulkkinen *et al*., 2010). Fish reared in aquaculture facilities are susceptible to infectious diseases caused by bacterial pathogens (Sudheesh *et al*., 2012).

The β-haemolytic, Gram-positive coccus, *Streptococcus iniae*, is increasingly being recognized as an important fish pathogen all over the world, with outbreaks occurring in many different cultured species specifically, *Oncorhynchus mykiss, Seriola quinquerodiata, Siganus canaliculatus*, and *Tilapia spp*. (Klesius *et al*., 2006). Although, it was originally isolated from freshwater dolphins in 1958 (Pier and Madin, 1976), and the bacterium has been isolated from a wide spectrum of fish living in freshwater, estuarine and salt water, particularly from animals farmed in intensive culture conditions (Perera *et al*., 1997). The annual cost impact of its infection on the USA aquaculture industry in 1997, alone was estimated at 10 million US dollar (Suanyuk *et al*., 2010).

In Fish, *Streptococcus iniae* causes septicemia leading to a high prevalence of meningoencephalitis, myocarditis and choroiditis (Keirstead *et al*., 2014). Moreover, the bacterium has been identified as a potential zoonotic pathogen causing infections in humans involved in the handling and preparation of the infected fish (Elizabeth *et al*., 2013), indicating a threat to public health (Zlotkin *et al*., 2003). At least 25 cases of human infection by *Streptococcus iniae* had been confirmed to date (Lau *et al*., 2006).

Current convectional phenotypic identification methods for Streptococcus can easily identify opportunistic pathogens such as *Streptococcus pyogenes* and *Streptococcus agalactiae*. However, the unambiguous identification of some of the other species of Streptococci such as the viridans group Streptococci and *Streptococcus iniae* can be challenging. Thus, this study was carried out to investigate the occurrence of *Streptococcus iniae* from pond cultured African catfish and to as well profile their antibiotic resistance.

MATERIALS AND METHODS

Study Area

Epe and Ikorodu were selected as the study locations based on the aggregations of fish farms in both locations.

Sample Collection and Processing

Depending on availability of diseased fish, fish samples showing signs of disease such of erratic swimming behavior, weakness and fin hemorrhage were randomly collected from different culture pond over a period of twelve weeks from eight consenting farms from Epe and Ikorodu fish farm estate. Water samples were collected using sterile one-liter plastic containers and were transported on ice in a cooler box, Moribund diseased fish were collected in a clean sterile cooler containing ice pack. Sample analysis was performed at the Aquaculture Laboratory of Nigerian Institute for

Oceanography and Marine Research (NIOMR), Lagos. Fish samples were aseptically dissected using a sterile dissecting kit, and were examined for signs of disease. Specimen from the gills, skin, liver, kidney and intestine were obtained using sterile scalpel One gram of each sample was weighed and mixed with 9ml of 0.1% sterile peptone water ((LAB M Ltd, United Kingdom) and homogenized in a stomacher blender (Seward medical, United kingdom). Ten-fold serial dilutions of the homogenates were made and plated out.

Isolation, Enumeration and Identification of *Streptococcus iniae*

All the chemicals and reagent used are of analytical grade. All media were prepared according to manufacturer's instructions and sterilized by autoclaving at temperature of 121°C for 15 minutes. From the ten-fold serial dilutions of homogenates, 1ml aliquots of homogenates were plated in replicates on Blood agar base supplemented with 5% sheep blood and Nutrient agar medium, using pour plate method. The plates were incubated at temperature of 37^{oC} for 18 – 24hours. The total viable aerobic bacterial count was performed on Nutrient agar. Colonies were counted using Lapiz® digital colony counter (Mumbai, India) and expressed as Colony forming unit per gram of suspension (Cfu/ml). Discrete colonies were sub-cultured into freshly prepared Blood agar base plates supplemented with 5% sheep blood by streaking aseptically to obtain pure culture of the isolates. Pure cultures of bacterial organisms were identified using standard colony morphological responses, phenotypic, microscopic and series of biochemical procedures (Barrow and Feltham, 1993).

Water Quality Assessment

PONDLAB freshwater quality test kit (NT Laboratories Ltd, United Kingdom) was used to determine levels of nitrate, nitrite, ammonia, alkalinity, total hardness, dissolved carbon dioxide and iron while pH and temperature were determined using digital pH meter and thermometer (pHep by HANNA, Mauritius) and dissolved oxygen was determined using dissolved oxygen meter (EXTECH-DO600, Taiwan).

Antibiotic Sensitivity Test

Commercially available antimicrobial susceptibility Test Single Discs from Oxoid Ltd, Basingstoke, RG24 8PW, United Kingdom, was used. Pure bacteria colonies were pick from nutrient broth using a sterile wire loop and transferred to tubes each containing 5ml of sterile normal saline. The suspension was vortexed and adjusted to match 0.5 McFarland turbidity standards. Sterile swab stick was then dipped, rotated and pressed firmly on the tube walls above the culture to remove excess inoculums from the swabs. This was then evenly swabbed on the dried surface of Mueller-Hinton agar (Oxoid Ltd, England) plates ensuring even distribution of the bacterium. Ten different antimicrobial susceptibility single discs were placed on the bacteria plates using sterile forceps and were incubated at temperature of 37^{oC} for 18 to 24 hours, after which the diameter of zone of inhibition were measured with white transparent meter rule in millimeter. The methods describe above and the interpretations of results were done using standard recommended by Clinical Laboratory Standard Institute (CLSI, 2016). The ten antibiotics used have the following concentrations: Ciprofloxacin (5 µg), Vancomycin (30 µg), Cefoxitin (30 µg), Oxacillin (1 µg), Erythromycin (15 µg), Streptomycin (30 µg), Gentamycin (30 µg), Oxytetracycline (30 µg), Pefloxacin (10 µg), Ceftriaxone (25 µg).

Extraction of Genomic of DNA from *Streptococcus iniae*

The DNA was extracted using protocol of bacteria DNA extraction kit from Jena Bioscience Germany (Spin column based genomic DNA purification).

Multiplex Polymerase Chain Reaction (PCR) Amplification.

A multiplex PCR reaction was carried out using the Solis Biodyne 5X HOT FIREPol Blend Master mix. PCR was performed in 20 µl of a reaction mixture, and the reaction concentration was brought down from 5x concentration to 1X concentration containing 1X Blend Master mix buffer (Solis Biodyne), 2.0 mM $MgCl_2$, 200µM of each deoxynucleoside triphosphates (dNTP)(Solis Biodyne), 20pMol of each primer (BIOMERS, Germany), 2 unit of Hot FIREPol DNA polymerase (Solis Biodyne), Proofreading Enzyme, 5µl of the extracted DNA, and sterile distilled water was used to make up the reaction mixture. Thermal cycling was conducted in an Peltier thermal cycler PTC 100 (MJ Research Series) for an initial denaturation of 95°C for 5 minutes followed by 35 amplification cycles of 30 seconds at 95°C; 1 minute at 55°C and 1 minute 30 Seconds at 72°C. This was followed by a final extension step of 10 minutes at 72°C. The amplification product was separated on a 1.5% agarose gel and electrophoresis was carried out at 80V for 1 hour 30 minutes. After electrophoresis, DNA bands were visualized by ethidium bromide staining. 100bp DNA ladder was used as DNA molecular weight standard.

Table 1: Primer names, oligonucleotides sequences and their size of amplicons.

S/N	Primer Name	Oligonucleotide primer Sequence ($5^{'}$ - 3^{1})	Target gene	Annealing Temperature	Size of Amplicon in base pair (bp)
1	LOX-1	AAGGGGAAATCGCAAGTGCC	Lactate oxidase	55 °C	870
	LOX-2	ATATCTGATTGGGCCGTCTAA		55 °C	
2	F1	GAGTTTGATCATGGCTCAG	16S rRNA/IMOD	55 °C	220
	IMOD	ACCAACATGTGTTAATTACTC			

RESULTS

The microbiological analysis of water from the fish culture system revealed that the total bacterial load from the water samples ranged between 2.1×10^6 to 3.2×10^7 cfu/ml on Blood Agar Base supplemented with 5% sheep blood and 4.1×10^5 to 4.0×10^6 cfu/ml on Nutrient Agar. The physico-chemical parameters of water from Epe fish farm and Ikorodu fish farm was below acceptable standard. The value for nitrite, total ammonia, alkalinity, total hardness and carbon dioxide were also above the recommended standard range, and the pond water from Ikorodu fish farm E was acidic with a pH value of 5.9.

There were different signs of infection of the fish samples from different fish farms during the studies while some were asymptomatic showing little or no clinical signs. The signs include:

hemorrhage at the base of fin, exophthalmia (Pop eye), bloated abdomen, some fish exhibits darkening of the skin, petechial on the operculum, accumulation of fluid in the peritoneal cavity, necrosis of caudal fin, hemorrhaging of the internal organs, with pale livers, enlarged spleen and septicemia were also observed.

A total of 30 bacterial isolates with unique similarity in morphology and biochemical characteristics to the control strain of Streptococcus iniae were obtained from diseased fish. The lactate oxidase (*lct*O) gene specific for identification of *S. iniae* was recognized in 16 (53.3%) of the 30 suspected isolates (Figure 1a and 1b).

The antimicrobial susceptibility data generated revealed a moderate resistance of the *Streptococcus iniae* to the antibiotics used, as the isolates were susceptible to 5 out of 10 antibiotics used. Resistance to Oxytetracycline, Pefloxacin, Ceftriaxone, Oxacillin and Erythromycin were 100%, 100%, 100%, 100%, and 68.75% respectively while susceptibility of the isolates to Cefoxitin, Ciprofloxacin, Streptomycin, Gentamycin and Vancomycin were 100%, 100%, 93.75%, 100% and 31.25% respectively (Figure 2).

Table 2: Microbial Load of Water Samples from ponds where Diseased Catfish were collected.

DISCUSSION

The physico-chemical parameters from the fish culture system reveal abnormal water quality from Epe fish farm III and Ikorodu fish farm A, where the value for nitrite, total ammonia, alkalinity, total hardness and carbon dioxide were above the recommended standard range and acidic pH in Ikorodu fish farm E. These factors could be the link that predisposed the fish to stress which consequently resulted in disease presentation. Stress in aquatic organisms occurs from environmental or other factors that extend the fish physiological processes beyond the normal range. These series of physiological responses occurs in such a way that the fish try to adapt to stress through the use of its metabolic, ionic, hematological and structural components. Thus, if the duration or the severity of the stress exceeds the tolerance limits of the fish and it is unable to acclimatize, then adverse physiological effects will ensue and subsequently results in immunosuppression, decrease swimming performance, osmotic instability and thermal intolerance. The poor water quality of these farms could be the primary cause of mortalities observed with the bacterial infection.

The disease signs of streptococcal infection from this work were similar to those observed in infected Asian sea bass, except that necrosis of caudal fin and convulsion followed by quiescence was found (Wendy and Andrew, 2007). Though the farmers from Epe fish farm III and Ikorodu fish farm A when interviewed were complaining that those fish samples with no obvious signs frequently die without showing any signs of disease and it was a great concern to them as they continue to lose their investment on a daily basis with little or no knowledge of what was wrong with their fish. It was also observed that water samples from Ikorodu fish farm A and Epe fish farm III had higher bacterial load than those from other farms. Contamination of the water may be as a result of *Streptococcus iniae* being able to replicate in the intestinal tract of fish and be released into the water through faecal waste (Bromage and Owens, 1999; McNulty *et al*., 2003).

The naturally infected catfish reported in this study were from fish farms that produced the fish in an outdoor at a high density between 100,000 to 150,000 at 400grams – 1.2 kilograms in a borehole water volume of 40,000 liters without an adequate biofilter system. The average daily mortality was 25 fishes. The ecological factors, production conditions and epidemiology of *Streptococcus iniae* at the studied catfish farms were not similar to those reported at a Japanese flounder farm having an outbreak of *Streptococcus iniae* (Nguyen *et al*., 2002). A study by Perera *et al*. (1997) had shown that immersion of fish in water containing *Streptococcus iniae* and co-habitation with diseased fish (Shoemaker *et al*., 2000) have resulted in experimental infections. There-after, Bromage and Owens (2002) proposed that *Streptococcus iniae* infection occurred orally through the consumption of infected carrier fish or through the faecal-oral route. Furthermore, water-borne infection through nares (Evans *et al*., 2001), gills (McNulty *et al*., 2003) and through damaged skin, especially at higher fish stocking densities and challenge doses (Shoemaker *et al*., 2000), are among the most likely routes of transmission.

The antimicrobial susceptibility result revealed a moderate resistance of the isolates to the antibiotics tested especially to oxytetracycline. This is not in agreement with the works of other researchers elsewhere (Pier and Madin, 1976), as all 30 the isolates were resistant to Oxytetracycline but sensitive to Streptomycin. The rate of resistance to this antibiotic could be attributed to abuse and frequent use of Oxytetracycline for diseases prevention and growth promoter in fish farming in Nigeria. However, the multiplex PCR confirmed the presence of *Streptococcus iniae* in sixteen of the isolates. Previously, Mata and others provided evidence that the lactate oxidase (*lct*O) gene was limited to a few species of streptococci and related genera (Mata *et al*., 2004). This result indicates that the *lct*O gene should be an appropriate target molecule for specific *Streptococcus iniae* PCR assay since variation was observed in the biochemical profile of the isolates and the control strain. The primer combination LOX-1/LOX-2 gave a single amplification product of 870bp, which was specific for *Streptococcus iniae* identification.

The findings of this study suggest that pond cultured African Catfish (*Clarias gariepinus*) are susceptible to *Streptococcus iniae*. The occurrence and distribution of this bacterium highlight the significance of the organism as a major pathogen in the aquaculture industry. Although, many studies have been done on *S. iniae* in other countries (Rodkhum *et al*., 2012), no investigation has been carried out in Nigeria especially on *Clarias gariepinus* associated *S. iniae* infections. *Clarias gariepinus* farming is one of the fastest growing industries in Nigeria today. Consequently, there could be an outbreak of *S. iniae* infection in intensive *Clarias gariepinus* culture system in the nearest future in Nigeria. Hence, the results from this study will serve as a baseline data for proper diagnostic approach and treatment protocol of *S. iniae* infection in case of any eventuality. Therefore, the presence of this organism could be a function of the level of hygiene of the fish ponds. In addition, the indiscriminate use of antibiotics for aquaculture portends a significant hazard to public health. Consequently, the implementation of effective, long-term vaccination programs is the most likely target for future control of the potentially industry-limiting disease caused by *S. iniae*. Further research is however needed to fully understand this pathogen, principally its serological diversity and epidemiology before vaccination programs can become successful in a worldwide scale.

ABSTRACT
Biochemical changes in Tilapia guineensis exposed to Paraquat dichloride, at various concentrations of 0.00 (control), 0.50, 1.00, 1.50, 2.00 and 2.50 mg/L were carried out to determine the levels of alterations in fish exposed to this chemical. A total of 180 T.guineensis were used for the study. Blood samples were collected from the exposed fish and analyzed with Randox test kits. Results from the study indicated that the values of metabolites such as creatinine, total bilirubin and total protein reduced significantly ($p<0.05$) in the exposed fish when compared to the control values, while significant elevation ($p < 0.05$) was observed in urea. The antioxidants analysis showed that the values of superoxide dismutase (SOD) and Glutathione-s- transferase (GSH) reduced significantly ($p<0.05$) while Catalase (CAT) and Lipid peroxidase (LPO) increased in both sizes when compared to the control. Also the enzymes analysis showed that all the enzymes under consideration were significantly ($p<0.05$) elevated when compared to the control values. Moreover, the values of electrolytes such as Na^+ and K^+ ions significantly increased ($P < 0.05$) in the exposed fish when compared to the control values, while significant reduction ($p < 0.05$) of Ca^{2+} was equally observed in the treated fish and no significant difference ($p > 0.05$) in the values of Cl^- between the control and exposed fish. In conclusion, the chemical caused some changes in biochemical profiles of the exposed fish, predisposing them to renal-hepatic malfunctions which could be attributed to stress behavioral responses resulting from the toxicity of the chemical.

Keywords: Paraquat, Aquatic Environment, Fish, Toxicology, Biochemical profiles.

INTRODUCTION
Increasing amount of industrial, agricultural and domestic wastes into the aquatic environment has led to various degrees of harmful effects on the aquatic organisms (Baron *et al*., 2003). Pesticides applications have been on the rise in recent times to control pests on the farms. This ultimately, finds their way in to the aquatic environment (Akinrotimi and Gabriel, 2012). Typically the use of

pesticides has increased within the last few decades due to extensive use in agricultural and industrial processes; as such they are becoming threats to living organisms (Adonis *et al*., 2003). Contamination of aquatic environments by pesticides in turn leads to oxygen depletion; poisoning and resultant mass mortality of fishes. Fish has the tendency to accumulate toxicants from their environment using their various parts. Xenobiotics such as pesticides could lead to physiological dysfunction in various biological system, hematological index, behavioral response, biochemical, electrolytes alterations in fish (Gabriel *et al.*, 2012).
Paraquat dichloride has become one of the most used herbicide due to its distinctive mode of action, and is one of the few chemical options that can be used to prevent and mitigate problems with weeds that have become resistant to the very widely used non-selective herbicide (Correia *et al.*, 2007). Several authors have evaluated the effects of this chemical on fish, but the information on *T.guineensis* is limited, hence the need for this study. The present paper contributes to the assessment of toxicity and the effects of paraquat on some biochemical profiles of *T.guineensis*, euryhaline specie commonly found in the brackish water zone in Nigeria.

MATERIALS AND METHODS

Experimental Location and Fish

The study was carried out in African Regional Aquaculture Center, an outstation of Nigerian Institute for Oceanography and Marine Research, Buguma, Rivers State, Nigeria. One hundred and eighty *T.guineensis* (mean length 19.87±2.99 cm; mean weight 220.99±3.11g) were sourced from ponds during the low tide. The fishes were transported in six open 50L plastic containers to the laboratory and acclimated for a period of seven days.

Preparation of Test Solutions and Exposure of Fish

Samples of paraquat dichloride used in this experiment were purchased from a commercial outlet in Port Harcourt, Nigeria. *T.guineensis* were exposed to the chemical at the concentrations of 0.00 (control), 0.50, 1.00, 1.50, 2.00 and 2.50 mg/L in triplicates. Ten fish were randomly distributed into each test tank. The experiment lasted for a period of 15 days. The water in the tanks was renewed daily. The fish were fed twice daily at 5% body weight with a commercial feed.

Determination of Biochemical Profiles

At the end of each experimental period, 2ml of fresh blood sample was collected by making a caudal puncture with the help of fine needle and poured in heparinized sample bottles. Serum was separated by centrifugation at 10,000rpm for 5-8 minutes in TG20-WS Tabletop High Speed Laboratory Centrifuge. Serum electrolytes such as Na+, K+, Ca^{2+} and Cl^- were determined by using Hitachi 902 automatic analyzer (Japan), following the method described by Gabriel *et al* (2012). The metabolites such as Creatinine, Total Bilirubin, Total urea and Total protein were analyzed in conformity with the standard methods as described by APHA (1998). Enzymes and anti-oxidants in the blood of the exposed *T.guineensis* were analyzed using a universal microplate reader on a Jenway visible spectrophotometer (Model 6405).

Statistical Analysis

All the data were expressed as mean and standard deviation of mean. The statistical package, SPSS Version 22 was used for the data analysis. The means were separated using two-way ANOVA and the two means were considered significant at 5 % ($p<0.05$).

RESULTS

The resultant effects of paraquat dichloride on the electrolytes in the plasma of *T.guineensis* are presented in Table 1. It was observed that sodium ion (Na^+) and K^+ increased with increasing concentrations of the pesticides. Also Ca^{2+} decreased significantly when compared to the control values while Cl^- were within the range of 13.0- 16.0. The effects of paraquat dichloride on the metabolites in the serum of *T.guineensis* are presented in Table 2. It was observed that creatinine, total protein and total bilurubin decreased with increasing concentrations of the herbicide while urea increased significantly when compared to the control values. The effects of paraquat on the enzymes in the serum of *T.guineensis* are presented in Table 3. It was observed that the values of AST, ALT, ACP, ALP and LDH increased with increasing concentrations of the chemical. The effects of paraquat dichloride on the antioxidants in the serum of *T.guineensis* juveniles are presented in Table 4. It was observed that the values of SOD and GSH decreased with increasing concentrations of the herbicide while CAT and LPO increased significantly when compared to the control values.

DISCUSSION

Electrolytes are needed for osmo-regulatory purposes in the body system of living organisms; therefore, alterations of the electrolyte balance of an organism would adversely affect the organism. A slight variation of values in this present study is an indication that the pesticides affected the *T.guineensis* electrolytes system in the tissue. According to Nte and Akinrotimi (2011) slight change in values of electrolytes can disturb osmotic and ionic regulation in fishes as well as general physiology in the fish. Slight fluctuation in sodium ($Na+$) values was also reported by Awoyinka *et al.*(2011) when they exposed *Clarias anguilaris* to crude oil.
ALT, AST, ALP are non-plasma specific enzymes that are localized in tissue cells of liver, heart, gills, kidneys, muscles and other organs and their presence in the blood may give specific information about organ dysfunction. Variations in the activity of these enzymes resulting from toxicant or contaminant effects in various organs of fish have been observed in other species by different authors (Gabriel *et al.*, 2012). In this study, activities of these enzymes increased, as the concentration of paraquat increased in the serum of *T.guineensis*. This assertion corroborated the findings of Gabriel *et al*. (2012) in *C. gariepinus* exposed to cypermethrin. These authors opined that the increase of transferases is as a result of diversion of alpha-amino acids in the tricarboxylic acid (TCA) cycle as keto-acids to augment energy production.

The decrease values of GSH observed in this study may be due to either direct scavenging of radicals or increased peroxidase activity (Simonata *et al*., 2008). In present study, SOD and GSH was suppressed by paraquat exposure in *T.guineensis* when compared to the control fish. Decreased SOD levels in the plasma of treated fish in this study indicate decreased ability of the tissues to handle O_{2-} free radicals. Similar findings on decreased SOD have been reported in the tissues of *Oreochromis niloticus* exposed to heavy metals intake (Firat and Kargin, 2010). The present study revealed that CAT activities in the plasma of *T.guineensis* exposed to paraquat increased significantly ($P<0.05$) after 15 days of exposure. The elevation of CAT in the present study may be physiological adaptation for the elimination of ROS generation. Similar results have been observed in Tilapia (*O.niloticus*) exposed to pesticides in the laboratory (Durmaz et al., 2006). In the present study, lipid peroxidase increased significantly in the plasma of *T.guineensis* after 15 days of exposure. The elevation of lipid peroxidation in the study, suggested participation of free radical induced oxidative cell injury in mediating the toxicity of paraquat.

In this study, total protein, creatinine and total bilurubin in the plasma of the exposed fish decreased with increased concentration of paraquat dichloride while urea increased considerably when compared to the control values. Inyang *et al.* (2016) reported similar results in plasma total protein, albumin, glucose and organ's total urea and creatinine of *Clarias gariepinus* exposed to diazinon. Similarly, Ben-Eledo et al. (2017), observed that exposure of fish for a long time to most toxicants including pesticides interferes with protein metabolism, depletion of total protein in the plasma and serum of fish. The decrease in total protein and creatinine levels may be due to impaired synthesis of protein or enhanced loss of protein via excretion and is also suggestive of some problem in the kidney (Gabriel and George, 2005). However, the very low levels of total bilirubin recorded in this study suggest that the liver may not have been affected by the toxicant. An increase in urea suggested that the kidney may have been affected by the toxicant. According to Kori-Siakpere *et al.*(2007), the ability of the kidney to excrete these products might further indicate an increase in glomerular filtration rate in the exposed fishes. Additionally, increase in values of these metabolites may suggest that the kidney is under stress to remove these metabolic wastes due to toxic effect of paraquat.

CONCLUSION

This study also showed that the toxicants caused significant alterations in biochemical profiles of the exposed *T.guineensis*, a clear indication that their usage in the fields and water environment may be a threat to aquatic biota.

24 - 28 Oct., 2022

ABSTRACT

Macro-invertebrates play an important role the ecosystem as food and also as bio-indicators of pollution due to their sensitivity to toxic compounds in the environment. a longitudinal survey of the macro-invertebrate fauna of yewa lagoon south-west nigeria was studied for a period of two years (april 2017-march 2019). Kick sampling method and van veen grab were used for sample collection from seven stations. a total of 40 species were identified belonging to 3 phyla: mollusca, arthropoda and annelida. The macro-invertebrates were dominated numerically by gastropoda (63.11%) followed by insecta (19.50%) and the least was bivalvia which contributed 0.01%. spatially, iyafin (25.3%) had the highest number of macro-invertebrates followed by ibawe (17.54%), while the least abundance was recorded at ere (9.43%). gastropoda had highest abundance at iyafin (86.9%) and least abundance at yewa river entrance (41.5%), while the sub-dominant group, insecta was the highest at yewa river entrance (41.7%). Seasonally, gastropoda was also the highest (43.15%) in abundance during the wet season followed by insecta (11.34%); the trend was the same in the dry season although the wet season had higher significant abundance. the abundance, distribution and composition of macro-invertebrate fauna of yewa lagoon were influenced by seasons.

Keywords: macro-invertebrate, Temporal abundance, Spatial distribution.

INTRODUCTION

Macro-invertebrates are important components of the aquatic ecosystem. They serve as food to some aquatic organisms especially fishes, and is a source of protein to humans directly and indirectly; they play important roles in energy flows, nutrient cycling and maintaining community balances in the ecosystems Idowu and Ugwumba (2005). Due to their limited movement, inability to avoid pollutant and sensitivity to toxic compounds, they are used as indicators and environmental monitors because they make contact with water column as well as sediments or substrates. The variations in abiotic factors always affect the macro-invertebrate in different ways and could be expressed as changes in reproduction, growth rate, mortality, distribution, diversity and abundance of these organisms in a given ecosystem (Ajao and Fagade 1990). The importance of macro-invertebrates in a given ecosystem cannot be over emphasized; so the need for quantitative as well as qualitative study to ensure sustainability of aquatic resources towards food security is of utmost importance.

Yewa Lagoon have recorded some scientific research which include the works of Olopade and Taiwo (2008) on the fish fauna of Yewa Lagoon. Taiwo and Olopade (2020) studied the fecundity and condition of *Chryschthys nigrodigitatus* and Taiwo *et al.* (2015) worked on heavy metals in the water, sediments and fish in Yewa Lagoon. Bamidele *et al.* (2015) studied the diversity of Tilapia in Yewa Lagoon. Effiong and Inyang (2015) worked on the epiphytic algae on aquatic macrophyte in Yewa Lagoon and their possible use as indicator. Effiong and Inyang (2016) studied diversity of phytoplankton in Iragbo part of Yewa Lagoon. Yewa Lagoon is a freshwater lagoon located in the western side of Lagos which lies approximately within latitudes $6^0 22'$ to $6^0 36'$ North and longitudes 2^0 50′ to 2^0 54′ East of the Greenwich Meridian. The lagoon has a total catchment area of approximately 5000 km^2 within the West African tropical climate (Lawson and Oloko, 2013). Yewa Lagoon is well known for some anthropogenic activities which include domestic chores (like bathing, and washing) logging, sand mining, boat transportation, fishing etc. The dearth of information on macro-invertebrate fauna of Yewa Lagoon motivated this research work as part of its biodiversity. The present study is focused on the abundance, distribution and species composition of macro-invertebrates of Yewa Lagoon which will contribute to the bio-data of the lagoon for research, policy making and conservation of its resources.

MATERIALS AND METHODS

Yewa Lagoon is a freshwater body located in the western side of Lagos which lies approximately within latitudes $6^0 22'$ to $6^0 36'$ North and longitudes 2^0 50′ to 2^0 54′ East of the Greenwich Meridian. Yewa River is the major sources of water to Yewa Lagoon, while it is drained by Port Novo Creek (Benin Republic) and Badagry Creek (Nigeria) in the south which empties into the Atlantic Ocean via Lagos Harboùr (Figure 1) The major activities in the lagoon include logging, sand mining, boat transportation and fishing. Yewa Lagoon is characterized by several plants like sedges (*Cyperu sarticulatus*, *C. papyrus*, and *Paspalum vaginatum*); ferns (*Achrosticum sp*, *Marsilea sp*, *Cyclosorus sp*, and Ceratopleris sp), water hyacinth (*Eichhornia crasipes*), water lettuce (*Pistia stratioles*), duck weeds (*Lemna sp)* and palms (*Pandanus candelabrum*, *Raphia hookeri*, and *Phoenix reclinata*). Seven sample stations were selected using a GPS and named after the villages closer to it as follows: Iyafin, Afowo, Ibawe, Itohun, Iragbo, Ere and Yewa River entrance.

A longitudinal survey using a random sampling design was carried out in Yewa Lagoon for a period of two years. Macro-invertebrate samples were collected monthly from all stations using kick sampling method and a grab (Van Veen) sample of the sediment was also collected for benthic macro-invertebrate, the sediment collected was sieved through a 0.5mm mesh sieve in order to reduce the bulk of material (Edward and Ugwumba 2011). The organisms were sorted out and preserved in 10% formalin to which Rose Bengal stain was added (Williams *et al.* 1999; Andem *et al.* 2012) in well labeled plastic containers and transported to the laboratory for further studies. In the laboratory, preserved samples were poured unto a white tray and sorted out and all animals in the sample were picked up with the help of a blunt forceps and magnifying lens. Macro-invertebrates were identified using relevant identification guides by Dance (1974), Morton (1971), Margo and Branch (1978), Pennak (1978) APHA/AWWA/WPCF (1985), Brown (1994), Yankson and Kendall (2001). Each identified species was counted and recorded accordingly. Macro-invertebrate data were subjected to descriptive statistics using excel for windows.

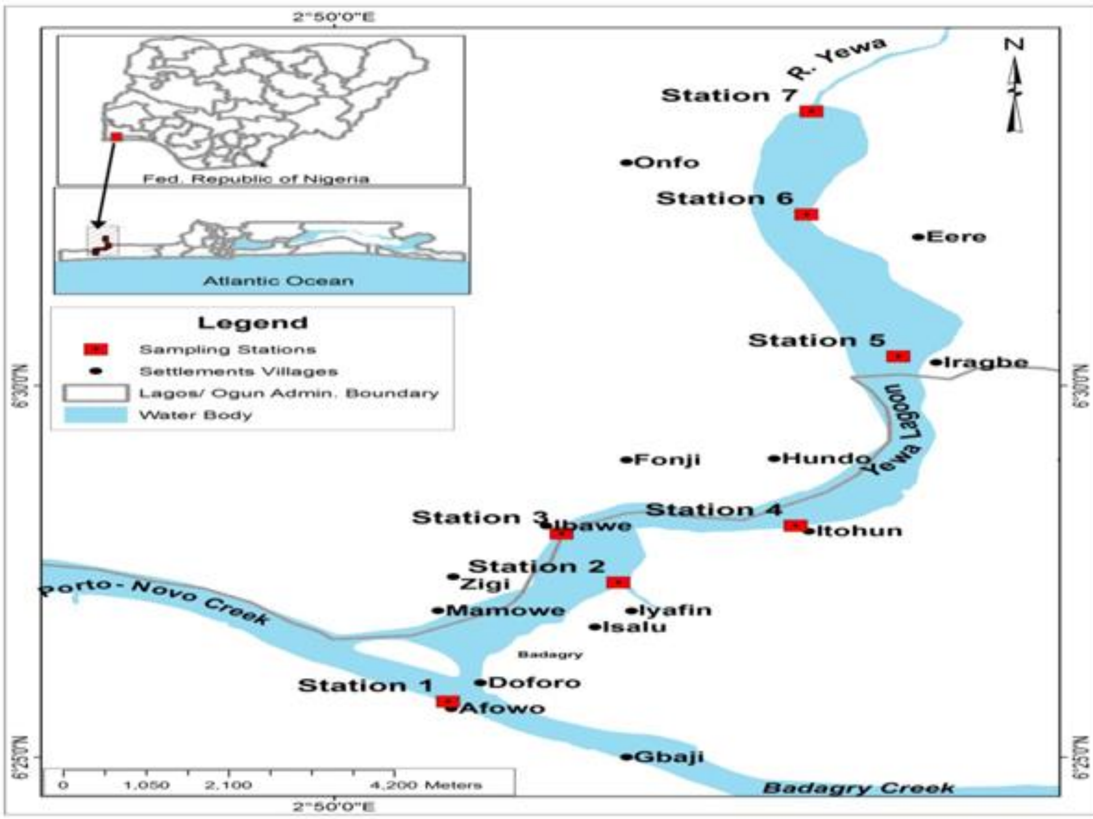

Figure 1. Map of Yewa Lagoon showing the sampling stations

RESULTS

Forty macro-invertebrate species were identified and was dominated by the Gastropoda comprising seventeen species, they constituted 63.11% of the total number of macro-invertebrates. *Pachymelania bryonensis* had the highest percentage composition (16.52%) followed by *P. fusca* (12.96%). The least abundant gastropod was *Neritina glabrata* and *Pseudosuccinea columella* which made up about 0.01% each of the total number of macro-invertebrate. The insect group was the subdominant and contributed 19.50% to the total macro-invertebrate abundance. *Dineatus sp* was the most abundant insect (7.90%), followed by *Hemicordulia* sp (5.80%) and the least abundant (0.01%) was recorded for *Aquarius remigis* and *Tipula sp*. Amongst the arthropods, Decapoda was the most dominant, with four species which constituted 11.19% of the total macro-invertebrate abundance by number. *Penaeus* sp had the highest abundance (9.89%) while *Diogenes pugilator* was the least (0.01%) abundant (Table 1). Bivalvia was the least in abundance and contributed 0.01% to the total number of macro-invertebrate during the study period (Table 1).

The trends of variations in the monthly abundance of macro-invertebrates was illustrated in Figure 2. Gastropods was higher in the wet season month of May 2017 and relatively lower in the dry season but had the least abundance in October 2017. The highest Insecta was recorded in the month of February 2018 and the lowest in the month of November 2017. The least group Bivalvia was recorded for only March 2018. Macro-invertebrate abundance was significantly higher in the wet season with Gastropoda as the highest followed by the Insect while the Bivalvia recorded the least abundance (Figure 3)

Spatially in the wet season, Gastropods were also the most abundant macro-invertebrate numerically (Figure 4). They constituted the highest percentage abundance (86.9%) at Iyafin and least (41.5%) at Yewa River Entrance. The subdominant group insecta were highest at Yewa River Entrance and lowest at Iyafin. The Decapoda had the highest (18.75%) composition by number at Afowo and least (6.51%) at Iyafin. Amphipoda had their highest composition by number (9.38 %) at Afowo and the least (2.98%) at Iyafin. Arachnida recorded the highest abundance (0.75%) at Itohun and the least (0.10%) at Afowo and Ibawe and was not found at Iyafin, Ere and Yewa River Entrance (Figure 4). During the dry season, Gastropoda took the lead with highest abundance (75.2%) at Iyafin and the lowest at Yewa River Entrance. Insecta recorded its peak abundance (60.9%) at Yewa River Entrance and lowest (13.1%) at Iyafin. Decapoda recorded highest (15.9%) at Afowo and the least (4.9%) at Iragbo. Amphipoda was highest (9.1%) at Itohun and lowest (4.4%) at Ere. Polychaete recorded the highest value (1.1%) at Ibawe and the least value (0.31%) at Afowo. Bivalvia was recorded only in the dry season with percentage composition of 0.18% at Ibawe station. Isopoda were recorded (0.37%) at Ibawe (Figure 5).

Generally, Iyafin had the highest percentage abundance of all the macro-invertebrate encountered throughout the study period. Ere station recorded the least in abundance in the combined seasons; however, Itohun recorded the least abundance during the wet season and Yewa River entrance had the least during the dry season (Figure 6).

Table 1. Checklist of Macro-invertebrate in Yewa Lagoon during the study period

Phylum	Order	Species	Wet season	Dry Season	Overall
Mollusca	Gastropoda	*Pachymelania bryonensis*	16.80	15.99	16.52
		Pachymeania fusca	13.01	12.86	12.96

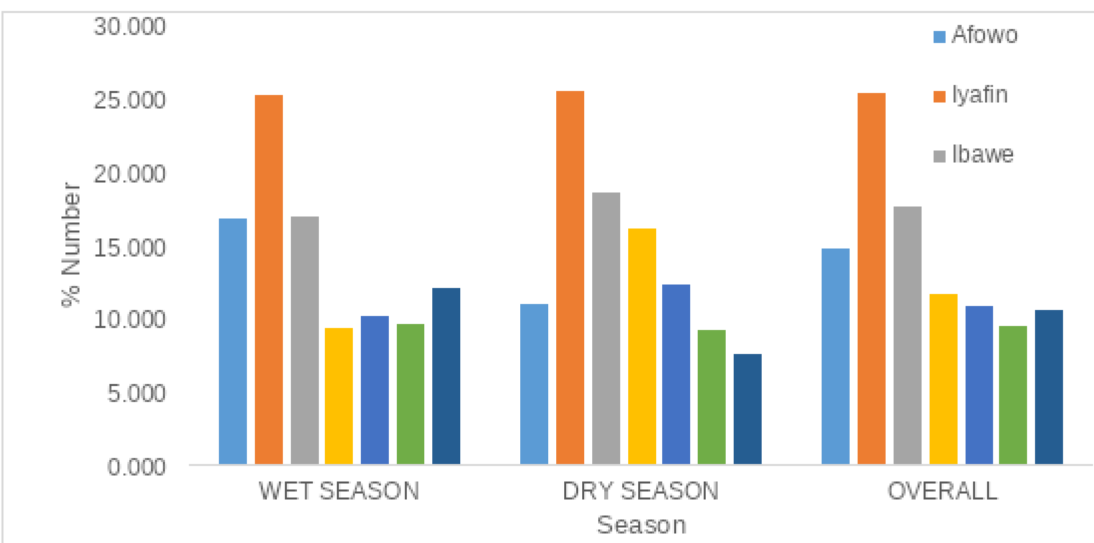

Figure 6. Spatial and seasonal abundance by number of macro-invertebrate during the period of study

DISCUSSION

The variations in the abundance, species composition and distribution of macro-invertebrates could be largely attributed to changes in the physico-chemical parameters, nature of substrate, seasons, macrophytes vegetation, predator-prey relationship as well as anthropogenic activities especially sand mining and sand filling which destroys the habitat. Yewa Lagoon will be classified as fairly rich in species composition as forty species of macro-invertebrate were encountered in this study. Similar numbers had been reported in different water bodies, Omoigberale and Ogbeibu (2010) recorded 51 species for Osse River, Ajao and Fagade (1990 and 2002) reported 42 species for Lagos Lagoon, Olomukoro and Ezemonye (2007) recorded 55 taxa of macro-invertebrates in Edo state, Ezemonye *et. al*. (2004) reported 51 taxa from Warri and Frocados Rivers in Delta state. The forty species of macro-invertebrate encountered in this present study far exceeded what had been reported in some other water bodies in the tropics (George *et al*. 2010; Sharma *et. al*. 2011, Edward and Ugwumba 2011, Andem *et.al*. 2012, Adedeji *et.al.* 2012). The most important fish species (*C. nigrodigitatus*) of Yewa Lagoon feed mainly on the gastropods as it's readily available as food sources. Ajao and Fagade (2002) considered physical variability, depths of investigation, prevailing ecological conditions, state of contamination as important factors influencing the species composition and abundance of macro-invertebrates in Lagos Lagoon.

Gastropoda is the most abundant group of macro-invertabrates in Yewa Lagoon. Their high abundance may be attributed to availability of macrophytes and suitable sediment type in the water which serves as habitat and nursery ground for them. Umeozor (1995) as well as Edward and Ugwumba (2011) reported that the most important factors causing variation in occurrence and abundance are physico-chemical qualities, nature of immediate substrate and availability of food. However, the molluscs (gastropods) and Arthropoda (insects) that dominated the macro-invertebrate population of Yewa Lagoon had been reported to be relatively tolerant of physico-chemical variations in the environment and widely distributed irrespective of seasons (Ormerod, 1988; Ajao and Fagade, 2002; Omoigberale and Ogbeibu, 2010; Sharma *et. al.,* 2011, Edward and Ugwumba 2011). Gastropod molluscs had been documented as the most dominant macro-invertebrate (Ajao and Fagade, 2002; Adedeji *et. al*., 2011, Edward and Ugwumba 2011). Molluscs are very important in the decomposition of plant matters and other detritus which forms the basis of many food chains. The most abundant gastropods in Yewa Lagoon is *Pachymelania bryonensis* followed by *P. fusca* serving as direct shell fish food for human consumption. The success of gastropods in Yewa Lagoon could be attributed to favourable physico-chemistry, food availability, suitable substrates for attachment and ability to stand fluctuation in water quality and habitat structure.

The sub-dominant group arthropoda of which Insecta ranked first in abundance and widely distributed, as they occurred throughout the sampled period, may be attributed to the abundance of macrophytes as habitat. Avoaja *et al*. 2007 reported arthropod as the most dominant group in a humid tropical zone water reservoir. The least group of macro-invertebrate in both abundance and species composition was the Bivalvia and their low abundance could be attributed to unfavourable physico-chemistry as well as unstable habitat structure. George *et al.* 2010 reported polychaete as the most dominant macroinvertebrate in Okpaka creek sediment and attributed their success to high level of pollution tolerance.

Spatially, gastropods recorded highest abundance at Iyafin station and this may be as a result of suitable substrate and observed low energy of transport of the sediment which allows them to settle there without being washed away by current or wave actions. The abundance of decapods at Yewa River entrance and may be attributed to high macrophytes and organic matter recorded while the least was recorded at Iyafin. Habitat preference is one of the factors responsible for low abundance or total disappearance of some organisms in an area as observed by Edward and Ugwumba (2011) in Egbe Reservoir. Pollution tolerant groups like dipteran and polychaete were high in Ibawe station and their success may be attributed to the nature of sediment substrate and resistance to pollution caused by anthropogenic activities. Dipterans like *Chironomus sp* are known as pollution indicator and burrow in soft sediments. Their usage as pollution indicators was documented by Williams and Feltmate (1992); Tan and Beh (2016). The disappearance of some macro-invertebrates in some stations could be as a result of the unfavourable habitat, nature of substrate, lack of the preferred food item as well as prevailing water quality and pollution status.

The higher abundance recorded in wet season in the present study conforms with the report of Edward and Ugwumba (2011). The result of this present study is not in agreement with the reports of Ajao and Fagade (2002), Omoigberale and Ogbeibu (2010), Ibemenuga and Iyang (2006), Sharma *et. al*. (2011), George *et al*. (2010) as they recorded higher abundance in the dry season and attributed the low density in the wet season to unstable substrate caused by rain. The high abundance reported in this work during the wet season could be attributed to increase in macrophytes, availability of food materials, and increased depth of water body (which makes it difficult for predators to locate them). According to Edward and Ugwumba (2011) other factors which may account for the increased abundance during the wet season is that predators like aquatic birds and some fishes exploit invertebrate prey better in the dry season as a result of the reduced water level, and clearer water that makes it easier to locate their prey.

Ogbeibu (2001) attributed the success of a particular organism in a given environment as a reflection of its heterogeneity and stability. However, the variations in abundance, occurrence and species composition at the study stations were influenced by the presence of macrophytes, sediment type, extent of pollution, availability of organic matters, seasons as well as rate of predation. The low diversity in some areas is an indication of pollution stress (Edward, and Ugwumba 2011). Some macro-invertebrates especially the arthropods thrive well in the presences of macrophytes for egg laying and attachment.

CONCLUSION

In conclusion, macro-invertebrate fauna of Yewa Lagoon is dominated by the Gastropoda species and more fauna abundance was recorded in the wet season and at Iyafin.

PROCEEDINGS
56th Annual Conference
Agricultural Society of Nigeria
24 - 28 Oct., 2022

ABSTRACT

The study was conducted to uncover Phytoplankton occurrence and distribution in five sites (Oke-Afa, Ago, Festac creek, Reservoir and Festac Link Bridge) of the Lagos Lagoon from November 2021 to April 2022. Phytoplankton sample was collected with a 55 µm mesh size standard plankton net towed from a motorized boat for 5 min at low speed and transferred into a well labeled plastic container with screw cap. Each sample was preserved with 4% unbuffered formalin and stored in the laboratory , microscopic analysis was done after 48hours. Five main algal groups were recorded namely Bacillariophyta, Cyanophyta, Chlorophyta, Dinoflagellates and Foraminifera. A total of 70 species belonging to 40 genera were observed. Diatoms formed the most abundant group making up 36 species from 22 genera. Cyanobacteria with 16 species from 6 genera, Chlorophyta with 9 species from 6 genera, Dinoflagellates 8 species from 5 genera and the foraminifera with 1 specie. Comparatively, a higher number of species was recorded in the dry season than in the wet season. The findings from this study provides useful information on the checklist of plankton species which could be potentially used as bio-indicators for assessing and monition the creek.

Keywords: Creek, checklist, algae, phytoplankton.

INTRODUCTION

Checklists of phytoplankton species in Nigeria have been documented by different workers even from the last century (Mills, 1932; Fox, 1957; Holden and Green, 1960; Imevbore, 1965; Egborge, 1973; Nwadiaro and Ezefili, 1986). Kadiri (1999) presented a list of phytoplankton species in some coastal waters of Nigeria and Opute (1991) presented a similar list for the phytoplankton of Warri/Forcados estuary. In the last two decades, there has been increasing interest in phytoplankton studies in Nigeria. This may be as a result of increased awareness of their importance in assessing the quality of water bodies, utilization of algal biomass for biofuels and bioremediation. Phytoplankton can be beneficial and/or harmful to ecosystems and public health. Their beneficial use include: acting as biological indicators, where their presence, absence, diversity, abundance and distribution are used to determine the health (nutrient) status or quality of an aquatic environment (Reynold, 2006). Phytoplankton form the base of any aquatic food chain and organic production in the coastal ecosystem (Carol and Timothy, 1993). They are the sources of oxygen in the aquatic systems and are the main primary producers in the food web (Akomeah et al., 2010). It is therefore imperative to study their taxonomy (Atici, 2002). In a pioneering report of phytoplankton species in off shore waters of Nigeria, Nwankwo and Onyema (2004) published a list of 63 species from offshore Lagos. The FESTAC creek is linked to the Porto-Novo creek, it flows into the badagry creek, and into the Atlantic Ocean through the Lagos harbour. Presently, no work has been published on the phytoplankton flora of waters around the Festac creek. The aim of this study is to produce a checklist of the phytoplankton community of the waters around the Festac creek and provide a systematic list that will therefore be useful in measuring our knowledge of the phytoplankton in the region and Nigeria.

MATERIALS AND METHODS

Description of study area:

Five sampling stations were chosen between latitudes 6°50′ and 6°2′ N and longitudes 3°18′ and 3°30′ E) and were characterised by slow flowing water.

Table 1: G.P.S. location and station name of sampled areas in the Festac Creek

STATION NO	STATION NAMES	GPS LOCATION
Station 1	Oke – Afa	Latitude 6°50'829N, Longitude 3°29'409E
Station 2	Ago	Latitude 6°48'554N, Longitude 3°30'124E
Station 3	Festac Creek	Latitude 6°27'154N, Longitude 3°18'438E
Station 4	Benny Reservoir	Latitude 6°47'772N, Longitude 3°29'662E
Station 5	Festac Link Bridge	Latitude 6°27'346N, Longitude 3°18'235E

Collection of Phytoplankton Samples

Phytoplankton sample was collected on each occasion and station with a 55 µm mesh size standard plankton net towed from a motorized boat for 5 min at low speed The net was hauled in and the sample transferred into well labeled plastic container with screw cap. Each sample was preserved with 4% unbuffered formalin and stored in the laboratory. After 48 hours and prior to microscope analysis samples were concentrated to 10ml (Nwankwo 1984)

Laboratory Analysis

In the laboratory, the samples were analyzed using a light microscope at different magnifications (X100 and X400). The drop count method described by Lackey (1938) and employed by Nwankwo (1984) was used.

Identification of Species

Appropriate texts were used to aid identification (Smith, 1950; Hendey, 1958, Wimpenny, 1966; Whitford and Schmacher, 1973 Nwankwo, 1984, 1990, 2004a

RESULTS

Five main algal groups were represented in the sampled areas of Festac Creek. These were Bacillariophyta, Cyanophyta, Chlorophyta, Dinoflagellates and Foraminifera. A total of 70 species belonging to 40 genera were observed. Diatoms formed the most abundant group making up 36 species from 22 genera. Cyanobacteria with 16 species from 6 genera, Chlorophyta with 9 species from 6 genera, Dinoflagellates 8 species from 5 genera while the foraminifera with 1 specie. Comparatively, a higher number of species was recorded in the dry season than in the wet season. Table 1 shows a checklist of phytoplankton species of the Festac area waters and their classification. Species that are first reports for South-western Nigeria with regard to existing checklists (Nwankwo, 1988; Nwankwo et al., 2003a, b; Nwankwo and Onyema, 2004; Wujek et al., 2004) are preceded by an asterick on the list (Table 1).

DISCUSSION

In the waters around the Festac Creek, phytoplankton diversity was higher in the dry than the wet season and diatoms were more important group among the phytoplankton categories recorded. Nwankwo (1988) had already reported that phytoplankton production in the Lagos lagoon was high and principally dominated by diatoms. Similar dominance of diatoms among phytoplankton assemblages have been reported by other ecologists in the coastal waters of Nigeria (Imevbore, 2006, Nwankwo 1988, 1998a, b; Nwankwo and Onyema, 2004; Onyema and Nwankwo, 2006). Similarly, Onyema et al. (2003, 2007) reported diatoms dominating the phytoplankton spectrum of the Lagos lagoon. In the Festac creek and surrounding waters, centric diatoms were more in number than the pennate diatoms. The attributed numerous centric forms recorded can be due to the effect of tidal mixing and actions of flood waters inflow that probably scours up the phytobenthic forms into the plankton of the Festac creek and surrounding waters. The flushing of planktonic algal forms towards the sea during the rains by flood waters, could also account for the reduced phytoplankton diversity in the wet season. Similarly, reduced phytoplankton diversity in the wet season may be linked to the low water clarity which reduces the amount of light available to the planktonic algal component for photosynthesis. Onyema and Nwankwo (2006) also reported similar inferences for the Ijora creek phytoplankton regime. In the waters around the Festac creek, there existed environmental gradients from the habour to areas in the creek further inland and the phytoplankton assemblages and distribution reflected these trends. The exact trend of environmental characteristics and trends were not known for the creek till now. About 15 phytoplankton species were reported to be potentially harmful/toxic bloom species Nwankwo et al. (2003b) had already reported on the toxins/potential danger and reported harmful effects of some of these species in South-Western Nigeria and especially for the Lagos lagoon. There is need for other extensive ecological studies to be carried out in the waters around Festac creek.

CONCLUSION

This study provides an important scientific information on the checklist of phytoplankton species which could be potentially used as bio-indicators for assessing and monition the creek.

ABSTRACT

The most popular, widely cultivated and mostly smoked fish in Nigeria is Clarias gariepinus. The efficacy of powder of Piper guineense, NSPRIDUST, Activated charcoal, Rice Husk Ash and Permethrin Dusts was investigated on smoked African mud catfish, Clarias gariepinus infested with fish beetle Dermestes maculatus. One hundred and twenty gram (120g) lot of disinfected smoked Clarias gariepinus were wrapped in black thin-walled polythene bag and placed into separate plastic jars. The powders were thoroughly mixed with ten newly emerged Dermestes maculatus at dosage rate of 0.1, 0.2 and 0.3% weight/weight, put in each jars and then covered with mesh. Similar method was used for control. Each treatment was replicated thrice in a Complete Randomize Design (CRD). Mortality was assessed after 7dand 14dpost-treatment, and weight loss was recorded after 68 d post-treatment.Mortalities induced by the experimental dusts against D. Maculatus were generally poor, except in permethrin dust where impressive kill was recorded. The highest mortality recorded among non-toxic dusts was 40% in NSPRIDUST with 0.3% concentration after 14d post-treatment. Future works should investigate applying this botanical at a higher dose rate or hermetically sealing the vial to entrap the pungent insecticidal volatiles of the dust.

INTRODUCTION

Fish supplies a good balance of protein, vitamins and minerals. It's harvesting, handling, processing, storage and distribution provides livelihood for millions, as well as providing foreign exchange earning to many countries (Aljufaili and Opara, 2006; Akinwumi *et al.*, 2007; Widjaja *et al.*, 2009). It is the most distributed and cheapest form of animal protein products in Nigeria (FDF, 2005; Mufutau, 2012). The Africa mud catsfish, *Clarias gariepinus* is the most popular, widely cultivated and mostly smoked fish in Nigeria (Aderolu and Akpabio, 2009).

One of the challenges facing the catfish industry is its high susceptibility to attack by insects, especially beetle species of the genera, *Dermestes* and *Necrobia* (Okpako and Agbor, 2015). The loss of dried fish to *Dermestes maculatus* especially under traditional storage conditions in Nigeria has been estimated at 40-50% (Lale and Sastawa, 1996; Lale 2002).

Various control measures have been put in place by stakeholders to check the menace by fish beetles. The use of pesticide against insect pests of stored product has long being used and still in use by farmers and fish mongers, but the pesticide/insecticides application caused illness to humans and other animals as well as nuisance to the environment (Sufi *et al.*, 2017). The use of botanicals, particularly medicinal plants and culinary species namely; *Dennettia tripetala* Baker, *Eugenia aromatic* Hook, *Monodoramyristica*Dunal, *Piper guineense*Schum and Thonn, have been tested and effective (Akinwumi, 2011; Olayinka-Olagunju, 2014). Diatomaceous earth (NSPRIDUST), activated charcoal, rice husk ash are all absorbent inert dusts with proven insecticidal actions on grain beetles (Rojht *et al.*, 2010; Shah and Khan, 2014; Ziaee and Ganji, 2016). There is dearth information on insecticidal impact of the selected dust materials on *D. maculatus*. Therefore, the objective of this study is to evaluate *P. guineense* (botanical), diatomaceous earths (NSPRI DUST), activated charcoal, rice husk ash and permethrin dusts for their effectiveness in checking *D. maculatus* population growth in fish stored in thin-walled polythene bags in the humid conditions of Port Harcourt, River State, Nigeria.

MATERIALS AND METHODS

Collection and maintenance of insect culture

The beetles (*D. maculatus)* were reared inside in the laboratory of the Nigerian Stored Products Research Institute (NSPRI), Port Harcourt, Rivers State, Nigeria at 27.5 ± 2°C and 86.5 ± 5% R.H. The beetles were obtained from the infested smoked dried fish purchased at Mile 3 market, Port Harcourt, River state, Nigeria. Unsexed adult insects were introduced into plastic drums that contained uninfected fish, allowed to mate and lay eggs. The new adults that emerged later were used for the tests. Several generations were reared in these cages for the study.

Preparation of Dusts

The five dusts used were prepared in the following ways;

1. The seed of *Piper guineense* is obtained from mile 3 market, Port Harcourt. The seeds were grind in electric grinder and sieved and kept in airtight Kilner jars for study purpose.
2. Diatomaceous Earth (NSPRI DUST®) is gotten from enhanced powder of Bularafa Diatomaceous Earth ground to dust by means of a laboratory mortar and pestle, sieved using a U.S. Standard #200 sieve (0.075 mm openings) (Seeduro Equipment Company, Chicago, IL))and kept in airtight Kilner jars for study purpose.
3. Activated charcoal was processed from Lagos with fine particles.
4. Rice Husk Ash was obtained by burning the Rice Husk obtained at a rice mill plant at temperature of 6oo^{o}C, then placed into the furnace and ashed completely for 5hours. It was cooled and sieved with laboratory sieve of 90µm aperture.
5. Permethrin0.6% Dust was purchased at commercial outlet.

Preparation of the fish sample

African mud catfish, *Clarias gariepinus* was harvested fresh, degutted and cut into sizes. The cut portions were smoked in fish kiln. In order to reduce polyaromatic hydrocarbon load, the fish was removed from the kiln after 3 hrs and transferred to NSPRI's Multicrop dryer where it was dried for 20 hrs at 55-60 ^{0}C (Pessu *et al.*, 2016).It was disinfected in the laboratory by heat in Searchtech (DHG) electrical oven at 60^{o}C for 2hours.

Bioassays

The varying concentration of *Piper guineense*, NSPRIDUST, Activated charcoal, Rice Husk Ash and Permethrin Dusts of 0.1, 0.2 and 0.3% weight/weight were mixed with ten newly emerged adults of *D. maculatus* each in separate 500ml plastic jars. A 120g lot of disinfected smoked *Clarias gariepinus* was wrapped in black thin-walled polythene bag and added to each plastic jar containing different concentration of the dusts. Each jar was closed using a cap lid, which had a hole that was covered with muslin cloth to allow aeration and prevent insects from escaping. Similar set up was set as a control. Each treatment was replicated thrice and arranged at laboratory table using complete randomize design. The mortality of the insect in each treatment was observed in 7th and 14th day post-treatment, and the weight loss after 68d post-treatment were recorded. The data were analyzed by ANOVA and mean calculated are separated using the Turkey's test when significant ($P < 0.05$).

RESULTS AND DISCUSSION

Table 1: Percentage mortality of *D. maculatus* at 7d and 14d post-treatment at 27.5 ± 2°C and 86.5 ± 5% R.H

Treatments	Conc. (%)	7d Percentage Mortality	14d Percentage Mortality

P<0.05		0.00	0.01

Means±SE and values are means of triplicate samples followed by the standard error of means. Means in the same column with different superscripts for each dusts are significantly different ($p<0.05$).

Table 1 shows that the mortality recorded by the dusts were relatively very low except the permethrin dust. This result also showed that the mortality increase as amount of dust and length of exposure increase. At 7 day post-treatment, the least mortality were recorded by *P. guineense* (all concentrations had mortality of <10%), the Rice Husk Ash performed better at all concentration with mortality of ≥30%, and permenthrin had mortality more than 60% among the concentrations. At 14 day post-treatment, the mortality of dusts increased and at concentration of 0.3%, the hierarchy of mortality in descending order is Permrthrin, NSPRI dust, Rice Husk Ash, Activate d charcoal and *P. guineense* shows 100, 40, 36.7, 33.3 and 33.3% respectively.

Mortalities induced by the experimental dusts against *D. Maculatus* were relatively very low except in permethrin dust where impressive kill was recorded. Poor insecticidal action by the inert dusts (NSPRIDUST, Activated charcoal and RHA) could be as a result of the prevailing high RH at the period of the assay, since high air RH and especially rain, greatly reduces or completely inactivate inert dusts (Subramanyam and Roesli 2000; Arthur 2001; Stathers *et al*. 2008; Korunic, 2013). Future studies should investigate applying this botanical at a higher dose rate because Jatau *et al.*, (2018) reported mortality of 33,3% after 7 day post-treatment with concentration of 12% of *P. guineense* dust or hermetically sealing the vial to entrap the pungent insecticidal volatiles of dust since this botanical has fumigant properties. The extract of *P. guineense* may seems to be toxic than the powder because, Akinwumi *et al.*, (2007) reported high mortality at concentration of >2.5% with the extract of the *P. gunineense*.The oil on the body of fish could also have played a role against the performance of inert dusts because the latter tend to absorb oil, reducing cuticular wax absorption (Korunic, 2013).

Table 2: Percentage weight loss of the fish after68d post-treatment

Treatments	Conc. (%)	Percentage weight loss
0.1% NSPRIDUST	0.1	$33.33±3.48^{cd}$
	0.2	$24.00±5.51^{abcd}$
	0.3	$19.00±1.53^{abc}$
0.1% Piper guineense	0.1	$21.67±3.84^{abcd}$
	0.2	$25.67±4.67^{abcd}$
	0.3	$23.33±4.41^{abcd}$
0.1% Act. Charcoal	0.1	$23.00±2.00^{abcd}$
	0.2	$30.67±6.44^{bcd}$
	0.3	$26.00±7.94^{abcd}$
0.1% Rice Husk Ash	0.1	$19.67±3.18^{abc}$
	0.2	$22.67±3.84^{abcd}$
	0.3	$21.67±5.24^{abcd}$
0.1% Permethrin	0.1	$7.67±1.33^{a}$
	0.2	$11.33±2.03^{ab}$
	0.3	$8.00±2.08^{a}$
Control		$42.00±1.73^{d}$

Means±SE and values are means of triplicate samples followed by the standard error of means. Means in the same column with different superscripts for each dusts are significantly different ($p<0.05$).

Table 2 shows the mean percentage weight loss of the fish(*Clarias gariepinus*) under the effect of the NSPRIDUST, *Piper guineense*, Activated charcoal, Rice Husk Ash and Permethrin dusts and control treatments against hide beetle (*D. maculatus*). The result of this study shows that fish treated with the dusts have high value of mean percentage weight loss when compared with the untreated fish in the control sample. The application of the dusts statistically had a significant (F = 4.528, P= 0.00) effect on the mean percentage weight loss of the fish. The result also revealed that fishes treated with permethrin gave the lowest mean percentage weight loss (between 8 to 8.33%). and the highest mean percentage weight loss (42%) observed in the negative control. The decrease in percentage weight loss of the fishes with dusts that have high percentage mortality observed in the study is similar to the findings of Tefera *et al.*, (2011) and Silva-Aguayo *et al.*, (2004), who reported that decrease in percentage weight loss associated with the greatest mortality.

CONCLUSION

The study has shown that the mortality recorded by nontoxic dusts (NSPRIDUST, *Piper guineense*, Activated charcoal and Rice Husk Ash) were relative less effective when compared with the toxic dust (permethrin), and this could be either attributed to low concentrations of the dusts or non-hermetical condition of the environment of the fish inside the storage facility. Findings from the study recommend that future works should investigate applying this botanical at a higher dose rate or hermetically sealing the vial to entrap the pungent insecticidal volatiles of the dusts.

24 - 28 Oct., 2022

ABSTRACT
Cuttlefish is one of the most valuable marine molluscs by-catch by industrial trawlers. Some aspects of reproductive biology were studied on S. officinalis collected off Lagos Coast, Nigeria. A total of 1,082 specimens were sampled from August 2018 to January 2020. The result of sex ratio showed that out of the total of 1,082 specimens, number of males (799) was substantially higher than females (283), resulting in a sex ratio of 1.00:0.35 (male:female). The calculated monthly χ2 test showed that males were significantly more abundant (P<0.05) than females as well as monthly sex ratio off the Lagos coast. The monthly GSI results indicated that the reproductive season of cuttlefish ranged from May to January, with a maximal GSI of 21.41% in November for females and a maximal GSI of 1.9% in April for males. Furthermore, females have two peaks in the year-round spawning period in May and November while males have homogeneous GSI values throughout the cycle except in the month of April during sampling period. The result of the gonadal development of cuttlefish varied with different eggs colour ranging from light yellow to deep yellow depending on the stage of maturity; four stages occurred in males; stage II—Immature, Stage III- Preparatory, Stage IV- Maturing and Stage V- Mature while females ranged from Stage III- Preparatory, Stage IV- maturing, Stage V- Mature and Stage VI- Spent. It is concluded that S. officinalis of all sizes and maturity stages congregate off Lagos coast, thus, spawning period covering the whole year with maximum peaks in May and November.

Keywords: *Sepia officinalis*, Sex ratio, Reproductive biology, Off Lagos Coast.

INTRODUCTION
Owing to the appearance of fins, it is referred to as a cuttlefish. It undergoes internal fertilization, have a high fecundity and growth rate, but has a short life span of 1–2 years (Beasley *et al.*, 2017). According to Duysak *et al.*, (2014), cuttlefish can exhibit variations in its life cycle, living for approximately 2years before exhibiting mass mortality of adults following a spring spawning

period. Gauvrıty *et al*., (1997) studied on the wild populations of *S. officinalis* and concluded that this species has a very long spawning period; moreover, comprehensive study was also performed on fecundity of *S. officinalis* by Laptikhovsky *et al*., (2003). Conversely, few detailed information are available on the reproductive biology of *S. officinalis* in Nigeria. Hence, basic knowledge on some aspects of reproductive biology of *S. officinalis* off Lagos coast is necessary to provide the biological basis for implementation of possible management measures aimed at sustainable exploitation of the resources.

MATERIALS AND METHODS

The study area is located between 6°20'N–6°34'N and 2°45E'–3°60'E and falls within the barrier lagoon complex (200 km). Three notable stations were selected as sampling points for this research based on representing the entire length of Lagos State off the coast of Lagos, Nigeria (Figure 1).

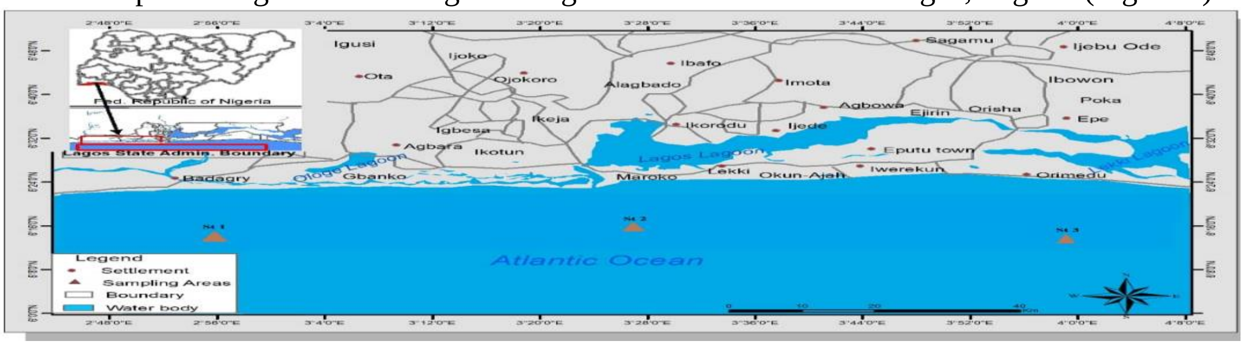

Figure 1: The study area, off the coast of Lagos, Nigeria showing the three sampling stations

A total, of 1,082 (283females, 799males) samples of cuttlefish were collected randomly between 1,000 hrs and 1,200 hrs over a period of 18 mth (August 2018 to January 2020) from 3 stations off the Lagos coast Nigeria. The specimens were immediately identified, sorted and sexed, after which the biometric parameters were measured in fresh condition.

The sex of each cuttlefish was determined using physical examination (presence of the left arm four (IV) hectocotylized (modified arm) typical for males). The male- female ratio statistical hypothesis of H_0 = 1:1 for male and female was tested using the Chi- square as described by (Zibran, 2007) shown in (Equation 1).

$$\chi^2 = \frac{\Sigma\,(\text{Observed} - \text{Expected})^2}{\text{Expected}} \qquad (1)$$

Where χ^2 = Chi-square to be calculated and compared with χ^2 (1 d.f, 5%). Data on reproductive components were done by weighing the following components (to 0.001 g): male testis and female ovary. Paired organs were weighed and recorded. These data were used to determine the maturity indices. Fecundity of this study was taken as the number of ripening eggs in a female prior to the next spawning season (Boyle and Daly, 2000). Maturity stages of male gametes were identified according to description given by (Boyle *et al.*, 1995) and were divided into four different stages based on (Rocha *et al.*, 2001). . The total number of ripe eggs was estimated from the ripe ovaries (stage III) using the gravimetric method and the relationship between female size and egg number is usually described as an allometric functions equivalent to that between size and weight as expressed by Arkhipkin and Mikheev (1992) (Equation 2):

$$Y = a + bX \qquad (2)$$

Where Y = fecundity estimate
X = total length (cm)/ total weight (g)
a = regression constant
b = regression coefficient

The weight of the cuttlefish and that of the gonads were used to determine the Gonado-somatic index (GSI). The GSI of both sexes were calculated for each sampling period using the formula reported by Önsoy and Salman, (2005): (Equation 3).

$$GSI = (\text{Gonad weight/Weight of cuttlefish}) \times 100 \qquad (3)$$

RESULTS

The result of sex ratio showed that number of males (799) was substantially higher than females (283), resulting in a sex ratio of 1.00:0.35 (male:female) shown in (Plate 1). The calculated monthly $\chi 2$ test showed that males were significantly more abundant than females off the Lagos coast. The monthly sex ratio shows that the males *S. officinalis* were more abundant than females in both the dry months (Nov.–Apr.) and wet months (May–Oct.) seasons throughout the sampling period (Figure 2)

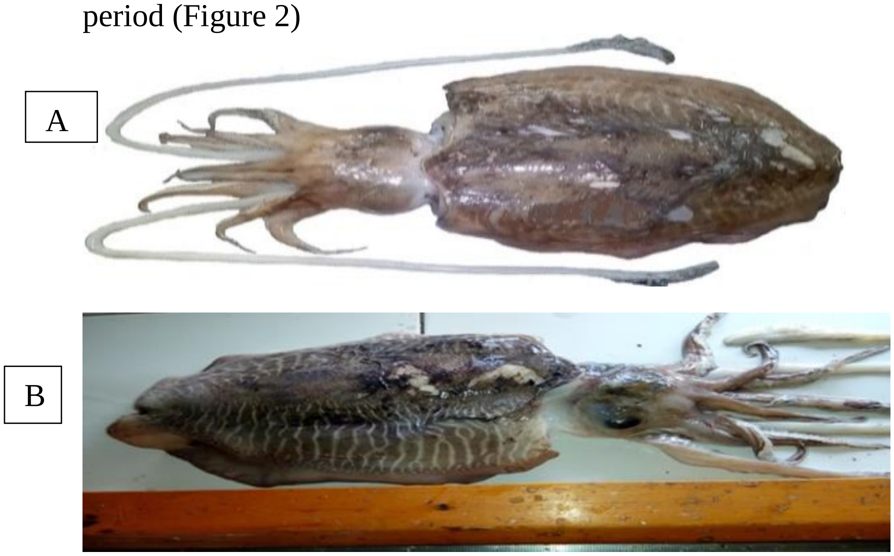

Plate 1: The dorsal view of *S. officinalis* (A) Female and (B) Male

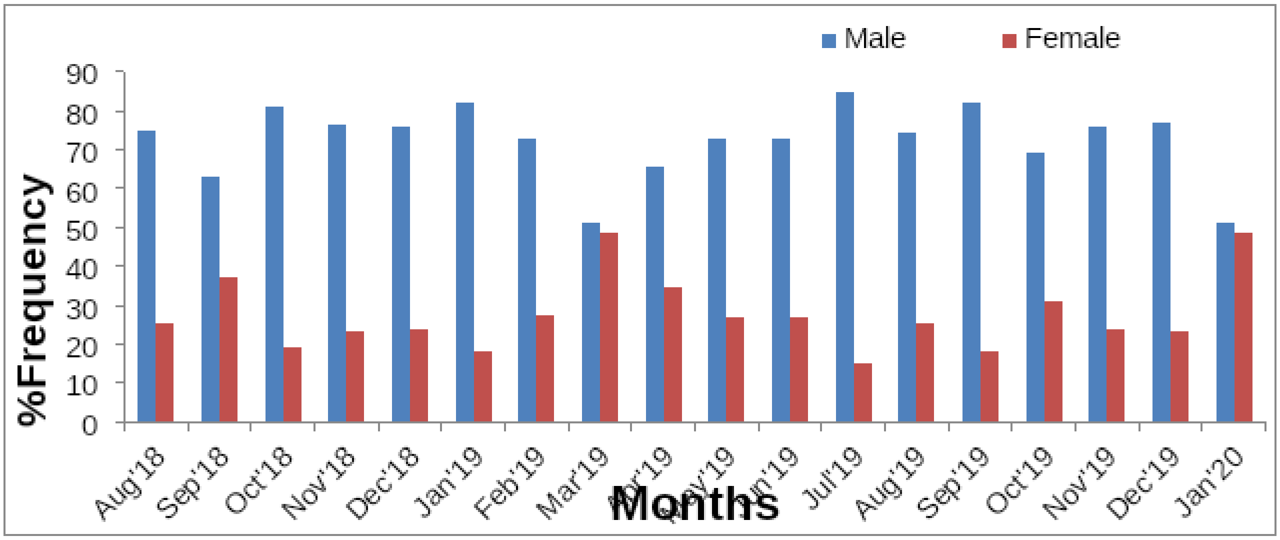

Figure 2: Monthly variation in sex ratio of *Sepia officinalis* off Lagos coast

A total of 50 berried *S. officinalis* were examined for fecundity. It ranged from 7.9 – 21.5cm and 62.0 – 939.5g for length and weight respectively. The fecundity estimates varied from 101 – 291 eggs with an average of 121 eggs. The Log fecundity – Log mantle length and Log fecundity – Log weight relationships are shown in (Figures 3 - 4). The linear regression equations were:

Log Fecundity = 1.3964 + 0.2631LogTW

(n = 50, R^2 = 0.1301, r = 0.3607

Log Fecundity = 0.3186 +1.4865 Log ML

(n = 50, R^2 = 0.3801, r = 0.6165

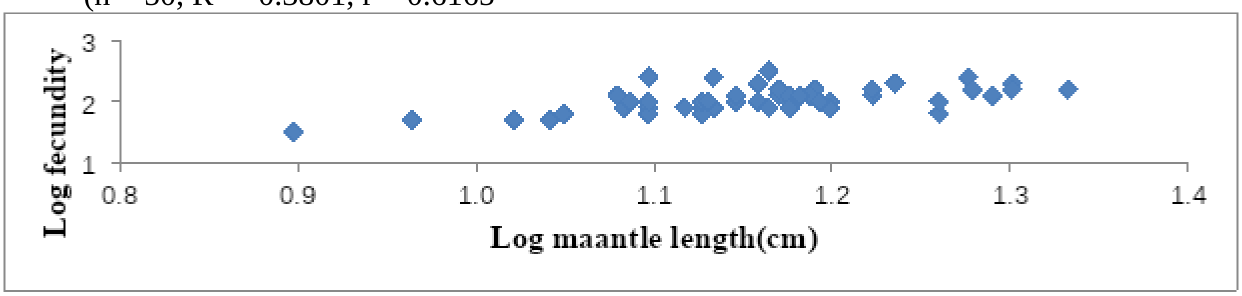

Figure 3: Log mantle length/Log fecundity relationship of *S. officinalis* off Lagos coast.

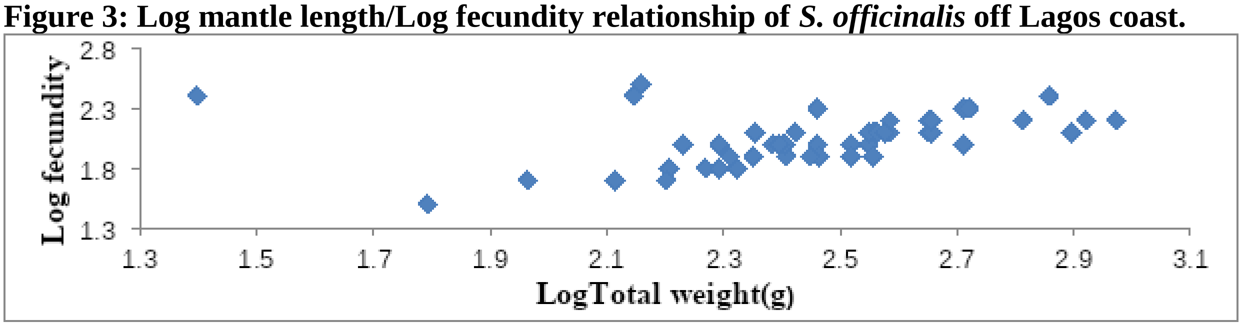

Figure 4: Log Total weight/Log fecundity relationship of *S. officinalis* off Lagos coast.

The result of the gonadal development of cuttlefish varied with different eggs colour ranging from light yellow to deep yellow depending on the stage of maturity. During the period of sampling four stages was observed in male; stage II—Immature, Stage III- Preparatory, Stage IV- Maturing and Stage V- Mature while female ranged from Stage III- Preparatory, Stage IV- maturing, Stage V- Mature and Stage VI- Spent. Hence, preparatory stage (Stage III) were most prominent while the mature (Stage V) were least observed in male while in female Maturing stage (Stage IV) were most prominent and Spent stage (Stage VI) were least occurred across all the studied areas shown in (Figures 5-6)

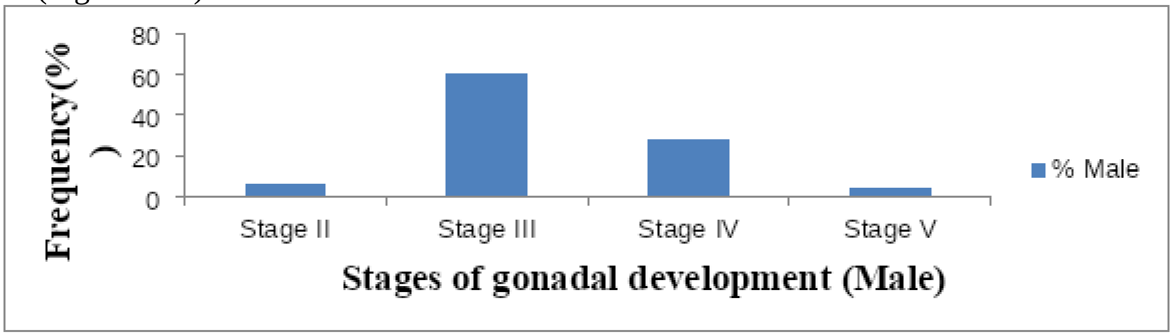

Figure 5: Stages of gonadal development of males S*epia officinalis* collected off Lagos coast (Aug., 2018 – Jan., 2020)

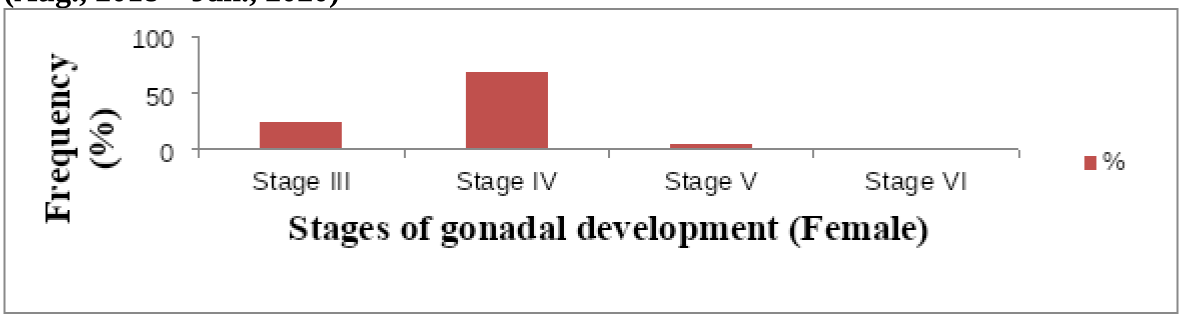

Figure 6: Stages of gonadal development of female *S. officinalis* collected off Lagos coast (Aug., 2018 – Jan., 2020)

The monthly GSI results indicated that the reproductive season of cuttlefish ranged from May to January, with a maximal GSI of 21.41% in November for females and a maximal GSI of 1.9% in April for males. During the sampling period from 2018 to 2020 breeding season, females have two peaks in the year-round spawning period (Figure 7). First peak was observed in May, while the second one was recorded in November. Besides, the males of *S. officinalis* have homogeneous GSI values throughout the cycle except in the month of April.

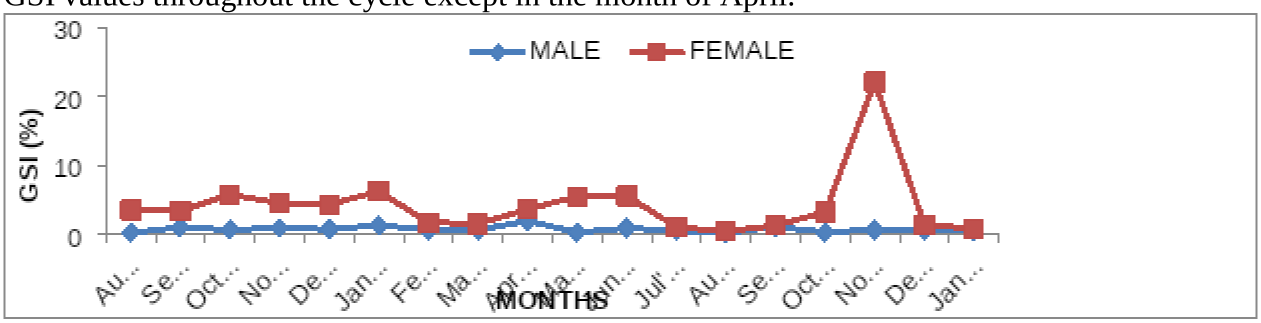

Figure 7: Monthly Gonadosomatic Indices (GSI) of both male and female *Sepia officinalis* specimens.

DISCUSSION

Environmental factors can influence the sex ratio of aquatic organisms either directly or indirectly (Moruf, 2020). The result of sex ratio obtained in the present study differs from those reported in İskenderun Bay, where out of the 2,006 *S. officinalis* examined, 992 (49.45%) were females, and 1,014 (50.55%) were males (Duysak et al., 2014). Similarly, Sujit and Sushant (2018) reported female *S. pharaonis* to be dominant in their study, with a male-to-female sex ratio of 1:1.24. The species' fecundityfor this study estimates varied from 101 – 291 eggs with an average of 121 eggs, was lower than some reported 400 in the west Mediterranean. This could be as a result of geographical differences. Gonado-somatic index(GSI) result of the present work differs from the findings of Önsoy and Salman (2005) who reported two peaks in March and June and spawning period of cuttlefish in Homa lagoon from March to June. Results of the present study are parallel to the findings of Önsoy and Salman (2005). Guven and Ozbaş (2007) observed a spawning period extending throughout the year in *S. officinalis* in the Antalya Bay. Furthermore, these authors noted two spawning peaks (June-July). This shows that the spawning season and the reproductive peaks for the cuttlefish are very variable and probably very closely connected to some abiotic environmental conditions. Türeli-Bilen *et al.,* (2010) reported that spawning period of cuttlefish in Karataş from April to September which is almost similar to the result of the present study off Lagos coast.

CONCLUSION

The study revealed that all sizes and maturity stages of *S. officinalis* congregate off Lagos coast, thus, spawning period covering the whole year with maximum peaks in May and November. Hence, basic knowledge on these aspects of reproductive of *S. officinalis* off Lagos coast is useful to provide the biological basis for implementation of possible management measures for its sustainable exploitation of the resources.

56th Annual Conference
Agricultural Society of Nigeria
24 - 28 Oct., 2022

ABSTRACT
This study investigated the level of heavy metals (lead (Pb), chromium (Cr), cadmium (Cd), nickel (Ni), mercury (Hg) and arsenic (As) in *Pseudotolithus elongatus*- brown Croaker, *Tilapiamariae* – Red Tilapia,)from Makoko, Ijora and Mushin markets for three months (November 2021-January, 2022). Lead (Pb) and Cd were not detected in *P. elongatus* across the three markets. Similarly, As was not detected in *P.elongatus* from Ijora and Mushin markets, Hg not recorded in *P. elongatus* collected from Makoko fish market. Values of Cr, Ni, Cu detected in *P.elongatus* across the three markets.While none of the *Tilapia mariae* across the markets contained lead, *T. mariae* from Ijora and Makoko had no arsenic and also Hg and Cd was not detected in *T. mariae* from Ijora and Mushin markets respectively. The Ni content from Makoko (1.8851±1.6270) was significantly higher than those from Ijora and Mushin. Levels of heavy metals detected in *P. elongatus*, across sampled markets were below the standard maximum permissible limits. Therefore, all the fish species examined in this study are considered safe for human consumptions. However, sellers and processors should embrace hygienic practices to avert further contamination of the fish.

Keywords: Safety, markets, fish species, Lagos

INTRODUCTION
Aquatic foods are essential delicacies and form an important staple food for daily living of every human being. One of the prominent aquatic foods in Nigeria is fish. Fish is a fundamental cheapest source of protein and other essential minerals such as omega -3 fatty acids which prevent cardio-related problems (Brawn, 2011). The contribution of fish to animal proteins cannot be overestimated (Abolagba and Melle, 2008).

Heavy metals pollution has become a major concern worldwide due to their toxicity, intrinsic persistence, non-biodegradable nature, and accumulative behaviours. These metals differ from other toxic materials in a way that they are neither created nor destroyed by human. They are inert in the environment and are often considered to be conservative pollutants if left undisturbed. However, the rapid industrialization, urbanization, population growth, agricultural and other human activities have resulted in severe pollution by heavy metals globally, especially in developing countries (Hossain *et al.*,2018).

Basically, heavy metals are unarguably the transition and post transition metals, and the examples which are common are lead (Pb), cadmium (Cd), vanadium (V), cobalt (Co), chromium (Cr), copper (Cu), iron (Fe), arsenic (As), nickel (Ni), manganese (Mn), tin (Sn), zinc(Zn), and mercury (Hg) (Lawal Are *et al*., 2018)..

Consequently, an analysis of the levels of heavy metals in fish could be used to investigate anthropogenic impacts on ecosystem and human health. Sequel to the above background, the present study aimed to assess heavy metals concentration in fresh fish from three Markets in Lagos state, Nigeria.

MATERIALS AND METHODS

Study Area

The study area is Lagos State which lies between latitudes 6°25'0"N and 6°32' 30"N and longitudes 3°20' 0"E and 3°25'0"E. However, three sampling stations (Makoko, Ijora and Mushin markets) were selected fromLagos state as shown in figure 1. Mushin fish market is on latitude 6.528660°N and longitudes 3.352564°E, Makoko on latitude 6.494552°N and longitudes 3.386143°E, while Ijora fish market is situated on latitude 6.46639°N and longitudes 3.37666°E. Mushin fish market is found in Mushin Local Government Area in Lagos. It is located 10km north of the city core, adjacent to the main road to Ikeja, and is largely a congested residential area with inadequate sanitation and low-quality housing. Ijora fish market is located in Ijora Olopa, Apapa, Lagos. This market is mainly into Agriculture and farms, food and frozen food where several Dealers are offering ice fish and provide fishery services. On the other hand, Makoko fish market is located on Herbert Macaulay Street Yaba and is one of the longest streets in the State which means it is always busy. Like Mushin and Ijora markets, Makoko fish market opens everyday but the best prices can be gotten very early in the morning on Tuesdays and Wednesdays.

Collection and Identification of Fish Samples

Samples of Fish were collected from the three sampling markets in Lagos State, Nigeria for three months (November 2021-January, 2022). Two samples of fishes(*Pseudotolithus elongatus*- brown Croaker, *Tilapiamariae* – Red Tilapia, were collected from each of the sampled fish markets. The fish samples collected were identified by Fisheries Expert in the Department of Fisheries, Lagos State University.

Pre- treatment of Fish Samples

All samples of fresh fish collected from the markets were transported in polyethylene bags previously treated with 5% $HNO_3$and at the laboratory were cleaned and rinsed with distilled water, following procedure of APHA (1998).The fish samples were later washed with tap water and stored in a freezer at -4°C for 96 hours prior laboratory analysis.

Heavy Metal Analysis in the Fish

All frozen fish samples were defrosted at 25°C which was attained in 4 hours. 6 Samples of whole fresh fish were selected from each sampling market, weighed and oven-dried at 105°C for 28 hours till a constant weight was obtained. Dried samples were grounded with ceramic mortar and pestle, into powdery form and 3g of each sample was digested according to APHA (1998) using Atomic Absorption Spectrophotometer (Buck scientific 210/211 VGP model). The concentration of the metals was calculated in mg/kg. The heavy metals (lead (Pb), chromium (Cr), cadmium (Cd), nickel (Ni), mercury (Hg) and arsenic (As)) concentrations in the sampled fish were determined using Buck Scientific Atomic AbsorptionSpectrophotometer (VGP 210 model, USA).

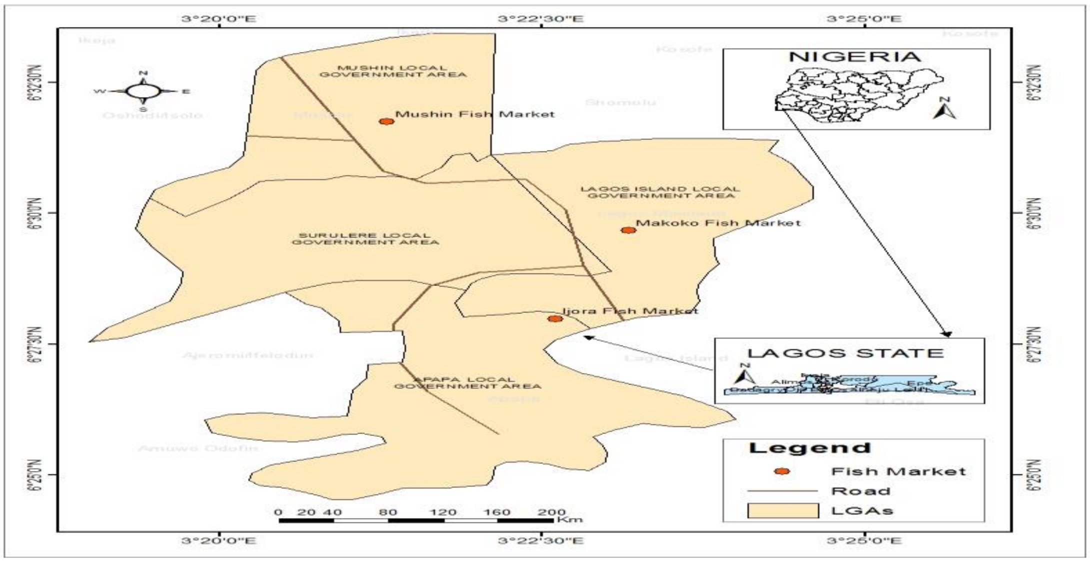

Figure 1: Map showing the location of the selected fish markets (Makoko, Ijora and Mushin) in Lagos State, Nigeria

Statistical Analyses

All Data for variations of the metals in the fish samples were tested by analysis of variance (ANOVA) and results expressed as mean ± standard deviation while LSD Post-hoc test was used to separate the similarity of means. The level of significance was set at $p<0.05$.

RESULTS

Table 1: Concentrations of heavy metals detected in *P.elongatus* from the markets

Heavy Metals	Ijora Market	Makoko Market	Mushin Market
Cr	0.0860 ± 0.0028[a]	0.0825 ± 0.0035[a]	0.0745 ± 0.0021[a]
Ni	0.3040 ± 0.0014[a]	0.3100 ± 0.0014[a]	0.3030 ± 0.0014[a]
As	ND	0.0045 ± 0.0007	ND
Cu	0.0460 ± 0.0028[a]	0.0600 ± 0.0014[a]	0.0765 ± 0.0021[a]
Hg	0.0050 ± 0.0014[a]	ND	0.0125 ± 0.0007[a]
Pb	ND	ND	ND

Cd	ND	ND	ND

DISCUSSION

Fish plays a significant role in food and nutrition security across the world, especially in Nigeria, where the people consume fish as a major supplement to carbohydrate-based diets. Fishes are reliable bio-indicators of aquatic ecosystems, since they occupy higher trophic levels and are also an important food source of humans. Since fishes are consumed by human as a major source of protein for many years. Human body is largely susceptible to enriched heavy metal concentration in fishes. Consequently, an analysis of the levels of heavy metals in fish could be used to investigate anthropogenic impacts on ecosystem and human health. In this study, no lead was found in *Pseudotolithus elongates* and *Tilapiamariae*. In this study, no lead was found in *Pseudotolithus elongates*. Arsenic not detected in *P. elongates* and *T.mariae* (from Ijora and Mushin). Also, mercury was not found in *P.elongatus* (Makoko) while cadmium was not detected in *T.mariae* (from mushin). The absence of these toxic metals in most of the fish sampled especially at Makoko and Mushin suggest that the aquatic environments from which these fish species were caught are less susceptible to heavy metals pollution. Different authors such as Babajide and Dauda (2009) and Mekuleyi *et al.* (2021) have shown that anthropogenic activities like agriculture and sewage disposal especially in developing countries where low-end waste management is a common practice, usually result in heavy metals pollution. Furthermore, the absence of Pb, Cd and Hg in most of the fish specimens indicated that the consumers patronizing these markets for fish are not likely to be prone to proteinuria, carcinogenesis, and apoptosis (Jaishankar *et al.* 2014, Engwa*et al.*, 2019). There was no significant difference in the values of Cr and Cu in *P.elongatus* from the three markets. However, Ni content from Makoko was significantly higher than those from Ijora and Mushin. This observation could imply that these fishes are source from similarly ecosystems before they were displayed for sales in these markets. The concentrations of all the heavy metals detected in fishes examined in this study were within the standard permissible limits (FAO/WHO, 2011). Similar findings of fish from Badagry market whose metals content did not exceed maximum permissible limit has been reported by Mekuleyi and Joseph (2017). However, the values of all metals recorded for this study were below those reported in *Chrysichthys filamentosus*, *Kribia nana* and *Pegusa lascaris* (Mekuleyi et al., 2021). Unlike the findings in this study, he reports on some heavy metal concentration in local fish species from different parts of the world (El-Moselhy *et al*., 2014; Thomas and Mohaideen, 2015) including Nigeria (Ugbomeh and Akani, 2016, Mekuleyi *et al*., 2019) were above permissible limits and this indicated a potential risk to humans and other aquatic organisms. Akpanyung *et al.*, (2014) also reported concentrations of some heavy metals (Pb, Cr, Zn and Cd) that exceeded the permissible limit in *Chrysichthys nigrodigitatus* from Ibaka and Ifiayong fishing sites in Akwa Ibom State. However, the values of Pb, Cr, Zn and Cd reported for *E.fimbriata* from Cross River Estuary were below the recommended permissible limits (Udo and Ndunobong, 2016). Similarly, Bolawa and Gbenle (2012) reported that the metal status in *Pseudotolithus senegalensis* and *E.fimbriata* from Carter Bridge River and Makoko River in Lagos, Nigeria, have not exceeded recommended limits for human consumption. Furthermore, research has shown that extent of accumulation of heavy metals in fish is dependent on the metal types, fish species, and the tissues of fish (Mekuleyi *et al.*, 2021).

In line with the outcome of the present study, Kuton *et al*.(2021) reported that the concentrations of the metals -Al, Fe, Mn,Pb ,Cr, Zn,Cd,Ba,Cu and Ni in the tissues of *Malapterurus electricus* collected from fish markets in Lekki were all below regulatory limits and thus were suitable for human consumption. However, Akinsanya *et al.* (2020) reported values of toxic heavy metals in the tissues of *Heterotis niloticus* collected from the same lagoon that are higher than recommended values. Sabreena *et al* (2020) examined the presence of heavy metals (Zn, Cr, Cu, As) in three different fishes (*Labeo rohita,Oreochromis niloticus andHeteropneustes fossilis*)which were collected from a local market in Dhaka, Bangladesh. The data in their paper suggests that the heavy metal concentration found in the fish muscles sampled from local market Dhaka, Bangladesh was significantly high. Therefore, they concluded that there are so many possible health risks to consumers due to the intake of studied fishes under the current consumption rate. As observed for this study, there was variation in the frequency of metals obtained in samples of *P. elongates across* the markets. This observation could be due to the fact that difference fish species have different affinity for metals absorption as a result of its need and environment. Perugini *et al.* (2014) and Anandkumar *et al. (*2017) reported that metal accumulation in varying parts of the body of fish depends on many factors such as water solubility, feeding behaviour, ecology and fish physiology including species, age, size, reproductive state, fish health, bioavailability and different habitats. Also, the accumulation of heavy metals in fish organs could also be driven by physiochemical variables such as pH, temperature, hardness, and exposure duration (Zeitoun *et al.*, 2014).

CONCLUSION

It has been established in this study that the level of heavy metals detected in *P. elongates* and *T.mariae* across sampled the markets were below the standard maximum permissible limits. Therefore, all the fish species examined in this study are considered safe for human consumptions. Also, some toxic metals such as mercury and lead which were not detected at all indicated that certain mercury and lead related diseases in human would be far away from consumers of the sampled fish species. However, sellers and processors should embrace hygienic practices to avert further contamination of the fish.

24 - 28 Oct., 2022

ABSTRACT
The zooplankton communities in Agboyi creek recorded a high abundance of 1,865 individuals comprising 22 species due to increased nutrient from organic and industrial waste and foliage deterioration from the riparian wetland around the study area. Physico-chemical factors fluctuated during the sampling period due to fluctuation of rainfall, with a record high of 125.80mm in April and 0.00mm in February recording no rain fall, and this significantly affected zooplankton composition and distribution within the creek.

INTRODUCTION
The Agboyi creek is a tidal creek with influxes from the Lagos Lagoon on one side and the from the Ogun river on the other side. It is open throughout the year and receives tidal influences - which are experienced far inland especially during the dry season - from the Lagos lagoon. It is a nursery ground for fish, crabs and herons that also avail the site. (Onyema and Nwankwo, 2006). The creek area is lined by human settlements and is typically a fishing community. The creek also serves as a major drainage channel for the area, receiving domestic waste discharges along with industrial wastes from nearby industries within the Lagos metropolis. Sand mining, mangrove harvesting - for fuelwood and brush parks - are some common practices in the area (Olawusi-Peters and Ayorinde, 2009).

Zooplanktons are an important part of aquatic food chain. They support all aquatic ecosystems by supplying energy from primary producers and recycling nutrients into the water column. They can strongly affect water quality, algal densities, fish production and nutrient as well as contaminant cycling. Their composition and distribution are influenced not only by biological factors such as predators and primary producers, but also by physical and chemical factors and as such can be included in biomonitoring programs because their densities and species composition can be sensitive to changes in environmental conditions. (Adedeji *et al.,* 2013).

This study aims to provide information on the effect of hydro-environmental influence on the zooplankton composition and distribution within the Agboyi creek. The results of this study can be used in water resources conservation and management as species of zooplankton can be introduced to water bodies to enhance fish production.

MATERIALS AND METHODS

Study site: The Agboyi creek is an adjourning creek to the Lagos lagoon, located on its northern side and drains the Ogun River. The sampling station was sampled for six months (November - April).

Collection of water samples: Water samples were collected each month using 75cl plastic containers. They were dipped into the water to collect the water samples and were taken to the laboratory for physical and chemical analysis.

Collection of plankton samples: Plankton samples were collected by standard plankton collection method.

Determination of air temperature (^{0}c): Air temperature was taken in-situ using a mercury-in glass thermometer.

determination of water temperature (^{o}c): The surface water temperature was determined in-situ.

Determination of transparency (cm): This was measured in-situ using a secchi disc.

Determination of total suspended solids (tss) (mg/l): This is estimated by using the Gravimetric Method 22540D.

Determination of total dissolved solids (tds) (mg/l): were determined using Gravimetric Method 2540C.

Collection of rainfall data (mm): data obtained from NIOMR.

Determination of pH: this was determined by the Electrometric Method using the Cole Parmer Test.

Determination of salinity (‰): this was determined using Saline test Salinity Meter (Hanna Instrument HI 98203).

Determination of conductivity (µs/cm): This was determined by using Philips PW9505 conductivity meter.

Determination of alkalinity (mg/l): This was determined using the Titration Method 2320B.

Determination of acidity (mg/l): this was determined using the titration method 2310B (APHA, 1998).

Determination of dissolved oxygen (DO) (mg/L): This was estimated by Titrimetric (Iodometric) Method using the Azide Modification procedure 4500ºC.

Determination of biological oxygen demand (BOD) (mg/L): This was determined using the Winkler method.

Determination of chemical oxygen demand (COD) (mg/L): This was determined by using the Closed Reflux Method 5220C with higher concentration of potassium dichromate solution.

Determination of total hardness (mg/L): This was determined by the buret titration method.

Determination of chloride (mg/L): this was determined in unfiltered water samples by buret titration method.

Determination of calcium (Ca^{2+}) (mg/L): This was estimated using the EDTA Titrimetric Method.

Determination of magnesium (Mg^{2+}) (mg/L): This was estimated using the Titrimetric method.

Determination of nitrate – Nitrogen (NO_3^-) (mg/L): This was determined using the Colorimetric Method 4500D.
Determination of phosphate – Phosphorus (PO_4^-) (mg/L): This was determined using the Colorimetric Method.
Determination of Sulphate (mg/L): This was determined using the Turbidimetric Method 4500 E.
Determination of silica (S_iO_2) (mg/L): The was measured using a pre-calibrated colorimeter (DR2010). **Determination of dissolved inorganic nitrogen (DIN) (mg/L):** This was determined on 10 ml aliquot by cadmium reduction method (HACH Method 8039), with NitraVer-5 reagent powder.
Determination of total dissolved nitrogen (TDN) (mg/L): This was determined using the HACH Method 10072.
Determination of dissolved organic nitrogen (DON) (mg/L): By calculating DON = TDN – DIN (by difference)
Determination of dissolved inorganic phosphate Reactive Phosphorus (Orthophosphate) (mg/L): This was determined by using a HACH DR 3900 spectrophotometer according to Hach Method 8048.
Determination of oil and grease (mg/L): This was determined using EPA Method 418.1.
Determination of copper (mg/L): This was determined using the Atomic Absorption Spectrophotometer (AAS).
Determination of iron (mg/L): This was determined using the AAS.
Determination of zinc (mg/L): This was determined using the AAS.
Determination of lead (mg/L): This was determined using the AAS.
Determination of cadmium (mg/L): This was determined using the AAS.
Determination of manganese (mg/L): This was determined using the AAS.
Determination of chromium (mg/L): This was estimated using the AAS.
Determination of nickel (mg/L): This was determined using the AAS.
Determination of biomass using Chlorophyll *a* (µg/L): determined by using spectrophotometer HACH DR 3900.
Determination of biomass in terms of numbers using counting methods (per ml): This was determined using the Drop Count Method.
Determination of community structure analysis: Species diversity index (d), Menhenicks (D), Species richness (d), Evenness or equitability indices (j) and Simpson's Dominance index (C) were used to estimate the phytoplankton biodiversity. They were calculated using associated equation.
Determination of statistical analysis: Standard deviation, correlation coefficient (r) and coefficient of similarity (S) were determined by equations.

RESULTS AND DISCUSSION

The monthly variations in the physicochemical parameters at Agboyi Creek from November to April are represented in Table 1 below. High air and water temperature values recorded during this study are typical of the region, however, the range of water temperature values are in contrast to earlier observations by Sandison and Hill (1966) reporting that water temperature in the Lagos lagoon never varied more than 4°C. This may be due to increased insolation arising from greater solar radiation, plausibly a reflection of global warming trends. The rainfall values showed great fluctuation, ranging from 0 - 125.80mm. Transparency was relatively low due to the effect of rainfall. The salinity regime was seasonal with high salinities from February to April and low salinities between November and December. The salinity during sampling ranged from 0.1-8.31‰ which confirms that the study site is a brackish ecosystem. pH values are consistent with tidal creeks which are usually slightly alkaline.

Table 1: Monthly variations in water quality parameters at Agboyi Creek, Lagos (November - April)

Nutrient levels were high due to the high amount of bio-degradable waste discharges in the region and reduced dilution effects from floodwaters. Conductivity values increased with increase in salinity and total dissolved solids, which may be the reason for the increase in total hardness. The trace elements were low throughout the study period except magnesium which had higher values. Studies have shown that the levels of algal pigments in water are influenced by environmental variables and as such, Chlorophyll *a* is an index of total phytoplankton abundance. Chlorophyll *a* values were positively strongly correlated with salinity, conductivity, dissolved oxygen (DO), total dissolved solids (TDS), total hardness and sulphate, and however, negatively correlated with pH, biological oxygen demand (BOD), chemical oxygen demand (COD), total suspended solid (TSS), nitrate, silica, iron, copper and zinc.

The total number of zooplankton species identified were 1,865 individuals comprising 22 species which were more in the dry months than the wet months. This high zooplankton diversity is an indication of increased nutrient from organic and industrial waste around the study area. Additionally, foliage deterioration from the riparian wetland flora may also have led to enrichment that eventually emptied into the creek. Such nutrient rich run-offs are more frequent with rain events (Nwankwo 1995). The zooplankton diversity was represented by three divisions namely; Arthropods, Cnidarian and Rotifera. The Arthropoda were represented by nine species from three orders (Order Calanoida, Cyclopoda, Harpacticoda), the Cnidarian were represented by one specie from one order (Semaestomeae), the Rotifera were represented by 1 specie from one order (Ploima) and then the Juvenile stages.

Among the zooplankton divisions, the Arthropods had the largest percentage of (82.57%), followed by the Juvenile stage with (14.75%) and the Rotifera and Cnidaria with (1.34%) in terms of abundance of individuals. The Arthropoda were the majority in abundance in terms of numbers. The genera notable of the Arthropoda were *the Acartia clansii*, *paracalanus parvus, Temora stylifera, Cyclops sp, Oithona nana, Cyclops tranum, Oithona sp, Cyclopina longiatus, microsetella.* The Juvenile stages *Barnacle nauplii*, Barnacle larvae, *Copepod nauplii*, Gastropod larvae, Fish larvae, Copepod egg, Zoea larvae, Cyprus larvae. The Cnidaria representing Jelly fish, while the Rotifera represented by *Lecane bulla.*

CONCLUSION

The study of zooplankton, which is - its key position in the trophic chain, gives a fundamental role in aquatic environments, and as a consequence, its study is essential to better understand the functioning of these aquatic systems. So, to have loss of zooplanktons would result in detrimental consequences that can go as far as the loss of biodiversity, thus leading to impairment of the biological equilibrium of creeks and even destruction of the aquatic ecosystems.

PROCEEDINGS
56th Annual Conference
Agricultural Society of Nigeria
24 - 28 Oct., 2022

ABSTRACT

Lagos state is a coastal and the most populous state in Nigeria. It is the economic hub and one of the country's highest fish-producing states. Owing to the geographical setting of the state i.e., its proximity to the Atlantic Ocean, it experiences a unique weather system (coastal climate) that is characterized by both atmospheric and oceanic processes. This unique weather system is affected by sharp changes in heat, moisture, and momentum transfer between the atmosphere and the sea surface, which have direct impacts on marine biodiversity. The extent of these sharp changes can be measured through climatological variables. The present study examined some climatological variables acquired from the NIOMR synoptic weather station, Badore, Lagos, for the year 2021 and their potential impacts on fisheries. The result shows that high temperature was recorded in the dry season and low temperature in the rainy season. Furthermore, the total amount of rainfall recorded through the year was 1411.11mm/hour with a monthly and daily maximum of 8.3017mm/month, 60.41mm/hour recorded in May and 16th of July respectively. High wind speed was recorded in the rainy season while the low wind speed recorded in the dry season with wind directions predominantly varies through the year with average directions in the southwest direction.

INTRODUCTION

The coastal areas often experience unique weather which results in a very special climate owing to their natural settings i.e., the boundary layers (interphase between the land and water), and the interactions with the atmosphere (air-sea interaction). This unique weather phenomenon in the coastal areas is climatologically induced and significantly affected by sharp changes in heat, moisture, and momentum transfer between the atmosphere and the sea surface. Evidently, variabilities in the climatic condition in the coastal environment do not only affect the coastal inhabitants but could also impact fisheries in multiple ways. Climate variabilities can also bring about significant ecological and biological changes to marine and freshwater ecosystems and the resultant fish population (Wabnitz et al., 2018). Climate change is predicted to have major impacts on fish production (Brander 2007). Furthermore, climatic factors influence the spatial and temporal distribution of marine species. Climate variables, specifically the temperature and rainfall, and wind pattern affect the distribution and health of coastal ecosystems, and the productivity of the industries that depend on them, such as fisheries. Lagos state is a low-lying coastal and the smallest state in Nigeria with approximately $3,577\ \text{km}^2$, and a coastline of about 186km. Nigeria's economic hub is the most populated state with 22% of its area covered by wetland (mainly Lagoon and Creeks) with (Odunuga et al., 2012; BRNCC2012). The climate system of the state is typical of a tropical monsoon. The state which is one of the highest fish-producing states in Nigeria will no doubt be impacted by climate variabilities. Hence, a need to monitor the year-to-year climate variables of the state. The present study examined some climatological variables acquired from the NIOMR synoptic weather station, Badore, Lagos, and their potential impacts on fisheries and the coastal environment. This is crucial in understanding the year-to-year climate variability of Lagos state and its potential impact on marine operations such as fisheries.

Figure 1.1. Map of Lagos state showing the location of NIOMR synoptic weather station

MATERIAL AND METHOD

The climatological variables used for the study were obtained from NIOMR meteorological station (Badore station) on an hourly basis from the 16th of January to the 31st of December 2021. The default format of the dataset as logged into the equipment is ACDSee Thumbnail Database Format (DTF) file extension (.dtf) and subsequently converted to excel data (.xlsx) with HOBO software. Quality data control (such as DateTime separation, variables nomenclature, etc.) was performed to prepare the data for Scipy software (python library for scientific analysis) analysis. The quality-controlled climatological variables were then introduced into Scipy software for data analysis. The hourly mean climatological were sliced and resampled into daily and monthly mean data, and each of the climatological variables (Temperature, Wind speed, Wind direction, and Rainfall) was then extracted afterward. No rain-hour (hours without rainfall, i.e., when rainfall amount equals zero) were eliminated from the extracted rainfall data. The hourly and resampled climatological variables (daily and monthly) were plotted with Matplotlib against time. The direction of the winds through the period of the study was also plotted and represented by the wind rose. The variables' hourly, daily, monthly minimum, and maximum value with their respective dates during the period under study were also calculated. Results of the analysis are presented in the result section of the paper

RESULTS AND DISCUSSION

Temperature plays an important role in the lives of fishes (e.g., spawning) and its ecological resources, like food and habitat which can influence individual fitness (Magnuson et al., 1 979). For instance, when temperature departs from optimal for an organism, it will act as a stressor and impair physiology and behavior (Donaldson et al., 2008). Furthermore, the production and catchability of fish in many aquatic ecosystems vary considerably as a result of seasons in their environment (Brander 2007), which is also a function of temperature. The result of the analysis of temperature as depicted in (Figure 3.1) shows that the high temperature was recorded throughout the dry season with a maximum temperature of $30.6776o_C$ recorded in February i.e., toward the end of the dry season. Consequently, the low temperature was recorded during the rainy season with a minimum value of $26.822o_C$ recorded in August. The high temperature recorded in the dry season could impact the temperature of the surface water, and as a result, marine ecosystems could be altered and consequently affect species migration, and breeding patterns, threaten sensitive ocean life such as corals, and change the frequency and intensity of harmful algal blooms, etc. This implies that the high temperature in the dry season does not favor biological abundance, especially in the inland and continental waters, thereby affecting the resilience of capture fisheries in Lagos (Olufemi et al., 2010).

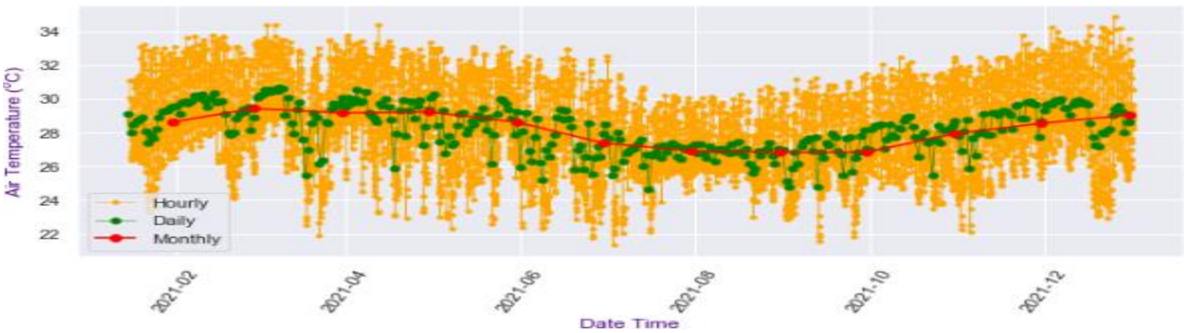

Figure 3.1 Air Temperature along Lagos coastal environment for the year 2021

The rainfall in the marine environment is capable of altering the ocean chemistry and its extreme cases could cause innumerable damage to coastal areas and their marine ecosystems. The total amount of rainfall recorded throughout the year was 1411.11mm/hour. The intensity and duration of rain at a place could impact both the coastal environment and the biological abundance of water in the area. For instance, the daily highest rainfall of 60.41 (mm/hour) was recorded on 16^{th} of July as depicted in (figure 3.2), and this coincides with the day most parts of Lagos were submerged. Such events favor biological abundance as heavy rain causing flooding of terrestrial vegetation has been identified as the ultimate cue for the spawning of cyprinids (Hontela et al., 1990).

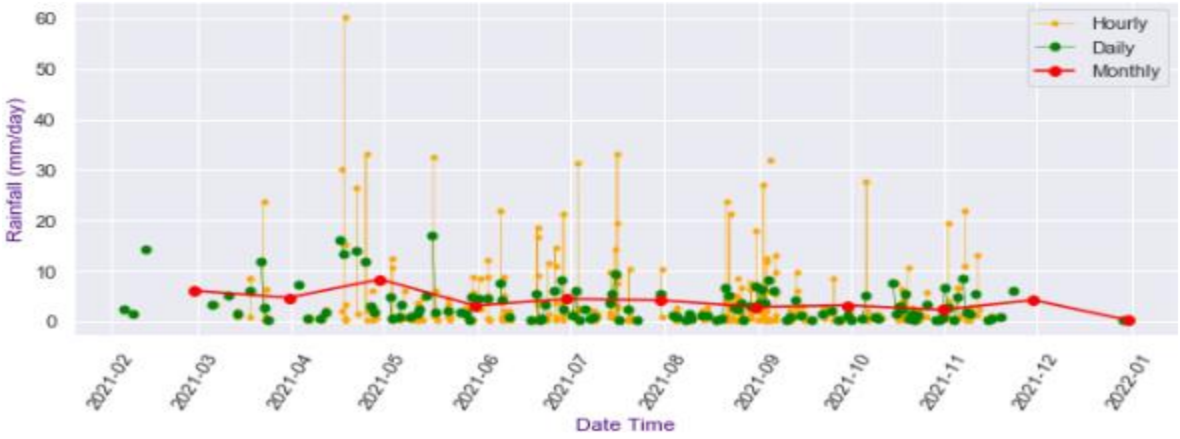

Figure 3.2. Rainfall along Lagos coastal environment for the year 2021

Effluents from the terrestrial vegetation consist of various nutrients which are washed into the water through runoff, thus making the water nutrient-rich (Ayinde et al., 2021). This has made the rainy season favorable to biological abundance thereby increasing the number of capture fisheries in Lagos (Olufemi et al., 2010). Although severe floods may reduce fish density and biomass and influence community composition (Milner et al., 2012). The wind system has also been identified as one of the most important climatological variables in the ocean as it drives the coastal upwelling systems, consequently driving primary productivity and fishery production. Upwelling areas on the continental shelf contribute 20% of global fish production while occupying less than 1% of the world's oceans' surface area (Mann, 2000). Biological production in upwelling areas induced by wind varies from year to year and between locations according to the magnitude and direction of the strongest wind, thereby causing associated fisheries to vary. Analysis of wind as shown in (Figure 3.3) shows that the highest values were recorded in the rainy season specifically in August, and the low values were recorded during the dry season with the lowest recorded in December. The wind results further show why the rainy season could be more biologically productive than the dry season.

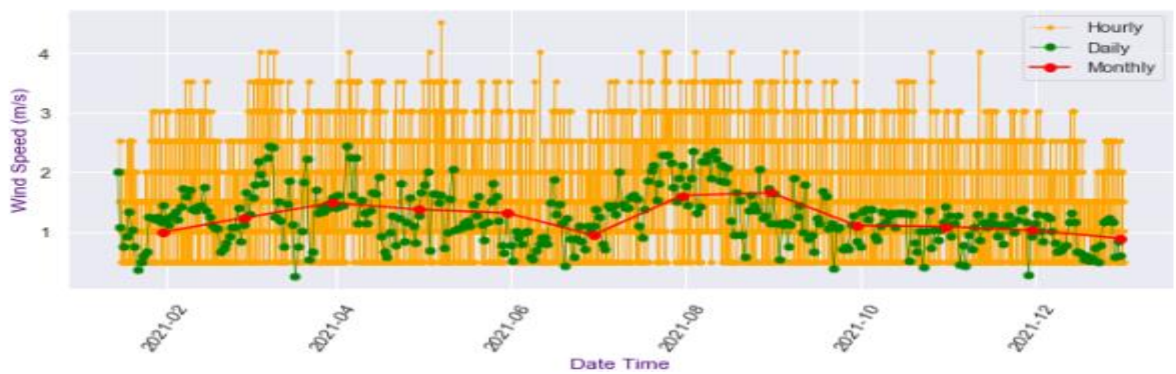

Figure 3.3. Wind Speed along Lagos coastal environment for the year 2021

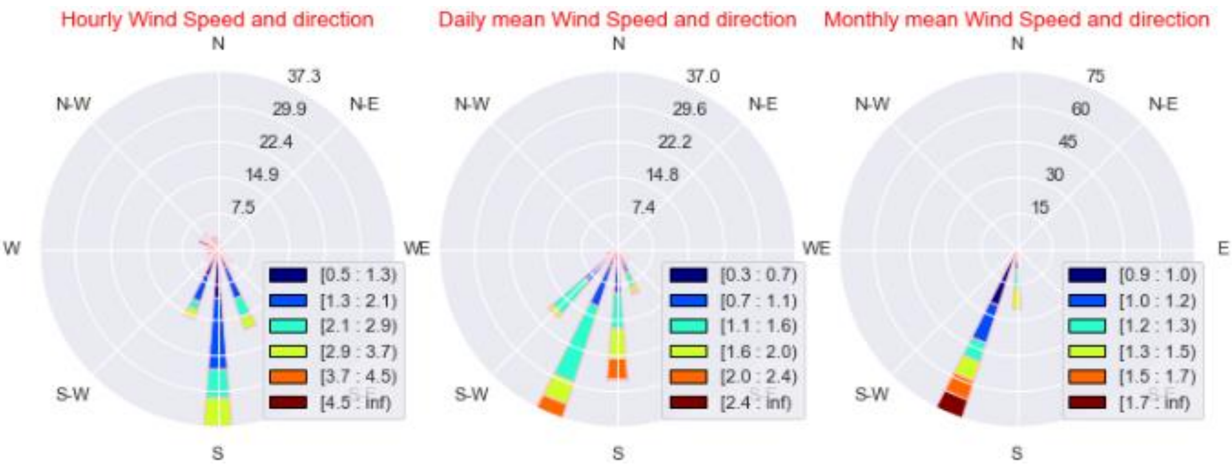

Figure 3.4. The direction of wind along Lagos coastal environment for the year 2021.

The wind direction analysis represented with wind rose as in (Figure 3.4) shows that wind direction predominantly varies through the year with average directions in the southwest direction. This result further confirms the prevailing high-pressure southwest monsoon wind from the Atlantic that pushes the inter-tropical front to the Sahara (northern) region of Nigeria, which practically defines the Nigerian's climate system. Figure (3.5) shows the spatial seasonal fish distribution and the depth as they were caught by a fishing trawler. It was discovered that the highest number of fish were caught during the rainy season.

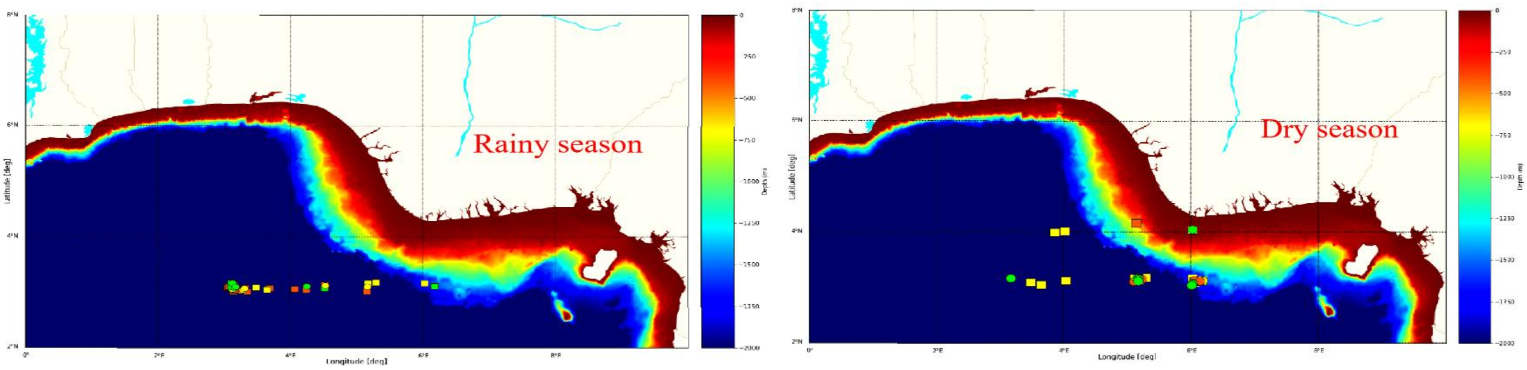

Figure 3.5. Spatial seasonal fish distribution as recorded by fishing trawler 2021.

CONCLUSIONS

Some climatological variables of Lagos state and their potential impacts on fisheries have been analyzed using a well-structured scientific analytical method. Results of the analysis show unique trends in the climatological variables through the year 2021 and their possible implications for the marine weather system. This is paramount in understanding the climate of Lagos state and its potential consequences on fisheries.

ABSTRACT
The intensity of anthropogenic and natural impacts as stressors has increased significantly overtime due growing demand for natural resources from the marine environment. This study assessed the ecological quality status (EcoQs) of Eastern Nigeria flank offshore using macrobenthic assemblages as ecological biotic indices (AZTI's Marine Biotic Index, multivariate-AMBI, Biotic Index and BENTIX). Sediments were collected across eight (8) stations from the Eastern flank using Van-Veen grab and water with a Niskin water sampler, measured onboard the RV-BAYAGBONA research vessel using a multi-parameter checker, HORIBA-U53.The analysis of variance (ANOVA) showed significant variations ($p<0.05$) in the physico-chemical parameters of Eastern Nigeria Offshore. A total of twenty-four (24) benthic macrofauna across the eight stations belonging to three (3) Phyla – Mollusca (95.08 %), Arthropoda (3.59%), and Annelida (1.23 %) were recorded. The abundance (244) and density (101.7 m^2) of macrobenthic assemblages was observed at the Eastern flank. The ecological quality index AMBI, of the Eastern Nigeria offshore had 51.25% slightly disturbed marine environment (AMBI - 1.5, 1.4, 1.3; M-AMBI – 0.5, 0.6 and 0.6; BI – 2 across station 3, 4, and 5) which indicates moderate to good ecological status. The Shannon-Wiener index of diversity ranged from 1.53 to 3.62 at the Eastern flank. The outcome of these findingscan support future management practices and policies in Nigeria offshoreusing benthic fauna as a robust bioindicator of pollution.

Keywords: Macrobenthic Assemblage, Ecological Quality Status, Eastern Nigeria, Offshore

INTRODUCTION
Macrobenthic fauna are considered to be useful biological indicators to assess the pollution impacts of the any aquatic environment. The intensity of anthropogenic and natural impacts as stressors has increased significantly overtime due growing demand for natural resources from the marine environment (Halpern *et al*., 2007). Stressors are commonly associated with varying categories of contaminants, loss of habitats, overexploitation of species, intrusion of invasive organisms and climate change (Jackson *et al*., 2001; Kappel, 2005). Marine ecological quality status can be estimated through a series of univariate measures of different nature, such as

indicator species, diversity measures and contaminant levels (Borja*et al.*, 2000; Labrune *et al.*, 2012). Usually, there are some variables such as salinity, sediment texture and food availability which plays most essential role in determining the faunistic composition of benthic communities. However, the relative significance of the various factors can differ considerablyamong habitats and regions. Thus, the objectives of this study are to determine the macrobenthic distribution patterns in the Eastern Nigeria Offshore, delineate the ecological quality status of the Nigeria offshore using macrobenthic assemblages, and establish the fundamental environmental variables that influence the distribution and composition of macrobenthic assemblages in the eastern Nigeria offshore.

MATERIALS AND METHODS

Study Area and Sample collection

The study area is the South-Eastern flank of Nigeria offshore which lies between latitudes $04^0$00'N and $04^0$40'N and longitudes of 07^0 20'E and 08^0 20'Ealong the Gulf of Guinea and mostly characterized by a tropical climate with a high temperature and humidity. Some anthropogenic activities such as oil and gas platforms for exploration and exploitation mostly predominates the South-Eastern/Southern flank offshore Nigeria.

Measurement of Environmental parameters of water

Water samples were collected using a Niskin bottle at each sampling station. The physico-chemical parameters measured and analyzed were water temperature, dissolved oxygen (DO), pH, alkalinity, and salinity onboard using a multi-parameter checker - HORIBA-U53. Fixed water samples were transported to the Department of Biological Oceanography laboratory at the Nigerian Institute for Oceanography and Marine Research, Lagos, for nutrients (nitrate, phosphate, and sulphate) were determined using spectrophotometric method at optical densities of 880nm, 543nm, 420nm and 430nm respectively (APHA, 2005).

Benthic macroinvertebrate Analysis

Composite sediment samples were collected across eight (8) stations at the Eastern flank of the Nigerian offshore waters using a 0.1 m^2 Van-Veen grab onboard the RV-BAYAGBONA research vessel in August 2022. Contents of the grab were washed with seawater through a sieve of 0.5mm mesh size. Benthic macro invertebrates were collected from the sieve and preserved with 10 % formalin in labeled jars for further analysis. Subsequently, the preserved benthos samples were adequately sorted and identified following standard protocols (Barnes, 1994; FAO, 1998; Branch *et al.*, 1998).

Figure 1: Sampling stations within the Eastern flank of the Nigerian offshore waters

Ecological Indices

The ecological indices utilised for the comparative study are the AZTI's Marine Biotic Index, multivariate-AMBI,Biotic and BENTIX indices to ascertain the ecological quality status of the Eastern flank of the Nigeria offshore waters in response to environmental stressors. Macrobenthic assemblages are grouped into five (5) ecological groups (EG I, EG II, EG III, EG IV, and EG V) centered on the levels of sensitivity to anthropogenic stressors (Sany *et al.* 2015) and the classification scales of indices are presented in Table 1. The BENTIX indices involve a sensitive group (%GS is the relative abundance of %GI, and %GII) and tolerant species (%GT is the relative abundance of %GIII, %GIV, and %GV) (Cardoso *et al.* 2012). The BENTIX equation is as follows; $\mathbf{BentixIndex} = (\mathbf{6} \times \%\mathbf{GS}) + (\mathbf{2} \times \%\mathbf{GT})/\mathbf{100}$

Table 1: Ecological indices with scales classifications

AMBI[a]	M-AMBI	Biotic index	BENTIX	EcoQs	Ecological group	Disturbance classification
0.0 < AMBI ≤ 1.2	≥ 0.77	0-1	4.5 – 6.0	High	I and II	Undisturbed
1.2 < AMBI ≤ 3.3	0.53 -0.77	1.1-3	3.5 – 4.5	Good	III	Slightly disturbed
3.3 < AMBI ≤ 4.3	0.39 – 0.53	3.1-4	2.5 – 3.5	Moderate	IV – V	Moderately disturbed
4.3 < AMBI ≤ 5.5	0.2 – 0.39	4.1-6	2.0 – 2.5	Poor	V	Heavily disturbed
5.5 < AMBI ≤ 7.0	<0.2	≥7	0 – 2.0	Bad	Azoic	Extremely disturbed

BI- Biotic index, Ecological quality status (EcoQs)

Statistical Analysis

Macrobenthic fauna composition and Physico-chemical parameters were subjected to multivariate analysis (canonical correspondence analysis- CCA, and hierarchical clustering Bray-Curtis similarity indices) utilizing the SPSS v.25 and PAST 4.11 (Hammer *et al.*, 2001) software package and Ecological Biotic Indices to ascertain the ecological quality status (Cardoso *et al.* 2012). The Physico-chemical parameters of the water were analyzed using analysis of variance (ANOVA) at 0.05 level of significance, while ArcGIS 10.6 software was used to generate map of the sampling stations.

RESULTS AND DISCUSSION

The mean variation of physico-chemical parameters of the Eastern Nigeria offshore are presented in Table 2. The analysis of variance (ANOVA) showed significant variations ($p<0.05$) in the physico-chemical parameters of Eastern Nigeria Offshore. Further analysis using Duncan Multiple range test (DMRT) revealed significant differences ($p<0.05$) in sulphate and total dissolved solids (TDS) at the Eastern Nigeria Offshore.

Table 2: Mean variations of physico-chemical parameters of the Eastern flank Nigeria offshore

Parameters	Eastern offshore		
	Mean ± S.E	**Min**	**Max**
Water Temperature	27.41 ± 0.43^{a}	25.89	29.41
pH	7.80 ± 0.06^{a}	7.50	7.92
Conductivity	46.90 ± 0.25^{a}	46.00	47.80
DO	7.59 ± 0.21^{a}	6.80	8.53
TDS	28612.50 ± 135.54^{c}	28100.00	29100.00
Salinity	30.49 ± 0.17^{a}	29.85	31.08
Nitrate	0.01 ± 0.0^{a}	0.00	0.03
Phosphate	0.07 ± 0.02^{a}	0.00	0.19
Sulphate	1265.00 ± 186.69^{b}	0.00	1580.00
Turbidity	0.18 ± 0.13^{a}	0.00	1.00

Distribution and Composition of macrobenthic assemblages

A total of twenty-four (24) benthic macroinvertebrate fauna across the eight stations from eastern Nigeria offshorebelongingto three (3) Phyla – Mollusca (95.08 %), which wererepresented by 20 species, Arthropoda (3.59%) which was represented by 2 species and Annelida (1.23 %) with 2 species (Figure 2). Bivalvia (61.07 %) were predominant while Polychaeta and Malacostraca were the least abundant class.

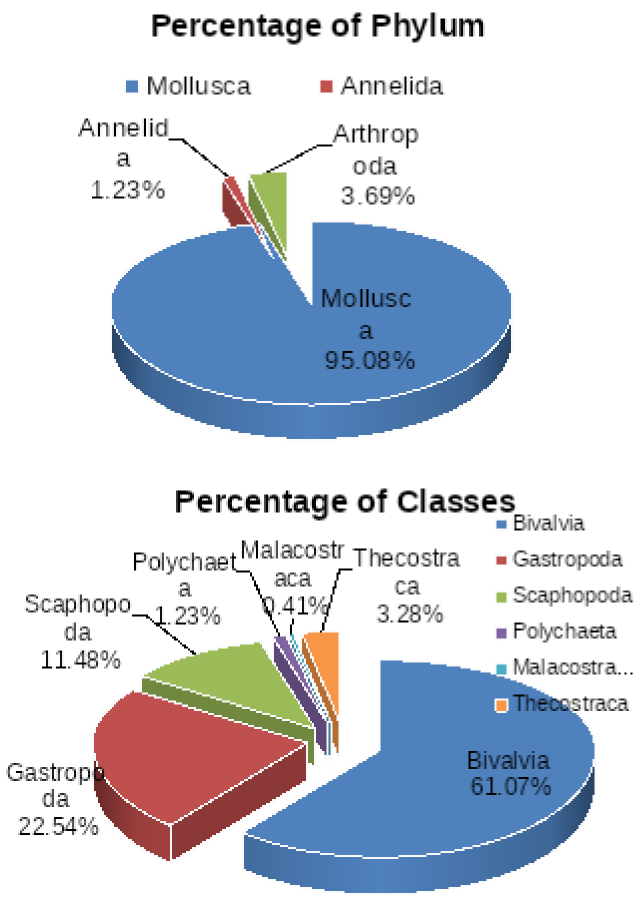

Figure 2: Percentage of the phyla and class constituting the macroinvertebrate fauna from Eastern Nigeria offshore

Abundance and Density of Benthic macrofauna assemblage

The abundance and density of macrobenthic assemblages recorded higher numerical abundance of 244 species and 101.7 m^2 from Eastern offshore.

Ecological indices of benthic macrofauna

Macrobenthic invertebrates are crucial parts of the marine environment as they support significant ecological functions such as bioturbation and nutrient recycling, and contribute substantially to energy flow from primary organic sources to upper trophic levels (Bolam and Eggleton 2014; Saulnier*et al.*, 2019).The ecological quality status of the Eastern Nigeria offshore across eight (8) stations is shown in Table 3. Slightly disturbed levels of AMBI (1.5, 1.4 and 1.3), M-AMBI (0.5, 0.6 and 0.7), and BI (2) were observed across stations 3, 4 and 5 and BENTIX (5.8) at Station 5 respectively. The AMBI Ecological quality status (Figures 3), macrobenthic species-ecological group distribution and M-AMBI quality status (6), while the benthic community was dominated by ecological groups I and II (0 – 100 %: sensitive species) and ecological group III (0–5.6 %: tolerant species). Based on water quality directive of Shannon-Wiener Index, the relationship between the indices and ecological level explained as follows: high status: >4, good status: 3-4, moderate status: 2-3, poor status: 1-2, and bad status: 0-1 (Kalyoncu and Zebek, 2011). In this study, the values of theShannon-Wiener index of diversity ranged from 1.53 to 3.62 at the Eastern flank.

Table 3: Ecological indices of benthic macrofauna along Eastern Nigeria offshore

Stations	AMBI	M-AMBI	BENTIX	BI	Diversity	Richness	Disturbance Classification
ST 1	0.6	1.0	6	1	3.62	14	Undisturbed
ST 2	0.7	0.9	6	1	3.16	11	Undisturbed
ST 3	1.5	0.5	6	2	1.53	3	Slightly disturbed
ST 4	1.4	0.6	6	2	2.28	6	Slightly disturbed
ST 5	1.3	0.7	5.8	2	2.41	7	Slightly disturbed
ST 6	0.8	0.8	6	1	2.72	8	Undisturbed
ST 7	1.1	0.6	6	1	1.9	4	Undisturbed
ST 8	0.7	0.7	6	1	2.48	6	Undisturbed

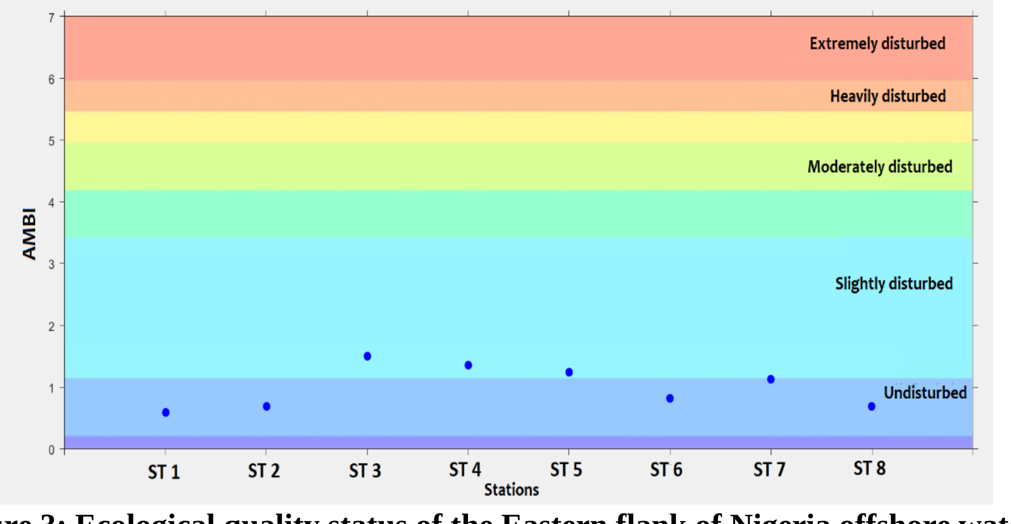

Figure 3: Ecological quality status of the Eastern flank of Nigeria offshore waters

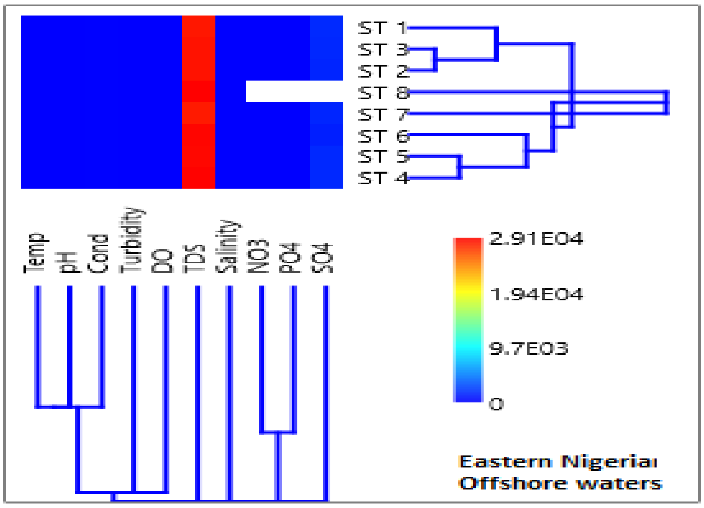
According to the ecological quality index AMBI, the Eastern Nigeria offshore had 51.25% slightly disturbed marine environment which indicates moderate to good ecological status.

Hierarchical Cluster Analysis



The hierarchical clustering using the Bray-Curtis similarity index of the Physico-chemical parameters of Eastern Nigeria offshore are presented in Figure 4. The Bray-Curtis index showed similarities in properties and characteristics of a. temperature, pH and conductivity; b. nutrients (phosphate, nitrate and sulphate); c. dissolved oxygen (DO) and turbidity; d. Salinity and total dissolved solids (TDS) at the Eastern offshore Nigeria. At the Eastern flank, station 2 and 3; station 7 and 8; station 4 and 5 possess similar physico-chemical characteristics.

Figure 4: Hierarchical Clustering of the physico-chemical parameters at the Eastern flank Nigeria offshore

Canonical Correspondence Analysis (CCA)

The CCA recorded 66.71% and 33.21% variances at the Eastern flank in axis 1 and axis 2 respectively. CCA establishes significant relationships between the environmental variables with macrobenthic assemblages as shown in Figure 5. The environmental variable (Turbidity) had a significant impact on the distribution of Annelida at station 5; phosphate had influences on the distribution of Arthropoda at station 4; other environmental variables (DO, pH, salinity, nitrate, sulphate, conductivity and TDS) significantly influences the composition and distribution of Mollusca across the Eastern Nigeria offshore. Macrobenthic studies in marine environment have demonstrated that the distribution of macrobenthosshows a clear affinity with abiotic variables (Hossain, 2011; Selleslagh*et al.*, 2012; Nishijima*et al.*, 2015; Xie*et al.*, 2016), and this is consistent with the CCA of this study.

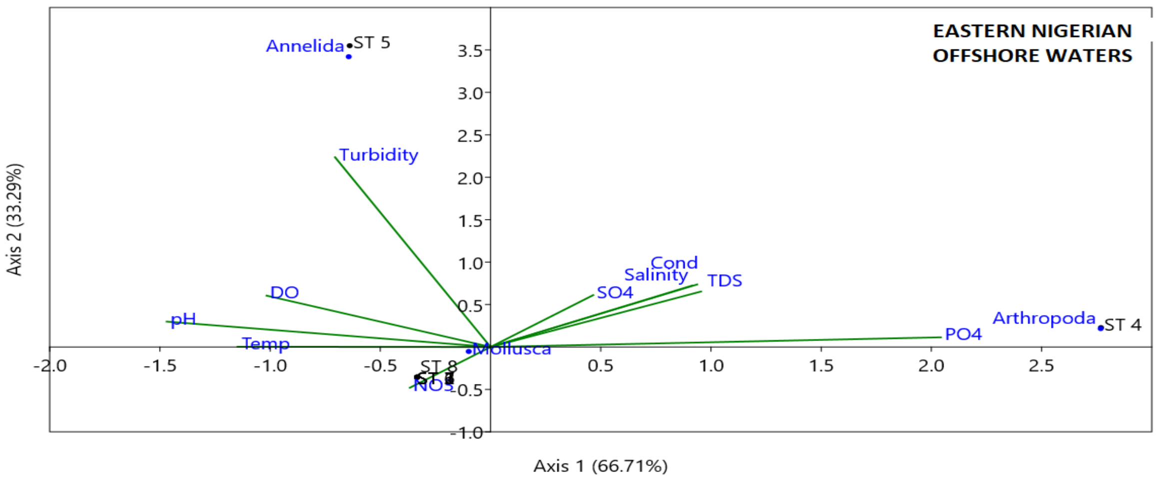


Figure 5: CCA plot of macroinvertebrate and environmental variables of Eastern Nigeria offshore

CONCLUSION

This study assessed the ecological quality status of stressors using macrobenthic communities from the Eastern Nigeria offshore. Our results indicated that the majority of Eastern offshore present a non-contaminated (undisturbed) to moderately contaminated status (slightly disturbed) marine environment which could be attributed to the oil and gas exploration and exploitation activities around the area. The outcome of these findings can support future management practices and policies in Nigeria offshore using benthic fauna as a robust bioindicator of pollution.

ACKNOWLEDGMENT

All authors are grateful to the management of Nigeria Institute for Oceanography and Marine Research (NIOMR) for providing funds for this research. We also wish to appreciate Executive Director – Prof. Sule A. Y. and Dr. Yakub A. S. (H.O.D Biological oceanography) for their immense support.

24 - 28 Oct., 2022

ABSTRACT

High concentration of iron in aquatic environments has been a major contributing factor to aquatic pollution due to their toxicity, bioaccumulation, and potential adverse effects on a biological system. This study was undertaken to evaluate the toxicological impacts of Iron (Fe) in the organs of *Synodontisclarias* and *Clariasagboyiensis*from Lekki and Epe Lagoon. The samples were collected from these lagoons seasonally between June 2014 and April 2016. Results showedthat the measured concentrations of Iron levels in the water and organs of the sampled fish species were higher than the standard permissible limit of 0.3mg/kg. The calculated Hazard Indices (HI) in liver and gill were less than 1.0 which implies non-carcinogenic adverse effect from the consumption of the fishes. Comparatively, the Hazard index values were higher in the liver than other organs. Levels of Iron in the organs of *Synodontis clarias* and *Clarias agboyensis* in both Epe and Lekki Lagoons calls for monitoring activities within and around the lagoon to curtail further negative impact. Also, policy development towards the sustainable ecosystem health services should be advocated.

Keywords: - Iron, *Synodontisclarias*, *Clariasagboyiensis*, Heavy metal, contaminant.

INTRODUCTION

Iron is a prevalent component of industrial and mining effluents that are often discharged into aquatic environments. Ferrous iron (Fe^{2+}) is considered to be more toxic to fish than the ferric (Fe^{3+}) form. Study has shown that the highest bioconcentration of iron in fish tissues was found in the liver and gonads, and thus making the liver the target organ for iron (Omar*et al.*, 2014). Iron is an essential metal with known biological functions (Abadi *et al*., 2014) and their toxicity occurs either at metabolic deficiencies or at high concentrations (Sivaperumal *et al*., 2007). Deficiency of iron can cause an adverse health effect, whereas its high concentration can also result in negative impacts which are equivalent to or worse than those caused by non-essential metals (Kennedy, 2011). Moreover, the toxicity of iron to fish is significantly affected by the form in which they occur in water. The ionic forms of iron are more toxic than the complex inorganic or organic compound and the toxic form are more pronounced in the early stages of fish development and adversely affects various metabolic processes in the developing fish particularly the embryos which results to developmental retardation, morphological and functional deformities or death (Sfakianakis *et al*., 2015).

Toxicity of iron is due to their ability to cause oxidative damage to living tissues which includes enhanced lipid peroxidation, DNA damage, inactivation of enzyme and oxidation of protein surfydryl groups (Taiz and Zeiger, 1998). Iron toxicity can also cause cardiovascular, immunological, neurological, reproductive and developmental diseases in humans. Iron contamination may have devastating effects on the ecological balance of the recipient environment and a diversity of aquatic organisms (Farombi*et al*., 2007).Iron produces toxic effects at high concentration, and thus could be considered as risk factors for several diseases (Mendil *et al*., 2010). Their toxicity could disturb the integrity of the physiological and biological mechanisms in fish that are not only an essential component, but also used as a food source (Ibrahim *et al*., 2013). Previous study has shown that marine fish, farmed fish and shellfish are significant contributors to consumer intake of iron and other contaminants due to their presence in the flesh of fish and shellfish (Rose *et al*., 2015). Thus, this study was undertaken to investigate the effects of iron on the fish health and their consequent use as bioindicators.

MATERIALS AND METHODS

Study area

The study was carried out in Lekki and Epe Lagoons, which was further sub-divided into 8 stations namely: Ibeju Town, Omu, Abejuoye, Okera-kekere, Ejirin, Oko-Orisan, Oju-alaro and Chief fish jetty.

Collection of Fish samples

The fish samples used for the study are *Synodontisclarias* and *Clariasagboyiensis.* The choice of the organisms was made based on their availability, ecological niche and sensitive response to pollutants from hotspots. The fish samples were caught using a trap net set at the bottom of the lagoon. The mean length and weight of *Synodontisclarias*and *Clariasagboyiensis*were 33.52 ± 0.22, 28.40 ± 0.25 cm and 210.06 ± 3.67 g, 185.2 ± 2.54 cm respectively.

Fish samples preparation and analysis

Blood samples were collected using sterile syringe (5 ml) followed by dissection to remove the gills, liver and gonad samples. The gills were collected by opening the operculum of the fish samples. The liver and gonad samples were dissected out of the fish through the ventral side. The liver and gonad samples were washed with normal saline solution and placed in a small plastic container with tight cover and preserved in freezer with temperature of (-20°C) until analysis (Ejimadu*et al.*, 2015). The gill, gonad and liver tissues were fixed in 10% formalin. The samples were analysed at the Anatomic and Molecular Pathology laboratory of the College of Medicine, University of Lagos Idi-Araba Lagos.

Determination of Iron in water sample

The analyses of iron were performed in accordance with APHA-AWWA-WEF, 2005, using Shimadzu Atomic Absorption Spectrophotometer (AAS)-AA 6300 model. The 1 litre water sample collected for heavy metal were fixed with 2ml of HCl for further analysis at the Nigerian Institute for Oceanography and Marine Research, Lagos.

Digestion of fish samples

Fish organs (gill, liver and gonad) were digested after dissection, according to AOAC (1990) methods. About 2.0g of partially thawed fish gill, liver and gonad were weighed into Teflon tubes and 4 ml of NHO_3 (conc.) was slowly added to the Teflon tube. The tubes were then tightly closed and placed in a stainless-steel bombs. The bombs were placed on a hot plate and heated at 110°C for one hour and then to 150°C for three hours. The samples were allowed to cool at room temperature, and the bombs were carefully open to transfer samples into 50 ml polypropylene graduated tubes in a fume chamber wearing nose gard. The tube was rinsed with deionized water three times adding the wash to the tube.

Hazard Indices

The dosages of the exposures were estimated by the expected quantities of Chromium in the ingested fish. The average daily dose (ADD) of the contaminant via the identified pathways (i.e., fish ingestion pathways) indicated the quantity of chemical substances, ingested per kilogram of body weight per day (Pacheco *et al*., 2013) that:

$$ADD = \frac{C \times IR \times ED \times EF}{Bw \times AT}$$

where C is the concentration of the contaminant in the environmental media (mg/kg); IR, the ingestion rate per unit time (0.028 mg/day); ED, the exposure duration (30 years); EF, the exposure frequency (days/year- 365); BW, the body weight of the receptor (60 kg); AT, the average time (years) equal to the life expectancy; and 365, the year-to-day conversion factor.

Hazard quotient (HQ)

Due to the exposure of harmful chemicals, toxic risks can also be referred as non-carcinogenic harms. The extent of the harm is indicated in terms of a hazard quotient (HQ):

$$HQ = \frac{ADD}{RfD}$$

where the RFD is the reference dose, the estimate of the highest dose that were taken every day over a prolonged time period without causing an adverse noncancer effect. The RFD value for ironwas 0.007 mg/kg/day, derived from USEPA-IRIS (2010) database.

Statistical Analysis

All metrics were reported as mean ± standard error (S.E), PAST Software version 3.18 (Hammer *et al.*, 2001) and statistical package SPSS 20.0 (SPSS Inc. Chicago, Illinois, USA) was used for statistical analyses. Data were analyzed by One-Way Analysis of Variance, and significant differences (*p*< 0.05) resulting from the test were reanalysed by the Duncan Multiple Range Test (DMRT).

RESULTS

The values of Iron concentration in water column from Epe and Lekki Lagoons are presented in Table 1. In each of the lagoon under consideration, the values were within the same range in both wet and dry season. The mean concentrations of Iron (Fe) in the tissues of *Synodontisclarias*and *Clariasagboyensis*with season from Epe and Lekki Lagoons are shown in Tables 2 and 3 respectively. The results obtained indicated that the values of Fe were higher in all the organs of sampled fishes from Lekki lagoon than those from Epe lagoon. The mean concentrations of average daily dose (ADD) of Iron (mg/kg) in the fish tissues with season are presented in Table 4. The values of ADD were higher in the specieClariasagboyensisthan that of*Synodontisclarias*in both season. On the other hand,the values of ADD were higher in dry season than that of wet season in the three organs for both species. the Hazard Quotient (HQ) of chromium (mg/kg) in the organs of sampled fish (Table 3), revealed that the values of HQ were within the same range in the organs of both sampled fish in the two season.

DISCUSSIONS

This research discovered that the measured concentrations of iron levels in the two lagoons were higher than the permissible limit of 0.3mg/kg (FAO, 2012), and itportends a potential danger to the consumption of fish from those lagoons. Perhaps fish accumulated iron in their organs through bioaccumulation from sediment and water column of Lekki and Epe Lagoon possibly due to anthropogenic activities in both Lagoons (Armah *et al.*, 2010). There weredifferences in the iron level across the species and seasons indicating a threat whenconsuming fish from the coastal water. Iron is an essential element in fish organs as they aid in biochemical processes as well as in storage and transport of oxygen. However, occurrence of excessive levels of iron from this study is regarded as a potential hazard which can endanger both animal and human health and this is in total agreement with the study of Iftah*et al*. (2015) who reported bioaccumulation and toxicity of Iron salt on Shingi fish *Heteropneustes fossils* and its possible impacts on human health.

Evaluation and monitoring programs for Iron bioaccumulation serve as a biomarker for fish from contaminated environment which provides information about the environmental status of an ecosystem. Thus, these biomarkers are designed for different aspects of risk assessment of an aquatic ecosystem. Nevertheless, several studies have shown that fish tissue alterations are reliable and efficient tools to detect and monitor environments that are influenced by anthropogenic activities (Adams *et al.,* 2000), which also helps to foresee potential environmental risks (Paulo *et al.,* 2012).Fish organs, such as the liver and gills, are metabolically active tissues that accumulate Iron at higher levels, as previously reported (Kennedy, 2011). Accumulation of iron in fish can be probably attributed to a response to the presence of these environmental contaminant in the ecosystems. It was observed in this research, that the stations of both lagoons were highly contaminated with Iron which accumulated in the organs of the fish species and could result to severe damages.

A recent study on toxicants in fish have clearly demonstrated that increased concentrations of iron can seriously damage the gills of fish and can results to hypertrophy, hyperplasia, gills erosion and lifting of lamellar epithelia (Mendil*et al.,* 2010). Several authors have equally reported various pathologies in relation to iron pollution in the gills of different fish species (Ibrahim*et al.,* 2013).Moreso, reduced development and morphological alterations of the gonads, including testicular oocytes, have been described in several fish species living in polluted water systems (Paulo *et al.,* 2012). The increase in iron in the liver may induce the hepatic pathological changes as observed in *Synodontisclarias*and *Clariasagboyiensis* in both lagoons. This iron can either increase or decrease hepatic enzyme activities and can lead to histopathological hepatic changes, depending on the concentration, fish species, duration of exposure and other environmental factors (Paulo *et al.,* 201).

CONCLUSION

This study evaluated the seasonal variation of iron on the organs of *Synodontisclarias* and *Clariasagboyiensis* from Epe and Lekki lagoons. Generally, results showed high level of accumulated iron in the organs of both *Synodontisclarias* and *Clariasagboyiensis* above the permissible limit of FAO. It is pertinent to constantly monitor the presence and level of anthropogenic influx of iron in the Lagoon because their continuous deposition will result to fish contamination and ultimately lead to food poisoning of the fish consumers.

24 - 28 Oct., 2022

ABSTRACT

Investigations into the physico-chemical characteristics and algal pigments at Makoko Creek and Okobaba area were carried out for six months between November, 2016 and April, 2017. Water samples were collected each month using 75cl plastic containers with each indicating the month of collection at the study site. Results showed monthly variations in the water quality parameters and were linked with rainfall pattern. Records were Air (31 – 35.40 ^{O}C) and water (29.40 – 32.50 ^{O}C), Salinity (2.90 – 22.03 ^{O}/o), Nutrients (Nitrate ≥ 2.22mg/L; Phosphate ≥ 0.19mg/L, Sulphate ≥ 203mg/L), alkaline pH (7.19 – 7.71), Transparency (21.50 – 74.50cm), Alkalinity (105 – 425.20mg/L), Conductivity (5439 – 36800 µS/cm), Dissolved Oxygen (5.09 – 6.57 mg/L), Chlorophyll *a* concentrations (5.50 - 19 mg/L), Chlorophyll *b* concentrations (0.20 - 1.30 mg/L) and Phaeophytin *a* concentrations (0.10 - 0.40 mg/L). Chlorophyll *a* concentrations were positively correlated with Salinity (r = -0.03), Rainfall (r = -0.60), Phosphate (r = -0.36), Sulphate (r = 0.33), Nitrate (r = -0.03), Biochemical Oxygen Demand (r = -0.4) and Dissolved Oxygen (r = -0.26). Chlorophyll *a* values were higher in months with lower precipitation which may be as a result of reduced suspended particles. The biochemical oxygen demands and nutrient values were above the regulatory standards and this could indicate that Makoko Creek is organically polluted as a result of anthropogenic activities.

Keywords: physico-chemistry, algal pigments, creeks.

INTRODUCTION

The physico-chemistry of aquatic ecosystem involves the physical and chemical parameters operating in any body of water. These parameters are very important in telling the production and productivity status or condition of a water body. They also determine biological activities and kinds of organism suited for such environments. In fact physical and chemical parameters are crucial to the survival of marine organisms (Varadharajan and Soundarapandian, 2014). Creeks are common hydrological features in the South-Western Nigeria and in this region they gravitate to coastal lagoons in their immediate area enroute to the sea via the Lagos harbor. The physico-chemical characteristics of any aquatic ecosystem and the nature and distribution of its biota are directly related to and influenced by each other and controlled by a multiplicity of natural regulatory mechanisms. However, because of man's exploitation of the water resources, the normal dynamic balance in the aquatic ecosystem is continuously disturbed, and often results in each dramatic response as depletion of fauna and flora, fish kill, change in physico-chemical character etc (Lee, 1999). Planktons have been diagnostic in assessing water quality and hydrological status. They qualify as suitable indicators in that they are simple, capable of quantifying changes in water quality, applicable over large geographic areas and can also furnish data on background conditions and natural variability (Lee, 1999). Biological communities respond to stresses over time, thereby, they provide information that a more rapidly- changing water chemistry measurements or toxicity tests do not always produce. As such, biological assessment provides a more reliable assessment of long-term biological changes in the condition of the water body. Therefore, this paper was aimed at investigating the algal pigments concentrations in the Makoko and Okobaba Creek of Lagos lagoon in relation to seasonal fluctuation and its physico-chemical parameters.

MATERIALS AND METHODS

Study Area

Two stations were selected and sampled for a period of six months, the Makoko creek and the Okobaba area . The Makoko creek is an adjoining creek to the Lagos lagoon and part of the Lagos lagoon complex in the southern part of Nigeria The Global Positioning System location for the site was (Latitude 6.49N and Longitude 3.38E). Okobaba creek of Lagos lagoon is impacted of sawmilling activities from the Okobaba sawmill hub. The Global Positioning System for the experimental site was Latitude $6°29^{1}25.57^{11}$N and Longitude $3°23^{1}34.20^{11}$E. The Okobaba sawmill industry is situated at Ebute Meta, in the Mainland of Lagos State, near the Third mainland Bridge.

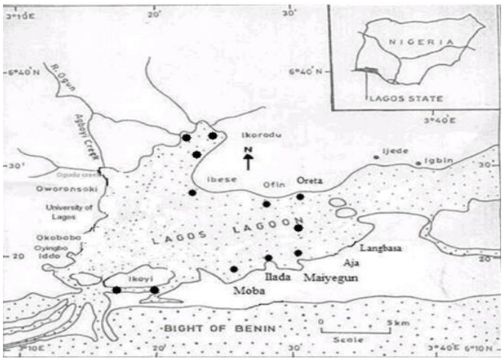

Fig 1. Map of Lagos Lagoon Showing the Study Area

Water Collection

Water samples were collected for water chemistry analysis in well labeled 75cl plastic containers with screw cap at the surface of the water body. The sample bottles were screwed tight, kept upright and transported to the laboratory for further analysis.

Plankton Collection

Plankton samples were collected using a plankton net of 55 µm mesh size, hauled horizontally on a motorized boat and towed at low speed (<4 knots) for five minutes. The collected samples were concentrated and stored in 500 ml plastic jars with screw caps, and preserved in 4% unbuffered formalin.

Physicochemical Analysis

Air and surface water temperatures (°C) were measured with a mercury-in-glass thermometer; salinity was determined using saline test meter (Hanna Instrument HI 98203; pH was measured in the laboratory using the electrometric method using the Cole Parmer Test; dissolved oxygen (mg/L) was estimated by the Titrimetric method using the Azide Modification procedure 4500°C (APHA, 2005).

Statistical Analysis

Data generated were analyzed using descriptive and inferential statistics such as Principal Components Analysis (PCA), Canonical Correspondence Analysis (CCA), Nutrient stoichiometry and Pearson's correlation coefficient.

RESULTS AND DISCUSSION

Monthly variations in the physico-chemical parameters as well as chlorophyll *a*, chlorophyll *b* and phaeophytin *a* values at Makoko (Station1) and Okobaba creek (Station 2) between November, 2016 and April, 2017 with the mean and standard deviation values are presented in Table 1.

DISCUSSIONS

The occurrence of phytoplankton in the Makoko and Okobaba creek cannot be considered alone but in relation to the prevailing environmental conditions particularly physicochemical parameters (Kadiri, 2006). Occurrence of phytoplankton alliances of pollution status of the water body. The regime of ecological characteristic operating in the Lagos lagoon has been documented by authors (Emmanuel and Onyema, 2007). The Makoko creek is an adjoining creek to the Lagos lagoon and part of the Lagos lagoon complex in the southern part of Nigeria. It is a place with high anthropogenic influence which is highly polluted with raw sewage, household wastes and human wastes. Okobaba creek of Lagos lagoon is a water body that is presented to direct impact of sawmilling movement and other local wellsprings of contamination of the water body. High air and water temperatures recorded during the study are typical for the region (Nwankwo and Onyema., 2003). Air temperature was higher in dry months for the two stations. These observations may be due to increased insolation due to lower cloud cover, and cessation of rainfall as previously reported by Nwankwo, (2004), Onyema, (2007) and Nwankwo and Amuda (1993). The water temperature didn't change steadily with the dry months, which could be as a result of water's high heat retaining capacity. During the study there was a direct relationship between Total Dissolved Solids (T.D.S), Total Suspended Solids (T.S.S), Transparency and Rainfall. In the dry months T.S.S was low possibly due to low flood water inflow to the creek. The salinity values recorded at the sites ranged from 2.90 to 18.90‰ in Station 1 and 3.91 to 22.03‰ in Station 2 which is high, representing a brackish condition. The increase in salinity in dry month could be due to increased evaporation and reduction of flood water at the cessation of rain. However, the lowest salinities were recorded in the month of November in both Stations because salinity regimes in the Lagos lagoon is seasonal, with high salinities reported from December to April and low salinities observed between May and November (Hill and Webb, 1958; Nwankwo, 1996 and Onyema et al., 2005). The creeks exhibited the usual alkaline properties with pH values ranging between 7.19 and 7.58 in Station 1 and 7.23 and 7.71 in Station 2. This is in agreement with Nwankwo and Akinsoji (1992) for tidal creeks in Lagos that are slightly alkaline. The Total hardness, Calcium ions and Chloride ions significantly reduced in the wet months as a result of increase in flood water. The lower total hardness of the water in the wet months could be as a result of dilution by flood waters. The dissolved oxygen concentration recorded at the sites may be associated with the effect of increased water temperature and increased microbial activities in the dry months. Nwankwo and Akinsoji (1988) reported that dissolved oxygen decreased in the Lagos lagoon benthos with increased temperature and bacterial activity. According to Nwankwo,

(2004), chemical oxygen demand (COD) and biochemical oxygen demand (BOD) can be employed in determining water quality. Biochemical oxygen demand value greater than 8mg/L reflects a high level of pollution. The biochemical oxygen demand observed for both Stations ranged between 1 and 7mg/L possibly indicating a moderately polluted environment which could be associated with the discharge of solid wastes, wood wastes and household wastes. The high availability of nutrients (nitrate, phosphate, silicate and sulphate) may have encouraged the growth and abundance of phytoplankton. The high levels of these nutrients may be due to the direct discharge of wastes into the creek from anthropogenic and household sources.
The heavy metal concentration was at trace levels (Copper: 0.001- 0.002mg/L and Zinc: 0.05-0.06mg/L in Station 1 and 0.05-0.07mg/L in Station 2, Iron: 0.07- 0.099 in Station 1 and 0.06-0.098 in Station 2). During the period of study oil and grease values were also recorded. Slight values of these could be attributed to boating activities, the saw mill and commercial activities in the study sites. Chlorophyll *a* measurement showed an increase in dry months which may be as a result of reduced suspended particles leading to an increase in light penetration. However, the highest value of chlorophyll *a* concentration was recorded in the wet month ($19.00\mu g/L$) at Station1 which could be due to the water being slightly transparent at the period of sampling. Chlorophyll *a* concentration observed at the creek exhibited significant negative correlations with salinity. The decrease in chlorophyll content at higher salinity might possibly be due to changes in the lipid protein ratio of pigment-protein complexes or increased chlorophyllase activity and may also be that the species, representing phytoplankton biomass are intolerant to salinity. Chlorophyll *a* concentration increased with reduction in Dissolved oxygen which maybe as a result of increased phytoplankton growth and microbial activities which makes nutrients available for the uptake of these organisms. Chlorophyll *a* increased as Chemical oxygen demand increased which may be associated with the availability of Carbon dioxide from the oxidation of organic matter in the water (Boyd, 1973). Chlorophyll *a* and Phaeophytin *a* concentration showed a direct relationship with nutrient (nitrate, phosphate, silicate and sulphate) levels which may be due to increased phytoplankton growth as a result of nutrient availability. It is a place with high anthropogenic influence which is highly polluted with raw sewage, household wastes and human wastes. Okobaba creek of Lagos lagoon is a water body that is presented to direct impact of sawmilling movement and other local wellsprings of contamination of the water body. High air and water temperatures recorded during the study are typical for the region. Air temperature was higher in dry months for the two stations. These observations may be due to increased insolation due to lower cloud cover, and cessation of rainfall as previously reported by Nwankwo and Onyema (2007). The water temperature didn't change steadily with the dry months, which could be as a result of water's high heat retaining capacity.

CONCLUSION

The physico-chemical parameters at the Makoko and Okobaba creek suggest the dominance of anthropogenic wastes such as raw sewage, wood wastes, domestic waste, industrial effluents, and the inflow of pollutant-laden water on land-based sources (Onyema, 2007). Salinity usually varies drastically between rainy and dry seasons; as such, the existence of an environmental gradient can be linked with rainfall pattern in the Lagos lagoon

ABSTRACT

Impurities found in fish have been a major cause of disease and illness to consumers. This study's objective was to evaluate the total aflatoxin, and heavy metal load in two frozen fish: *Scomber scombrus* and *Clupea harengus* from two (2) cold room facilities in Omu-aran and Ilorin. 5 kg fish samples each was bought per carton of 20 kg of *Scomber scombrus* and *Clupea harengus* per time for three months. Heavy metal load and total aflatoxin was investigated using standard methods. Health risk was also determined using Health Risk Index HRI), Daily intake of Metals (DIM), and health quotient (HQ), and Total toxicity of metals (TTM). Cd, Cu, Ni, Pb, Mn and Cr were not significantly different (p>0.05) in both species from both locations. Nickel was lower than the recommended limit by WHO. Level of Mn and Cr were higher in both species. Mn load was higher in the muscles (1.037, 1.187, 0.830) ppm than in the gills (0.509, 0.518, 0.550) ppm all through the months. Cr was higher in the gills (0.794, 0.856, 0.881) ppm than muscles (0.445, 0.350, 0.288) ppm all through the months. HRI was > 1 in the different age groups for the different metals. TTM was > 1 in both species. Total aflatoxin level was highest in the gills (4.25 – 5) ppb than in the muscle (1.5 - 3) ppb for both locations respectively. The study concludes that heavy metal loads (Mn, Cd, Cu, Cr, and Ni) were more than the permitted limitations imposed by FAO, WHO and EU legislation for fish and fish products placing consumers at health risk.

Keywords: Aflatoxin, Heavy metals, *Scomber scombrus*, *Clupea harengus*

INTRODUCTION

In Nigeria, fish is recognized and cherished as one of the healthiest, safest and one of the cheapest sources of protein (Ukoha et al., 2014) adding about 17% of the protein intake (Boyd et al., 2022), with per capita consumption of 20.2 kg per annum in 2020, and a total consumption of 157 million Mt (FAO, 2022). In Nigeria, fish importation according to the Minister of Agriculture and Rural Development accounts for about 75% of the total consumption. White croaker (*Umbrina canosai*),

African mackerel (*Scomber scombrus*), and herrings (*Clupea harengus*) are three (3) popular frozen fish in the Nigerian markets (Linnaeus 1788), and they make up a sizable portion of the imported fish consumed in Nigeria. However, water body pollution due to the presence of heavy metal has grown to be a significant public health and environmental concern.
Nigeria has many public frozen fish sales outlets and retail marketplaces spread out around the nation, where a sizable number of people regularly purchase frozen seafood items. According to Bintsis (2017), perhaps the most pervasive health issue of our time is foodborne disease, which also contributes significantly to lower economic output. Numerous elements, including Sodium (Na), Potassium (K), Iron (Fe), Calcium (Ca), Boron (B), Magnesium (Mg), Selenium (Se), Copper (Cu), and Zinc (Zn) are present in both the fish and its surroundings. For the maintenance of biological activities, these substances are necessary in very small amounts. Most metals are naturally occurring components of the earth's crust. In addition to being naturally present in fish and its surroundings, as a result of human activity, such as agricultural and manufacturing processes, metals and other elements may also find their way into food (Briffa et al., 2020). The World Health Organization (WHO) as well as the Food and Agriculture Organization of the United Nations (FAO) listed eight (8) elements that are present in fish that requires constant monitoring. They include; Mercury (Hg), Cadmium (Cd), Lead (Pb), Arsenic (As), Copper (Cu), Zinc (Zn), Iron (Fe), and Selenium (Sn), while screening of others—while not required—might be advantageous (Simpson & Uche, 2019).
In order to assess the amount of heavy metals present in two commonly consumed imported frozen fish bought from cold room facilities in Ilorin and Omu-Aran, Kwara State, this research was carried out. Also, the microbial load and total aflatoxin of the species were investigated. The detrimental effects on human health from eating such fish was also assessed.

MATERIALS AND METHODS

Purchase of fish

Fish samples were purchased from two cold rooms in Ilorin and Omu-Aran, Kwara State, Nigeria. 5 kg fish samples each was bought per carton of 20 kg of the various forms (*Scomber scombrus* Linnaeus, 1758 and *Clupea harengus* Linnaeus, 1758) per time. Fish samples were kept in an ice chest and transported to the wet laboratory of the Department of Animal Science, Landmark University, Omu-Aran, Kwara State, Nigeria. The preference for the species led to the selection of fish species for the study. Purchase was done once every third week of the month, for three months (September, October and November). This is because the cold rooms' operators informed that new batch of importation arrived at such interval most of the times.

Laboratory procedure

Using a Camry electronic weighing scale (Model EK3250.5kg), the weight of the fish samples was determined to the nearest 0.1 g. The frozen fish samples were rinsed with clean water. Before digestion, fish gills and muscles were removed, and each item was preserved individually in well-marked plastic bags.

Digestion of fish samples

This study used a wet acid digestion method (Raimi et al., 2019). Gills and muscle (0.5g each) were collected from each samples, blended using an electronic blender (Binatone BLG-595 MK2) and kept in a beaker. To the blended sample, 4 ml of nitric acid was added. The beaker containing the mixture was then placed on a hot plate for 15 minutes until the solution became clear, and was made up to 50 ml using distilled water and poured into sterile bottles until use.

Fish digest was exposed to Atomic Absorption Spectrophotometry (AAS) (Model 211 VGP Buck Scientific) for heavy metal analysis using the calibration plot technique (Adedire et al., 2021) at Afe Babalola University, Ado-Ekiti, Nigeria. The instrument was auto-zeroed for each element using the blank (distilled water), and then the standards were aspirated into the flame from lowest to highest concentration. The apparatus measured the corresponding absorbance, and a graph of absorbance against concentration was drawn. The samples were analyzed with the concentration of the metals present being displayed in parts per million (ppm) after extrapolation from the standard curve.

Total aflatoxin in sampled fish

Total aflatoxin test protocol was carried out as described in the Romer labs test kits with slight modification. Five (5) g of the fish sample was weighed and was added to 25 mls of 70% methanol and left for 10 minutes for extraction of aflatoxin. Then the mixture was filtered using a No. 1 Whatman filter paper. A ⅒ dilution was then made by adding 100 µl of the filtrate to 900 µl of 70% methanol. 50 µl of the diluent and 100 µl of conjugate was then dispensed into the green-bordered well. 100 µl from the filtrate-conjugate mixture was taken and dispensed into the antibody coated wells and incubated at room temp for 15 minutes. The content of the well was then discarded and washed with distilled water 3 times. 100 µl of substrate was added to the well and incubated for 5 minutes and observed for color change (different shades of blue to colorless) after which a 100 µl of stop solution was added and the plates were read with ELISA plate reader at 450 nm wavelength. Optical density of the samples was recorded and multiplied by 10.

On Microsoft Excel, a graph was plotted of the standard concentrations versus optical densities. From this graph, extrapolations were made to determine levels of total aflatoxin in fish samples.

Risk assessment

Using hazard quotient (HQ), risk evaluation was conducted to measure the danger presented by human consumption of tainted seafood (Khan et al., 2006), health risk index (HRI) according to methods by (Abubakar et al., 2015) total toxicity of mixtures (TTM) index (ANZECC & ARMCANZ, 2000) and daily intake of metal (DIM) (Okunola et al., 2011).

Hazard Quotient (HQ)

HQ was determined using the equation

$$\mathrm{HQ} = \frac{Wfish * Mfish}{RfD * \ Bo})$$

Where,

Wfish = daily dry weight of fish that is eaten (gd-1). For nutritional needs, a daily consumption of 20.9 grams of fish per adult with an average body weight of 79.96 kilograms and older, 10.1 grams per child with an average body weight of 49.7 kilograms and below, and 6.2 grams per person with a body weight of 17.3 kilograms was advised (aged range 0years – 9years).

Mfish = metal concentration in fish (mgkg-1),

RfD = metal reference dose (mgkg-1d-1); RfD used; Iron (Fe) (0.7), Manganese (Mn) (0.014), Zinc (Zn) (0.3), Copper (Cu) (0.04), Nickel (Ni) (0.02), Cadmium (Cd) (0.001).

Bo = average body weight (kg)

3.6.2 Daily Intake of Metals (DIM)

The DIM formula was developed to estimate the daily loading of metals into the human system from fish intake.

$$\mathrm{DIM} = (Cmetal \frac{Dfish}{Bo})$$

Where,
Cmetal = concentration of heavy metals in the fish (mgkg-1),
Dfish = daily nutritional intake of fish (gday-1),
Bo = average body weight (Kg)

Health Risk Index (HRI)

The Health Risk Index (HRI) was calculated using the formula below.

$$\text{HRI} = \frac{DIM}{RfD}$$

A Health Risk Index (HRI) value of less than one (1) denotes a safe exposure to such a heavy metal and is regarded as acceptable; otherwise, the fish may be at danger for exposure to heavy metals.

Total Toxicity of Mixtures (TTM)

Total Toxicity of Mixtures (TTM) for heavy metals was determined by applying the TTM index.

$$\text{TTM} = \Sigma(1\frac{Ci}{GVi})$$

Where:
Ci = Concentration of the 'ith' component of mixture
GVi = Value to use as a guide for the 'ith' component. values that should be used as triggers for low-risk livestock water consumption. Iron not enough hazardous, Lead 0.1 mg/L, Manganese not sufficiently toxic, Nickel 1 mg/L, Zinc 20 mg/L, Cadmium 0.01 mg/L, Chromium 1 mg/L, Copper 0.4 - 5 mg/L.
TTM >1= The mixture was shown to be above the Guideline value

Statistical Analysis

The Statistical Analytical Standard (SAS) was applied to all the data. The differences in the heavy metal concentration of the two fish species were ascertained using one-way and two-way analysis of variance (ANOVA).

RESULTS

Heavy metals in sampled fish

Table 1 showed the concentrations of specific metals in the fish that were sampled. Levels of all the heavy metals showed that there was no significant difference in both species of the sampled fish (p>0.05). Mn and Cr were higher in both species.

Table 1: Heavy metals in the fish species

Heavy Metals	African Mackerel	Frozen Herrings	Standard Deviation	Permissible limits
Cd	0.01^a	0.01^a	0.01	0.0000001
Cu	0.290^a	0.290^a	0.10	0.000003
Cr	0.594^a	0.609^a	0.33	0.03
Mn	0.804^a	0.742^a	0.31	0.000025
Ni	0.005^a	0.006^a	0.01	0.05
Pb	0.024^a	0.027^a	0.02	0.00007

Means with different superscript in same row are significantly different (p>0.05).

Metal load in organs of sampled fishes

Tables 2a-c showed the burden of these substance in the gills and muscles of sampled fish for Three (3) consecutive months. Mn load was higher in the muscles of the fish than in the gills all through the months. Significant variation at 95% probability was observed in all the heavy metals across the three months of purchase of the sampled fish.

Table 2a: Metal load (ppm) in gills and muscles of sampled fishes in September

Metals	Gill	Muscle	Standard deviation
Mn	0.509^{b}	1.037^{a}	0.09
Cu	0.277^{a}	0.166^{b}	0.04
Cr	0.794^{a}	0.445^{b}	0.12
Cd	0.011^{a}	0.003^{b}	0.00
Pb	0.041^{a}	0.013^{b}	0.01
Ni	0.006^{a}	0.002^{b}	0.00

Means with different superscript in same row are significantly different (p<0.05)

Table 2b: Metal load (ppm) in gills, and muscles of sampled fishes in October

Metals	Gill	Tissue	Standard deviation
Mn	0.518^{b}	1.187^{a}	0.14
Cu	0.309^{a}	0.180^{b}	0.05
Cr	0.856^{a}	0.350^{b}	0.17
Cd	0.014^{a}	0.007^{b}	0.01
Pb	0.047^{a}	0.008^{b}	0.01
Ni	0.006^{a}	0.003^{b}	0.01

Means with different superscript in same row are significantly different (p<0.05)

Table 2c: Metal load (ppm) in gills, and muscles of sampled fish in November

Metals	Gill	Tissue	Standard deviation
Mn	0.550^{b}	0.830^{a}	0.17
Cu	0.326^{b}	0.420^{b}	0.06
Cr	0.881^{a}	0.288^{b}	0.25
Cd	0.025^{a}	0.009^{b}	0.01
Pb	0.038^{a}	0.008^{b}	0.01
Ni	0.009^{a}	0.005^{b}	0.01

Means with different superscript in same row are significantly different (p<0.05)

Metal load in the organs of fish species

Comparison of the heavy metal load in the gills and muscles of the species showed no significant difference (p>0.05) in the gills and muscles of both species. The highest level of Mn and Cr, were observed in the muscles and gills of both species Table 3a. Table 3b shows the heavy metal load in the two (2) species from the different markets.

Table 3a: Heavy Metals in the organs of fish species

Organs	Species	Metals (ppm)					
		Mn	**Cu**	**Cr**	**Cd**	**Pb**	**Ni**
Gills	***S. scombrus***	0.512±0.14	0.0304±0.04	0.892±0.28	0.018±0.01	0.045±0.02	0.008±0.01

Total aflatoxin in sampled fish organs

Aflatoxin levels in the organs of the sampled fishes from both markets revealed that there was no significant difference ($p>0.05$). Highest levels of aflatoxin were recorded in the gills of fishes from the markets Table 6.

Table 6: Aflatoxins level in sampled fish

LOCATION	GILLS (ppb)	MUSCLES (ppb)
Omu-aran	5	1.5
Ilorin	4.25	3

Microbial load in sampled fishes

Table 7a shows the bacteria and fungi found in the muscles of the experimental fish. 2 cfu/100µl and 80 cfu/100µl of the coliform and non-coliform bacteria were present in *S. scombrus* bought from Omu-aran market in the month of September Table 7a. Other bacteria identified include *Enterobacter intermedius* and *Shigella sonnei*. Coliform and non-coliform bacteria load in the month of November were observed to be higher to too numerous to count in both species. Table 7b.

DISCUSSION

The concentration of Manganese observed in this study to have exceeded the recommended permissible limit for fish and fish products 2.50 mg/kg according to (Skovgaard, 2003) is an indication of the state of the water from which the fish was captured. This report is however at variance with the study by (Benzer et al., 2013). Differences could be attributable to the differences in location from which the sampled species were obtained. The levels of Mn in the analyzed fish are beyond the risk limit for humans and therefore poses to be a source of danger to people's health, according to the HRI value of Mn, which was > 1 in all age classifications.

Chromium levels also reported in this study to exceed the permissible limit for fish and fish products, though, in biological usable form plays an important role in glucose metabolism, is also a notable hazardous metal. The adequate intake (AI) of Cr is 35 µg/day and 25 µg/day for young men and women, and could be less for younger persons (Trumbo et al., 2001). That means, the level reported in this study could be hazardous to the consumers of the fish when it accumulates in the body overtime. Also, risk assessment indices calculated in this study was high for this metal across the different age classification (DIM, HQ, HRI, and TTM). Findings of this study corroborates with the report (Hothem et al., 2007).

Cu, Pb, Cd, which were also higher than the permissible levels for fish and fish products in the current study aligns with (Abubakar et al., 2015) did not agree with previous work on the heavy metals of fish species. Though Cu is essential for good health but an intake above the permissible level can result in liver and kidney damage (Ahmad et al., 2022). The mean concentrations of copper reported in this study was lower than that reported in previous studies (Frías-Espericueta et al., 2014; Kareem et al., 2016). Also, the HRI of Cu and Cd were >1 making the consumption of the fish sampled hazardous to the consumers.

The Total aflatoxins recorded in the gills of sampled fish from both coldrooms reported to have exceeded the permissible limits (4 ppb) could be due to its direct contact with the water and thus, the major organ of accumulation of aflatoxins. It is the first barrier of defense and the first organ to be exposed to suspended particles in the water column (Ahmed et al., 2015). Though, recorded to be lower in the muscle of the fish than the permissible limit, it is too close to the maximum aflatoxin level for human food (4ppb) according to the Commission of the European Communities (2001). Aflatoxins are immunosuppressive, mutagenic, teratogenic, and carcinogenic, if found in large quantities in foods, it can cause several health hazards to consumers (Gholamour Azizi & Rouhi, 2013).

CONCLUSION

The heavy metal loads (Mn, Cd, Cu, Cr, and Ni) were respectively above the permissible limits set by FAO, WHO and EU legislation for fish and fish products. Thereby posing a risk to the final consumer of the fish species as revealed by the risk indices of DIM, HQ, HRI, and TTM, and this calls for serious public health concern. Total aflatoxin levels in the fish muscle sampled did not pose any threat to consumers as it was below the permissible limit. The study recommends that government should provide screening centres at the various entry points to ensure proper monitoring and screening of imported frozen fish before entry into the country.

ABSTRACT
One of the basic requirements for proper and correct organism (Fish) identification is ability to classify scientifically using DNA barcoding which is used to assign a biological specimen of species. The aim of this study was to establish an inclusive barcoding reference database of Tilapia guineensis and assess the applicability of using the cytochrome c oxidase subunit I (COI) gene for the identification of fish at the species level. DNA was extracted from fresh fish tissue (caudal fin) using phenol-chloroform isoamyl alcohol method, DNA quantification with spectrophotometer and barcode gene region 5′ region of the mitochondrial cytochrome oxidase subunit 1 (CO1) was amplified using Fish F1 primer. Amplified products were visualized on 1% agarose gel electrophoresis, purified and sequenced unidirectionally. The sequence obtained were edited, viewed, aligned and compared with sequence from Gene bank. Phylogenetic tree constructed among the populations and with other sequences from Gene bank. Three major clusters were generated with 99% of similarity in identification among the populations; 94%-96% of similarity was also observed with other species from other countries. This study shows high degree of confidence and proper taxonomic identification by DNA barcoding of these species in the studied water bodies. This suggests pure strains of Tilapia guineensis for broodstocks can be obtained from wild which will require proper conservation and management for breeding program.

INTRODUCTION
Mitochondrial DNA molecular technique (mtDNA) is widely used for species identification. One of the most popular genes in mitochondrial DNA used for identification is Cytochrome c oxidase I (COI) gene. This CO1 gene proved to reveal species identity, phylogenetic pattern and genetic diversity of aquatic species (Tan *et al*., 2019). The success of CO1 gene in identifying species cannot be separated from gene amplification in polymerase chain reaction (PCR) technique.

Cichlid, generally known as Tilapia has become an important well-established sea food commodity. *Tilapia guineensis* is one of the most important estuaries fish in world aquaculture. It is widely cultured in many tropical and subtropical countries of the world; this is because of its rapid growth rates, high tolerance to adverse environmental conditions, efficient feed conversion, ease of spawning, resistance to diseases and good consumer acceptance make it a suitable fish for culture (Shelton, 2002). Despite these attributes, little is known about DNA sequences major source of new information for advance understanding of identification, evolutionary and genetic relationships (Hajibabaei,2007) for increasing fish production in aquaculture purposes. It is therefore necessary that the gene sequence, CO1, may serve as milestone for the identification of related species at molecular level. This study was done to assess DNA barcoding of wild cichlid (*Tilapia guineensis*) from some water bodies in south-west, Nigeria.

MATERIALS AND METHODS

Sampling Location

The sampling locations were Ondo Lagoon, Oyan dam and Lagos Lagoon with coordinates N $5^0$55′05″ and E$4^0$59^{0}′ 2″; N$7^0$15′30 ′ and E$3^0$15′20′ and N$6^0$29′ 24″ and E$3^0$23′58″ respectively

Collection of Samples

The species were collected from the sampling locations with cast net by the help of fishermen; taxonomic classification was done with the aid of the field guide to Nigerian freshwater fish and freshwater fishes of Nigeria (Idodo-Umeh,2003. Their caudal fin clips were cut and stored in Eppendorf tubes filled with 95% ethanol for molecular analysis.

DNA extraction and quantification

DNA was extracted from the caudal fin tissues (0.5g- 0.75g) of 6 samples; 2 samples per location using phenol-chloroform isoamyl alcohol method according to Sambrook and Russell (2001). The DNA quantification was checked with nano-spec photometer (Shimadzu corporation Japan, MODEL UV-1800,2000 series) by measuring absorbance at 260nm and 280nm.

Agarose gel

Agarose gel of 0.8% (Plate 9) and 1% weight per volume (w/v) were used to run both the DNA and PCR

PCR and Sequencing

Amplification was carried out in 20 µl final volume containing 10 µl of 2 x mastermix (Syd Labs, Inc., USA), 8 µl of nuclease free water and 0.5 µl (about 10pmol) each of forward and reverse primer (FISH1), and 1 µl (about 50 ng) of the genomic DNA in a thermocycler (Biorad, USA). The cycling conditions for the PCR reactions were: 94^0Cfor 5 minutes initial denaturation, 30 cycles of 94^0C for 60 s, 59.5^0C for 60 s and 72^0C for 120 s with final extension at 72^0C for 8 minutes. The PCR products of COI and IGF-1 genes were sequenced unidirectionally using Big Dye Terminator cycle sequencing kit (Applied Biosystems, Foster City, CA, USA) at at Inqaba West Africa Laboratory in South Africa using the forward primers.

Statistical Analysis

Sequence analysis was carried out using Bio Edit (version 7.0) and Mega 5.0.

RESULTS

DNA Purity and Quantification

The concentration and purity values are shown in Table 1, with mean Concentration value range between 672.04ng/l to 3889.40ng/l and Purity value range of 1.75 to 2.02 with the use of nano-Spectrophotometer. The dendrogram showed 4 major clusters (figure 1) namely: Cluster 1 consists (Lagos broodstock TG 1); Cluster 2 (Ondo broodstock TG 11, Lagos TG broodstock); Cluster 3 (Oyan dam broodstock TG 15, Ondo broodstock TG 10) and cluster 4 (Oyan dam broodstock TG 09) were 99% in similarity of identification. Figure 2, showed dendrogram of the fish population with other countries from Asia (Philippines) and Africa (Mauritania) samples where 3 major clusters were generated. The level of similarity in Figure 2 showed that 94% and 96% of *Tilapia guineensis* (broodstocks) with other *Tilapia guineensis* from other countries Asia (Philippines) and Africa (Mauritania) respectively.

Table 1: DNA Quantification

Locations	Concentration	Purity
Lagos Lagoon broodstock 1	830.87	1.76
Lagos Lagoon broodstock 2	2036.24	1.93
Ondo Lagoon broodstock 1	1319.40	1.75
Ondo Lagoon broodstock 2	3889.40	1.91
Oyan dam broodstock1	672.04	1.89
Oyan dam broodstock 2	1260.09	2.02

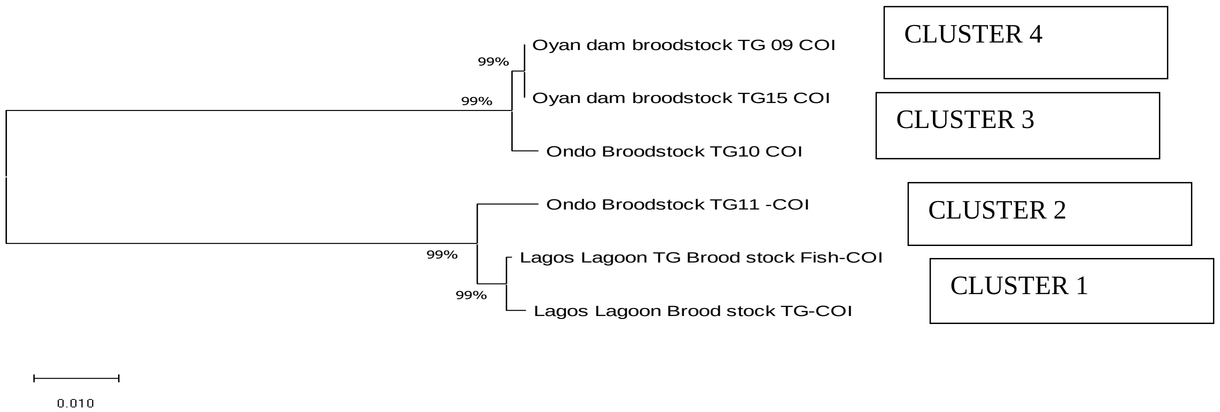

Figure 1: Dendrogram showing the identification relationship among *Tilapia guineensis* broodstocks populations in the study locations.

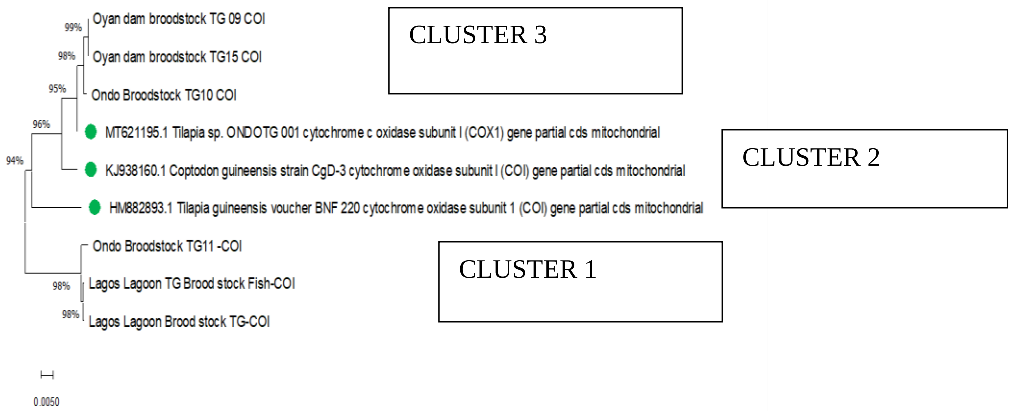

Figure 2: Dendrogram showing the identification relationship between *Tilapia guineensis* broodstocks populations from the study locations and other countries from Asia (Philippines) and Africa (Mauritania) samples.

DISCUSSION

In the present study, the results of DNA concentration showed good quantity and quality with high purity. This is in agreement with Usman *et al.* (2021) who observed large amounts of high quality and quantity of DNA on comparison of different incubation times in the DNA quantification using modified phenol- chloroform isoamlyl alcohol protocol for extraction. CO1 sequence results of the samples (broodstocks) also showed the identification of broodstocks from different locations with low intraspecies variation and high divergence from closely allied taxa which suggests high genetic similarity among the species from different locations. This is in accordance with Popoola *et al.* (2022) who observed distinct cluster on phylogenetic tree on DNA barcoding of Tilapia species from North-east part of Nigeria. The level of similarity with other countries is similar to the finding of Hurbert *et al*. (2008) and Mohanty *et al*. (2015) in which CO1gene was used in distinguishing North-American freshwater fishes and cultivable with high similarity in their study of cultivable cryptic species into different clustered group respectively.

CONCLUSION

There is little or no information about the genetic diversity among the populations of these cichlid fish. This study contributes to the use of DNA barcoding as a high degree of confidence and proper taxonomic identification of these species in the studied water bodies. This study suggests pure strains of *Tilapia guineensis* for broodstocks can be obtained from wild which will require proper conservation and management for breeding program.

ABSTRACT
Fish are an excellent source of high quality protein, vitamin and other nutrients vital to good health, including iron, calcium, potassium and iodine. Moisture, protein, ash and fat content in the bodies of 3 fish species *Dasyatis margarita* (Gunther 1870), *Claries gariepinus* (Burchel 1822) and *Pseudotolithus senegalensis* (Valenciennes 1833), were investigated. Moisture content ranges from 72.1 to 75.4%, with *P. Senegalensis* having the highest moisture content followed by *C. gariepinus*. The protein content ranges from 23.7 to 20.2%. The maximum and minimum protein values were reported for *D. margarita* and *P. senegalensis* respectively. Average concentration for ash content was found to be highest in *D. margarita* (2.6%) and lowest in *C. gariepinus* (2.1%). All the fish species were found to be low in fat content with *D. margarita* having the least (0.2%). This information can be harnessed for maximum benefits of the consumer, however, further research on the lipid compositions of this fishes are needed for the maximum benefits.
Key words: Proximate analysis, Fish, Moisture, Protein, Ash and Fat.

INTRODUCTION
Fish plays a vital role in feeding the world’s population and contributes significantly to the dietary protein intake of millions of the populace. Fish are an excellent source of high quality protein, vitamin and other nutrients vital to good health, including iron, calcium, potassium and iodine. (Suganthi *et.al.*, 2015). The fats found in fish contain unsaturated fatty acids which do not pose a threat to the heart as they help reduce blood triglycerides.

Some authors have reported on proximate composition of fishes (Ndome *et.al*, 2010, Akpambang 2015, Suganthi *et.al.*, 2015). However, such information is scanty and there is still need to further analysize the proximate composition of some other fishes. The present study is aimed at evaluating the proximate composition of three common fish species which are readily available and consumed in Nigeria.

MATERIALS AND METHODS

Sample Collections and Preparation.

Three fish samples comprising of *Dasyatis margarita*, *Clarias griepinus* and *Pseudotolithus senegalensis* were used for this study. All the samples were identified using standard taxanomical texts (FOA 2012). They were purchased from Makoko fish market, Yaba Lagos Nigeria. Cleaning, eviscerating, filleting and deboning were carried out on the samples. All the samples were lyophilized (SB4 Freeze drying machines, UK), milled (Sharp blender, model HR 2815), Wrapped with aluminium foil and packaged into labeled plastic containers. The samples were stored at a temperature of -20^{0}C prior to analysis.

Chemical Analysis

The moisture contents of the fishes were determined before freeze-drying the samples. This was done using a forced air oven at 105^{0}C first for five hours and repeated for 30 minutes interval until a constant weight was obtained. The loss in weight was calculated as the moisture content A.O.A.C. (2005). Fat was quantified using procedure of A.O.A.C.(2005) with hexane (68.5^0 -69.1^{0}C) as solvent. The protein content of content of each fish was assayed by the micro-kjeldahl method as reported by Kirk and Sawyer (1991). The gram of nitrogen obtained was multiplied by the factor of 6.25 to obtain the protein content of each fish sample. The ash content of respective sample was determined by dry-ashing the samples at 55^{0}C for 24h. Data obtained for protein, ash and fat were correlated for moisture and presented on weight basis.

,

Statistical Analysis:

Analysis of samples were carried out in triplicates. One way analysis of variance (ANOVA) was used for data analysis, post hoc analysis was done by the use of Duncan's multiple range test and means were separated at $P<0.01$ using the statistical package for social scientist computer software packages (IBM 2012).

RESULTS AND DISCUSSION.

The biochemical composition of fish varies from one species to another, depending on the number of factors, including feeding, breeding, fishing season and migration (Suganthi *et.,al* 2015). The moisture contents of the fish samples are represented in figure 1. The fish species have moisture contents within the range of 72.1 to 75.4%. The moisture content in decreasing order *P. senegalensis, C. gariepinus to D. margarita*. The values obtained in this study are within the values reported by Boran and Karacam (2011) for horse mackerel (65-75%) from black sea of turkey.

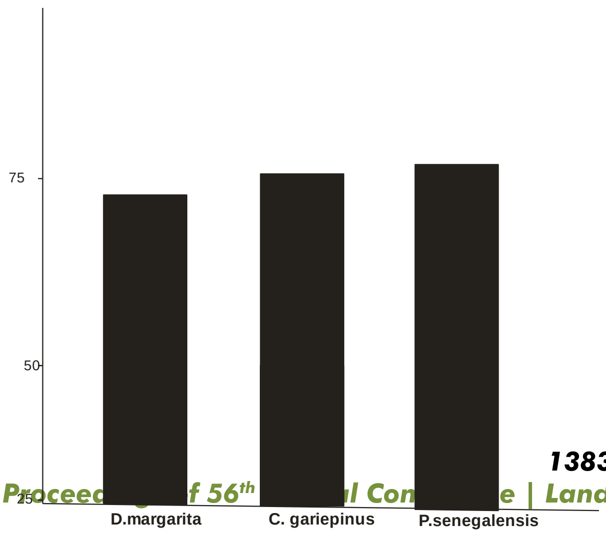

Figure 1: Moisture content of fish samples

The protein content of the fishes in his study are within the range of 23.7 to 20.2%. This present result is in agreement with the values reported by (Suganthi *et.al*, 2015) for *Stolephorus commersonii* (23.67%) from Muthet mangrove. *D. margarita* is of high nutritional value with (23.7%) protein than *C. gariepinus* and *P. senegalensis*. This could be as a result of its preference for shrimps diet which is equally of very high nutrient value (Oyebanji 1991).

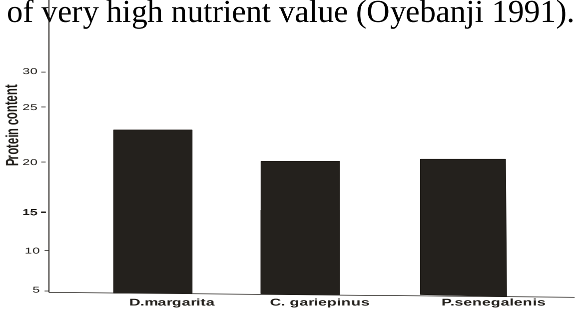

Figure 2: Protein content of fish samples

Ash content varied from (2.6%) in *D. margarita* to (2.1%) in *C. gariepinus*. The value obtained for ash content in the present study are similar to the observation made by Oyebanji (1991) who recorded 2.7% ash content for *D. margarita*.

The observed range of ash content indicated that the studied species are a good source of minerals such as calcium, potassium, zinc, iron and magnesium (Ndome *et. al*, 2010).

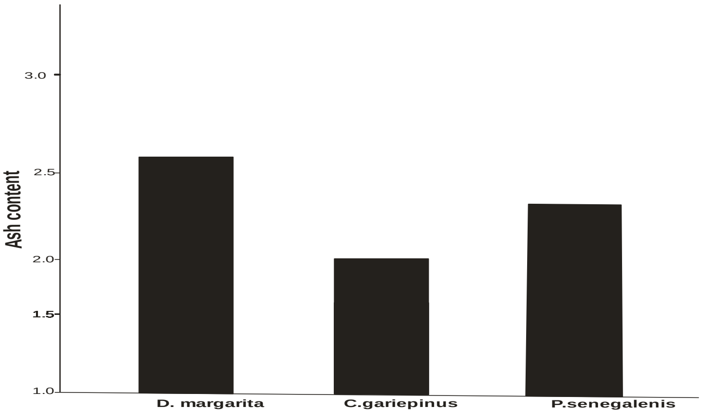

Figure 3: Ash contents of fish samples

All fish types were found to be low in fat content with *D.magarita* having the lowest value (0.2%).

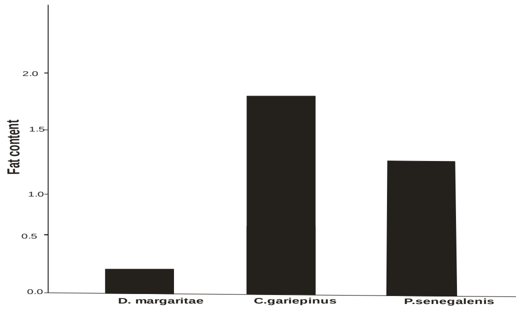

Figure 4. Fat contents of fish samples

CONCLUSION:

The study has revealed variation in nutritional benefits derived from the fish species studied. This information can be harnessed for maximum benefits of the consumer, however, further research on the lipid compositions of this fishes are needed for the maximum benefits.

ABSTRACT
Up to 80% wastes and by-products are generated from fish processing activities; by-products can be used to develop functional products of positive health, economic and environmental impacts. Catfish roe butter (CRB) was developed. The nutritional composition and acceptability of CRB were determined. The protein, lipid, moisture and ash contents of the developed product were (22.65±0.15), (28.10±0.10), (46.87 ±0.01) and (1.22±0.00) % respectively. The calcium, iron, magnesium, phosphorus and zinc contents of CRB were (11.38±0.06), (0.75±0.00), (18.80±0.13), (396.35±0.20) and (2.14±0.02)mg/100g respectively. The oil of the CRB was found to be `rich in polyunsaturated fatty acids while the cholesterol level was (326.33±1.70) mg/100g. The developed CRB is nutritious and well-accepted by the sensory panellists. The developed CRB constitute healthy food that can be used as source of nutrient especially in children diet.

Keywords: Catfish roe, catfish roe butter, Nutritional Composition, Sensory Attributes

INTRODUCTION
There is a strong demand for fish products due to increasing consumer awareness of the nutritional benefits of fish (Diouf, 2019) and a source of high quality food (Abeywardena and Patten, 2011; Dyck *et al.,* 2011) recommended as a means of preventing cardiovascular and other diseases (Alasalvar *et al*. 2011; Cruz Casallas *et al.,* 2012).
Nigeria is the largest producer of catfish in Africa with over 300 Metric Tonnes annually (FDF, 2017). Fish roe (eggs) and other by-products could be derived from catfish processing and value addition activities such as filleting, drying, smoking and canning. To maximise profits, wealth creation and to save the environment, it is very important to make use of fisheries wastes and under-utilized fisheries resources as by-products for functional products that are nutritious and of health benefits.

MATERIALS AND METHODS
Fresh catfish roe was collected from Kado fish market, Abuja, transported in icebox to the laboratory of Fisheries and Aquaculture Department, Prince Abubakar Audu University, Anyigba. The roe was rinsed with clean water, soaked in 3% brine solution for 5 minutes and steamed for 2 minutes. The steamed catfish roe was then added to the mixture of coconut milk and groundnut oil. Blended banana paste was added to serve as a binder and sweetener, turmeric and lime were added

for colour and preservation. The mixture was thoroughly mixed to give a uniform paste, which was packaged in a plastic tube and refrigerated for nutritional and sensory analyses.

Proximate analysis

Protein was determined in triplicate by Kjeldahl method using Foss Kjeltex^{TM} 2100. There were three steps involved: Digestion, distillation and titration as described by (ISO, 2005).

Lipid content was determined in triplicate by Bligh and Dyer (1959) with slight modification of breaking up the lipids with N-hexane.

Moisture content was determined by difference in weight of the homogenised samples before and after drying for 24hr in an electronic oven at a temperature of 104± 2 °C (AOAC, 2004).

Mineral determination

Wet digestion of the sample was done and the minerals were identified and quantified with the use of Atomic Absorption Spectroscopy (AAS) and as described by AOAC, 2004 and EPA 7000A and B, (1990).

Fatty acids composition

The fatty acid composition of the total lipids extract was determined by gas chromatography of fatty acid methyl esters (FAMEs) based on AOAC 996.06 (2001).

Cholesterol determination

The total cholesterol was determined by AOAC, (2010), official method 994.10, cholesterol in foods.

Sensory analysis

Twenty (20) trained panellists who are familiar with and usually include fish products in their diet made judgement on the appearance, taste, flavour and overall acceptability of the dried catfish roe products. The sensory analysis was done using the following points: Like extremely (9), Like very much (8), Like moderately (7), Like slightly (6), Neither Like nor Dislike (5), Dislike slightly (4), Dislike moderately (3), Dislike very much (2), Dislike extremely (1). The sensory panellists were selected by the procedure described by Meilgaard *et al.* (2006) with slight modification.

Data analysis

The data generated were analyzed using Microsoft Office Excel 2013.

RESULTS AND DISCUSSION

The results of the proximate analysis of fresh catfish roe (CR) and catfish roe butter (CRB) are presented in Table 1. It was observed that CR and CRB are rich in protein. Wirth *et al*, 2011 reported similar chemical and biochemical composition of sturgeon roe. Protein rich food is necessary for growth and repair of body cells, increase protein intake improves gain in muscle mass and strength in adults (Wirth *et al.*, 2020).

Table 1: Proximate composition (%) of catfish roe and catfish roe butter

Proximate composition	Catfish roe	Catfish roe butter
Protein	27.77±0.01	22.65±0.15
Lipid	1.59±0.01	28.10±0.10

Moisture	62.77±0.06	46.87±0.01
Ash	2.56±0.01	1.22±0.00

The mineral composition of CRB is presented in Table 2. CRB is a good source of minerals such as calcium, iron, magnesium, phosphorus and zinc. Food rich in minerals are needed for body growth and development. They are needed to live long and stay healthy and their deficiency can lead to disorders and disease symptoms (Gharibzahedi and Jafari, 2017). According to Food and Agriculture Organization (FAO) food balance data, it has been calculated that about 20% of the world's population could be at risk of zinc deficiency (FAO, 2001). CRB is rich in phosphorus which is needed in bones and teeth formation. It helps the body to utilize carbohydrate and fats and make protein for growth (NIH, 2021).

Table 2: Mineral composition (mg/100g) of catfish roe butter

Mineral	Catfish roe butter
Calcium	11.38±0.06
Iron	0.75±0.00
Magnesium	18.80±0.13
Phosphorus	396.35±0.2
Zinc	2.14±0.02

Catfish roe butter is rich in fatty acids composition, the ratios of omega-6 to omega-3 and polyunsaturated fatty acids to saturated fatty acids fall within the acceptable limits by WHO, 2005. The ratio of omega-6 to omega-3 in modern diets is approximately 15:1, whereas ratios of 2:1 to 4:1 have been associated with reduced mortality from cardiovascular disease, suppressed inflammation in patients with rheumatoid arthritis, and decreased risk of breast cancer (HMSO, 2001). There is increasing interest in dietary cholesterol due to the connection of plasma cholesterol levels with the risk of cardiovascular diseases. (Zhong, *et al*. 2019; Zhuang, *et al*., 2021). It has been reported that between 20-25% of the cholesterol in the body comes from the food of animal origin such as egg, Zhuang, *et al*., 2021). It is therefore necessary to know the concentration of cholesterol in our diet to prevent cardiovascular diseases. The body needs about 300 mg dietary cholesterol per day and an individual should eat moderately dietary cholesterol for proper body metabolism (Clayton, *et. al*., 2017).

Ta**ble 3: Fatty acids composition (%) and cholesterol composition mg/100g of catfish roe butter**

Fatty acids composition (%)	Mean ±SD
Total fatty acids composition	98.66±0.68
Saturated fatty acids (SFA)	41.25±0.25
Monounsaturated fatty acids (MUFA)	35.45±0.18
Polyunsaturated fatty acids (PUFA)	21.86±0.35
PUFA/SFA	**0.53**
Eicosapentaenoic acid (EPA)	0.11±0.01
Docosahexaenoic acid (DHA)	0.59±0.02
n-3 (Omega -3 fatty acids	4.96±0.22
n-6 (omega -6 fatty acids	17.10±0.22

n-3:n-6	**1: 3.45**
Cholesterol (mg/100g)	389.92±5.66

SD = Standard Deviation
Values in red are some indices for measurement of oil quality; WHO, 2005 (n-3/n-6≤5:1 PUFA/SFA>0.4

The results of the sensorial analysis, demonstrating preference criteria like appearance, taste, flavor and overall acceptability for the CRB is presented in Table 4. The results showed high level of acceptability of CRB.

Table 4: Sensory attributes of catfish roe butter

Attributes	Catfish roe butter
Appearance	7.60±1.10
Taste	7.40±1.39
Flavour	7.35±1.23
Overall acceptability	7.60±1.10

CONCLUSION

It was observed that appreciable percentage of roe (eggs) and other by-products could be derived from catfish processing and value addition activities such as filleting, drying, smoking and canning. The study indicated that catfish roe butter was well accepted by the panellists and is a good source of protein, minerals and lipids which are excellent in polyunsaturated fatty acids. The PUFA: SFA and n-3: n-6 ratios of the catfish roe butter is within the recommended value by WHO, thus constituting healthy food.

24 - 28 Oct., 2022

ABSTRACT
The food processing industry is one of the fast growing sub-sectors in Nigeria. The industry which is mainly composed of medium and small scale firms depends on the locally developed food processing equipment. Due to lack of proper material selection practices employed by the equipment manufacturers, the materials normally selected for most designs are not the most appropriate ones hence compromising the quality of the equipment produced. This has not only led to poor quality food products due to contamination but could also turn hazardous to the health of the product consumers. This study involved the assessment of the current materials selection and fabrication procedures used by the food processing equipment manufacturers with a view of devising best practices that can be used to improve the quality of the food products processed using the locally fabricated machines. Results of the study show that fabricators experience business biasness, and their desire to minimize cost, compromise the material selection procedures. In addition to failing to choose the best material for a given application, most machine fabricators are commonly fabricating machines with inadequate surface finish and improper weldments. This hinders the machine's ability to meet food hygiene standards. This study also accessed agricultural mechanization in Nigeria, and the choice of material used for fabricating most food processing machines. The benefits of agricultural mechanization and proper material selection were identified. The level and problems of Agricultural mechanization in Nigeria were also highlighted.

Keywords: Material selection, proper, Agriculture, Mechanization, food contamination, product contact surface, design

INTRODUCTION
Food security and sustainable agriculture have become burning in the national discuss at all levels of government as plans are being made for a changing global climate and increasing global population. (Asoegwu, 2007). Hence the need for engineers who would enhance, through technology, the production, processing, storage and distribution of food across our country, Nigeria, so as to maximize production and minimize losses of food. Researchers over the years have proven that agricultural mechanization which involves a balanced application of the trio of technologies (biochemical Technology, Physical/Engineering Technology and socio-economic Technology) is the key (Ani and Onwualu, 2002). In any product development the major aim is to achieve equipment

that fulfils its engineering function. However, specifically for food processing equipment, the requirements for hygiene is often conflicted. Whilst, in seeking any acceptable compromise, it is imperative that food safety is never compromised to this kind of risk. The criteria for hygiene design of food contact surface should ensure that the surface are smooth, impervious, free of cracks and crevices, non-porous, non-absorbent, non-contaminating, non-reactive, corrosion resistant, durable and maintenance free, non-toxic and cleanable (). If the surface is coated with metal alloy, ceramics, plastic, or rubber in any way, the final surface must meet the previous criteria but also the 3A hygiene standards. The 3A standards require that such coating maintain corrosion resistance, and be free from surface delamination, pitting, flaking, chipping, blistering, and distortion under conditions of intended use. Similarly, if any modifications or process is used in fabrication it should be done using appropriate materials and in a manner that ensures the final surface meets the hygiene design criteria.

There is no doubt that the application of farm power to appropriate tools, implements and machines – “farm mechanization”- is an essential agricultural input in sub-saharan Africa (SSA) with the potential to transform the lives and economies of millions of rural families. Farm mechanization can facilitate increased output of higher value products while eliminating the drudgery associated with human muscle-powered agricultural production. (faborode, 2005). Improved livelihoods for smallholder farmers means increased access to input supply chains and integration in modern food systems, resulting in improved incomes, numerous and renewed business opportunities, further value addition and overall improved livelihoods for smallholder families. Moreover, agricultural mechanization in its broadest sense can contribute significantly to the sustainable development of food systems globally, as it has the potential to render post-harvest, processing and marketing activities and functions more efficient, effective and environmentally friendly. (FAO, 2007). Material selection is a step in the process of designing any physical object. In the context of product design, the main goal of material selection is to minimize cost while meeting product performance goals. Systematic selection of the material for a given application begins with properties and costs of candidate materials. Material selection is often benefited by the use of material index or performance index relevant to the desired material properties. A thermal blanket must have a poor thermal conductivity in order to minimize heat transfer for a given temperature difference. It is essential that a designer should have thorough knowledge of the properties of the material and their behavior under working conditions. Some of the important characteristics of materials are: strength, durability, flexibility, weight, resistance to heat and corrosion, ability to cast, welded or hardened, machinability and electrical conductivity. Systematic selection for application requiring multiple criteria is more complex. (Aamir, 2020). The objective of this study was therefore to evaluate the advantages of proper material selection in agricultural machine fabrication.

Problems of Agricultural Mechanization and Material Selection for Food Processing

The agricultural sector notwithstanding many decades of neglect remains the highest employer of labour in Nigeria. The sector employs about 70% of the labour force in the country. Despite this landmarks made by Agriculture in Nigeria, the sector has been unable to meet the food demands of its populace. (Odigbo, 2000). There are many constraints to successful farm mechanization in Nigeria and they include: land tenure system, poverty of farmers, inadequate spare parts, seasonality of operation, and lack of extension agents. Other noticeable problems of Agricultural mechanization are: lack of experts to handle machines, peasant farmers have small fragment of farm land, most of the machines cannot adapt to our local soil type, land tenure system in Nigeria, economic factors, government policies, inadequate operators. (IFPRI, 2010.)

The problem of material selection and that of agricultural mechanization are interwoven with little disparity in line with food processing. In other to reduce health challenges like cancer and other life threatening ailment caused by the introduction of heavy metals into our food during processing, material selection for food processing dos and don’ts cannot be overemphasized. There are many constraints to successful material selection in Nigeria and they include: finishing: production deficiencies and cooling methods. (Shanian, 2006). stainless steel has been recommended for use in design and fabrication of food processing machines, presence of defects and holes in the plates are cracks and corrosion initiation sites. The mechanical and physical properties of a selected material are not known to the designer. (Rao, 2008).

Benefits of Agricultural Mechanization and material selection for food processing
Advent of agricultural mechanization in the first republic in Nigeria was targeted on getting the youth involved in agriculture. Then the federal government discovered that to meet up with the demand of the international market and also to tackle the menace of rising unemployment with the increasing number of graduates, it had to make agriculture very attractive to the youths of that time by importing some good number machines to help ease human-powered efforts. (sahel, 2017). Agricultural mechanization have scored some good points in Nigeria and its benefits includes: increased productivity, reduced health hazard due to manual or over labour drudgery, it saves time, encourages large scale farming, promotes specialization of available manpower, create employment for youths, hand-on knowledge of the material selected, encourages multiple cropping which was not possible under traditional farming and supplements human-powered effort in several folds for heavy jobs. Proper material selection will give assurance on its overall stability, sustainability and mechanical attributes. Most importantly, good selection of materials for design and fabrication of engineering machines meant for food processing industry, promotes good health because of the following: right material selection (stainless is preferred to mild steel even if that mild steel was coated with the best of insulators), it promotes HQC, saves cost of maintenance, promotes durability, and encourages exportation.

Level of Agricultural Mechanization and Material Selection in Nigeria
Nigeria mechanization rate of 0,27HPH is well below the FAO recommended rate of 1.5HPH. For every 10,000 hectares of arable land, farmers have access to 6 tractors (sahel, 2017). Agricultural mechanization includes three main power sources: human, animal and mechanical. Based on these sources, the technological levels of mechanization have been broadly classified as (i) hand-tool technology, (ii) animal draught technology, and (iii) mechanical power technology. Though, the mechanical power technology has suffered a setback in Nigeria, because of government policy and leadership negligence. (Adamade and Jackson, 2014)
The level of food processing in Nigeria is below par. The food processing landscape in Nigeria is underdeveloped and largely dependent on imported processed foods, due to the minimal investment in technology and knowledge for local processing. Nigeria is the world sixth largest producer of cocoa beans producing 248,000 tons in 2016; however, only about 74,400 tons (representing 30% of total production) of cocoa beans are processed locally. The remainders are processed in countries such as France and the Netherlands, from which Nigeria imports end products like chocolate and cocoa powder. Similarly, a lack of processing facilities has resulted in Nigeria, the largest producer of tomatoes in sub-saharan Africa becoming the largest importer of tomato paste in the region. (Rao, 2008)

Solution to Problems of Agricultural Mechanization and Material Selection
Solution to agricultural mechanization in Nigeria includes: provision of credit facilities which should accessible to farmers, availability of farm machines, farmers should form a cooperative society, loans are easily accessed as a team, the land tenure system should be reviewed to make land available for farming, simple and less expensive machines should be developed and made accessible to farmers, there should trained engineering personnel to maintain either imported or located built machines, machines should be produced using the best health friendly material in the case of food processing machines, fertilizers and manure should be used to increase production of crops in the available

lands, crop rotation should be practiced by farmers, there should be a synergy between the agriculture extension workers and the rural farmers, the land use decree of 1978 should be fully implemented to minimize the problems of land tenure and provide adequate education to farmers. (sahel et al., 2017). For a good material to be achieved, engineers must know the following: material environmental impact, durability, material tensile and compressive strength, hardness, manufacturing process, cooling methods, elasticity and toughness. Engineers and fabricators must take decision of the material to be used before hand, material to be purchased must be inspected, and there is need for market survey and preparedness as choice materials are often expensive. Fabricators must have the knowledge of the material they want to purchase. During design and fabrication, there is need for production carefulness so as to avoid producing machines with many point defect and imperfections.

CONCLUSION AND RECOMMENDATIONS

Engineers are in the forefront of providing solutions to the problems of food insecurity in Nigeria through mechanization by introduction of machineries to boost agricultural and food production. Agricultural mechanization in Nigeria is undergoing a process of transition to a market economy, with substantial changes in the social, legal, structural, productive and supply set-ups. Since the world is shifting emphasis from traditional ways of farming to a wider spectrum, the government is expected to formulate policies that will encourage mechanization of agriculture. Government should create a body that will certify food processing machines okay for use in food processing industries; this will help control the rising number of cancer patients and other terminal health challenges on the increase due to heavy metal found in our processed foods in Nigeria. Majority of newly discover illness are traceable to wrong material selection used for food processing purposes, since there are little or no government regulation on material selection, the choice of material for fabrication of food processing machines are mostly decided by the local fabricators, leaving much to be desired about processed foods in Nigeria. It is important that a product designer should know the mechanical and physical properties of the material to be used for fabrication.

This study suggests that proper awareness, education and training should be encouraged, and government should enact laws that will prohibit the use of substandard metals and coatings for fabrication of mainly food processing machines. This will go a long to giving agricultural mechanization its footing in Nigeria, and at the same time encourage exportation.

Table 1: AISI, DIN and EN designations of stainless steels for food equipment

AISI	DIN/EN	Typical analyses					
		C%	Cr%	Ni%	Mo%	Ti%	N%

ABSTRACT
The presence of heavy metal in processed foods is on the increase in recent years due to corrosion and improper material selection for food processing purposes. This research was conducted to determine the corrosivity of mild steel (uncoated), galvanized steel and stainless steel (304L) using the weight loss method over a period of 98 days with measurements made at 14 days interval in ground melon (locally called Egusi), cassava pulp, mashed palm fruit, tomato pulp and black-eyed bean pulp respectively. The result obtained show that the average corrosion rate of 304 stainless steel, galvanized steel and mild steel are in ground melon (1.98×10^{-3}, 1.81×10^{-2}, 2.65×10^{-2}) mpy; in cassava pulp (3.68×10^{-3}, 7.09×10^{-1}, 5.64×10^{-1}) mpy; in mashed palm fruit ($4,75 \times 10^{-3}$, 2.38×10^{-1}, 2.83×10^{-3}) mpy; in bean pulp (3.07×10^{-3}, 9.25×10^{-1}, 1.16) mpy, and in tomato pulp (5.46×10^{-2}, 6.99×10^{-1}, 7.83×10^{-2}) mpy respectively. Comparing these corrosion rate data with respect to that of stainless steel in each condition shows that in ground melon galvanized steel and mild steel had corrosion rates 91.41 and 13.38 times that of stainless steel; in cassava pulp 183.68 and 148.11 times that of stainless steel: in mashed palm pulp 50.08 and 58.58 times that of stainless steel: and in bean pulp 301.3 and 377.85 times: and in tomato pulp 128.2 and 14.34 times respectively. Presentation of the average corrosion rate and average specific weight loss of mild steel and galvanized steel, relative to that of stainless steel enables an easier assessment of the corrosion resistance of these substitute steels, which is envisaged will be of immense benefit to the local food and quality regulatory agencies and food processing equipment fabricators. These results suggest a dependable data when the questions on material selection for food processing are asked.
Keywords: Corrosion, Steel, Behavior, Food Processing, Nigeria

INTRODUCTION
Corrosion which is the deterioration of a material of construction or its properties due to reaction with the environment is a problem in a lot of industries and is even a greater challenge in the food processing and pharmaceutical industries, where in addition to the loss of production time for maintenance and risk of equipment failure, there exists the additional risk of product contamination by corrosion products which may result in food poisoning. As a consequence food processing machines are fabricated with stainless steel irrespective of the cost. Despite wide recommendation of stainless steel, other materials like tinned copper had

been employed successfully. (Fontana, 1987). There has been an increase in the local fabrication of food processing equipment using materials that are not stainless steel, thus reducing cost. The fabricators uses different varieties of metallic materials ranging from mild steel, galvanized steel to different grade of stainless steel.

The chemical composition of the metals and the food processing environment is important as it will to a large extent determine the possible corrosion reactions rate. Food stuff contain a lot of chemicals (mainly organic), which when allowed to stand can become substrates for microbial attack which may lead to production of chemical products which are aggressive to metallic materials. The organic acid present in food is the major corrosion agents. The effects of these chemicals can be influenced by the environmental conditions of processing such as temperature, flow rate, viscosity of the food media, and presence of stresses in the system. Exact analysis of the constituents of food stuff is a challenge due to their very complex composition (purseglove, 1981).

Most foods are acidic (McSwane et al, 2003; Bailey and Bailey, 2005; Reger et al. 2009) and since steels are active in acidic medium are susceptible to corrosion in food processing media. The processing of cassava tubers yields hydrogen cyanide with most varieties reoorted to contain 15-400mg cyanide/kg fresh weight and a few varieties containing up to 1300-2000mg cyanide/kg (fresh weight) in the tubers and 1000-2000mg/kg cyanogenic glucosides on a dry matter basis in the cassava leaves (Padmaja and Steinkraus, 1995). In cassava products, cyanide exist in three forms; as linamarin and lotaustralin, as cyanohydrins, and as the free hydrocyanic acid (HCN) (Tewe, 1991). HCN is a weak acid and is normally not corrosive, however, it exhibits a corrosive effect under two special conditions; in solution with water HCN cause transcrystalline stress cracking of carbon steels under stress even at room temperature and when in dilute solution in water containing H_2SO_4, HCN severely corrode steel above 40℃ and stainless steels above 80℃ (Maxwell, 2004). The corrosion effect of cassava fluid on steel has been the focus of a lot of research efforts (Jekayinfa et al, 2009; Loto and Atanda, 1998; Oluwadare and Agbaje, 2007; Oluwole et al., 2009). Tomato is acidic, with most varieties having pH below 4.5 as it contains a cocktail of organic acids. The major organic acids present are citric acid and to a lesser extent, malic acid, in addition to several carboxylic acids, sugar acids and alicyclic acids. (Yilmaz, 2001). The ripe oil palm fruit (Elaeis guineensis) contain in the oily mesocarp, fat of composition 70-75% of dry matter, which consists of 39-52% oleic acid, 32-45% palmitic acid, 5-11% linoleic acid, 2-16% stearic acid and 1-6% myristic acid (Asiedu, 1972). Same was derived for Egusi seed and Black-eyed beans respectively.

MATERIALS AND METHODS

Forty-five samples of each type of steel was cut from metal sheets to dimensions of (25 x 50 x 1.15)mm for stainless steel, (24.5 x 50 x 0.9)mm for galvanized steel, and (24 x 50 x 1)mm for mild steel, with a 3mm diameter hole drilled towards one longitudinal end for suspension in the test media. The sharp edges were smoothened with a hand file. Next the specimens were cleaned in acetone, dried, weighed with an analytical balance to an accuracy of 1/10th of a milligram to obtain the initial weights of the test coupons, labeled and polypropylene strings attached for suspension in the media.

The five indigenous food environments employed in this study; ground melon locally called egusi (Citrullus lanatus), cassava pulp (Manihot esculenta), mashed palm fruit (Elaeis guineensis), tomato pulp (Lycopersicon esculentum), and black-eyed bean pulp (Vigna unguiculata unguiculata), were prepared as follows. The melon, cassava pulp, the mashed palm fruit, black-eyed bean, and the tomato pulp environment was prepared by grinding 1500g of all the selected food except for black-eyed bean which was prepared by soaking 1500g of the beans in cold water for about 10 minutes.

This study of three trial environment were poured into plastic containers and labeled. Nine specimen of each of the three types of steels used in the study were immersed in these four different food media respectively. Every 14 days, samples of each type of steel is removed from each food media, observed, washed in running water with a rubber bung to remove corrosion products, washed in ethanol, and then acetone, dried and weighed to determine the final weight from which the total weight loss, specific weight loss (weight loss per unit exposed area) and consequently the corrosion rate is computed.

RESULTS AND DISCUSSIONS

The results obtained show that the average corrosion rates of 304 stainless steel, galvanized steel and mild steel are in ground melon melon (1.98×10^{-3}, 1.81×10^{-2}, 2.65×10^{-2}) mpy; in cassava pulp (3.68×10^{-3}, 7.09×10^{-1}, 5.64×10^{-1}) mpy; in mashed palm fruit ($4{,}75 \times 10^{-3}$, 2.38×10^{-1}, 2.83×10^{-3}) mpy; in bean pulp (3.07×10^{-3}, 9.25×10^{-1}, 1.16) mpy, and in tomato pulp (5.46×10^{-2}, 6.99×10^{-1}, 7.83×10^{-2}) mpy respectively. Normalizing these corrosion rate results (Table 1) with respect to that of stainless steel in the respective media enable easy comparison of how fast the substitute materials corrode in each media relative to 304L stainless steel. Manipulation of corrosion data in this way, is believed to be suited to the equipment designer, and shows that in ground melon galvanized steel and mild steel had corrosion rate 91.41 and 13.38 times that of stainless steel; in cassava pulp 183.68 and 148.11 times that of stainless steel: in mashed palm pulp 50.08 and 58.58 times that of stainless steel: and in bean pulp 301.3 and 377.85 times: and in tomato pulp 128.2 and 14.34 times respectively. Since the corrosion in food processing environment is usually more concerned with product contamination than with equipment failure, the presentation of corrosion data, in a form that gives the knowledge of quantity of metal likely to be passed into the product as a result of corrosion is preferable. In this regard the corrosion data has been presented in mpy (mils per year) and also in terms of (specific metal loss per unit time in $mg/cm^2/day$). To indicate the quantity of metal getting into the food per unit area of the metal exposed per unit time. This is beneficial with knowledge of the chemical composition of the metal alloy and assuming a uniform corrosion of all the constituent elements in the alloy, the elemental contamination in the food can be evaluated. The specific metal los into the food media was recorded to be for stainless steel, galvanized steel and mild steel as; (1.15×10^{-3}, 6.84×10^{-2}, 1.19×10^{-2}) $mg/cm^2/day$ in ground melon; in cassava pulp (1.05×10^{-3}, 1.57×10^{-2}, 1.96×10^{-1}) $mg/cm^2/day$; in mashed palm fruit (1.53×10^{-3}, 5.67×10^{-2}, 7.74×10^{-2}) $mg/cm^2/day$; in bean pulp (1.34×10^{-3}, 2.4×10^{-1}, 1.89×10^{-2}) $mg/cm^2/day$, and in tomato pulp ($1.82 \times 10^{*3}$, 1.3×10^{-1}, 1.91×10^{-2}) $mg/cm^2/day$ respectively. Normalizing these data, with respect to that of stainless steel shows that in metal ingress per cm^2 per day of galvanized steel and mild steel in ground melon is 59.5 and 10.31 times that of stainless steel; in cassava pulp 149.68 and 186.59 times; in mashed palm fruit 37.02 and 50.57 times; in bean pulp 179,29 and 14.07 times, and in tomato pulp 71.17 and 10.49 times respectively,

CONCLUSION

It is observed that the corrosion rate was generally lower for the two oily food processing environments; ground melon (Citrullus lanatus), and mashed palm fruit (Elaeis guineensis), than for the water based ones for the three steels studied. This is believed to be gradual penetration of oily corrosion products which inhibited further corrosive activity. As expected, the corrosion rates for stainless steel was negligible in all the food processing environments while black-eyed bean pulp environment was most corrosive to mild steel and galvanized steel. The highest corrosion activity was observed in the galvanized steel while in the bean pulp, then in cassava pulp and tomato pulp environments within the initial 28 days, at that time all zinc coating on the galvanized steel had been washed off.

The results obtained show that (i) mild steel possess better corrosion resistance than galvanized steel in Nigeria food processing environments except in the bean pulp environment. (ii) the use of galvanized steel for food processing purposes is not beneficial (from the corrosion and economic point of view), (iii) the experiment show that the ground melon environment was the least corrosive of the food processing environments, (iv) while the black-eyed bean pulp environment was the most aggressive of all the other steel under study except stainless steel. (v) tomato pulp environment is the most aggressive of them all.

Table 1: Normalizing average spec. wt. loss and average corrosion rates based on 304 stainless steel, showing how many times mild steel and galvanized steel corrode in different media compared to stainless steel

24 - 28 Oct., 2022

ABSTRACT

The need to control the erosion in part or whole of metals, which is responsible for food contamination, failure of machines, and cost of maintenance birthed sacrificial anode cathodic protection (SACP) system. The purpose of cathodic protection (CP) is to reduce the potential difference between anodes and cathodes to a small value. This study explores empirically the role of cathodic protection in corrosion control. A metal is said to be cathodically protection at a stipulated value of (-850mV) and overprotected at a value above (-1150mV). The problems of cathodic protection using magnesium as sacrificial anodes were identified. Coating technology as a means of metal protection by cathodic involvement was discussed. The benefits of cathodic protection were highlighted. The process of installation of a working CP system and the type of soil that will guarantee a good CP system were discussed also. The level of CP system application in Nigeria was discussed also and its relevance analysed.

Key Words; Cathodic Protection, Electrochemical, Corrosion, Coating, Soil Analysis

INTRODUCTION

The invention and first application of cathodic protection is attributed to Davy in 1824 in a project financed by the British Navy which succeeded in preventing the corrosion of copper sheathing of the wooden hulls of the British Naval ships (Peabody, 2001). About 1820 the Navy Board was anxious to find the reason why copper sometimes got fouled, whilst iron was dissolving, and at other times the copper was dissolving rather too quickly which birthed cathodic protection. Kuhn made considerable research in connection with the corrosion of cast iron pipes in the soil. Those studies indicated that galvanic currents of great magnitude circulated around a corroding pipe and that these currents discharge at the points of corrosion and collected on other areas. He stated that ordinary corrosion could be prevented by reversing these currents. In 1933, Kuhn postulated that the potential needed to step down corrosion rate is probably in the range of -850mV (Kuhn, 2006). The methods used in the control of corrosion are coating, cathodic protection, material selection, environmental modification, and design practices. Control of underground corrosion is primarily achieved by two methods: coating and cathodic protection. An effective external coating can provide corrosion protection to over 99% of the exposed pipe surface (Kuhn, 2006).

Corrosion cell resulting from contact of dissimilar metals leads to a cell in which one is active (negative) with respect to the other. In cathodic protection, the above stated is taken advantage of by purposely establishing a dissimilar metal cells normally existing on pipelines. This is accomplished by connecting a very active metal to the pipeline. (Umezurike, 2008). This metal will corrode and in so doing will discharge current to the pipeline. Cathodic protection does not eliminate corrosion; rather it displaces corrosion from the structure being protected to sacrificial anodes. (Jones, 2011). The sacrificial anode must have a potential that is more negative than that of the protected structure. When the sacrificial anode is connected to the structure, it is polarized anodically and the two will reach the same potential, provided the resistance of the electrolyte is sufficiently low. Thus an essential requirement is that the anode will polarize the steel to a potential where it will not corrode at all, or corrode at an acceptable rate, for an acceptable period of time at an acceptable cost. For maximum efficiency of protection, self-corrosion of the anodes should be eliminated by alloying. (Ovri, 2011). To a large extent, the economic impact of corrosion control to any society can be clearly seen in terms of its effect on the GNP. Nevertheless, some relatively high-resistivity soils may be very corrosive, e.g. acidic peaty soils and anaerobic soils containing sulphate reducing bacteria. Corrosion can also occur in fairly high resistivity soils if there is a considerable variation in the resistivity at different points along the route of the pipeline to be protected, causing concentration-cell effects.

The resistivity of the soil can vary greatly with its water content and with the electrolyte dissolved in the water. Thus the soil resistivity at a given location may vary with the season of the year and the rainfall. For a proper design of a cathodic protection system, current output can be predicted from soil resistivity data. It is estimated that between 3-5% loss is recorded on the Gross National Products of industrialized countries. These have been attributed to corrosion damages. (Peabody, 2001).

Problems to be avoided in the use of cathodic protection

The major problem relating to cathodic protection systems is the production of hydrogen ions. A side effect of improperly applied cathodic protection is the production of atomic hydrogen, leading to its absorption in the protected metal and subsequent hydrogen embrittlement of welds and materials. Excessive negative potentials can cause accelerated corrosion of lead and aluminium structures because of the alkaline environments created at the cathode. These alkaline conditions may also be detrimental to certain coating systems and may cause loss of adhesion of the coating (Davies *et al*., 2012). Hydrogen evolution at the cathode surface may be on high strength level, this will result to hydrogen embrittlement of the steel, with subsequent loss of strength. On some high strength steels, this may lead to catastrophic failure. It may also cause disbondment of coatings; the coating would then act as an insulating shield to the cathodic currents. Any secondary structure residing in the same electrolyte may receive and discharge the cathodic protection direct current by acting as an alternative low-resistance path (interaction). Other problems resulting to failure of installed CP systems are: soil type, cathodic shielding, the handling of some important components of a CP system, high Ph environment, and expensiveness of packaged anodes. (Mattson, 1996).

Soil condition

Soils are complex and their aggressiveness is determined by factors such as moisture content, oxygen content, dissolved salts, pH and organic matter content. The major constituents that accelerate corrosion are chlorides, sulphates and the acidity (pH) of the soil. Calcium and magnesium tend to form insoluble oxide and bicarbonate precipitates in basic environments, which can create a protective layer over the metal surface and reduce the corrosion. In contrast, the chloride ion tends to break down the otherwise protective surface deposits and can result in corrosion pitting of buried metallic structures. Bicarbonates are not typically detrimental to buried metallic structures. (Okorafor, 2001).

Coating technology as an assistance to effective CP system

Coatings are used to isolate the anode and cathode regions. Coatings also prevent diffusion of oxygen or water vapour that initiates corrosion or oxidation. Temporary coatings, such as grease or oil, provide some protection but are easily disrupted. Organic coating, such as paint, or ceramic coating, such as enamel or glass, provides better protection. However, if the coating is disrupted, a small anodic site is exposed, that exposed site undergoes rapid, localized corrosion (Ronald, 2001). Factors to be considered when selecting coating materials are nature of surface to be coated, type of contaminants (environment), compatible surface cleaning and coating application methods, number of coats to be applied, compatibility of various coats, requirements for maintenance, and economic selection of a particular system must be justified by maximum protection for money spent, both initially and during maintenance of project. (Ashworth, 1994).

CP system benefits and level of application in Nigeria

Cathodic protection is mainly used in the oil and gas industry in Nigeria. It is used to control the degree of corrosion of pipeline. Cathodic protection had not found wide application in Nigeria as it is only efficient in places with dense rainfall. (Ovri, 2011). Cathodic protection can preserve the metallic components of heavy duty machines, food processing machine among others. Corrosion can be economically and effectively mitigated using a combination of coating and cathodic protection on grain storage tanks, food processing machine, pressure tanks and pipes. (Schewedtfeger, 2010).

Solutions to problems of cathodic protection

- Steel structures corrosion can be curbed and hence environmental hazard controlled by applying systematic corrosion prevention measures.
- Instrument used for data collection or for taking readings should be cleaned after use. This is to ensure accuracy when taking subsequent readings. For example, the half-cell reference electrodes gather soils at the tip immediately it touches the earth. It is then advisable that it should be kept neat especially if it is not to be used frequently.
- Installing the anode very close to the pipe affects the performance of the CP system, the distance between the anode and pipe were supposed to be (0.5m). If this standard is not obeyed, potential readings will not conform to expected results.
- Installed sacrificial anode cathodic protection system should be allowed a minimum of 2 weeks for the system to be fully polarized without which definite values will not be achieved.
- In the cause of installation, researcher should be careful as to know if the cable(s) were still attached to the pipe and/or damage of the PVC-PVC cable. This is important when experimenting on small structures (as implies this project).
- During dry season, it is advisable to water the SACP zone for optimum values(s) to be achieved.

To achieve CP systems set objectives, more attention needed to be paid to the purchase and handling of these following materials: the polyethylene tape, the handicaps, the PVC-PVC cables, the packaged anode and gun powders.

CONCLUSION AND RECOMMENDATIONS

Cathodic protection had proven to be an effective means by which rusting in machines, metal and pipe can be controlled. Cathodic protection works by allowing a more reactive, sacrificial metal to corrode instead of the protected metal. CP application is almost predominant in oil and gas industry of Nigeria, CP can also flourish in an aggressive surrounding. With the knowledge of the amount of rainfall and soil PH of a given environment, one can draw conclusions of the performance of an installed CP system. It is therefore recommended that metal-to-soil potential measurement using -850Mv criterion is adequate to evaluate the cathodic protection performance of any structure. Installed sacrificial anode cathodic protection (SACP) system should be allowed a minimum of 2 weeks for the system to fully polarise without which definite values will not be achieved. There is need for carefulness while installing the anode so no cable attached to the anode will detach unknowingly. The government should form a policy that will promote the use of SACP both as a protection technique and also as a maintenance technique to our agro machines and tractors. This will reduce the degree of wear and tear on our locally or imported machines.

Table 1.1 Effect of chlorides, sulphates and pH on corrosion of buried steel pipelines

Concentration (ppm)	Degree of Corrosivity
Chlorides	
>5000	Severe

ABSTRACT

Optimization of cassava grating machine which has two mode of operation was achieved. It can be either electrically or manually operated. The machine is protected against corrosion by attachment of magnesium anode across the metallic frames of the machine. Due to the kilogram of cassava pulp this machine is designed to produce per day (200kg), magnesium anode was attached to the hub of the grating machine to help reduce the corrosive effect of the cassava fluid. The anode attachment controls corrosion of the frames that come in contact with the cassava to be grated and the grated cassava pulp fluid. The cassava fluid is acidic and could become corrosion propagate medium to the hopper and metal chute being the movement channel of the cassava pulp. This process was necessary to help control the introduction of heavy metal found most times in our processed food. The quantity of anode required to protect home scale cassava grating machine was calculated and achieved.

However, this paper is interested in the electrical and manual usage of this machine with sacrificial anode attachment, high throughput and reduced cost of production. It takes care of rusting, power failure and/or erratic power supply issues, and can be used in rural areas where electric supply is either non-existent and/or unpredictable. The mechanism is such that cassava is fed to the machine through the hopper made of steel to the grating drum, which rotates at a given speed. The pulp collection chamber is inclined at an angle which permits a free fall of the pulp into the collection chamber. The efficiency when manually operated was found to be 90.84% while the efficiency of the electrically operated was 89.24%. The magnesium anode current required to protect the hopper, drum, and metal chute of the grater was 0.0096mV. The protection potential obtained was in the range of (-850mV to -1150mV) for a protected mild steel or stainless steel as NACE specified standard. This research work has the common objective of providing optimum cassava grating machine suited for garri processing with reduced contamination.

INTRODUCTION

Cassava was first introduced to Africa soil at about 1558, since then, cassava have become a major staple food providing the basic diet for over a billion of world population (Grubben, 2014). In Nigeria, cassava is mostly grown on small farms, usually a mixed-cropping system. The root starch for cassava which has been the core for its cultivation is mainly used as food 48% and as feed 34%. It is used as feedstock 18% and for biofuel and as well as biochemical (FAO, 2008).

Presently in Nigeria, the products of cassava are usually locally consumed and exportation is limited because the products do not always meet the international standards for healthy foods. There is urgent need to encourage small scale cassava machine fabrication to ensure high quality cassava products produced with the assurances of good hygienic values. FAO/GIEWS, 2001 survey conducted discovered that most of the cassava graters in the research area are usually corroding (reducing service life) due to the acidic nature of the cassava fluid and materials used for the fabrication. To ensure all cassava products is free from any taste, odor, or infected by iron content of parts (food poisoning) This study was carried out to evaluate the performance of a dual operational cassava grating machine, its output per day and the efficiency of the duality while making sure defects are not introduced into the pulp by attaching magnesium anode to the hub of the fabricated cassava grating machine for metal parts corrosion control.

Over the year, the need to transform cassava root to pulp for garri production has led to invention of several cassava grating machines available today. Hence, the trend of consistent research works that has to the progressive development of grating machines. In other to cater for the group of garri producers who have no access to electricity and/or lack the resources or know-how, Odigboh (1984) designed a manually operated cassava grating machine. Ndaliman (2006) focused on power failure problems by developing a grating machine that can be powered either electrically or manually. Adetunji (2011) designed and fabricated an improved cassava grater which modified the design of the existing cassava grater to the home use small scale sized, and to change the crude wooden drums used in cassava grating machines to lasting stainless steel and galvanized pipe.

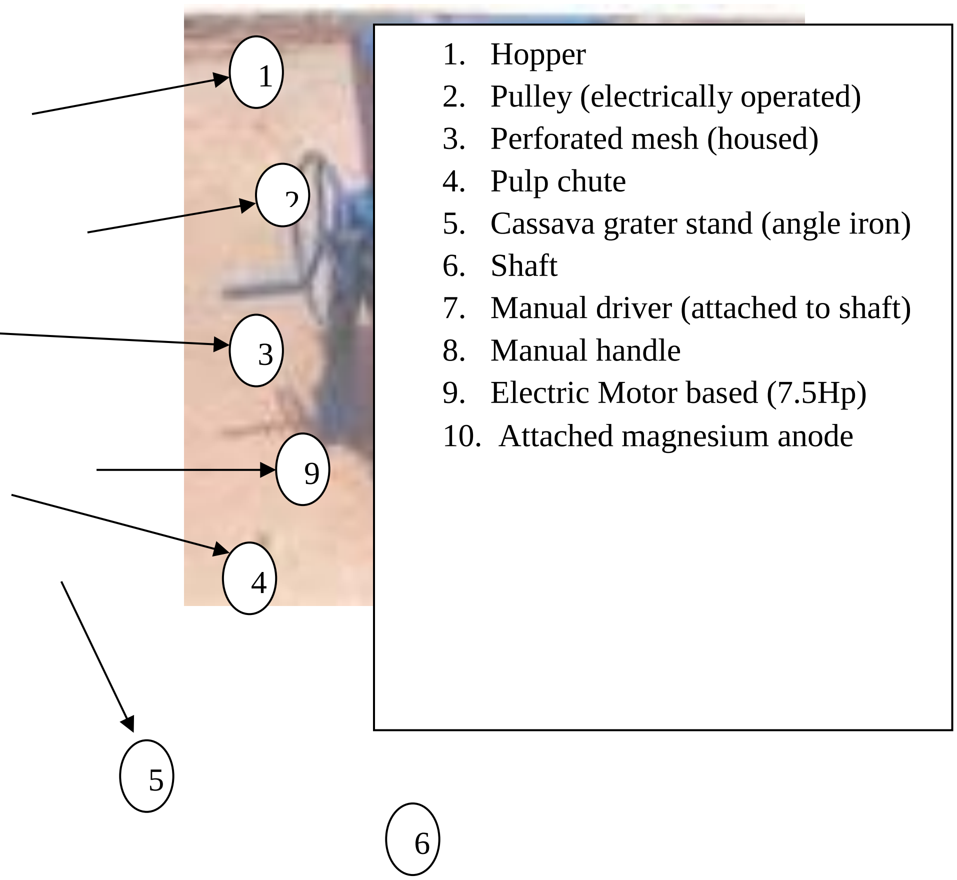
Ajao et al (2013) worked on design and fabrication*n of a home scale pedal powered cassava grater, erratic power supply, scarcity and high cost of petroleum products which necessitated the need to address the issue of cassava grating to a certain extent by developing a mechanism that will make life easier in food processing for rural dwellers and improve their economic wellbeing. Onwubali (2022) cathodic protected cassava grating machine with magnesium anode to bring to barest minimum the effect of rusting and introduction of heavy metals to grated cassava pulp. With the concept of commercialization, Oriaku et al (2015) designed and evaluated the performance of a double action cassava grating machine, while Okonkwo et al (2020) optimized a similar system with the aim of achieving a very high throughput in cassava grating and at a reduced grating time. Okoli (2021) designed and improved the performance of double barrel cassava grating machine, the consideration for the design was to achieve light weight cassava grating machine.

MATERIALS AND METHODS

Design Considerations

- The operational mode should be considered making sure its meets stipulated standard
- The machine should be easily assembled and dismantled without difficulties
- The hopper should be wide enough to be able to house 8 to 15kg cassava tubers introduced at a time
- Another problem is that cassava produces large amount of cyanogenic glycosides so in selecting materials, for fabrication, adequate care must be taken not to use materials that degrade/corrode easily.

Table 1: Materials used in the fabrication of a dual-operated cassava grating machine with attached magnesium anode for corrosion control



Description of Machine Parts

The main frame: the main frame was constructed with angle iron, this is to give the grating machine a definite shape and to stamp out wobbling. The thickness of the angle iron is 4mm.

The hopper: The hopper is the medium o by which cassava roots are introduced into the cassava grating machine. A hopper with rectangular cross section was considered. The volume of the hopper was obtained as:

$V = B (H) L (m^3)$

(1)

Where: V = Volume of the hopper, L = Length of hopper, B = Breadth of hopper, and H = height of hopper.

The mass of hopper was obtained as: $M = \rho V$ (kg)

(2)

Where: M = mass of the hopper, ρ = density of the material.

The Grating Unit: This unit consists of the shaft, perforated mesh, rolled sheet, circular discs, and rivet pins, the grating drum is cylindrical in shape. The volume of the cylinder was obtained as: $CV = 3.142.r^2 L$ (m^3) (3)

Where: CV = Volume of cylinder, r = Radius of the cylinder, L = Length of cylinder.

The force acting on the cylindrical drum was obtained as: $F_C = V.\rho.g$ [g = constant]

(4)

Where: F_C = Force exerted on the rotating drum, V = Volume of the cylinder, ρ = density of the material

Shaft Design

A shaft is a rotating machine element which is used to transmit power from one place to another. The power is transmitted by some tangential force and the resultant torque set up within the shaft permits the power to be transferred to various machine or its elements linked up to the shaft. To be able to transfer the power to the shaft, the various members such as pulleys, bearing, and grating drum are mounted on the shaft. These members along with the force exerted upon them causes the shaft to bend. To achieve this, a solid circular shaft was considered for analysis of combined torsional and bending stresses.

For a shaft with axial load, the diameter was obtained as: $D^3 = 16/3.142T_S ((B_KB_M)^2 + (T_KT_M)^2)^{1/2}$ (5)

Force exerted on Shaft was obtained as: $W_P = M_P$

(6)

Where: M_P = Mass of the pulley, g = acceleration due to gravity, W_p = weight of the pulley

Weight of cylindrical drum was obtained as: $W_d = \rho V g$

(7)

Where: ρ = density of the matetrial, V = Volume of the material, g = acceleration due to gravity

Anode Required Protection Current: $I_A = S_A \times I_D \times F_S$

(8)

Where: I_A = Anode current, S_A = Surface area of metal, I_D = Current density, F_S = Factor of safety

Anode Designed Life Expectancy (in years): $0.058 \times W_A \times A_E \times U_{AF}/A_C$

(9)

Where: A_{EL} = Anode life expectancy, A_{LB} = Anode weight in pounds, A_{PW} = Packaged anode weight, A_E = Anode efficiency, U_{AF} = Anode Utilization factor, 0.085 = Magnesium anode constant (Stern, M. and Geary, A.L. 1957).

METHODS

Machineries and machining processes used in the fabrication processes are as follows: Drilling machine, welding machine, bending machine, milling machine, lathe machine, hand drilling/cutting disc machine, and pedal drilling machine. The anode was prepared outside the machine and the cables attached to the metallic frames.

RESULTS AND DISCUSSIONS

Performance test was carried out on the optimized cassava grater in comparison with the old wooden frame and drum cassava grating machine type, typical of the rural areas. The time taken to grate 100kg/3batches of cassava roots was compared to that of the ancient cassava grater. The time taken for each batch was obtained and data collected. The process was done using manual effort and electric powered process respectively. The result gotten was as a result of the electric motors used. It was likewise observed after a fortnight that the sacrificial anode started changing colour thereby giving up its life for the preservation of the entire machine metallic structure.
It was observed that the performance of the optimized dual-operational mode cassava grating machine improve over time. This improvement was likewise seen on the smoothness of the cassava pulp with respect to time of usage. It was observed that the perforated mesh, give smoother pulp after a given number of usages.

Table 3 gives the cost analysis used in production of one unit of the machine. The total cost of production (both manufacturing and overhead cost) of one unit is estimated to be about N66, 150:00. All material used are locally sourced.

Table 3: Cost analysis of cassava grating machine

Description	Size	Amount (Naira)
Electric Motor	(1)horse power/single phase	20,000
Bolts, rivets, electrode	Drilling bits(15pcs/13pcs/2pcs and two packets of electrodes)	8000
Cutting Discs, grinding, painting, Carrier and Flanges bearing	9”/7’ (2/1) (10kg of oil paint) (1) (8”Ø)	8150
Sacrificial Anode	7.5kg	30,000
Total		**66,150**

CONCLUSION

The optimized cassava grating machine was found to be efficient. It can grate about 200kg/hr. the magnesium anode attached to the frame of the hopper helps control the rate of corrosion from cassava fluid, fabrication defects, and other corrosion propagation channels. The machine can be powered electrically and/or manually.

This machine can be used at home-scale level for domestic purposes and is affordable since the cost of production is relatively low. Based on the anode attached to the machine and the choice of material used for fabrication of the dual-operational machine, the machine is expected to last longer than other dual-operated cassava graters. The reading gotten from the multimeter attached to the sacrificial anode used show that condition necessary for protection to take place was achieved (-860mV).

ABSTRACT
A prototype manually controlled multi-crop planter was designed with changeable metering devices to reduce drudgery involved in the manual method of planting in small farms. The planter was developed and produced specifically for cowpea, maize and soybean planting to increase the productivity of planting. In this configuration, the drive shaft governs directly the seed metering function, which totally removes attachments such as pulleys, belt systems and gears, thus eliminating the complexity of conventional planters, which increase costs. Laboratory and field experiments were performed on the planter to assess the weight of seeds emitted from the planter, the percentage of damaged seed, field capacity, average seed depth in the furrow, and average seed spacing. The planter had a field efficiency of 76.3%, a field capacity of 0.39 ha/hr, and seed rates of 0.25 kg/ha, 0.18 kg/ha, and 0.21 kg/ha for cowpea, maize, and soybean, respectively. Percentage of seed damage was 3.54% (cowpea), 2.32% (maize) and 1.32% (soybean) of an average spacing of 40.8 cm and a depth of 3.98 cm. With the exception of occasional lubrication of the bearings needed to let the ground wheel to freely rotate, the single-row multi-crop planter is relatively simple to operate and requires no maintenance. The planter can be managed safely and easily. Materials for production were found locally, which means that farmers can rapidly replace worn-out sections.

Keywords: Agriculture, cowpea, maize, multi - crop planter, peasant farmers, soybean.

1. INTRODUCTION
Cereals crops, which belong to the grass family (Gramineae), are generally grown for their edible starchy seeds. Cereal crops include barley, maize (corn), millet, oats, soybean, wheat, rice, rye, etc. In Nigeria, uses of cereals range from "Akamu," "Agidi", to "Nrioka", "tuwo shinkafa" and "tuwo masara". They are used as animal feeds and fodder and in some parts of Nigeria, cereal stems are used in the construction of local huts. Cereal grains are relatively low in proteins especially the essential amino acids. They require supplements with legumes and proteins (Henry, 2005).

There are many factors responsible for low agricultural yields. These include the use of low yielding varieties, insect, diseases, weed control, inadequate cultural management practices particularly in the area of fertilization and most importantly, planting operation. Planting operation is one of the most important tasks that grains growers undertake. Planting operation of grains in Nigeria is at low level as many farmers still use bare hands or hand tools to plant their crops. However, manual method of seed planting results in low seed placement, spacing efficiencies and serious backache for the farmer, which limits the size of field that can be cultivated. Moreover, manual planting is tedious and time consuming; a hectare of land requires eight-man (Cruz and Dela, 2007). About 95% of the Nigerian farmers have small land holdings and are much below living standard.

Researchers have developed many types of implements to mechanize seed planting operation. Singh *et al.* (1985) developed a two-row ridge planter for planting winter maize and evaluated in the field over an area of 0.4 ha. Average seed distance was found to be 0.198 m, row to row spacing 0.60 m and the average ridge height was 0.25 m. The capacity of the planter was 0.10 ha/hr at a forward speed of 2.5km/h. Braide and Njidda (1989) developed a combined jab planter, which was found to be 73.4% efficient and was three times faster than manual planting with hoes and cutlass. Braide and Ahmadu (1990) developed a transplanter for some selected crops in Guinea Savannah of Nigeria, which had 0.19 ha/h field capacity and 20% field efficiency. Sule and Ohanwe (1999) developed a hand-pushed seed planter/fertilizer application for the small scale farmers. Olaoye and Bolufawi (2001) developed a tractor drawn planter for planting grains both on flat lands and on ridges. Plant spacing, uniformity and emergence rate are the most common characteristics used by producers to evaluate planter performance (Staggenborg *et al*., 2004). Ojomo and Ale (2008), investigated the performance evaluation of a row crop planter on a tilled soil.
Seed planters available in the market were imported, specifically designed to operate in large farms, expensive and not suited to local conditions. It is difficult for peasant farmers to acquire costly imported agricultural machinery and equipment (Odigboh and Ahmed, 1980; 1982; Olaoye and Bolufawi, 2001). Timeliness of operations is one of the most important factors which can only be achieved if appropriate use of agricultural machines is advocated. Presently, there is awareness in Nigeria and other developing countries that the rapid development of agriculture depends largely on the successful introduction of modern and small-scale agricultural machinery largely (Adekanye and Olaoye, 2013). Therefore, there is the need to develop a small mechanical device for small-scale planting operation. The main objective of this study was to design and fabricate a simple multi-crop hand push planter for cowpea, maize and soybean with locally available materials, evaluate the machine and determine its capacity and efficiency.

2 MATERIAL AND METHODS

2. 1 Machine Description

The manually operated multi-crop planter consists of the following parts as shown in Figure 1.
Seed hopper -The feed hopper was made of mild steel having a trapezoidal shape. The design capacity of the hopper is 200cm^3. The dimension of the hoppers is 210mm x 90mm x 200mm.
Metering disc- The metering disc or flute roller was made of 5 mm plastic (Teflon). The dimension of the flute is 10mm x 5mm with a hollow opening of 3mm.
Drive wheels - The drive wheels were made of mild steel and they are integral parts of the seed metering mechanism. The wheels have spindles that bear bolts and rotate the metering device. The surfaces of the drive wheels are fixed with 10mm long steels cut from 10mm diameter iron rod that provide necessary soil rolling resistance during forward movement of the machine.
Discharge spout - the discharged spout has an opening beneath the hollow pipe from the metering housing. The seed drops directly into the furrow.
Furrow opening device - The furrow opener (adjustable) was made of 50mm mild steel angle iron with a length of 390mm. The mild steel is slightly beveled at the lower edge (5^o) to

facilitate an easy cut through the soil. To facilitate the attachment of the furrow – opening device to its support, a pipe of 50mm and 390mm long was drilled to accommodate an 8mm diameter bolt with the nut welded on the periphery of the drilled hole. The pipe was then welded at the underside of the top portion of the furrow opening device.

Furrow covering device - was made of mild steel angle iron rectangular plate of dimension 195mm x 95mm. The rod for attachment to the support was welded to the middle of the upper edge of the plate. The covering device is inclined at an angle of 45^{o} with a spring to the direction of travel for optimum covering of the soil.

Handle - The handle consists of a hollow pipe of 9mm internal diameter, length 900mm x 420mm. A bushing of 21mm internal diameter was welded in a horizontal position to accommodate the handle. The handle can meet the heights of various operators.

Bracer: - the bracer was used to create a support between the wheel and the housing bearing the shaft.

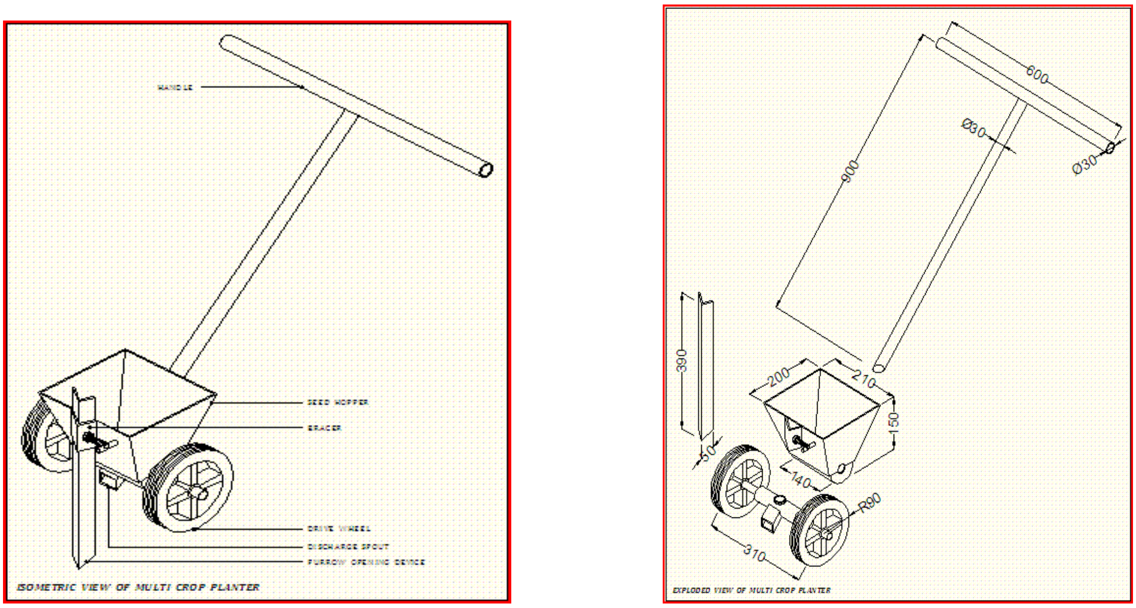

Fig. 1: Isometric and exploded views of the planter

Multi crop planter Side view of the wheel

Furrow opener and closer

Fig. 2: Component parts of the planter

2.2 Design Assumptions

The following assumptions were made in the design of the planter:

i. the linear sowing speed of the manually operated planter, 5m/s;

ii. the exposed surface of the roller, 28 cm;

iii. the bulk density of soybean, maize, and cowpea are 640.7, 716.2 and 768.8 kg/m^3, respectively; and

iv. the seed rate per hectare for cowpea (0.25kg/ha), maize (0.18kg/ha), and soybean (0.21kg/ha).

v. In the form of simulated work or pedaling at about 30 to 40 rpm, the sustainable input to any human power is regarded as 75W. The power requirement for pushing the planter is therefore assumed to be 50 watts.

2.3 Determination of physical and mechanical properties of soybean, maize, and cowpea

The range of shapes and sizes of agricultural grain crops and their physical properties like bulk density, grain length, width and thickness as determined by Ndirika and Oyeleke (2002), Shepherd and Bhardwaj, 1986, Mohammed (2002) Deshpande and Ali, 1988 and Oyeleke (2002) were adopted in designing grain cell sizes on the seed metering unit.

2.4 Design calculations

2.4.1 Determination of shaft diameter

The shaft diameter of the planter was determined using standard formula for calculating the diameter of shaft as given in Equation (1) by Gupta and Khurmi (2005):

$$d^3 = \left[\frac{16}{\pi} S_s\right] \times [(K_b M_b)^2 + (K_t M_t)^2]^{1/2} \qquad (1)$$

Where; d = diameter of the shaft, m, M_t = torsional moment, Nm, M_b = bending moment, Nm, K_b = combined shock and fatigue factor applied to bending moment, K_t = combined shock and fatigue factor applied to torsional moment, S_s = axial stress, N/m^2, S_b= bending stress, N/m^2, γ_{XY} = torsional shear stress, N/m^2. The value for the selected shaft diameter was 18.5 mm.

2.4.2 Determination of maximum draft of planter

The maximum draft on the planter is the horizontal component of push parallel to the line of motion in order to overcome the soil resistance on the planter. The maximum draft is expressed in Equation (2):

$$D_{FM} = R_S \times A_{FO} \times Acceleration\ due\ to\ gravity \qquad (2)$$

Where; D_{FM} = Maximum draft, R_S = Surface area of furrow opener in contact with soil, A_{FO} = Recommended depth of cut * thickness of furrow opener

2.4.3 Determination of seed rate requirement and the volume of hopper

The seed rate requirement, according to Gupta and Herwanto (1992) is given in Equations (3) and (4):

$$SR = \frac{1000}{W \times S_C} \times \frac{1}{1 - S} \times SW_{IR} \qquad (3)$$

$$W_{IR} = Zab \times \frac{q}{1000} \qquad (4)$$

Where; W = Working width (0.90 m as the inter row spacing, commonly used in the study area).
S_C = Circumference of the ground wheel,
S = Slip expressed in fraction,
W_{IR} = Weight of seeds fallen for one revolution or driving wheel,
Z = Number of grooves (maximum value of 4, from machine assumption),
a = number of grains per stand (2-3),
b = number of rows (1),
q = weight of 1000 grains (242.8g cowpea, 256.9g maize and 200g soybean from the assumed value of bulk density)
The volume of hopper was determined using Eq. (5):

$$V = \frac{SR}{n \times BD} \qquad (5)$$

Where; SR = seed rate per hectare, BD = bulk density, n = number of refilling per ha
The calculated values for the design were;
Volume = 163cm^3, seed rate of required: 0.25kgha^{-1} for cowpea, 0.18 and 0.21kgha^{-1} for maize and soybean respectively.

2.4.4 Determination of the force required to push the planter

The force required to push the planter was derived from Equations (6) and (7):

$$F_P = \frac{R_S cos\emptyset + W_P}{cos\theta} \qquad (6)$$

Where; F_P = Planter push force, F_R = Horizontal soil resistance force,
R_S = Soil frictional resistance force;

$$R_S = \frac{F_R tan\theta + W_P}{(\sin\emptyset - \cos\emptyset\tan\theta)} \qquad (7)$$

Ø = Angle of friction, θ = Angle between planter handle and horizontal plane,
W_P = Weight of planter.

2.4.5 Determination of planter capacity

The capacity of the planter was determined from the following expression:

$$C_{PA} = \frac{Area\ covered\ by\ planter}{10000m^2}\left(\frac{hectare}{time}\right) \qquad (8)$$

Where; C_{PA} = Capacity of planter in hectare/time,

Area covered by planter = (Inter-row spacing) x (Distance covered by planter) (m^2/time) (9)

Distance covered by planter = (Speed of planter) x (Time of planting) (m/time) (10)

3. PRINCIPLE OF OPERATION

The principle of operation of the machine is very simple and requires only one man to operate. Planting is accomplished by just pushing the device in a pre-established furrow. Since the seed hopper is directly attached to the wheel shaft, it will rotate as the wheel rotates. As the seed hopper rotates, seeds will automatically drop into the soil through the seed outlet by means of gravity. After seeding, the furrow will be covered with soil using a spike-toothed harrow.

3.1 Testing and Evaluation

3.1.1 Laboratory Test

Laboratory test was undertaken to determine and check any malfunctioning parts and defects in the design as suggested by Kepner *et al*. (1978) and Christianson and Rohrbach (1986), discovering any defect will lead to changes and improvement in the design. During the test, the number of seed discharged per outlet and number of damaged seeds were noted and recorded. The hopper was loaded with 333g of cowpea seeds, 311g of maize and 317g of soybean. The planter was suspended on a vice and turning the wheel rotates the metering device. For each investigation, the drive wheels were rotated 25 times at low speed. A stop clock was used to record the time taken to complete the revolutions. The seed discharged were weighed on a weighing balance and the procedure was repeated five times.

3.1.2 Damage Test

The test for percentage of seed damage was done with the planter held in the same position as described above; the hopper was loaded with 1kg of cowpea seeds, 1.3kg and 1.1kg of maize and soybean respectively. The wheel was rotated 20 times in turns and the time taken to complete the revolution recorded with the aid of stop clock. The seeds discharged from the spout were observed for any visible external damage.

3.1.3 Field Test

The planting of the seeds was conducted directly on a plot of 10m x 10m area (100m^2) was marked out on the field. The plot was ploughed and harrowed to get a flat bed. The planting operation was carried out to determine the distribution of seeds along rows, observe the number of seeds discharged and planted per plant stand. Furthermore, the missing points along rows, seed emergence, effective field capacity, field efficiency and percentage of germinations were determined. The effects of preparation methods of the field on which the seeds were to be planted, hopper loading capacity and the types of seeds were examined on the field with three replications.

The investigation for the field efficiency and effective field of the planter involved continuous observation and timing of each activity involved in the planting operation. Two people were involved in the determination of the field efficiency, one person operated the planter on the field while the other person observed and recorded the time for the activities. The time losses, such as turning at field ends, removal of stump and adjustments (changing metering device) were recorded. Field efficiency and field capacity of the planter was determined using Equations (11) and (12) as follows;

$$\text{Field efficiency} = \frac{Area}{Total\,time\,taken} \times 100 \qquad (11)$$

$$\text{Field capacity} = \frac{Area}{Total\,time\,taken} \qquad (12)$$

The average depth of the seeds placement was determined by running the planter at a tilted angle 45^o to the soil surface to and from over an area of 10m without the furrow covering closing the hole with a moderate setting of the furrow opener. The time taken to go across the length of the field was recorded to get the average depth; five rows were selected to take the depth using a steel rule to measure. The distances between successive seedlings within row were measured using measuring tape.

4 RESULT ANALYSIS

4.1 Laboratory and field tests

Table 1, Table 2 and Table 3 show the laboratory results obtained from the calibration of the planter for cowpea, maize and soybean. Based on the Tables, the results show that the weight of seed discharged were 4.54g, 4.44g and 4.64g respectively. The total average weight of seeds discharged during calibration was 13.62g while the mean discharge was 4.54g. This is within the range of ±7 recommended for optimum inter-furrow variation (Bamgboye and Mofolasayo, 2006). The planter effectively discharged 2 to 3 seeds per hole on the average. The planter design performance was satisfactory because the expected number of seeds were discharged from the metering device.

Table 1. Calibration Result from Laboratory Experiment of planter (Cowpea)

Weight discharged (g)	Time for 25 (sec)	Speed (rev/sec)
4.4	50	30
4.56	47	28.2
5.01	45	27
4.65	49	29.4
4.08	50	30

Table 2. Calibration result from laboratory experiment of planter (Maize)

Weight discharged (g)	Time for 25 (sec)	Speed (rev/sec)
4.8	48	28.8
3.96	50	30
4.93	47	28.2
4.37	53	31.8
4.51	49	29.4

Table 3. Calibration result from laboratory experiment of planter (Soybean)

Weight discharged (g)	Time for 25 (sec)	Speed (rev/sec)
5.01	46	27.6
4.44	53	31.8
4.63	43	25.8
4.28	40	24
4.85	41	24.6

4.2 Determination of field efficiency and field capacity

From Table 4, field efficiency was observed to be 76.3% from the average values of field efficiency trials. This shows a good and satisfactory performance as it was within the range of values obtained for planting operation by investigators (Kepner *et al*, 1978; Bamgboye and Mofolasayo, 2006). Also, the effective field capacity of the planter was 0.39ha/hr. This value agrees with that reported by Bamgboye and Mofolasayo (2006) and has a higher value than that of the manually operated seeding attachment of 0.28 ha/hr for an animal drawn cultivator developed by Kumar et al., (1986) and that of template row planter developed by Adisa and Braide (2012). This satisfactory result was due to its maneuverability, which saves time in moving and turning the planter from one point to another. Braide and Njidda (1989) developed a combined jab planter, which was found to be 73.4% efficient and was three times faster than manual planting with hoes and cutlass. Olajide and Manuwa (2014) reported effective field capacity of 0.36 ha/hr and 71% field efficiency for a row crop planter.

Table 4. Field Efficiency and Field Capacity Determination of the planter

Activity	Time for 1/10 ha (sec)	Time/ha (min)
Turning at field ends	50	8.3
Removal of stumps	120	20
Adjustments	50	8.3
Actual planting	710	118.3
Total Time	930	154.9

The design and fabrication of a manually operated multi-crop hand push planter was successfully carried out and evaluated to determine its performance. This multi-crop planter was primarily designed to cater for the need of small farm holders. The overall cost of production was minimal and would be affordable for intended end users, it is easy to maintain and required less labour to use. This planter will go a long way in making farming more attractive. All parts of the planter were fabricated from mild steel material except for the metering devices that were made from good quality plastic (Teflon).

The seed metering devices used for this work was plastic roller type with cells on its periphery. The shaft directly controls the metering device that eliminates attachment such as pulleys, belt systems, gears and thereby removing the complexities of the existing planter, which decreases the cost and increases the efficiency at a highly reduced cost. The planter was able to meter 2-3 seeds per hole with a minimum damage to the seeds. The multi-crop planter was able to plant on a flat seedbed at average field capacity of 0.39 $hahr^{-1}$ and field efficiency of 76.3% that will be quite adequate for small-scale farming. The total cost of fabrication was twenty-two thousand, five hundred naira only (about USD 61). The machine can be easily maintained without any technicality.

ABSTRACT
Every natural or synthetic product is subject to some form of natural degradation over time under the right enabling environmental conditions. Bio-deterioration is one of the natural means of degradation. It is any undesirable or adverse change in the property of a material caused by the activities of living organisms. It involves a process of chemical and physical spoilage, caused by the continuous growth of organisms. It is sometimes complex; leading to alterations in the physicochemical and mechanical properties of the material by the action of organisms which depends on the microorganisms involved, type of substrate, and environmental conditions. The scope of bio-deterioration, products affected, causative agents, mode of action were looked into and methods available to man to tackle this natural phenomenon was also reviewed. Some of the methods were from simple cultural practices to advance techniques like nanotechnology but more work need to be done.

Keywords; Bio-deterioration, Food, Food spoilage, Microorganisms

INTRODUCTION
Bio-deterioration is a process of chemical and physical spoilage, caused by the continuous growth of identifiable organisms that can be present in foods prior to packaging and on surfaces of packaging materials (Aduroja *et al.,* 2018). This process of bio-deterioration is complex; involving alterations in the physicochemical and mechanical properties by the action of organisms, which depends on the microorganisms involved type of substrate, and environmental conditions. Food spoilage refers to various changes to food in which the food becomes less palatable or even toxic to consumers these changes may be accompanied by alterations in smell taste appearance or texture (Akinmusire, 2011).

In the case of food or agricultural products, these spoilage microorganisms can come in contact with the product from the seed before planting, through product development in the field, harvest/storage of the product and during processing and transportation (Barth *et al*., 2009).

Zabihi *et al*. (2021) further reported that physical, chemical, and biological factors work together, moving from coexistence to antagonism to cause bio-deterioration. It can apply to diverse types of materials such as food, wood, paper, leather, fuels, cosmetics, building materials and building structures and could be as a result of the metabolic activities of one of many micro-organisms or may be caused by insect, rodent or bird damage (Featherstone, 2008). The present review aims to reveal different agricultural products that are lost through the process of bio-deterioration by providing reports on the factors that influences bio-deterioration. Many fresh fruits and vegetables are sensitive to oxygen, water permeability and ethylene leading to deterioration of food quality (Gaikwad *et al*. 2018, 2020). Biotechnological techniques used to control and prevent bio-deterioration were also highlighted.

Chemical bio-deterioration

Chemical bio-deterioration is divided into two with similar results (the material becomes spoilt, damaged or unsafe) but from different causes or biochemistry.

- Biochemical assimilatory bio-deterioration – the organism uses the material as food - an energy source.
- Biochemical dissimilatory bio-deterioration – the chemical change in the food is as a result of waste products from the organisms.

Physical bio-deterioration

- Mechanical bio-deterioration – this occurs when the nature of material is physically disrupted/damaged by the growth or activities of the organisms.
- Soiling/fouling – with this kind of bio-deterioration the material or product is not necessarily unsafe, but as its appearance has been compromised, it is rendered unacceptable. The building up of biofilms on the surface of a material can affect the performance of that material.

Causes of bio-deterioration

A number of ecological factors contribute to the bio-deterioration of materials in the immediate environment apart from the inherent characteristics of organisms (Beimforde, 2011). The growth and colonization of specific biological species in specific materials is dependent on the nature and properties of the materials (mineral composition, pH, relative percentage of different minerals, salinity, moisture, and texture) and specific environmental factors such as temperature, relative humidity, light conditions, oxygen, nitrogen, level of atmospheric pollution, wind, and precipitation (Zabihi *et al*., 2021).

The bio-deterioration of different materials and substances has been extensively studied across the world.
Oyeyipo (2012) worked on the bio-deterioration of sweet potato (*Ipomoea batatas*) in Port Harcourt, Nigeria and observed that *Aspergillus niger*, *Fusarium oxysporum*, *Rhizopus stolonifer*, *Botryodiplodia theobroma* and *Penicillium* sp. were associated with deterioration of sweet potato tubers.

Hodges *et al* (2014) attributed greater post-harvest losses in cereals in sub-Saharan Africa to bio-deterioration. The organisms involved are mainly arthropods (mostly insects such as beetles and moths and sometimes mites), moulds, and vertebrates (mostly rodents such as rats and mice and sometimes birds). The study observed that bio-deterioration was enhanced by natural changes to the chemicals within grain itself and extremes of temperature and humidity. The study further observed that the weather conditions at the time of harvest are a major issue. For example, rotting grain (a special category of bio-deterioration), becomes a major problem when the harvest is close to a wet season that commences before harvesting is completed. As a result the damp cloudy weather prevents the harvested crop, or even the crop still on the plant, from drying and vulnerable to mould attacks. Postharvest losses due to bio-deterioration may start as the crop reaches physiological maturity (the crop is close to harvest). While the crop is still standing in the field, storage pests may make their first attack at this stage and when unseasonal rains dampens the crop, some mould will start to grow.

Aduroja *et al.* (2018) studied the role of three fungal species (*Neocosmospora ramosa, Aspergillus tamari* and *Aspergillus violaceofuscus*) in the bio-deterioration of onions and cucumbers in Nigeria. The study reported that *N. ramosa* was responsible for the highest rate of bio-deterioration for onions and cucumber and was resistant to both the anti-fungals (voriconazole and fluconazole) applied. The study recommended good agricultural practices that emphasize harvest and storage hygiene as effective intervention against fungal invasion of vegetables in Nigeria.

Mohammed and Kuhiyep (2020) investigated the bacteria and fungi associated with the deterioration of fresh tomatoes, (*Lycopersicum esculentum*) in Kaduna, Nigeria. The study identified the bacteria and fungi responsible for the bio-deterioration of tomato as *Escherichia coli*, *Salmonella* sp, *Staphylococcus aureus* and *A. niger Penicillium* sp, *A. flavus* respectively. The bacteria and fungi isolates were both sensitive and resistant to antibiotics and antifungal agents used.

Prevention and control of bio-deterioration

Bio-deterioration can be effectively controlled or prevented by proper understanding of the materials and the possible spoilage organisms and mechanisms (Featherstone, 2008). Bio-deterioration is as a result of either separate or combined activities of several organisms on different substrates and under different ecological conditions, therefore the prevention and control require the combined knowledge from different branches of biology, biochemistry, chemistry, physics-chemistry, etc. (Dunca *et al.*, 2014). The methods of controlling or preventing bio-deterioration range from simple cultural practices to advance application of biotechnology.

Mohammed and Kuhiyep (2020) recommended thorough washing of harvested tomatoes with clean or chlorinated water, proper handling during harvest to prevent bruises and scars or other mechanical injuries and refrigeration. Refrigeration however, is a major challenge in developing countries like Nigeria where power supply is not steady.

Sridhar *et al* (2021) studied food wastages as a result of bio-deterioration and reviewed a number of food preservation techniques including nanotechnology to increase the shelf life of fruits, vegetables, beverages and spices. The study listed heat or thermal treatment as one of the novel techniques for food preservation, used extensively in various food sectors; from bakery and dairy to fruits and vegetables (Wurlitzer *et al*.2019; Gharibi *et al*. 2020). Others are cooling and freezing used in preservation of leafy vegetables, spices and milk products to maintain all the attributes and qualities. The freezing techniques include air blast, cryogenic, direct contact and immersion freezing, while advanced techniques include high pressure freezing, ultrasound assisted freezing, electromagnetic disturbance freezing and dehydration freezing (Cheng *et al*. 2017). Ultrasound treatment involves the passing of high intensity and frequency sound waves through the food materials. This technique is versatile and has been applied in different fields ranging from medicine, healthcare to food industry (Dai and Mumper, 2010). Ozone treatment technology has been on the increase since inception due to ozone's diverse properties and quick disintegration (Sridhar *et al*., 2021). The compound quickly decomposes into oxygen molecule and produces a high oxidation potential which makes it a good antimicrobial and antiviral agent (Nakamura *et al*. 2017). This technique in combination with ultrasound has been used to maintain bacterial safety without any damage in cabbages (Mamadou *et al*. 2019). Pulse electric field technology is advancement in pre-drying treatment and requires shorter residence time for treatment of foods (Sridhar *et al*., 2021). It could be considered as a substitute to thermal drying and could enhance the food drying because of its very low temperature requirement to function (Wiktor *et al*. 2016).The use of pulse electric field has grown rapidly over the years in all food sector areas. It has been successfully applied in the preservation of Blueberries (Yu *et al*., 2017), Date palm fruit (Yeom *et al*., 2004) and Clover sprouts (Gała̧zka-Czarnecka *et al*., 2020).

Nanotechnology is the most recent concept in food preservation and has enhanced the processing and formulation of colorants, sensors, flavors, additives, preservatives and food supplements (nanoencapsulation and nanoemulsion) in both animal and plant based products (He *et al*. 2019). The introduction of nanosensors in food processing industries was as a result of its successes in other fields and nanomaterials have revealed several electrochemical and optical properties in different sauces, beverages, oils and juices (Sridhar *et al*., 2021). Different nanomaterials have been applied as sensors in different food industries - edible oils in bakery industry (Delfino *et al*., 2020), mixed fruit juices (Ye *et al*., 2020), milk (Goud *et al*., 2020), potato, onion and cabbage (Naser-Sadrabadi *et al*., 2020). In Sridhar *et al*. (2021), the emphasis was on electrothermal, freezing and pulse electric field methods because they allow both pathogen reduction and improvement of nutritional and physicochemical properties.

On the other hand, ultrasound technology and ozone treatment was recommended suitable to preserve heat sensitive foods while nanoparticles and polymer-based composites have proven to be the best solutions in food and crop preservation (Auffan *et al*. 2009; Joshi *et al*. 2019). Nanotechnology is preferred as it possess different properties like slow release action, target specific nature, precise action on active sites and high surface area (Joshi *et al*. 2019). The reason for the success of nanotechnology is due to its promising results, no pollutant release, energy efficient and less space requirements. Apart from these success factors, nanotechnology has also shown versatile applications in terms of safety, toxicity and risk assessment in areas of agriculture, food and environment (Sridhar *et al*. 2021).

CONCLUSION

Bio-deterioration is an inevitable natural phenomenon with a huge cost to man. It is capable of frustrating human development especially global food security and programmes. Bio-deterioration in different facets including scope, products affected, causative agents, mode of action, etc., have been reviewed. Because of the dimension of this natural challenge, man has devised means of minimizing its effects and has also continued to improve upon them. Some of these methods which range from simple cultural practices to advance techniques like nanotechnology were also reviewed. This review has also shown that man cannot rest on his oars now but to keep on looking for better ways of tacking this problem.

ABSTRACT

This study investigated some nutritional and bioactive contents of artificially ventilated onion bulbs under seven months of storage. Moisture, protein, total carbohydrates, oil contents, energy values, total polyphenolics (TP), total carotenoids (TC) and ascorbic acids (AA) were estimated according to the standard protocols during storage period.The increasing trends in the proteins, carbohydrates and oil contents of Artificially Aerated Ventilated Stored Onions (AAVSO) were significantly different ($p< 0.05$) from control; this gave rise to a 50.08% and 5.20% energy value at the sixth month of storage. There were continuous declining trends in ascorbic acids and total carotenoids contents in the AAVSO and the control respectively leaving a 5.48% (AA) and 4.90% (TC) more retention in the AAVSO than in the control respectively. Total polyphenolic contents increased from an initial 5.10±0.02 GAE (mg/g) fresh weight to 12.08±0.00 and 9.95±1.03 GAE(mg/g) fresh weight. From the findings of this research, onion storage in an artificially ventilated structure have shown to be more desirable to curb the enormous wastage during glut and for better retention of more nutritional and bioactive compounds prior to use at home or industry. It is therefore pertinent that policy makers and non-governmental organizations should encourage and support a larger scale onion storage in an artificially ventilated structure.

Keywords: ***storage, artificial ventilation, bioactive compounds, onion***

INTRODUCTION

Onions (*Allium cepa* L.) is one of the most important and commonly used spicy vegetable through the ages not only for its culinary uses but also for its therapeutic properties. Its production remains steadily on the increase and thus making it the second most important horticultural crop after tomatoes (Prithiani *et al.*, 2022). Over 93 million metric tonnes of onion are produced globally while about 1.38 million metric tonnes are from Nigeria (FAOSTAT, 2020). Kaduna, Kano, Bauchi, Katsina, Sokoto, Borno, Nasarawa, and Gombe States account for nearly 100% (99.97) of the total production in the country (Adeoti *et al.*, 2021). Remarkably known for its aroma, taste and lachrymatory effects; it plays significant role in the industries as constituents for moth repellent, beverages, expectorants as well as condiment in biscuits (Li, et al., 2021). Studies have shown that onion bioactive molecules contribute in lowering bone reabsorption, and in prevention of degenerative diseases due to some ample amount of polyphenols and potential antioxidants. Onions have been evaluated for considerable nutritional value such as lipid, protein, reducing sugar, iron, calcium, vitamin C, phenolic contents as well as antioxidant activity (Mahmood *et al.*, 2021). Common onion varieties in Nigeria are the red Tropicana, Bombay red (brown onion), white onion among others (Oniya, *et al.*, 2021). As a seasonal crop, price tends to hit the roof during off-season thus making its availability very limited. Several attempts made to store and minimize spoilage of onion is still not very efficient and yielding especially in Africa, this can be attributed to its high moisture content (≥80%) which allows for microbial infestations (Ewekeye *et al.*, 2021). Artificial aeration of onion storage structure provides a controllable surrounding temperature and relative humidity that slows deterioration especially during long-term storage. Therefore, this study is aimed at evaluating some nutritional and bioactive compositions bimonthly of red onion stored in artificially ventilated structure with a view to minimize postharvest losses encountered in onion bulb storage.

MATERIALS AND METHODS

Collection and Sample Preparation

Red onion bulbs locally known as Yan-Gashua in Hausa language were purchased from onion farm gate in Kura, Kano state. After curing, the onions were carefully packed into an artificially ventilated onion structure and a pallet (control) for a seven-month storage period. The control used in this study is a common practice among onion handlers in Kano state. Three (3) pieces of onions representing big, medium and small in terms of weight and size were taken every two months for chemical analysis Experimental analyses were in triplicates in all cases and was initially conducted before the storage time counts as zeroth month.

Determination of Moisture Contents

Moisture content was determined according to AOAC hot-air oven method of 2006. Five grams (5g) of onion sliced was weighed into pre-weighed moisture dishes and kept in an oven set at 105°C for four hours. After a constant weight were recorded twice, the difference in weight of the moisture dishes were then weighed again post-drying and the moisture contents was calculated from the equation:

$$\% \text{ Moisture content} = \frac{(\text{weight of wet sample+ pan}) - (\text{weight of dried sample + pan}) \times 100}{(\text{Weight of wet sample + pan}) - (\text{weight of pan})}$$

Determination of Ascorbic Acid Content

Vitamin C content was determined according to titration method (AOAC, 2010). About 2.0g of macerated sample was weighed into 10ml distilled water.7.0ml of extraction solution containing 15g Metaphosphoric acid, 40ml acetic acid glacial in about 500ml distilled water was dispensed to 2.0 ml of sample aliquot. 2-3 drops of thymol blue indicator (0.1g thymol blue in 10.75ml of 0.03M NaOH diluted in 250ml water) was added to aliquot and then titrated with indophenol standard solution to rosy pink at end-point. Standard ascorbic acid solution prepared by dissolving 0.05 g in 50ml in extraction solution was then titrated in similar ways to samples.

Vitamin C (mg/100g) was then calculated as = <u>Average titer (sample -blank)</u> x 100

Average titer of standard

Determination of Total Carbohydrates

About 1g of macerated sample was placed in 25ml conical flask containing 10ml distilled water which was shake vigorously and followed by 15ml of 52% perchloric acid. After 30 minutes of votexing, mixture was filtered and about 1.0ml of filtrate was was mixed with Anthrone reagent in a test tube and absorbance taken at wavelenght 620nm using a PG-T80 Spectrophotometer. The total soluble carbohydrates was then estimated using the standard curve of glucose (Pearson, *et al*.,1976).

Determination of Oil content

Oil content was determined using soxhlet extraction method according to AOAC 2006. Three (3g) of pulverized onion sample was weighed into a thimble. The thimble was placed in the extraction unit of the soxhlet apparatus. About 230ml of petroleum ether was poured into a pre-weighed round bottom flask. The apparatus was set to boil at 80°C for 4 hours after continuous reflux of condensed solvent through the sample in the extraction thimble. The oil content was calculated using the formula: % oil content = (weight of oil extracted ÷ weight of sample) x 100%.

Determination of Protein Content

Crude Protein Content was determined as described by Kjedhal procedure in AOAC method 2006. Approximately 0.5g of pulverized sample was weighed into digestion tube, followed by addition of Kjedhal table (catalyst) then 15ml of concentrated hydrochloric acid was added. The mixture was digested at 420°C on digest stove. After digestion (clearly solution), a 40% sodium hydroxide solution was suctioned into it; then a distillation process involving the solution mixture and boric acid was made through continuous flow of distilled water in the distillation set-ups. After about 50ml of distillate was collected into the boric acid, the distillate was then titrated with 0.05M HCl using mixed indicator of bromo-cresol green and methyl red.

Protein composition was calculated as: protein (%) = $\frac{(A-B) \times 0.05 \times 1.4007 \times 6.25}{\text{Weight of sample used (0.5g)}}$

Where A = titer value of sample (ml); B = titer value of blank (ml)

Molarity of HCl used = 0.05M; 1.4007 = equivalent of atomic mass of Nitrogen

6.25 = conversion factor of nitrogen.

Determination of Total Phenolic Content

Extraction of aliquot

About 500mg of pulverized onion sample was added to 25ml of methanol-water (80:20v/v) and then sonicated for 1hour. The mixture was then centrifuged at 3000g rpm for 30minutes and extract was collected twice after being spun for the second time into Eppendorf tube and completely wrapped with aluminium foil ready for analysis.

Gallic Acid Standard Preparation

12.5mg of gallic acid crystal was weighed and dissolved in 50ml volumetric flask made up to mark methanol-water (50:50) to produce a stock solution of 250mg/L which was then used to produce solutions of 50, 100, 150 and 200mg/L.

Determination of Total Phenolic Contents

Total polyphenols contents (TPC) were determined by the Lachman *et al* (2003) method and expressed in mg gallic acid equivalent(mg/dl) of dried weight matter. 0.25ml of 500mg/L solution of each sample was added to 2.5ml Folin Ciocalteu Reagent (FCR) followed by 2.0ml of 1M sodium carbonate. Likewise, 0.25ml of each of the gallic standard solutions were used in lieu of sample to obtain calibration curve; while 0.25ml of methanol-water (50:50) was used as blank in place of sample. The reaction mixes were allowed to stand at room temperature for 15minutes in a dim light room where the absorbance were then measured spectrophotometrically at 765nm using a T80 PG-UV/Vis spectrometer. TPC was expressed as gallic acid equivalent (GAE) mg/g fresh weight (FW) of sample.

Determination of Total Carotenoids

The total carotenoids were evaluated by the spectrophotometric method described by Chan and Cavaletto (1982). About 6g of pulverized onion sample was mixed with 5.0g of celite and 15ml Methanol(70%V/V) and then filtered using Whatman No 1 filter paper. The residue was extracted up to three times using 20ml of 1:1 acetone-petroleum ether (v/v). The extract was then transferred to 500ml separating funnel where a 5ml of 10% KOH (v/v) in methanol was added and mixture allowed to stand for 90minutes. Partition achieved following the addition of 15ml petroleum ether and 20ml NaCl (20%w/v) was separated as the hypophasic layer were discarded while the epiphasic (upper) layer was washed three times with 20ml of distilled water to remove excess acetone. It was then filtered through a funnel plugged with 3.0g anhydrous sodium sulfate to remove residual water. The filtrate was made up to 100ml petroleum ether and absorbance was measured at 450nm wavelength. The total carotenoids content (µg/g) was calculated using Beer-Lambert's Law equation: A = ECL Where A = absorbance, E = Extinction coefficient of carotenoids = 1.25x104 µg/L;

C = Concentration and L = path length of cuvette (1cm)

Data Analysis

Experimental analysis was carried out in triplicate and expressed as means ± standard deviation. Data were analyzed using the t-test (SPSS 16.0 version 2007) to determine the statistical significance ($p \leq 0.05$).

RESULTS AND DISCUSSION

Nutritional Composition of stored onions

To many, onion is just a spice for food delicacies. However, its nutritional compositions cannot be over emphasized. Macromolecules such as proteins, carbohydrates, lipid (oil) contents which are precursors of total derivable energy value for any form of food substance also constitutes a profile of nutritional exigencies in onion bulbs. The onions bulbs initially collected for this research was estimated to have energy value of 80.17Kcal/100g which steadily increases during the storage periods to 92.26Kcal/100g and 84.34Kcal/100g in the experimental structure tagged AAVSO and in the control respectively (Table 1). The normal body physiology is majorly dependent on derivable energy following cascades of metabolism of protein, carbohydrates and lipid asides other micro and macronutrients. From Table 1, the observed increase in carbohydrates were quite more than it was observed in protein and oil contents. Many food substances have showed increase in protein and carbohydrates as moisture contents declines due to concentrated linkages in the amino groups and glycolytic bonds respectively (Tao and Linchun, 2008). The decreasing moisture content were due to tissue respiration of onion bulbs and was more observed with the AAVSO due to steady aeration of the storage environment.

Table 1: Some Nutritional Parameters and Energy Value of Fresh Red onion in Storage

Bioactive Composition of stored onions

The onion for this study was analysed only for ascorbic acids, total polyphenolics and total carotenoids from among many known bioactive compounds of onion bulbs. Prior to storage, the onions were analysed to have 6.21±0.05 mg/100g, 5.10±0.02GAE (mg/g) Fresh weight and 1.02±0.00 µg/g contents of Ascorbic acids, total polyphenols and total carotenoids respectively. **Fruits and vegetables with less** moisture content as a result of dehydration tends to increase some bioactive compounds (Jayeeta, *et al*.,2012, Bala *et* al., 2021). Although the composition and concentration of any bioactive compounds are dependent of certain intrinsic and extrinsic factors such as genetic and cultivars, soil and growing conditions, maturity status and postharvest storage conditions (Chaudhary, *et al.*, 2018)**. Ascorbic acids have been reported to be thermo-labile and photo-sensitive which are prone to degradation on thermal processing and storage (Jayathunge *et al.*, 2019). Table 2 above depicted the initial estimated value of ascorbic acids to be 6.21**±0.05 mg/100g prior to storage. However, there was steady decline from this initial value to 3.20±0.05 mg/100g and 2.86mg/100g in the artificially ventilated onions and the control onion respectively. This indicated that ascorbic acid declined more in the normal crib ventilated onions. This difference could be due to subsequent increase in temperature in the **control** structure than in the artificially ventilated structure during the March- July period of storage in Kano state, Nigeria. Similarly, total carotenoids were initially estimated to be 1.02±00µg/g before storage. There was continuous decline in the total carotenoids contents of the onion during the storage periods but no significant ($p>0.05$) difference in the **AAVSO** and **control** respectively. Carotenoids are less affected compared to ascorbic acid levels during storage of fruits and vegetables (Jayeeta, *et al*.,2012). The total polyphenol contents of the onions were extrapolated from the equation: $y= 0.0053x+ 0.0023$; $R^2 = 0.9986$) of gallic acid standard as shown in figure 1. It was observed that total polyphenolic content increased from the initial estimate of 5.10±0.02GAE (mg/g) fresh weight prior to storage to 12.08±0.00 GAE (mg/g) FW and 9.95±1.03GAE (mg/g) FW in **the artificially ventilated onions and the normal crib ventilated onions respectively. There was significant ($p<0.05$) in the value of total polyphenols in each periodic analysis from both onion structures. The AAVSO retained a 41.8% more of the total polyphenols than the control. This could be attributed to a less moisture content, lower temperature difference in the artificially ventilated onion structure than the normal crib onion structure.**

Table 2: Some Bioactive Parameters of Fresh Red onion in Storage

Storage Time (Months)	Ascorbic acid (mg/100g)		Total polyphenols (GAE mg/g) FW		Total carotenoids (µg/g)	
	AAVSO	control	AAVSO	control	AAVSO	control
0th	**6.21±0.05^a**	**6.21±0.05^a**	**5.10±0.02^a**	**5.10±0.02^a**	**1.02± 0.00^b**	**1.02± 0.00^b**

Values are data expressed as mean ±SD of three replicates. Different superscript in the same column indicates significant difference at $P<0.05$. AVO= Artificially Ventilated Onions; nCVO = normal Crib Ventilated Onions.

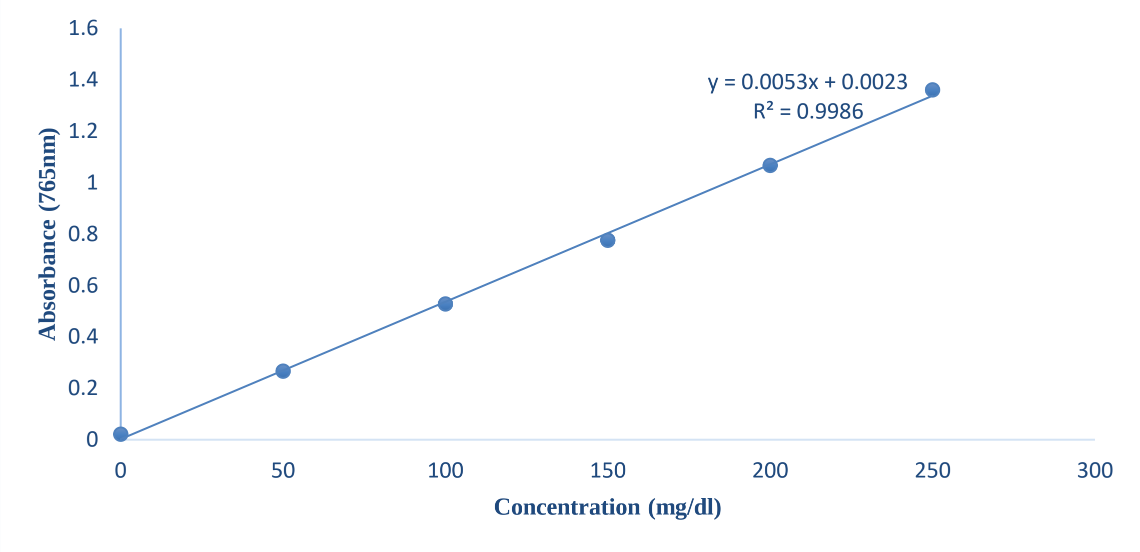

Figure 1: Plot of Gallic Acid Standard Absorbance (nm) Against Concentration (mg/dl).

CONCLUSIONS AND RECOMMENDATION

The study confirmed that there was more retention of the evaluated nutritional and bioactive compounds in the artificially ventilated onion structure than the control structure. Conclusively, onion storage in an artificially ventilated structure have shown to be more desirable to curb the enormous wastage during glut and for better retention of more nutritional and bioactive compounds prior to use at home or industry. It is therefore pertinent that policy makers and non-governmental organizations should encourage and support a larger scale onion storage in an artificially ventilated structure.

ABSTRACT

A three year study was conducted at the National Root Crops Research Institute Umuahia Abia State to evaluate the different storage methods of living stone potato and as well affect the yield potentials. Early sprouting and rot are the major problems of living stone potato post-harvest storage. The objective was to determine the effect of different storage methods on reduction of early sprouting that will affect the yield potentials of the crop .The experiment was conducted in two stages; the first stage was the screening stage while the second stage involved field evaluation. Nine storage method used in the first stage were; bamboo raised platform , raffia palm raised platform, pit with wood shaving, pit with saw dust, pit with river sand, pit with wood ash, pit with rice husk , cemented floor, floor under shade of a tree and buried in the field,(control or farmers method), .In the second experiment pit with saw dust and cemented floor were screened out of the nine storage methods adopted due to their storage inefficiency .In 2016, seven (7) the treatments were evaluated in the field and were laid out in a randomized complete block design (RCBD) with three replicates. During the first stage of the experiment, significant differences were observed (P<0.05) in the percentage sprout count. The highest mean for both years were observed in cemented platform(17%) and pit with saw dust (16%). The highest mean percentage reduction sprout count was obtained in pit rice husk (99.5%) followed by pit with river sand (99.0%) while the least was recorded in cemented platform (83.3%) and pit with sawdust (83%).The field evaluation revealed that the tuber stored with rice husk (2 t/h) and that of river sand (2.60 t/h) gave the highest yield. The lowest yield were observed in the tubers buried in the field (0.78 t/h) and those stored in the bamboo raised platform(0.85 t/h). For effective storage of living stone potato for maximum yield, storing the tubers in pit with rice husk and pit with river sand maintained in a 60cm deep with 1mx1m is therefore recommended.

Keywords : Livingstone potato, storage methods, Postharvest, early sprouting.

INTRODUCTION

Living stone potato (*Plenthrantus esculentus*) or Rigza is one of the underutilized crop species which are very nutritious for both human and animals, the tubers are often used for substitute for potato or sweet potato. (Olojede, *et al.*, 2004). It is a dicot perennial herb and a member of a *lamiaceae* family. It is indigenous to Africa where it is grown for its nutritious edible tubers .The leaves contain a lot of vitamins and can help in digestive problems and abdominal pain.(Alleman and Coertze,1997). The tubers are mostly boiled but can be roasted baked, or fried ,it is rich in carbohydrate, vitamin A, mineral and essential amino acid. (Lukhoba *et al*,2006) . Early sprouting and rot are the major problems of living stone potato during post-harvest storage. The end of dormancy leads to initiation of sprouting which in turn means increased respiration and dry matter loss. It also determines the factor, on how long the commodity can be stored (Soctt, *et al.*, 2000). The use of different storage methods implies a strict control of environmental temperature and humidity in the storage chamber (Treche and Agbor-Egbe,1996). It is important to determine the best storage method that will control or reduce an early sprouting in living stone potato. The objective was to determine the effects of different storage methods on reduction of early sprouting and yield performance of Rizga.

MATERIALS AND METHOD

First Stage: The study was carried out in NRCRI, Umudike 2014 and 2015 cropping seasons for four months of each year. Nine different methods used were as follows; Bamboo raised platform , raffia raised platform, pit with wood shaving, pit with saw dust, pit with river sand, pit with wood ash, pit with rice husk ,buried in the field (control) cemented floor and floor under shade. Twenty 20 kg each of living stone potato and storage materials (sand, wood ash, rice husk, wood shaving and saw dust) were weighed out for the pit treatments . The weighed materials were poured inside the pit which was maintained at 60 cm deep and 1 m x 1 m size . They were mixed with the weighed tubers inside the pit. Moreover the tubers were also buried in the field and covered with soil (control or farmers method) ,the cemented floor under and floor under shade of a tree, raised platform of bamboo poles and raffia fronds also received the same quantity of weighed tubers of living stone potato . The storage sites were visited every two week interval to record Percentage sprout count and cumulative percentage.

Second stage : In 2016 two methods (pit with saw dust and cemented floor) were screened out of the nine storage methods adopted in 2014 and 2015 due to their storage inefficiency .The seven storage methods were evaluated in the field, after clearing the existing vegetation ploughed, harrowed and ridged. The field was demarcated into different plots of 2 m x 2 m with three replicates, plant spacing was 0.3 m x 1 m laid out in randomized complete block design (RCBD). All other agronomic practices were done and data were collected as at when due and subjected to analysis of variance. Means were separated with least significant difference (LSD<0.05).

RESULTS AND DISCUSSION

During the first stage of the experiment (Table1), significant differences were observed (P<0.05) in the percentage sprout count. The highest mean for the years were observed in cemented platform (17%) and pit with saw dust (16%). Consequently, one percent stand count (1%) was further observed on the following storage methods; pit with river sand, buried in the field and pit with rice husk. This also reflected in the percentage reduction sprout count. The highest mean was obtained in pit rice husk (99.5%) followed by pit with river sand (99.0) while the least was recorded in cemented platform (83.3%) and pit with sawdust (83%).

Table 2 depict the evaluation of the seven methods in the field, it was observed that the tuber stored with rice husk (2 t/h) and that of river sand gave the highest yield (2.60 t/h) . The lowest yield were observed in the tubers buried in the field (0.78 t/h) and those stored in the bamboo raised platform (0.851t/ha). The highest value obtained in storage with rice husk could be due to its bio-energy products that has a high count of cellulose and lignin according to Sheng ,(2000),this attributes contributes to the storage and yield of agricultural products. The highest yield obtained in river sand could be as a result of its cooling and drying effect on the tuber, thereby maintaining the temperature of the micro environment which result to an efficient reserve of energy from storage to the field, this confirmed the work done by Treche and Agbor-Egbe,(1996).They stated that biochemical changes during storage can affect the yield potential of tubers. The lowest value obtained in the yield of tuber stored in a raffia palm (1.05 t/h) could have resulted due to the dryness of the palm leaves after a period of time of storage which perhaps allowed the sun to penetrate towards the stored tubers which must have affected the storability and physiological components of the tubers..

CONCLUSION /RECOMMENDATION

In the first two years of the experiment there was an evidence that four storage methods (buried in the field, pit with rice husk ,pit with river sand and pit with wood ash) among the nine methods gave a better result than other storage methods, this was because their percentage sprout count reduction was above 90%. After the evaluation in the field, pit with river sand and pit with rice husk gave the highest yield in t/ha. The two methods also gave potential post-harvest storability. Therefore for effective storage of living stone potato for maximum yield, storing the tubers in pit with rice husk and pit with river sand maintained in a 60 cm deep with 1 m x 1 m is recommended.

Table1. Effects of Different Storage Methods on Percentage Sprouting of Living Stone potato

Storage methods	% Sprout count			% Reduction sprout count	
	2014	2015	me	2014	2015
Floor under shade	3.00	4.00	3.	97.0	96.0
Cemented platform	16.30	17.43	1'	83.7	82.6

ABSTRACT

This study investigated some nutritional and bioactive contents of artificially ventilated onion bulbs under seven months of storage. Moisture, protein, total carbohydrates, oil contents, energy values, total polyphenolics (TP), total carotenoids (TC) and ascorbic acids (AA) were estimated according to the standard protocols during storage period.The increasing trends in the proteins, carbohydrates and oil contents of Artificially Aerated Ventilated Stored Onions (AAVSO) were significantly different ($p< 0.05$) from control; this gave rise to a 50.08% and 5.20% energy value at the sixth month of storage. There were continuous declining trends in ascorbic acids and total carotenoids contents in the AAVSO and the control respectively leaving a 5.48% (AA) and 4.90% (TC) more retention in the AAVSO than in the control respectively. Total polyphenolic contents increased from an initial 5.10±0.02 GAE (mg/g) fresh weight to 12.08±0.00 and 9.95±1.03 GAE(mg/g) fresh weight. From the findings of this research, onion storage in an artificially ventilated structure have shown to be more desirable to curb the enormous wastage during glut and for better retention of more nutritional and bioactive compounds prior to use at home or industry. It is therefore pertinent that policy makers and non-governmental organizations should encourage and support a larger scale onion storage in an artificially ventilated structure.

Keywords: ***storage, artificial ventilation, bioactive compounds, onion***

INTRODUCTION

Onions (*Allium cepa* L.) is one of the most important and commonly used spicy vegetable through the ages not only for its culinary uses but also for its therapeutic properties. Its production remains steadily on the increase and thus making it the second most important horticultural crop after tomatoes (Prithiani *et al.*, 2022). Over 93 million metric tonnes of onion are produced globally while about 1.38 million metric tonnes are from Nigeria (FAOSTAT, 2020). Kaduna, Kano, Bauchi, Katsina, Sokoto, Borno, Nasarawa, and Gombe States account for nearly 100% (99.97) of the total production in the country (Adeoti *et al.*, 2021). Remarkably known for its aroma, taste and lachrymatory effects; it plays significant role in the industries as constituents for moth repellent, beverages, expectorants as well as condiment in biscuits (Li, et al., 2021). Studies have shown that onion bioactive molecules contribute in lowering bone reabsorption, and in prevention of degenerative diseases due to some ample amount of polyphenols and potential antioxidants. Onions have been evaluated for considerable nutritional value such as lipid, protein, reducing sugar, iron, calcium, vitamin C, phenolic contents as well as antioxidant activity (Mahmood *et al.*, 2021). Common onion varieties in Nigeria are the red Tropicana, Bombay red (brown onion), white onion among others (Oniya, *et al*., 2021). As a seasonal crop, price tends to hit the roof during off-season thus making its availability very limited. Several attempts made to store and minimize spoilage of onion is still not very efficient and yielding especially in Africa, this can be attributed to its high moisture content (≥80%) which allows for microbial infestations (Ewekeye *et al.*, 2021). Artificial aeration of onion storage structure provides a controllable surrounding temperature and relative humidity that slows deterioration especially during long-term storage. Therefore, this study is aimed at evaluating some nutritional and bioactive compositions bimonthly of red onion stored in artificially ventilated structure with a view to minimize postharvest losses encountered in onion bulb storage.

MATERIALS AND METHODS

Collection and Sample Preparation

Red onion bulbs locally known as Yan-Gashua in Hausa language were purchased from onion farm gate in Kura, Kano state. After curing, the onions were carefully packed into an artificially ventilated onion structure and a pallet (control) for a seven-month storage period. The control used in this study is a common practice among onion handlers in Kano state. Three (3) pieces of onions representing big, medium and small in terms of weight and size were taken every two months for chemical analysis Experimental analyses were in triplicates in all cases and was initially conducted before the storage time counts as zeroth month.

Determination of Moisture Contents

Moisture content was determined according to AOAC hot-air oven method of 2006. Five grams (5g) of onion sliced was weighed into pre-weighed moisture dishes and kept in an oven set at 105°C for four hours. After a constant weight were recorded twice, the difference in weight of the moisture dishes were then weighed again post-drying and the moisture contents was calculated from the equation:

$$\%\text{ Moisture content} = \frac{(\text{weight of wet sample+ pan}) - (\text{weight of dried sample + pan}) \times 100}{(\text{Weight of wet sample + pan}) - (\text{weight of pan})}$$

Determination of Ascorbic Acid Content

Vitamin C content was determined according to titration method (AOAC, 2010). About 2.0g of macerated sample was weighed into 10ml distilled water.7.0ml of extraction solution containing 15g Metaphosphoric acid, 40ml acetic acid glacial in about 500ml distilled water was dispensed to 2.0 ml of sample aliquot. 2-3 drops of thymol blue indicator (0.1g thymol blue in 10.75ml of 0.03M NaOH diluted in 250ml water) was added to aliquot and then titrated with indophenol standard solution to rosy pink at end-point. Standard ascorbic acid solution prepared by dissolving 0.05 g in 50ml in extraction solution was then titrated in similar ways to samples.

Vitamin C (mg/100g) was then calculated as = Average titer (sample -blank) x 100

Average titer of standard

Determination of Total Carbohydrates

About 1g of macerated sample was placed in 25ml conical flask containing 10ml distilled water which was shake vigorously and followed by 15ml of 52% perchloric acid. After 30 minutes of votexing, mixture was filtered and about 1.0ml of filtrate was was mixed with Anthrone reagent in a test tube and absorbance taken at wavelenght 620nm using a PG-T80 Spectrophotometer. The total soluble carbohydrates was then estimated using the standard curve of glucose (Pearson, *et al*.,1976).

Determination of Oil content

Oil content was determined using soxhlet extraction method according to AOAC 2006. Three (3g) of pulverized onion sample was weighed into a thimble. The thimble was placed in the extraction unit of the soxhlet apparatus. About 230ml of petroleum ether was poured into a pre-weighed round bottom flask. The apparatus was set to boil at 80°C for 4 hours after continuous reflux of condensed solvent through the sample in the extraction thimble. The oil content was calculated using the formula: % oil content = (weight of oil extracted ÷ weight of sample) x 100%.

Determination of Protein Content

Crude Protein Content was determined as described by Kjedhal procedure in AOAC method 2006. Approximately 0.5g of pulverized sample was weighed into digestion tube, followed by addition of Kjedhal table (catalyst) then 15ml of concentrated hydrochloric acid was added. The mixture was digested at 420°C on digest stove. After digestion (clearly solution), a 40% sodium hydroxide solution was suctioned into it; then a distillation process involving the solution mixture and boric acid was made through continuous flow of distilled water in the distillation set-ups. After about 50ml of distillate was collected into the boric acid, the distillate was then titrated with 0.05M HCl using mixed indicator of bromo-cresol green and methyl red.

Protein composition was calculated as: $\text{protein (\%)} = \dfrac{(A-B) \times 0.05 \times 1.4007 \times 6.25}{\text{Weight of sample used (0.5g)}}$

Where A = titer value of sample (ml); B = titer value of blank (ml)

Molarity of HCl used = 0.05M; 1.4007 = equivalent of atomic mass of Nitrogen

6.25 = conversion factor of nitrogen.

Determination of Total Phenolic Content

Extraction of aliquot

About 500mg of pulverized onion sample was added to 25ml of methanol-water (80:20v/v) and then sonicated for 1hour. The mixture was then centrifuged at 3000g rpm for 30minutes and extract was collected twice after being spun for the second time into Eppendorf tube and completely wrapped with aluminium foil ready for analysis.

Gallic Acid Standard Preparation

12.5mg of gallic acid crystal was weighed and dissolved in 50ml volumetric flask made up to mark methanol-water (50:50) to produce a stock solution of 250mg/L which was then used to produce solutions of 50, 100, 150 and 200mg/L.

Determination of Total Phenolic Contents

Total polyphenols contents (TPC) were determined by the Lachman *et al* (2003) method and expressed in mg gallic acid equivalent(mg/dl) of dried weight matter. 0.25ml of 500mg/L solution of each sample was added to 2.5ml Folin Ciocalteu Reagent (FCR) followed by 2.0ml of 1M sodium carbonate. Likewise, 0.25ml of each of the gallic standard solutions were used in lieu of sample to obtain calibration curve; while 0.25ml of methanol-water (50:50) was used as blank in place of sample. The reaction mixes were allowed to stand at room temperature for 15minutes in a dim light room where the absorbance were then measured spectrophotometrically at 765nm using a T80 PG-UV/Vis spectrometer. TPC was expressed as gallic acid equivalent (GAE) mg/g fresh weight (FW) of sample.

Determination of Total Carotenoids

The total carotenoids were evaluated by the spectrophotometric method described by Chan and Cavaletto (1982). About 6g of pulverized onion sample was mixed with 5.0g of celite and 15ml Methanol(70%V/V) and then filtered using Whatman No 1 filter paper. The residue was extracted up to three times using 20ml of 1:1 acetone-petroleum ether (v/v). The extract was then transferred to 500ml separating funnel where a 5ml of 10% KOH (v/v) in methanol was added and mixture allowed to stand for 90minutes. Partition achieved following the addition of 15ml petroleum ether and 20ml NaCl (20%w/v) was separated as the hypophasic layer were discarded while the epiphasic (upper) layer was washed three times with 20ml of distilled water to remove excess acetone. It was then filtered through a funnel plugged with 3.0g anhydrous sodium sulfate to remove residual water. The filtrate was made up to 100ml petroleum ether and absorbance was measured at 450nm wavelength. The total carotenoids content (µg/g) was calculated using Beer-Lambert's Law equation: A = ECL Where A = absorbance, E = Extinction coefficient of carotenoids = 1.25x104 µg/L;

C = Concentration and L = path length of cuvette (1cm)

Data Analysis

Experimental analysis was carried out in triplicate and expressed as means ± standard deviation. Data were analyzed using the t-test (SPSS 16.0 version 2007) to determine the statistical significance ($p \leq 0.05$).

RESULTS AND DISCUSSION

Nutritional Composition of stored onions

To many, onion is just a spice for food delicacies. However, its nutritional compositions cannot be over emphasized. Macromolecules such as proteins, carbohydrates, lipid (oil) contents which are precursors of total derivable energy value for any form of food substance also constitutes a profile of nutritional exigencies in onion bulbs. The onions bulbs initially collected for this research was estimated to have energy value of 80.17Kcal/100g which steadily increases during the storage periods to 92.26Kcal/100g and 84.34Kcal/100g in the experimental structure tagged AAVSO and in the control respectively (Table 1). The normal body physiology is majorly dependent on derivable energy following cascades of metabolism of protein, carbohydrates and lipid asides other micro and macronutrients. From Table 1, the observed increase in carbohydrates were quite more than it was observed in protein and oil contents. Many food substances have showed increase in protein and carbohydrates as moisture contents declines due to concentrated linkages in the amino groups and glycolytic bonds respectively (Tao and Linchun, 2008). The decreasing moisture content were due to tissue respiration of onion bulbs and was more observed with the AAVSO due to steady aeration of the storage environment.

Table 1: Some Nutritional Parameters and Energy Value of Fresh Red onion in Storage

Storage Time	**Moisture (%)**		**Protein (%)**		**Total Carbs (%)**		**Oil (%)**		**Energy Value (Kcal/100g)**	
Month	AAVSO	Control	AAVSO	control	AAVSO	control	AAVSO	control	AAVSO	control
0th	78.39 $\pm0.01^{e}$	78.39 $\pm0.01^{e}$	1.95 $\pm0.1^{g}$	1.95 $\pm0.10^{g}$	15.35 $\pm1.0^{h}$	15.35 $\pm1.00^{h}$	0.93 $\pm0.0^{a}$	0.9$\pm$ 0.01^{a}	80.17	80.17

Bioactive Composition of stored onions

The onion for this study was analysed only for ascorbic acids, total polyphenolics and total carotenoids from among many known bioactive compounds of onion bulbs. Prior to storage, the onions were analysed to have 6.21±0.05 mg/100g, 5.10±0.02GAE (mg/g) Fresh weight and 1.02±0.00 µg/g contents of Ascorbic acids, total polyphenols and total carotenoids respectively. Fruits and vegetables with less moisture content as a result of dehydration tends to increase some bioactive compounds (Jayeeta, *et al*.,2012, Bala *et* al., 2021). Although the composition and concentration of any bioactive compounds are dependent of certain intrinsic and extrinsic factors such as genetic and cultivars, soil and growing conditions, maturity status and postharvest storage conditions (Chaudhary, *et al.*, 2018). Ascorbic acids have been reported to be thermo-labile and photo-sensitive which are prone to degradation on thermal processing and storage (Jayathunge *et al.*, 2019). Table 2 above depicted the initial estimated value of ascorbic acids to be 6.21±0.05 mg/100g prior to storage. However, there was steady decline from this initial value to 3.20±0.05 mg/100g and 2.86mg/100g in the artificially ventilated onions and the control onion respectively. This indicated that ascorbic acid declined more in the normal crib ventilated onions. This difference could be due to subsequent increase in temperature in the control structure than in the artificially ventilated structure during the

March- July period of storage in Kano state, Nigeria. Similarly, total carotenoids were initially estimated to be 1.02±00µg/g before storage. There was continuous decline in the total carotenoids contents of the onion during the storage periods but no significant ($p>0.05$) difference in the AAVSO and control respectively. Carotenoids are less affected compared to ascorbic acid levels during storage of fruits and vegetables (Jayeeta, *et al*.,2012). The total polyphenol contents of the onions were extrapolated from the equation: $y= 0.0053x+ 0.0023$; $R^2 = 0.9986$) of gallic acid standard as shown in figure 1. It was observed that total polyphenolic content increased from the initial estimate of 5.10±0.02GAE (mg/g) fresh weight prior to storage to 12.08±0.00 GAE (mg/g) FW and 9.95±1.03GAE (mg/g) FW in the artificially ventilated onions and the normal crib ventilated onions respectively. There was significant ($p<0.05$) in the value of total polyphenols in each periodic analysis from both onion structures. The AAVSO retained a 41.8% more of the total polyphenols than the control. This could be attributed to a less moisture content, lower temperature difference in the artificially ventilated onion structure than the normal crib onion structure.

Table 2: Some Bioactive Parameters of Fresh Red onion in Storage

Storage Time (Months)	Ascorbic acid (mg/100g)		Total polyphenols (GAE mg/g) FW		Total carotenoids (µg/g)	
	AAVSO	control	AAVSO	control	AAVSO	control
0th	6.21 ± 0.05^{a}	6.21 ± 0.05^{a}	5.10 ± 0.02^{a}	5.10 ± 0.02^{a}	1.02 ± 0.00^{b}	1.02 ± 0.00^{b}
2nd	5.40 ± 0.11^{c}	5.00 ± 0.02^{g}	5.61 ± 0.11^{b}	5.65 ± 0.05^{d}	0.77 ± 0.01^{e}	0.77 ± 0.01^{e}

Values are data expressed as mean ±SD of three replicates. Different superscript in the same column indicates significant difference at $P<0.05$. AVO= Artificially Ventilated Onions; nCVO = normal Crib Ventilated Onions.

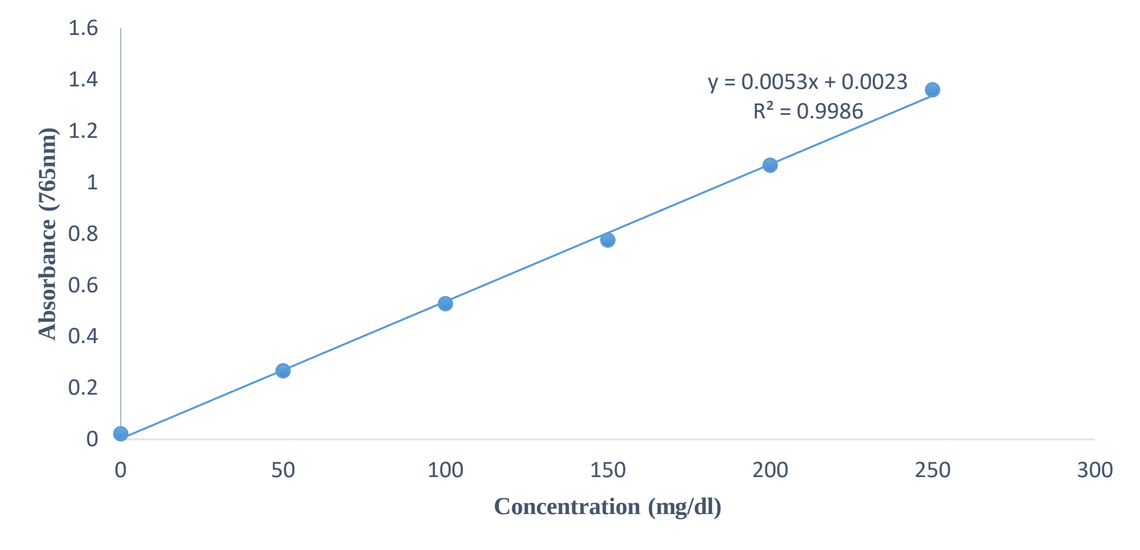

Figure 1: Plot of Gallic Acid Standard Absorbance (nm) Against Concentration (mg/dl).

CONCLUSIONS AND RECOMMENDATION

The study confirmed that there was more retention of the evaluated nutritional and bioactive compounds in the artificially ventilated onion structure than the control structure. Conclusively, onion storage in an artificially ventilated structure have shown to be more desirable to curb the enormous wastage during glut and for better retention of more nutritional and bioactive compounds prior to use at home or industry. It is therefore pertinent that policy makers and non-governmental organizations should encourage and support a larger scale onion storage in an artificially ventilated structure.

ABSTRACT

A three year study was conducted at the National Root Crops Research Institute Umuahia Abia State to evaluate the different storage methods of living stone potato and as well affect the yield potentials. Early sprouting and rot are the major problems of living stone potato post-harvest storage. The objective was to determine the effect of different storage methods on reduction of early sprouting that will affect the yield potentials of the crop .The experiment was conducted in two stages; the first stage was the screening stage while the second stage involved field evaluation. Nine storage method used in the first stage were; bamboo raised platform , raffia palm raised platform, pit with wood shaving, pit with saw dust, pit with river sand, pit with wood ash, pit with rice husk , cemented floor, floor under shade of a tree and buried in the field,(control or farmers method), .In the second experiment pit with saw dust and cemented floor were screened out of the nine storage methods adopted due to their storage inefficiency .In 2016, seven (7) the treatments were evaluated in the field and were laid out in a randomized complete block design (RCBD) with three replicates. During the first stage of the experiment, significant differences were observed ($P<0.05$) in the percentage sprout count. The highest mean for both years were observed in cemented platform(17%) and pit with saw dust (16%). The highest mean percentage reduction sprout count was obtained in pit rice husk (99.5%) followed by pit with river sand (99.0%) while the least was recorded in cemented platform (83.3%) and pit with sawdust (83%).The field evaluation revealed that the tuber stored with rice husk (2 t/h) and that of river sand (2.60 t/h) gave the highest yield. The lowest yield were observed in the tubers buried in the field (0.78 t/h) and those stored in the bamboo raised platform(0.85 t/h). For effective storage of living stone potato for maximum yield, storing the tubers in pit with rice husk and pit with river sand maintained in a 60cm deep with 1mx1m is therefore recommended.

Keywords : Livingstone potato, storage methods, Postharvest, early sprouting.

INTRODUCTION

Living stone potato (*Plenthrantus esculentus*) or Rigza is one of the underutilized crop species which are very nutritious for both human and animals, the tubers are often used for substitute for potato or sweet potato. (Olojede, *et al.*, 2004). It is a dicot perennial herb and a member of a *lamiaceae* family. It is indigenous to Africa where it is grown for its nutritious edible tubers .The leaves contain a lot of vitamins and can help in digestive problems and abdominal pain.(Alleman and Coertze,1997). The tubers are mostly boiled but can be roasted baked, or fried ,it is rich in carbohydrate, vitamin A, mineral and essential amino acid. (Lukhoba *et al*,2006) . Early sprouting and rot are the major problems of living stone potato during post-harvest storage. The end of dormancy leads to initiation of sprouting which in turn means increased respiration and dry matter loss. It also determines the factor, on how long the commodity can be stored (Soctt, *et al.*, 2000). The use of different storage methods implies a strict control of environmental temperature and humidity in the storage chamber (Treche and Agbor-Egbe,1996). It is important to determine the best storage method that will control or reduce an early sprouting in living stone potato. The objective was to determine the effects of different storage methods on reduction of early sprouting and yield performance of Rizga.

MATERIALS AND METHOD

First Stage: The study was carried out in NRCRI, Umudike 2014 and 2015 cropping seasons for four months of each year. Nine different methods used were as follows; Bamboo raised platform , raffia raised platform, pit with wood shaving, pit with saw dust, pit with river sand, pit with wood ash, pit with rice husk ,buried in the field (control) cemented floor and floor under shade. Twenty 20 kg each of living stone potato and storage materials (sand, wood ash, rice husk, wood shaving and saw dust) were weighed out for the pit treatments . The weighed materials were poured inside the pit which was maintained at 60 cm deep and 1 m x 1 m size . They were mixed with the weighed tubers inside the pit. Moreover the tubers were also buried in the field and covered with soil (control or farmers method) ,the cemented floor under and floor under shade of a tree, raised platform of bamboo poles and raffia fronds also received the same quantity of weighed tubers of living stone potato . The storage sites were visited every two week interval to record Percentage sprout count and cumulative percentage.

Second stage : In 2016 two methods (pit with saw dust and cemented floor) were screened out of the nine storage methods adopted in 2014 and 2015 due to their storage inefficiency .The seven storage methods were evaluated in the field, after clearing the existing vegetation ploughed, harrowed and ridged. The field was demarcated into different plots of 2 m x 2 m with three replicates, plant spacing was 0.3 m x 1 m laid out in randomized complete block design (RCBD). All other agronomic practices were done and data were collected as at when due and subjected to analysis of variance. Means were separated with least significant difference (LSD<0.05).

RESULTS AND DISCUSSION

During the first stage of the experiment (Table1), significant differences were observed (P<0.05) in the percentage sprout count. The highest mean for the years were observed in cemented platform (17%) and pit with saw dust (16%). Consequently, one percent stand count (1%) was further observed on the following storage methods; pit with river sand, buried in the field and pit with rice husk. This also reflected in the percentage reduction sprout count. The highest mean was obtained in pit rice husk (99.5%) followed by pit with river sand (99.0) while the least was recorded in cemented platform (83.3%) and pit with sawdust (83%).

Table 2 depict the evaluation of the seven methods in the field, it was observed that the tuber stored with rice husk (2 t/h) and that of river sand gave the highest yield (2.60 t/h) . The lowest yield were observed in the tubers buried in the field (0.78 t/h) and those stored in the bamboo raised platform (0.851t/ha). The highest value obtained in storage with rice husk could be due to its bio-energy products that has a high count of cellulose and lignin according to Sheng ,(2000),this attributes contributes to the storage and yield of agricultural products. The highest yield obtained in river sand could be as a result of its cooling and drying effect on the tuber, thereby maintaining the temperature of the micro environment which result to an efficient reserve of energy from storage to the field, this confirmed the work done by Treche and Agbor-Egbe,(1996).They stated that biochemical changes during storage can affect the yield potential of tubers. The lowest value obtained in the yield of tuber stored in a raffia palm (1.05 t/h) could have resulted due to the dryness of the palm leaves after a period of time of storage which perhaps allowed the sun to penetrate towards the stored tubers which must have affected the storability and physiological components of the tubers..

CONCLUSION /RECOMMENDATION

In the first two years of the experiment there was an evidence that four storage methods (buried in the field, pit with rice husk ,pit with river sand and pit with wood ash) among the nine methods gave a better result than other storage methods, this was because their percentage sprout count reduction was above 90%. After the evaluation in the field, pit with river sand and pit with rice husk gave the highest yield in t/ha. The two methods also gave potential post-harvest storability. Therefore for effective storage of living stone potato for maximum yield, storing the tubers in pit with rice husk and pit with river sand maintained in a 60 cm deep with 1 m x 1 m is recommended.

Table1. Effects of Different Storage Methods on Percentage Sprouting of Living Stone potato

Storage methods	% Sprout count			% Reduction sprout count		
	2014	2015	mean	2014	2015	mean
Floor under shade	3.00	4.00	3.50	97.0	96.0	96.5
Cemented platform	16.30	17.43	17.0	83.7	82.6	83.3
Buried in the field	1.66	0	1.66	90.8	100	95.0
Rafia palm raised	9.30	10.7	10.0	90.7	89.3	90.0
Pit with river sand	1.40	1.20	1.30	99.0	99.0	99.0
Pit with Rice husk	1.00	0	1.00	99.0	100	99.5
Pit with saw dust	15.0	17.0	16.0	85.0	82.0	83.3
Pit with wood ash	4.66	6.80	5.73	95.3	93.2	94.2
Bambo raised platform	5.00	5.81	5.40	95.0	94.2	95.0

LSD 0.05	**2.83**	**2.80**	**NS**	**NS**

Table 1.Effects of the Storage Methods on the Yield of living stone potato

Treatments	**Total no. of tubers/plot (3 sampled plant)**	**Yield/ tonnes/ha**
Buried in the field	18.05	0.780
Pit with Rice husk	21.60.	2.031
Pit with wood ash	28.45.	1.080
Pit with river sand	34.38	2.60
Pit with wood shavings	27.01	1.860
Raffia raised platform	21.22	1.050
Bamboo raised platform	19.01	0.851
LSD 0.05	**2.21**	**0.34**

ABSTRACT

The study was conducted to know the nutritional implication of Ginger-garlic spices on the oven-dried C. gariepinus.Analysis of variance (ANOVA) using F-test was used to determine the treatments level of significance. The samples were divided into Two (2) batches, Sample A (Fresh catfish), and Sample B (Spiced oven-dried catfish (garlic- ginger mixed). The proximate and mineral compositions of the both samples were determined. The research work shows a significant difference $P < 0.05$.in the percentage of Moisture, Ash, Crude fibre, Fat, Protein, Total carbohydrate and energy value of fresh fish and spiced-oven dried C. gariepinus with the mean values of 58.10±0.17, 5.32±0.02, 0.14±0.02, 6.95±0.15, 27.39±0.11, 2.11±0.40, and 180.51±0.47 for fresh fish and 13.91±0.16, 6.42±0.09, 9.10±0.13, 10.09±0.22, 41.97±0.11, 18.53±0.32, and 331.01±1.93 respectively for spiced oven-dried fish. The significant increase in Protein, ash, lipid and fibre content of the spiced oven-dried sample might be as a result of the change in moisture content and the inclusion of Ginger-garlic spices to the sample respectively. The mineral contents of the fresh fish to spiced oven dried fish indicated an increased significant difference $P < 0.05$ in Calcium and Iron with the mean value from 74.07±0.03 to 126.01±0 and 3.46±0 to 5.88±0 respectively. Hence, a ginger-garlic spice enhances the nutrient and mineral composition of oven-dried Clarias gariepinus.

Keywords: Spices, chemical properties, mineral components, *Clarias gariepinus*

INTRODUCTION

Fish is said to be a very good source of animal protein rich in essential amino acid and has been generally accepted as a good source of protein and other elements for the maintenance of healthy body (Ryu *et al*., 2011; Hegazy *et al*., 2011). *Clarias gariepinus*, one of the species of catfish is a highly nutritious fish that contain high amount of vitamins, proteins, minerals and a little or no saturated fat, and is low in carbohydrates (Idris, 20I0). It is an economically important freshwater fish, and enjoys wide acceptability; it is extensively cultivated in ponds but is sometimes underpriced (Kumolu-Johnson, 2010). Furthermore, as important as fish is, high degree of fish spoilage still occur in Nigerian due to the absence of storage facilities and this serves a major constraint to the development of fishing industry in Nigeria. Bellagha *et al.*, (2007) reported that due to the perishable nature of fish, traditional methods of preservation have been developed over the years which include salting, drying and smoking. The importance of fish smoking differs but in Nigeria, the process has proven relevant to prolonging shelf-life, enhancing flavour and increasing protein availability to people throughout the year (Kumolu-Johnson *et al.*, 2011). The fish could be spiced to enhance flavor and nutrient availability. According to Ayeloja *et al.*, 2013, spices (ginger, onion, garlic, etc.) are edible plant materials that possess anti-oxidant, antiseptic and bacteriostatic properties. They are added to foods to delay onset of deterioration, such as rancidity, and also function as seasonings to foods as well as impart flavor to the foods (Abdel-Hamied *et al.*, 2009). Ginger as a spice has a geographical spread that covers every part of the globe and it is consumed whole as a delicacy, used in traditional oriental medicine, or as spice in foods, such as fish (Onyeagba *et al.*, 2004). Garlic is one of the most used natural ingredient to enhance flavour in food. It has a wide spectrum of actions, which include: antibacterial, antifungal and anti-oxidative. It also has a beneficial effect on cardiovascular and immune system of human (Sallam 2004). Ginger contains spectra of biologically active compounds, such as curcumin, 6-gingerol, 6-shagaols, zingiberene, bisabolene and several other types of lipids that confer on it, the properties of being pungent and a stimulant. However, these compounds are responsible for the unique aroma and flavour of ginger, and account for about 1-3% of the weight of fresh ginger (Akram *et al.*, 2011). This study was therefore carried out to investigate the effect of spices on the chemical and mineral properties of smoked catfish.

MATERIALS AND METHOD

Fish and preparation

Twenty five (25) live catfish (*Clarias gariepinus*) were purchased from a reputable farm at command, Alimosho Lagos. The samples were immediately transported in an oxygen bag to the Sofunk foods processing unit Ajasa command, Alimosho, Lagos for smoking and the rest samples to Federal Institute of industrial Research chemistry laboratory, Oshodi Lagos, for chemical analysis. The samples were divided into Two (2) batches, Sample A (Fresh), and Sample B (Spiced oven-dried). The spiced (garlic- ginger) ingredient were properly cleaned, washed and blended in an electrical grinder machine to produce their juice and it was stored in a refrigerator prior use. However the samples were degutted, cleaned and soaked in garlic: ginger juice (spiced) for 15min after which were oven-dried for 48hrs at the temperature of 40-70^{0}C using a smoking kiln. Hence the oven-dried spiced catfish was allowed to cool for 8hours prior further chemical analysis.

Chemical Analysis: The proximate composition of the fish samples was determined using the standard methods of AOAC (2005). The minerals were determined using Atomic Absorption Spectrophotometer (AAS). The samples used for the analysis were assayed in triplicate.

Statistical Analysis: Analysis of variance (ANOVA) was carried out using F-test to determine the treatments level of significance. Treatments were separated using Duncan Multiple Range Test (DMRT) at 95%.

RESULT AND DISCUSSION

Table 1: Proximate composition of fresh and spiced oven-dried Catfish (*Clarias gariepinus*)

	A	B
Parameter (%)	**Mean ±SE**	
Moisture	58.10±0.17[b]	13.91±0.16[a]
Ash content	5.32±0.02[a].	6.42±0.09[b]
Crude fibre	0.14±0.02[a]	9.10±0.13[b]
Fat content	6.95±0.15[a]	10.09±0.22[b]
Protein content	27.39±0.11[a]	41.97±0.11[b]
Total carbohydrate	2.11±0.40[a]	18.53±0.32[b]
Energyvalue (kcal)	180.51±0.47[a]	331.01±1.93[b]

A – Fresh catfish, B- Spiced oven-dried catfish, SE – Standard error, Kcal- kilocalorie
Means on the same row followed by the same letter are not significantly different at $P < 0.05$.

Table 2: Mineral composition of fresh and spiced oven-dried Catfish (*Clarias gariepinus*)

	A	B
Parameter (ppm)	**Mean ±SE**	
Calcium	74.07±0.03[a]	126.01±0[b]
Potassium	74.41±0.01[c]	74.35±0[b]
Magnesium	41.81±0[a]	42.62±0[b]
Sodium	251.52±0.01[a]	295.34±0.01[b]
Zinc	2.39±0[a]	3.10±0[b]
Iron	3.46±0[a]	5.88±0[b]
Chromium	1.02±0[a]	1.34±0[b]

A – Fresh catfish, B- Spiced oven-dried catfish, SE – Standard error, ppm – part per million
Means on the same row followed by the same letter are not significantly different at $P < 0.05$.

The proximate composition of fresh and spiced oven-dried catfish was presented in Table 1 Moisture content of fresh catfish has the highest value of 58.10±0.17 and spiced oven-dried catfish was represented by a low value of 13.91±0.16. Ayeloja *et al.*, 2013 reviewed that, the differences in moisture content could be due to variation in the moisture absorbing properties of the spices applied before smoking. The resultant reduction in the moisture content of the smoked fish products will prolong the shelf life of the products. This is in line with the findings of Fapohunda and Ogunkoya (2006), Daramola *et al.*, (2007) also reported that the removal of moisture content increased the shelf life of fish products. There is a significant increase in the protein of fresh catfish from 27.39±0.11 to 41.97±0.11 when oven -dried with spices. The results, indicated that the crude protein in the mean proximate composition formed the largest quantity of the dry matter in all the fish products and this is in line with the report of Ajani *et a1.*, (2013) stating that crude protein formed the largest quantity of the dry matter in all fish. The significant increase in protein levels, when compared with the fresh fish, suggests that protein nitrogen was not lost during oven-drying. This is in accordance with the findings of

Puwastien *et al.*, 1999; Gokoglu *et al.*, (2004); Tao and Linchun (2008) and Foline *et.al.*, (2011). Hence the result of the crude fibre content shows that the fresh fish had the lowest value with a mean value of 0.14±0.02 which was significantly different ($p < 0.05$) from spiced oven-dried catfish. However, this might be a product which is a function of fibre content of the spices applied to the fish product before smoking. Ash is the inorganic residue resulting from the removal of moisture and organic matter by applying heat treatment. Mineral content in food is also represented by ash content (Kurniaty *et al.*, 2018). Higher ash content indicates a higher value of mineral composition for human health (Magara *et al.*, 2020).Thus, these concentrations of minerals and trace elements may be different due to feeding behaviour, environment ecosystem and migration (Andres *et al.*, 2000). Spiced oven-dried fish fat indicates a significantly different higher mean value of 10.09±0.22 than the fresh fish (6.95±0.15) sample. Hence, the increase might be due to reduction in moisture content during smoking as reported by (*Ogbonnaya and Ibrahim* 2009; Tenyang *et al*., 2020).

The result of the mineral composition presented on Table 2 indicated that the spiced oven-dried smoked fish were rich in calcium with the spiced product having the highest value of calcium (126.01±0), while the fresh fish had the lowest calcium value (74.07±0.03). Calcium is required in maintaining and building bone and tooth, and also performs the functions of adjusting the acid-base balance, blood coagulation and transportation of nerve impulses (Meta *et al.*, 2010). The spiced oven dried catfish having the highest level of iron, while the fresh having the lowest mean value. This result is in conjunction with the work of Ayeloja *et al.*, 2013. Iron supply is needed for the bounding of hemoglobin therefore iron took an important role by oxygen transportation (Meta *et al.*, 2010). Generally, the minerals occurred at low levels within international limits, thereby making this fish product safe for consumption. Magnesiun, Sodium, zinc, iron and chromium have higher value in this study, but are not above the recommended value.

CONCLUSION

The result of this study shows significant differences ($p < 0.05$) in the nutritional composition and mineral contents of fresh and spiced oven-dried catfish products. However, addition of Galic-ginger spices improves the nutritional value of protein, Ash, fiber and fat content as well as the mineral contents of the products because low moisture content of the spiced fish product, enhances the increase in the nutritional composition of the product. Hence the use of spices (garlic-ginger) in the present study added quality value to spiced oven-dried fish products.

ABSTRACT
Arsenic is an environmental toxicant, and the exposure can occur through the workplace and food. due to arsenic toxicological effects, exposure to humans can cause degenerative disorders. this study examined the toxic effect of arsenic and the protective roles of ginger (zingiber officinale) on experimental rats exposed to arsenic. animals were divided into three groups: the control group that received the normal feed, the arsenic group fed with arsenic-contaminated feed, and the arsenic + z. officinale group that received arsenic-contaminated feed with zingiber officinale for 90 days. the animal's percentage weight, hematological analysis, biochemical evaluation, and dna damage in comet and micronucleus assays were determined. the results were analysed using the graph pad prism. results obtained revealed that co-administration of arsenic contaminated feed with zingiber officinale decreased the weight of the animals. when compared to zingiber officinale and control group, the results showed that exposure to arsenic for 90 days decreased the amounts of white blood cells and red blood cells. the result showed a significant increase in liver enzymes (ast, alt and ggt), and arsenic contaminated group also had higher levels of urea and creatinine than expected. normal and arsenic–contaminated groups in the treated group showed a significant difference. arsenic was shown to affect hepatocytes and caused dna damage in comet and increased %mnpce in micronucleus assay however co-administration of zingiber officinale restored the hepatocytes to normal and decreased the level of %mnpce. this study demonstrated that eating foods polluted with arsenic has toxicological consequences on the body but adding spices like zingiber officinale to regular meals can protect us from these effects.

INTRODUCTION
When compared heavy metals to water, the metallic elements with a comparatively high density of metals are referred to as heavy metals (Alam et al., 2020). Heavy metals also include metalloids like arsenic, which might have low toxicity when exposed to the environment and on the basis of its heaviness and toxicity (Luo *et al.*, 2020). The public health issues brought on by the environmental degradation by these metals have gotten worse in recent years. Due to the exponential rise of a variety of industrial, agricultural, residential, and technical applications, exposure to organisms has also substantially expanded (Proshad *et al.*, 2020).

Heavy metals are divided into two essential and non-essential categories. Essential heavy metals, also referred to as micronutrients, include; cobalt (Co), copper (Cu), chromium (Cr), iron (Fe), magnesium (Mg), manganese (Mn), molybdenum (Mo), nickel (Ni), selenium (Se) and zinc (Zn), and are needed for a variety of biochemical and physiological processes (WHO/FAO/IAEA, 1996)

One example of heavy metal is arsenic. It is a common element that can be found in soil, water, food, air and it comes from both natural and artificial sources, and it is also released into the environment. Arsenic consequences range from immediate death to long-term ones like cancer and cardiovascular disorder. Based on known or suspected toxicants, arsenic is ranked first among toxicants that pose a significant risk to human health (Zheng *et al.*, 2022).

The spice ginger (*Zingiber officinale*) is one of the most popular in the world. It has a long history of use as herbal remedy for conditions like indigestion, discomfort, vomiting, and cold-induced disorders (Zhang *et al* 2021). Ginger is well known for its antioxidant, and anti-inflammatory, and anticancer properties. The volatile oils and different phenolic compounds like gingerols, shogaols, zingerone, and gingiberols are regarded to be the active ingredients in ginger. One potential mechanism for scavenging oxygen free radical and reducing the generation of reactive oxygen species (ROS) has been identified as the antigenotoxic activity of ginger (Celik, 2020). This study was done to determine the toxicological effects of short-term exposure of rat to arsenic and protective role of ginger (*Zingiber officinale)*

MATERIALS AND METHODS

Plant collection and Identification: From the area of Sabo Baptist Church Market, in Ogbomoso, *Zingiber officinale* was gathered. It was blended into a powder at the market and packaged for the animal.

Experimental Animal: Seventeen male Wistar rats (weighing between 120-160grams) were bought from Mama Rat Animal Holding in Ogbomoso, Oyo State. Animals were maintained in polycarbonate cages and placed in the animal house under regular conditions. They have undergone two weeks of acclimatization in a chamber with 12hour light/12hour dark photoperiod schedule at a temperature of 32 ± 2°C. The normal group received only food, the second group received food infected with arsenic and the third group received food infected with arsenic + ginger

Contamination of feed with heavy metal: Feeds + Heavy metal (Arsenic) + Supplement or Spices (ginger)

Feed contamination is accomplished by combining the heavy metal and the feed's raw powder separately. Following the addition of spices, the final combination is then converted into granules for the rats to easily consume at the Ladoke Akintola University of Technology Ogbomoso animal house.

Biochemical analysis: Prior to biochemical analysis, the clot-filled blood in the lithium tubes was spun at 3000 g for 10 min to separate the serum (supernatant) and stored at −70 ◦C. WBC, HGB, HCT, RBC, PLT, and %LYM were the hematological parameters that the obtained blood was examined for using an auto analyzer. Standard techniques were used to evaluate the serum biochemical indicators, according to Constantino, Serum functional test indicators for the liver and kidneys were measured (Constantino, 2017). Utilizing HAICE®, DR 3000, (Germany), the absorbance for each reaction were determined spectrophotometrically. Jiraungkoorskul et al., 2007's protocol for the micronucleus and comet assay was followed.

Statistical Analysis: Microsoft Excel and Graph pad prism 5 were used for the statistical analysis. Analysis of variance was used to analyze the outcome (One way ANOVA).

RESULTS

Percentage change in body weight of rats fed with Arsenic-contaminated feed after 90 days of exposure.

Table 1: As shown in this table, the percentage weight growth of rats fed with arsenic contaminant feed decreased significantly from 30 days to 90 days as compared arsenic-contaminated with *Z.officinale* to normal group. There was a significant difference when compared arsenic to arsenic + *Z.officinale* after 90days of exposure.

	% Body weight gain		
Group	30days	60 days	90 days
Normal	21.66[a]	4.88[a]	4.26[a]
Arsenic-contaminated feed	27.91[b]	15.64[b]	12.17[c]
Arsenic-contaminated feed + Ginger	25.84[a]	15.39[b]	8.71[b]

Value was expressed as mean± SEM and considered significant at P value <0.05 after 30-90days of exposure

Normal control

a- Not significantly difference when compared treated group to normal

b- Significantly difference when compared arsenic and arsenic+ *Z.officinale* to normal

c- Significantly difference when compared the arsenic to arsenic+ *Z.officinale*

The effect of Arsenic and *Z.officinale* on the hematological parameters of Rats.

Table 2: The data from this table below indicated how *Z.officinale* and arsenic affected the rat's hematological parameters. After 90 days of exposure, the arsenic contaminated feed group and arsenic contaminated with *Z.officinale* group showed a significantly lower levels of WBC, RBC and other parameters as compared to the control group (p<0.05). After 90 days of rat exposure, there was no significant difference between the arsenic contaminated feed group and the normal control group in RBC, HGB and PLT (p<0.05). However, there was no significant different when compared arsenic and arsenic with *Z.officinale* in RBC, HCT and HGB.

Parameters	**Duration**	**Normal**	**Arsenic-contaminated Feed**	**Arsenic contaminated feed + Ginger**

Normal control

a- Not significantly difference when compared treated group to normal
b- Significantly difference when compared arsenic and arsenic+ *Z.officinale* to normal
c- Significantly difference when compared the arsenic to arsenic+ *Z.officinale*

The Effect of Arsenic and *Z.officinale* on the hepatic function and renal function levels.

Table 3: The results showed that, when compared arsenic contaminated feed group to normal group, the levels of AST, ALT and GGT increased significantly, however, in the arsenic contaminated with *Z.officinale*, the levels of AST, GGT and ALT significantly increased when compared to normal group. The results from this table demonstrated a substantial difference in urea level and creatinine level between normal group, arsenic-contaminated diet and arsenic contaminated with ginger. When compared to the normal group, the arsenic-contaminated group and the arsenic-contaminated with *Z.officinale* group both have higher levels of creatinine. There was a significant difference when compared arsenic-contaminated group and the arsenic-contaminated with *Z.officinale* group in AST and ALT but there was no significant different in GGT.

GROUP	**AST(μ/L)**	**ALT (μ /L)**	**GGT (μ /L)**	**UREA**	**CREATININE**
NORMAL	50.93±6.63	69.79±7. 10	56.45±2.65	30.91±1.32	90.00±16.21
Arsenic contaminated feed	123.50±46.07 [b]	156.50±38.75 [b]	60.77±1.94 [a]	50.71±0.56 [a]	125.50±23.67[b]
Arsenic contaminated feed +Ginger	98.80±60.15[b]	104.80±95.22 [b]	58.71±5.93 [b]	45.94±8.52 [b]	107.00±80.67[b]

Value was expressed as mean± SEM and considered significant at P value <0.05 after 30-90days of exposure

The Effect of Arsenic and *Z.officinale* on the %MNPCE and % tail DNA of Rats fed.

Table 4: The results of this study demonstrated that after 90 days of exposure to arsenic, the %MNPCE level in the normal group dramatically increased when compared to arsenic contaminated group but there was little difference when compared to arsenic with *Z.officinale* group, whereas there was no significant different when compared arsenic to arsenic with ginger . According to the comet results, after 90days of exposure, there was a significant difference

between the arsenic-contaminated group and the normal group, but not between the arsenic contaminated + *Z.officinale* group and the normal group, while there was a significant different when compared arsenic to arsenic with *Z.officinale*.

Parameters	Duration	Normal	Arsenic	Ginger
Comet	30days	13.85±0.37	15.88±1.34[a]	14.96±0.30[a]

DISCUSSION

Toxicants are ingested and are carried by the blood to many different organs, including the liver and kidney where they may have negative consequences in the body. In this study, the amount of weight growth experienced by rat fed with arsenic contamination and the healthy control group declines over time. According to recent studies, *Z.officinale* may help people lose weight and prevent obesity-related disorders (Suk *et al*, 2017). Hemolytic anemia, infections, inflammation-tissue necrosis and stress are examples of benign disorders that can result in Leukocytosis and thrombocytosis (Claire *et al.*, 2021). RBC, HTC and HGB levels in the exposed with arsenic rat group and arsenic+ *Z.officinale* group significantly decline with time from 30 to 90 days which is a sign of anemia which could be as a result of gastrointestinal tract bleeding suggesting that arsenic suppresses the immune system. According to Aysel *et al*, (2016), administration of arsenic+ *Z.officinale* result in the preservation of haematological parameters.

Because liver enzymes are secreted into the extracellular space by hepatocytes, they are employed as indictors of liver damage (Zhang *et al*, 2020). When hepatocytes are harmed or eliminated, the liver releases alanine and aspartate aminotransferases. When arsenic poisoning causes hepatocellular damage, the serum activity of these enzymes increases. Apart from the arsenic-contaminated diet mixed with *Z.officinale* in the exposed rat, liver enzymes AST and ALT were higher ($p<0.05$) in the arsenic exposed rat compared to the arsenic+ *Z.officinale* rat. According to Talpur *et al*, (2013), supplementing *Z.officinale* in rat diets as an alternative to antibiotics and therapeutic drugs had significantly as an additive and may improve the immune status of rats, however in GGT the exposed rats are significantly higher compared to arsenic+ *Z.officinale* rat. The arsenic contaminated exposed group shows a significant increase which trend in the exposure period of the rat when compared to arsenic+ *Z.officinale* rats. The micronucleus test is determined using %MNPCE in the blood of exposed rat and normal rat, arsenic-induced toxicity has been linked to a number of mechanisms, including the inhibition of several enzymes involved in DNA repair and expression, which are responsible for the types of genotoxic damage seen in this work (Andersen et al., 2018).

As a sensitive, quick and affordable method for detecting DNA strand breakage, the comet assay is an excellent non-specific indicator of genotoxicity in rats (Andersen et al., 2018). After 90 days, the amount of DNA damage found in the tissue of rats exposed to an arsenic contaminated diet increased. *Z.officinale* played a protective role which could lead to the decrease in the level of arsenic in the tissue which result in repaired DNA, the loss of cells with severely damage DNA, or both (Muller et al., 2021). The toxicology of a contaminant that could interfere with the enzymatic activities in the generation of DNA damage may be the cause of the inverse association between time of exposure and DNA damage (Muller et al., 2021).

CONCLUSION

These findings suggested that care should be given to long-term exposure to feed contaminated with arsenic. In this investigation, arsenic was specifically found in the rat liver as evidenced by the micronucleus assay that was carried out. *Z.officinale*, which has numerous biological properties including antioxidant, anti-inflammatory, antibacterial, anticancer, neuroprotective, hepatoprotective, cardiovascular protection, and antidiabectic, can be used to evaluate the degree of exposure and damage, potentially reverse these effects.

56th Annual Conference
Agricultural Society of Nigeria
24 - 28 Oct., 2022

ABSTRACT

Yam (Dioscorea spp.) is the second most important tropical root crop in West Africa after cassava. Postharvest loss, which has largely been associated with lack of appropriate storage systems, is the most common problem faced by smallholder yam farmers. The high level of yam postharvest losses has become a serious economic and food security threat. Existing yam storage structures have all that is required of improved storage structures but the cost is a great disincentive to farmers, which has greatly affected their adoption over the years. Case studies were reviewed, general and common practices analysed. The analysis was approached under a broad categorization of traditional and modern methods. The findings revealed many traditional and modern storage structures in use by farmers in Nigeria. The study discovered that lack of finance accounted for the predominance of traditional methods. It is recommended that fund should be made available to farmers at zero or minimal interest rates. Also, more efforts should be made to educate farmers on the benefits of modern storage techniques.

INTRODUCTION

Yam is an annual crop, so for it to be available throughout the year, harvested tubers must be stored for six to eight months before new yams are harvested. The possibility to store fresh yam tubers is decisively influenced by their dormancy which occurs shortly after their physiological maturity (wilting point). During dormancy, the metabolic function of the tuber is reduced to a minimum. It allows the tuber as an organ of vegetative propagation to overcome an unfavourable climatic period. (Knoth J. 1993). During the storage period a substantial amount of yam is lost. Some of these losses are endogenous, i.e. physiological, and include transpiration, respiration and germination. Other losses are caused by exogenous factors like insects, pests, nematodes, rodents, rot bacteria and fungi on the stored product (Wilson, 1980). Good management can easily control the exogenous loss factors while the environment controls other sources of loss. In addition, Umogbai, (2013) pointed out that successful storage of yams requires the use of healthy and sound tubers, proper curing if possible combined with fungicide treatment, adequate ventilation to remove heat generated by respiration of sprouts and rotted tubers that develop. Monitoring the presence of rodents and protection from direct sunlight and rain is also necessary. Yams can be best stored in a cool, dry and well ventilated surrounding. The review highlighted selected traditional and modern storage structures in use by farmers in Nigeria.

Storage Yam

Yam storage structures and methods were evaluated in different zones of Nigeria (Osunde,. and YIsa, 2000; Adejumo, 1998). They come in different shapes and sizes depending on the ability of the farmer, locality and cultural practices. The construction materials are usually wood, ropes, palm fronds, guinea corn stalks, and mud (FAO, 2004; Umogbai and Satimehin, 2004). The most common problems faced by farmers are post-harvest losses. Umogbai (2013) opined that wastage occurs because the apparent surplus during the harvest season cannot be consumed within a short period. However, few months after the harvest, there is always a diminishing availability of yam produce. Therefore, it becomes imperative that the existing yam tubers are stored in structures for later use.

According to Opara (1999), there are several traditional low-cost storage methods and structures for yam tubers; the most common of them include leaving the tubers in the ground until it is needed, storing under tree shades, yam barns, underground structures such as pits, ditches and mud structures. Umogbai (2013) and Okoedo-Okojie and Onemolease (2009) also reported that there are well ventilated weather-proof, insect and rodent proof strong shelters for storage of yam tubers.

Storage structures usually depend on the construction material available, amount of tuber produced, prevailing climatic condition of the area, purpose of yam tuber storage, socio-cultural aspects of storage and the resources of the farmer, in particular the availability of labour and capital. In most rural yam producing areas, yam is stored in a yam barn which is the principal traditional yam storage structure in the major producing areas. Barns are usually located under the shade and constructed so as to facilitate adequate ventilation while protecting tubers from flooding, direct sunlight and insect attack. There are several designs, but they all consist of a vertical wooden framework to which the tubers are individually attached (Opara 1999; Igbeka 1985).

Yam Barn Yam Crip

Tubers are tied to a rope and hung on horizontal poles 1-2 m high (Figure 1); barns up to 4 m high are not uncommon. Osunde and Yisa (2000) asserted that depending on the quantity of tuber to be stored, frames can be 2 m or more in length. The ropes are usually fibrous; in southeastern Nigeria they are made from the raffia obtained from the top part of the palm wine tree. Many farmers have permanent barns that need annual maintenance during the year's harvest. In these situations, the vertical posts are often made from growing trees which are trimmed periodically. Palm fronds and other materials are used to provide shade. The vegetative growth on the vertical trees also shades the tubers from excessive solar heat and rain (Opara 1999). Figure 2 is a typical yam barn constructed from guinea corn stalk, sticks, grass and yam vines. The yams are heaped at different positions in the barn (Ijabo and Jirgba 1989). Such barns are constructed every year and are situated near the house under a tree to protect the tuber from excessive heat.

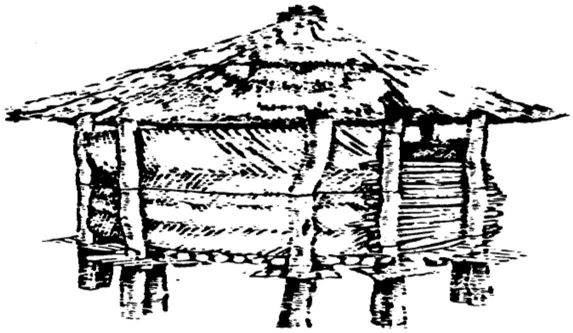

Figure 3: **Yam Houses**

Another yam storage structure found in the North central zones of Nigeria is the yam house (Opara 1999; Wilson 1980). "Yam houses" have thatched roofs and wooden floors, and the walls are sometimes made simply out of bamboo. They are raised well off the ground with rat guards fitted to the pillars. Yam tubers are stacked carefully inside the crib (Figure 3). Yam is also stored underground in trench or clamp silos. In both methods a pit is excavated and lined with straw or similar material (Nwankiti and Makurdi 1989). The tubers are then stored on the layer of straw either horizontally on top of each other or with the tip vertically downwards beside each other. The yams are then covered with straw or similar materials; in some cases a layer of earth is also added.

Modern yam storage

There are several improved yam storage structures which basically involves an improvement on the traditional storage structures already existing with numerous structural problems which marks their ineffectiveness. Traditional yam storage methods such as: delayed harvesting, pit storage, ditches, clamps and especially the yam barn which involves heaping yams on the barn floor makes yams vulnerable to attack by rodents and other mammals. Also, the method which involves tying individual yam tubers to the poles' framework is very tedious and can also restrict ventilation and consequently accentuate any tendency to deterioration. It is therefore, worthy of note that virtually all the improved yam storage methods represent attempts to overcome the shortcomings of the typical traditional storage methods.

i. The Open-Sided Shelves Store

This yam storage structure is similar to the traditional yam barn structure where yam tubers are tied to the framework. However, the design of the open-sided shelves store provides that the yam tubers will be placed in single layers on shelves rather than being tied to the framework.

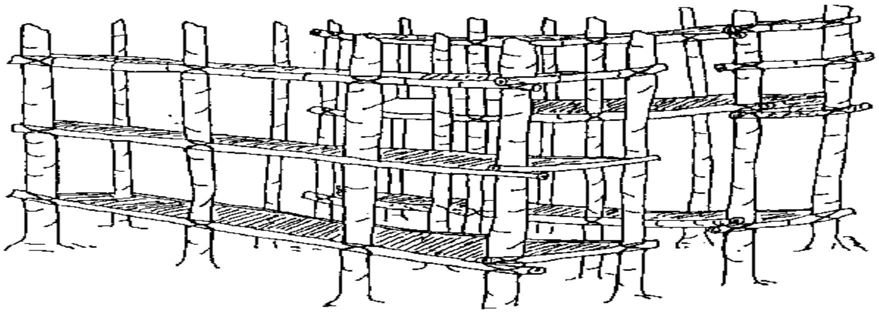

Figure 4: Simple Wooden Shelves for Yam Storage. Source: NISPRI (1982)

The Nigerian Stored Products Research Institute (NSPRI) who designed this yam storage structure opined that the structure ensures simple and easy operation in the storage and allows the stored yams to be handled more carefully so as to avoid the tediousity involved in tying the tubers to the framework and the consequent damage associated with it.

ii. The Ventilated-Pit Store or Ventilated Cellar

FAO (1998) submits that this yam storage structure was designed by the Department of Agricultural Engineering of the University of Nigeria, Nsukka, for the storage of fresh yam tuber. That the structure is a rectangular pit which is 2.9 meter long, 1.3 meter wide and 1.5 meter deep, with a capacity to accommodate 200 yam tubers placed on wooden shelves. According to Ezeike (1995), the pit is covered by a Cupola shaped galvanized sheet metal roof which serves to protect it from sun and rain.

Key: A= Door
B= Grilled openings
C= Chimney

Source: MFCL, GMC and NARI (2004)

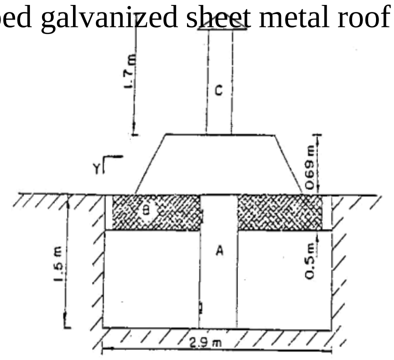

Figure 5: Simple Ventilated Cellar

Temperatures in the pit structure remained constant over the range of 21^{0}C to 24^{0}C, which is lesser than the temperature in the barn. The mean weekly relative humidity of the pit was consistently high and ranged from 83.9% to 93% (FAO (1998)

Weight Losses in Yams Stored Inside the Ventilated Pit Stores and the Yam Barn at Different Stages

Post-Harvest Stage	Weight loss due to respiration % per day	Total weight loss % per day	
		Ventilated Pit	Yam Barn
Harvest	0.08	0.25	0.25
Dormancy	0.02	0.17	0.27

Sprouting	0.07		0.23	0.35

Source: FAO (1998)

iii. The Thatched-roof Pit

This storage structure which is in other words known as the cellar-hut is noted to be similar to ventilated pit store, but with a significant variation which is a thatched roof as showed on figure 6 below.

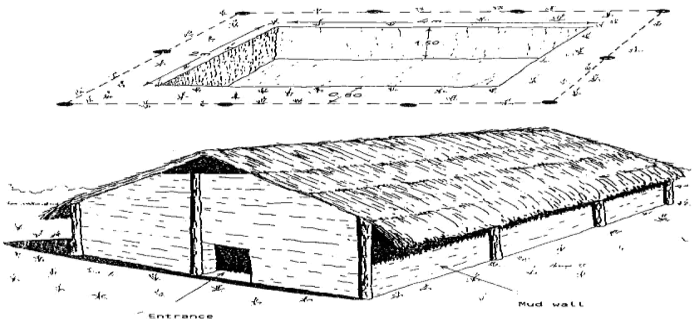

Figure 6: The Thatched-roof Pit or Cellar-hut Storage Structure. Source: MFCL, GMC & NARI (2004)

In regard to the effectiveness of this storage structure, MFCL et al (2004:6) observed that a high relative humidity is established inside the cellar-hut which results in less tuber weight loss.

iv. The Elevated Shed Store

The elevated shed store is also known as raised hut or yam house or crib. MFCL, et al (2004:6) noted that this storage structure can be made from locally available materials such as: wood, bamboo, straw, etc. and can hold about 3tons of yams. That the raised hut should be mounted on poles fitted with anti-rodent shields or guard. That the rodent guards consist of metal sheets that are wrapped around the poles supporting the structure, which its floor should be about 1 meter above the ground, as shown on figure 7 below.

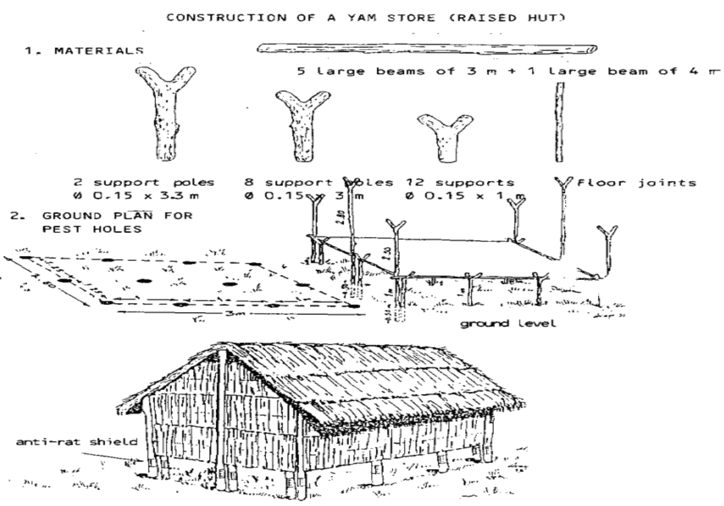

Figure 7 Construction of a Raised hut Storage Structure Source: MFLC, et al (2004)

Again, success has also been recorded in the use of other more advanced yam storage method like refrigeration. FAO (1998) established that refrigerated yam storage at about 15^0C in combination with the use of fungicides has been successful. However, there is no empirical statistics on the extent of the success or effectiveness of the method. The lack of data on refrigerated yam storage could be as a result of the lack of widespread adaptation of the method, to which the FAO have argued that the widespread use of cold storage of yams is not yet feasible because of the high capital cost and the need for a technical support structure. Nevertheless, with the combination of some yam storage application methods like Gamma radiation which has been successfully used to inhibit yam sprouting and reduce weight losses in tubers for up to eight months as shown in the works of Adesuyi (1982) and Demeaux, Babacauh and Vivier (1982), coupled with proper storage management practices, optimal results can always be recorded with the improved storage methods against the traditional yam storage methods.

CONCLUSION

Yam tubers are generally abundant and sold cheaply in the study zone at harvest, but later (especially during the planting season) they become scares and expensive. If yam could be stored without heavy losses, suppliers could become steadier, price would fluctuate less and farmers would be encouraged to grow their yam by being assured of steadier income. The study discovered that lack of finance accounted for the predominance of traditional methods and recommended that government should also help to subsidized modern storage facilities to the tuber farmers

ABSTRACT

This study evaluated the effect of different processing methods on the swelling power and water absorption capacity of stored flour processed from Orange fleshed sweet potato variety Umuspo1. The fresh roots were harvested, peeled, washed and divided into 4 equal portions for blanching, boiling, treating with metabisulphite and the last one without treatment. Each of the samples were further divided into 2 equal parts for oven and sun drying and thereafter packaged and stored for 3months. Analysis was carried out on the stored flour samples in interval of 1 month basis till end of storage period. The result obtained showed that there were significant differences (P>0.05) in the parameters of the flour samples evaluated Swelling power and water absorption capacity of the flour samples ranged from 13.27g/ml (Untreated sun dried) - 15.54g/ml (Untreated oven dried) while water absorption capacity ranged from 2.36% (boiled oven dried) -2.75% (untreated oven dried). There were steady decreases in the parameters evaluated across the storage period of 3months.
Key words: Flour, functional properties, sweet potato

INTRODUCTION

Sweet potato (*ipomea batatas Lam*) has been described as a food security crop owing to its appreciable quantity of an organic pigment called b-carotene as well as other nutrients such as vitamins, minerals, protein, dietary fiber and polyphenols (Motasa et al., 2015). Orange-fleshed sweet potato, a variety of sweet potato is a bio- fortified crop developed solely as part of global effort to checkmate vitamin A deficiency (Harvestplus, 2009). Post-harvest losses are minimized by processing sweet potato into flour, an intermediate product. This makes it available all round the season by extending its shelf life and also serve different purposes in food industries where they are used as raw materials in making confectionaries such as bread as well as thickening agent for soups and gravy, there by increasing its utilization(Eleazu and Ironua, 2013). The knowledge of Functional properties of flour are valuable as it gives an insight into its behavior when used in industrial food application. Functional attributes of flour are affected by processing methods (Osundahunsi et al., 2003), drying as well as pretreatment methods (Yadav et al., 2006, Maruf et al., 2010b). Sweet potato flour is usually stored for a period of time however different factors such as the moisture content, processing method and condition of the processing area as well as storage environment affects the storability (Kakichevsky et al., 2000). This study therefore aims at evaluating the effect of processing method on selected functional properties of the stored sweet potato flour.

MATERIALS AND METHOD

Fresh orange fleshed sweet potato variety, UMUSPO 1 (6kg) was harvested from the National Root Crops Research Institute (NRCRI) experimental farm. These roots were washed, peeled, diced (2.5mm) and divided into four portions for processing into flour using three pre-treatment methods: Blanching (5mins at 80 ^{0}C), boiling (till tender) and soaking with 0.5% sodium metabisulphite solution for 10mins. The fourth portion was untreated and was used as the control sample. All the samples were divided into equal parts for oven and sun drying. They were thereafter milled into flour and then packaged for further analysis. The flour samples were packaged in transparent polyethylene bags and stored at ambient temperature (30± 2ºC) (Ukpabi et al., 2014) and were evaluated for swelling power and water absorption capacity.

Swelling Power determination

The methods described by Li and Yeh (2001) was used in the determination of the swelling power of the stored flour samples. Swelling power is a measure of the hydration capacity of starch and is expressed as the weight of centrifuged swollen granules, divided by the weight of the original dry starch used to make the paste. About 2g of the samples was suspended in 10ml of water and incubated in a thermostatically controlled water bath at 95^{0}C in a tarred screw cap tube of 15 ml. the suspension was stirred intermittently over 30 minute's periods to keep the starch granules suspended. After this, the weight of the swollen sediment was determined.

Supernatant liquid (dissolved starch) was poured into a tarred evaporating dish and put in air oven 10 100^0 C for 4 hours.

$$\text{Swelling power} = \frac{W_2\ x\ 100}{W_{dm}\ (100 - Solubility)} \qquad (1)$$

Water absorption capacity determination

The method described by Onwuka (2005) was used in determining the water capacity of the samples. Exactly one gram (1.0g) of each sample was weighed into a graduated 15ml centrifuge tube and 10ml distilled water was added. The flour samples were mixed thoroughly and allowed to stand for 30 minutes at room temperature and centrifuged at 2000-5000rpm for 30 minutes. The volume of free water was then determined (the supernatant was read directly from the graduated centrifuge tube).

Calculation

$$\text{Water absorption capacity} = (V_1 - V_2)\ \text{ml/g} \qquad (2)$$

Where

V_1 = initial volume of water before centrifugation.

V_2 = final volume of water after centrifugation.

RESULTS AND DISCUSSIONS

Table 1: Effect of storage on swelling power (g/ml) of OFSP flour

Sample	Month 0	Month 1	Month 2	Month 3
UOD	15.54 ^{a} ±0.00	15.45 ^{b} ±0.01	15.40 ^{c} ±0.01	15.32 ^{c} ± 0.06
MOD	15.54 ^{a} ±0.01	15.34 ^{b} ±0.01	15.20 ^{c} ±0.02	14.91^{d} ± 0.04
BOD	14.29 ^{a} ± 0.01	14.25 ^{a} ± 0.04	14.22 ^{b} ± 0.04	14.08 ^{c} ± 0.06
BoOD	13.59 ^{a} ± 0.01	13.57 ^{a} ±0.01	13.57 ^{a} ± 0.02	13.54 ^{b} 0.02
USD	13.27 ^{a} ±0.01	13.15 ^{c} ±0.00	13.24 ^{b} ± 0.01	13.12 ^{c}± 0.04
MSD	13.37 ^{a} ±0.04	13.30 ^{b} ± 0.03	13.25 ^{c} ±0.00	13.24 ^{d} ±0.01
BSD	13.50 ^{a} ±0.01	13.49 ^{a} ± 0.01	13.48 ^{a} ±0.00	13.43^{b} ± 0.01
BOSD	13.32 ^{a} ±0.06	13.29 ^{a} ±0.04	13.20 ^{b} ±0.01	13.17^{c}±0.00

The values are means ± Standard Deviation of three determinations. For each variety, means with the same superscript across the row are not significantly different (p<0.05)

UOD = untreated oven dried, MOD = metabisulphite treated oven dried, BOD = Blanched oven dried, BoOD = Boiled oven dried, BSD = Blanched sun dried, BoSD = Boiled sun dried, USD = Untreated sun dried, MSD = Metabisulphite treated sun dried. The effect of storage in the swelling power of the flour samples is represented in Table 1 and the result showed that at 0 month, all the samples had high swelling power ranging from 13.27g/ml in untreated sun-dried sample to 15.54g/ml in untreated oven dried sample at 0 month. There was no significant difference in the swelling power of untreated oven dried sample and metabisulphite treated oven dried sample at 0 month. As storage progressed from 1st to the 2nd month, decreases were observed in the samples except in boiled oven dried and blanched sundried samples which showed no significant difference in the swelling power of these samples from 0-2nd month. At the end of storage period (3 months), it was observed that all the samples had reduced swelling power indicating that storage had a significant effect in swelling power of the flour samples during storage. This is supported by Katekhong and Charoenrein (2012) in his work on rice flour sample as starch granules of stored flour are resistant to swelling when compared to fresh flour samples hence the ability to soak more water and swell up is reduced as storage progressed

Table 2. Effect of storage on water absorption of capacity (%) of OFSP flour

Sample	Month 0	Month 1	Month 2	Month 3
UOD	3.05 ^{a} ±0.07	3.00 ^{b} ±0.00	2.85 ^{c} ±0.07	2.75 ^{d} ± 0.07
MOD	2.95 ^{a} ± 0.07	2.95 ^{a} ± 0.07	2.75 ^{b} ± 0.07	2.70 ^{c} ± 0.00
BOD	2.75 ^{a} ± 0.07	2.65 ^{b} ± 0.07	2.45 ^{c} ± 0.07	2.40 ^{d} ± 0.00
BoOD	2.63 ^{a} ± 0.07	2.60 ^{b} ± 0.00	2.40 ^{c} ± 0.07	2.36 ^{d} ± 0.85
USD	2.90 ^{a} ± 0.00	2.85 ^{b} ± 0.07	2.65 ^{c} ± 0.07	2.51 ^{d} ±0.01

MSD	3.00 ^{a} ± 0.00	2.95 ^{a} ± 0.07	2.85 ^{b} ± 0.07	2.70 ± 0.00
BSD	2.85 ^{a} ± 0.07	2.65 ^{b} ± 0.07	2.60 ^{c} ± 0.00	2.45 ^{d} ± 0.20^{d}
BOSD	2.80 ^{a} ± 0.00	2.65 ^{b} ± 0.00	2.35 ^{d} ± 0.0	2.45 ^{c} ± 0.07

The values are means ± Standard Deviation of three determinations. For each variety, means with the same superscript across the row are not significantly different ($p<0.05$)

Oil absorption capacity of stored flour is shown in Table 2. The values obtained showed that storage caused a significant difference ($p<0.05$) in the water absorption capacities of the flour samples during storage. All the samples showed a steady decrease in their water absorption capacities from 0month – 3rd month however, untreated oven dried sample had the of highest WAC 2.75% while boiled oven dried sample had the least value of 2.36% at the end of storage. Blanched and boiled sun dried flour samples recorded the same WAC at the end of the storage period. Water absorption capacity is used to describe the ability of the flour samples to absorb water and swell as this helps for improved consistency in the food. (Osundahunsi *et al.,* 2003; Malomo *et al.,* 2012). It is also used to describe the degree of interaction of the starch granules of food with water (Ruales *et al.* 1993). Reduction **o**bserved in water absorption capacities of the flour samples at the end of storage period may be due to the increased moisture content values of the flour samples and the corresponding associative force which occurs within the granules of the starch during storage

ABSTRACT

The study was conducted to determine the effects of hydrothermal treatments on the proximate and some mineral compositions of cassava peels. Three dry samples of cassava peels were treated as raw (A), heated in water at 60°C (B) and 80°C (C) respectively, dried and ground into powder. Standard methods of analysis were used to determine the parameters. The results showed the following values for proximate compositions (%) for A, B and C respectively:. There were increase in the concentrations of crude protein from 4.75 in A to 5.48 in C , crude fibres from 2.40 in A to 2.59in C , ash contents from 6.88 in A to 8.10 in C and mineral elements (insert the name and value minerals here) determined as the temperature increased. It could be concluded from the results that generally, the nutritional qualities of the cassava peels increases with the temperature of treatment though they did not meet the standards required for farm animal in some cases

INTRODUCTION

Rearing of animals for domestic and commercial purposes these days usually involves the provision of adequate feedstuffs for the animals andone of such feedstuffs that serveas sources of nutrients for feeding ruminant animals today is cassava peel. According to Anaeto *et al.* (2013), Cassava peels form the bulk of residue from cassava root after post-harvest and processing. It is a good source of energy in ruminant feeding systems, serving either as the main basal diet or as a supplement. The processing of cassava tubers yields cassava peels which is a by-product that is valuable ruminant feeds when properly processed (Aro *et al*.,2010). Cassava (*Manihot esculentus*)is a tuberous root crop belonging to the family *Euphorbiaceae***,** genus *Manihot.* Carbohydrate, protein, vitamins, and minerals are all found in its roots and leaves (Bayata, 2019). Cassava peels derived from *garri* processing are normally discarded as wastes and allowed to rot in the open, thus resulting in health hazards(Antai and Mbongo, 1994). Since these peels could make up to 10% of the wet weight of the roots, they constitute an important potential resource for animal feeds if properly processed by a bio-system (Antai and Mbongo, 1994).

There are reports of different methods being used for the processing cassava peel to improve its nutrient contents. However, there is no record of the use of hydrothermal treatment, at different temperatures, to find out if there will be improvement or otherwise in the nutrient content of cassava peel. This study, therefore, sets out to bridge this gap by using hydrothermal treatment at different temperatures and evaluate the effects of the treatments on proximate and some mineral element compositions of cassava peel and determine if there is improvement or not on nutritional quality of cassava peel.

MATERIALS AND METHODS

Area of the study: The study was carried out at the Research Laboratory of Oyo State College of Agriculture and Technology, Igboora, Oyo State, Nigeria.Igboora is located in derived Savannah Zone of 7°15' North and 3°30'East of the Equator with an average annual rainfall of 1278mm and an annual temperature of 27°C (Akamigbo, 2010).

Sample and sample treatments: Cassava peels were obtained from cassava (*Manihot esculenta)* uprooted (from College Farm of Oyo State College of Agriculture and Technology, Igboora, washed and peeled. The cassava peels were again properly washed with water and air-dried for four weeks. The air-dried cassava peels were divided into three portions (1kg each) to form three treatments used in the study. A portion of the samples was not treated (raw) and served as control while the other two portions were heated in water (hydrothermally treated) at 60°C and 80°C respectively.The hydrothermally treated sample were removed from water and air-dried. Thereafter, the three samples were pulverized using the hammer mill and stored in air tight containers until required for chemical analysis.

Proximate composition analysis: Proximate composition analyses were carried out on the three samples to ascertain the differential composition of the various nutritional components and their concentrations the amount in which they are compose The following nutritional parameters were determined as proximate composition: ash content,moisture content, crude fat, carbohydrate,crude fibre, total protein and mineral composition.The official method of AOAC (2005) was used to determinethe moisture contents, while Tecator Digestion System and Kjeltec Auto 1030 Analyzer (Tecator AB, Sweden) wasused to determine the protein contents. The Soxtec SystemHT method (Tecator Soxtec System HT 1043 Extraction Unit, Tecator AB, Sweden) was used to determine the fatcontents. The AOAC (2005) official method was used to determine the ash contents. The crude fibre contents weredetermined in accordance with AOAC (2005).

The valueof 5.95 was used as protein conversion factor during calculation.Protein yields were thus calculated as follows: The value of 5.95 was used as protein conversion factor during calculation. Protein yields were thus calculated as follows:

$$\text{Yield (\%)} = \frac{\text{weight (g) of PBPI} \times \text{protein content (\%) of PBPI} \times 100}{\text{10 g (weight of DPB)} \times \text{Protein content (\%) of DPB}}$$

The carbohydrate content was determined by difference, after addition of all the percentages of moisture, fat, crude protein, ash, and crude fiber and was subtracted from100%.

Carbohydrate (%)=100 −[protein (%) + Moisture (%) + Ash (%) + Fiber (%) + Fat (%)].This gave the amount of nitrogen-free extract otherwise known as carbohydrate content.

Mineral analysis: The official method of AOAC (2005) was adopted for the mineral analysis of the samples: the samples were previously ash in a furnace for 5 h at 600°C, and then refluxed with 20% hydrochloric acid. The mixture was filtered into a 100 mL standard flask; the filtrate was then made up to the mark with deionized water. Sodium(Na) and potassium (K) levels of the samples were ascertained using a flame emission photometer with NaCl andKCl as standards. All other metals were determined byatomic absorption spectrometry (AAS).

Statistical analysis: All values are presented as the mean ± standard error of two replicate analyses. For multiple comparisons, the data were analyzed by one-way ANOVA followed by Tukey's posthoc test (GraphPad Prism. 5.03, La Jolla, CA). The differences were considered significant at $P < 0.05$.

RESULTS AND DISCUSSION

Table 1: Proximate composition of raw and hydrothermally treated cassava peel

Proximate (%)	Raw samples	Hydrothermally treated samples	
		60°C	80°C
Crude protein	4.75±0.00	5.07±0.02	5.48±0.01
Crude fat	2.40±0.00	2.21±0.05	2.59±0.00
Crude fibre	6.88±0.01	7.25±0.00	8.10±0.01
Ash	3.49±0.01	3.61±0.01	3.74±0.02
Moisture contents	10.11±0.01	9.90±0.00	9.80±0.05
Carbohydrates	72.37±0.02	71.96±0.01	70.29±0.01

Data were expressed as mean ± SD.

ND = Not determined

Table 1 showed the results for the proximate compositionsof raw and hydrothermally treated cassava peels. Proximate composition is animportant criterion to determine the nutritional values and quality of food (Qayyum *et al*., 2012).The high protein content of sample heated at 60°C and 80°C could be attributed to the heat effects on the samples which increase the composition and availability of protein the sample by inactivating antinutritional factors. It is on record that dietary proteins plays important roles in natural synthesis and maintenance of body tissues, enzymes, and hormones as well as other substances required for healthy functioning (Hayat *et al*. 2014). The crude fibre (cell wall contents) fractions of the raw cassava peels were not as high as the values for the hydrothermally treated samples and the highest crude fibre were obtained at 80°C. This suggested that blanching cassava peel may improve the fibre content and its digestibility thereby promoting its use in livestock production. The higher ash contents of the samples heated at 60°C and 80°Cas compared to the raw sample is also an indication that heat treatment was able to free some antinutrient-bound mineral elements since high ash contents is an indicationthat a sample contains abundant mineral content (Iqbal *et al*., 2012).The lower moisture contents of heat treated samples when compared to that of the raw sample is desirable because high moisture content encourages the growth of bacteria and mould, which could reduce stability and shelf storage capability. The low moisture contents will therefore increase the shelf life of the samples. The low moisture contents may be as a result of enhancement of soluble proteins into the blanching water of the hydrothermally treated samples (Lola, 2009). The higher fat content of the heat treated sample as compared to the raw sample is, however, not desirable The low carbohydrate contents of the heat treated sample could be beneficial to likely diabetic animals with increased serum lipid levels.

Table 2 shows the results of mineral element concentration of raw and hydrothermally treated samples. The results revealed that both raw and hydrothermally treated cassava peels contained macro/micro minerals in varying amounts as evidenced in the concentrations obtained. The values obtained for all the treatments were lower than the standards for farm animals quoted by Lee (2009), there were improvements in the quantities of the minerals when the samples were blanched at 80^{o}C (Table 2) Minerals are good for maintaining proper body function and good health. Deficiency of minerals leads to increased susceptibility to infectious diseases due to weakened immune systems. Kermanshah *et al.* (2003) and Mlitan(2014) reported that ‘’iron is an essential trace element for haemoglobin formation, normal functioning of central nervous system and in the oxidation of carbohydrates protein and fats’’. It also plays an active role in oxygen transfer in the body and low iron content causes gastrointestinal infection, nose bleeding myocardial infection. According to Longo and Camaschella (2015) iron deficiency results in anaemic condition when there is decreased level of red blood cells as a result of significant reduction of iron content in the animal body. The appreciable copper content of the heat treated sample at 80^{0}C implies that it is a good source of copper. Copper plays a fundamental role in cellular metabolism as it serves as cofactors for various important enzymes to function properly as well as in the formation of hemoglobin, myelin, and melanin, where it has been identified toplay an essential role. Added to this, copper may also act as an antioxidant or a prooxidant. Zinc is an essential trace element which plays an important role in various cell processes including normal growth, brain development, behavioural response, bone formation and wound healing (Ullah *et al*., 2012). A deficiency in zinc results increased rate of diarrhoea, delayed wound healing process, impaired immune function and some psychological disorders (Lonneral,2000). Calcium is the major component of bone and assists in teeth developments, essential for blood coagulation and the integrity of intracellular cement substances (Ullah *et al*., 2012). Deficiency of calcium also known as hypocalcaemia leads to diseases such as osteoporosis and osteopenia. The macro metals concentrations obtained in this study for raw and hydrothermally treated peel were relatively low (Prasad, 2013). It is on record that calcium also enhances the effective use of iron in the system (Adeyeye, 2013). Iron is also an essential mineral element present in in adequate amount in sample treated 80°C, but this element is required for a number of biological functions, including proper functioning of the immune system, electron transfer reactions, gene regulation,cell growth and differentiation as well as binding and transport of oxygen (Siddiqui *et al*., 2014). (Piero *et al*. 2012; Akhuemokhan *et* *al*. 2013; Khan and Awan, 2014). The contents of zinc present in the samples treated at 80°C and 60ºC were higher than that of the standard (Table 2)

CONCLUSION

In conclusion, this study has shown that hydrothermal treatments had significant effect in the enhancement of nutritional components and mineral elements of cassava peels. Hydrothermal treatment at 80°C was found, in this study, to be the most effective method in the enhancement of nutritional components and mineral elements of cassava peels. It is hereby recommended that cassava peel, when hydrothermally treated,can be effectively incorporated in livestock feed as energy and mineral sources. There is the need for future research in the same manner to ascertain whether at temperature above 80°C the nutritional and mineral elements concentration will be improved upon.

ABSTRACT

Every crops is unique in its way in that it comes with a different nutrient content and the nutrients are altered based on the processing method adopted during preparation. Two varieties of Xanthosoma sagittifolium, ede ocha (NXs001 (white flesh) and ede uhie (NXs002 (purple flesh), were purchased from Ndi oru market Umudike, Abia State. Two different pretreatment methods where one portion was blanched in hot water at 95^{O}C for 5 min (NXs 001B) and the other portion was soaked in 0.3 % sodium metabisulphite solution for 30 min (NXs 001S). The same was done for xanthosoma NXs 002 (ede uhie), thus having three from ede ocha. Also same pretreatment was done for ehe uhie to get NXs 002C, (Control sample with no treatment), NXs 002B (Blanched sample) and NXs 002S (treated with 0.3% sodium metabisulphate) . They were processed into six flour samples. The resultant flour samples were used for proximate and phytochemical determination. The result generated indicated that the treatment method caused a significant different in the proximate composition with an increase in the moisture, protein. Fiber, ash and a decrease in the carbohydrate content for both ede ofe and ede uhie .The treatment method brought a reduction in the phytochemical content for all samples investigated. The study suggest that the adoption of blanching and sodium metabisulphate as a method of processing flour is recommended to reduce the anti-nutrients

INTRODUCTION

Cocoyam (*Colocasia esculenta and Xanthosoma sagittifolium)* is an herbaceous perennial that belong to the family *Araceae* and the edible root is the main purpose of growing coco yam. The corms and cornels are edible starch (Rashmi *et al*., 2018). Africa is the largest producer of cocoyam with Nigeria and Ghana taking the lead. Over 30-40 species of cocoyams have been identified but only few of about 5 to 6 species are edible because they produce edible parts (Obongekpe 2020). Two genera of cocoyam are widely cultivated in Africa-which are the taro (*Colocasia esculenta*) and tannia (*Xanthosoma sagittifolium*). The nutritional values of a crop plays a vital role in considering it as a food source. Several factors influence the nutritional content of food. These include the genetic make-up of the plant, agronomic practices adopted during planting, maturity at harvest, storage conditions and method utilized for processing (Adesina *et al*., 2020.) The presence of anti-nutrients in coco yam has been a source of major concern to human health (Ukom and Okorue 2018).

Processing method such as cooking heating are known to partially removed, reduced or completely inactivate most anti nutrients find in coco yam (Suhag et *al*., 2021). Processing (cooking) can be both beneficial and detrimental to nutrient composition of foods. This is true because the processing techniques adopted may decrease the food quality of the original crops (Kumar. and Kalita 2017). It may enhance the nutritional quality of the food by destroying some of the harmful anti- nutrient available thereby, improving the digestibility of protein and starch (Ertop, and Bektaş 2018).Objectives of the study were the evaluation of effect of varietal differences and treatment method on the proximate content and the phytochemical composition of *xanthosoma sagittifolium* flour

MATERIALS AND METHODS

Two varieties of *Xanthosoma sagittifolium*, NXs 001 (ede ocha (white flesh) and NXs 002 (ede Uhie (purple flesh), were purchased from Ndi oru market Umudike, Abia state. The samples NXs 001 (ede ocha) and NXs 002 (ede uhie) were sorted, peeled, washed and cut into 2 mm slices and each was divided into 3 equal parts of 500 grams to be processed using 2 different pretreatments and the first portion serve as control. For *xanthosoma* NXs 001 (ede ocha) the first portion served as Control (NXs 001C), then pretreatments were done in two parts. One was blanched in hot water at $95^{O}C$ for 5 min (NXs 001B) and the other portion was soaked in 0.3 % sodium metabisulphite solution for 30 min (NXs 001S). The same was done for *xanthosom*a NXs 002 (ede uhie), thus having three samples; NXs 002C, (Control sample with no treatment), NXs 002B (Blanched sample) and NXs 002S (treated with 0.3% sodium metabisulphate). The samples were later dried at 70°C for 6 hrs and milled in attrition mill, sieved and stored in an air tight container for further use. Anti-nutritional factors and proximate composition were determined with the method as described by AOAC (2012).

Data generated were subjected to statistical package IBM SPSS Programme version 22. Results were expressed as mean ± standard error of mean (SEM). One-way analysis of variance (ANOVA) with Duncan post hoc test were used to evaluate the statistical difference between the different groups. The graph was done with graph pad prism 5.

RESULT AND DISCUSSIONS

The results in Table 1 showed that moisture content, protein, fiber, fat, ash and carbohydrate which ranged from 6.18% to 8.70%, 4.90% to 6.42%, 3.10% to 5.00%, 0.22% to 1.13%, 3.80% to 7.18% and 74.67% to 81.73% respectively. The result showed that the treatment methods improved the proximate composition. The reduction as seen in the blanched samples can be attributed to denaturation of the protein of the flour during blanching and diminution of the protein solubility of the cocoyam flour due to the heat treatment (Liu, *et al*., 2019). The fat content ranged from 0.59 to 1.13 and 0.17 to 0.36 for the white and purple *xanthosoma.* The result showed that treatment by blanching and sodium metabisulphate caused an increase in the fat content of the flour samples. The values were relatively comparable with the average crude fat contents (0.22-0.85%) of cocoyam as reported by Wada et al. (2019). Pretreatment of the samples brought an increase in the parameters tested, however, pretreatment brought about a progressive decrease in the carbohydrate content of treated samples. This is in line with the finding of Ndagui *et al.*, 2014. The moisture content is within the acceptable limit, thereby making the samples storage stable, which will encourage a longer shelf life

Table: 1. Effect of Treatment on the Proximate of *Xanthosoma* species

Sample	Moisture%	Protein%	Fiber%	Fat%	Ash%	CHO%
						White xanthosoma
NXs 001S	7.42±0.06^{a}	5.34±0.01^{a}	4.20±0.00^{a}	1.13±0.04^{a}	4.78±0.03^{a}	77.13±0.00^{c}
NXs 001B	6.81±0.01^{b}	4.90±0.03^{b}	3.76±0.01^{b}	0.90±0.02^{b}	4.33±0.03^{b}	79.30±0.00^{b}
NXs 001C	6.18±0.04^{c}	4.60±0.08^{c}	3.10±0.03^{c}	0.59±0.02^{c}	3.80±0.00^{c}	81.73±0.00^{a}
						Purple xanthosoma
NXs 002S	7.53±0.04^{c}	6.43±0.03^{a}	3.83±0.04^{c}	0.36±0.01^{a}	7.18±0.04^{a}	74.67±0.00^{a}
NXs 002B	8.11±0.01^{b}	5.26±0.08^{b}	4.64±0.04^{b}	0.22±0.00^{b}	6.73±0.04^{b}	75.04±0.00^{b}
NXs 002C	8.70±0.01^{a}	4.90±0.14^{c}	5.00±0.00^{a}	0.17±0.01^{c}	4.92±0.04^{c}	76.31±0.00^{c}

Values are mean± SD of 3 replications .Means within a column with the same superscripts were not significant difference (P>0.05). Key: NXs 001C (ede ocha), NXs 001B (ede ocha blanched), NXs 001S (ede ocha treated with sodium metabisulphate), NXs 002C (ede uhie control), NXs 002B (ede uhie blanched), NXs 002S (ede uhie treated with sodium metabisulphate

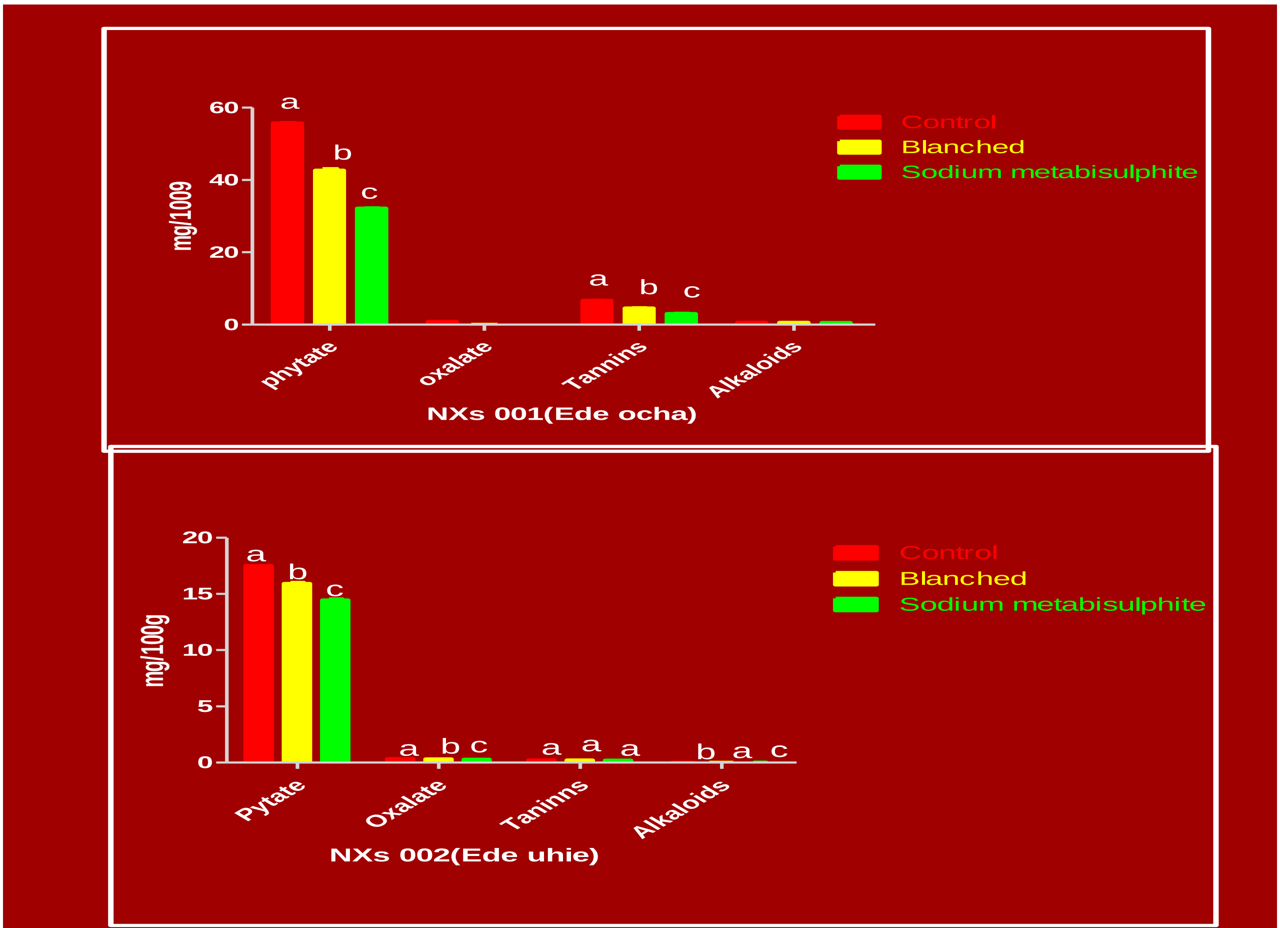

Fig. 1 Effect of variety and methods of treatment on phytochemicals

Fig. 1 showed the phytate, tannins and the alkaloid content of NXs001 ede ocha which recorded high values than the ede uhie NXs002, which ranged from 32.19 to 55.76, 3.04 to 6.75, 0.55 to 0.69 for ede ocha and 14.45 to 17. 52, 2.04 to 2, 48 and .27 to 0.42 respectively. There values varied significantly. Both treatment method caused a reduction in the anti-nutrient investigated. Phytate content is high in the ede ocha and ede uhie when compared with the other anti-nutritional factor investigated. This variation can be attributed to the varietal differences as reported by Calle *et al*. (2021) Phytate phosphorous is unavailable to human, but its presence lowers the availability of many other dietary minerals such as iron and zinc

CONCLUSION

Based on the results generated from this study, it is therefore concluded that subjecting different *xanthosoma* species (NXs 001 and NXs 002) to blanching and sodium metabisulphite as pretreatment methods have significantly changed and improved the nutritional parameters investigated as evidenced in the results generated

PROCEEDINGS
56th Annual Conference
Agricultural Society of Nigeria
24 - 28 Oct., 2022

ABSTRACT
Agricultural sector is a strong driver of the Nigerian economy. It employs about 70% of the nation's labour force and has the capacity to alleviate poverty, improve nutrition, health and ensure food security. Investment in agricultural sector enhances economic growth of a country which brings about food security. This paper reviewed Pro-vitamin A cassava: processing produce into products for nutrition and health in Nigeria. The methodology adopted for this study was entirely theoretical; hence there was no indication of quantitative analysis or data. The study found out that Nigeria is one of the countries in the world with serious micronutrient malnutrition problems, and also has the highest number of stunted children in sub-Saharan African. Hence processing pro-vitamin A cassava produce into products like garri, fufu, abacha, cassava bread, cake and chips will reduce the level of malnutrition and stuntedness, thus improving nutritional and health status of her citizen. The paper recommended that the extension linkage with research should be strengthened so as to facilitate the spread of improved cultivars and management practices to farmers. The involvement of more cooperative societies in the multiplication and sales of stems should be encouraged. Also effective integration of information and supply of various inputs is highly recommended.

Keywords: Pro-vitamin A cassava, Processing, Produce, Products, Nutrition and Health

INTRODUCTION
There are many challenges confronting the world, but hunger and malnutrition are two major food issues confronting policy makers and governments due to their link to food insecurity and health (International Institute for Tropical Agriculture (IITA), 2009; Saad, 2009; Anugwa and Agwu, 2019).
Food must be acceptable, affordable, and available to consumers, and consumers must have the resources, knowledge, and correct mindset to purchase and consume these foods (Ogbonnaya, Oteh and Agwu, 2020).

Regrettably, Nigeria is one of the countries in the world with serious micronutrient malnutrition issues leading to major public health especially among vulnerable groups of young children and pregnant women.(Agwu, 2011). In Nigeria, more than 14 million people representing 8.5% of the population are undernourished, based on a 2014 report of the National Health Component of the National Strategic plan Action for nutrition (2014 – 2019). In addition Nigeria has the highest number of stunted children, estimated at 10million in Africa; 37% of these children under the age of five are stunted, 29% are under weight and 18% are wasted (Agwu, 2011, Nwajiuba, 2013). At the global level approximately 250,000 to 500,000 malnourished children in the developing world go blind each year from a deficiency of vitamin A, half of whom die within a year of becoming blind (Adesina, 2011).

The prevalence of night blindness due to vitamin A deficiency is also high among pregnant women in many developing countries. Vitamin A deficiency also contributes to maternal mortality and other outcomes in pregnancy and lactation (Adesina, 2011). Stunting rates are highest in Asia and sub-Saharan Africa. Once established, stunting and its effects typically become permanent. Stunted children may never regain the height lost and most will never gain the corresponding weight. And when the window of early childhood is closed, the associated cognitive damage is often irreversible. UNICEF reports show that 43% of under five children in Nigeria are stunted. This is high when compared to 39% for all developing countries. (Adesina, 2011).

Annually, Nigeria loses over US$1.5billion in GDP to vitamin and mineral deficiencies as many staple foods are low in essential micronutrients (Adesina 2011). These challenges arise as a result of a combination of poor awareness of dietary requirements, feeding practices, and high levels of poverty (Agwu, 2011; Nwajiuba, 2013).

Poor diet is an important factor of vitamin-A deficiency in Nigeria, where rural dwellers consume mostly local staple food crops with relatively low micronutrients, with cassava constituting a major staple in Africa and specifically in Nigeria. Cassava production in Africa is the largest in the world, representing about 54% of global cassava production, while based on country production; Nigeria is the largest cassava producer (Wossen et al., 2017). Significant proportion of vulnerable groups such as rural women of child-bearing age and children whose diets consist mostly of cassava (and cassava by-products) are potentially at risk of vitamin-A deficiency, leading to efforts being intensified to develop and distribute vitamin-A-enriched cassava varieties across Nigeria through a process known as bio-fortification (De Moura et al., 2015).Bio-fortification is an innovation commonly in use now aimed at improving the diet quality of nutritional vulnerable groups, such as children and women. It is recommended where complementary foods do not provide enough essential nutrients(De Moura et al., 2015)..

Cassava and Pro – Vitamin A Cassava in Nigeria

Cassava (*Manihot esculenta*) is one of the staple crops cultivated by both small and large scale farmers in Nigeria and is of strategic importance to the economy of the country. Nigeria is the highest producer of cassava in the world with an estimated annual production of 59,485,947 metric tons (FAO, 2018). The importance of cassava to the livelihoods of many millions of the poor people has made the crop a target for intervention (Agunannah, 2021). The potential of the crop is numerous because it offers the cheap source of food calories and the highest yield per unit area. Cassava has multiple roles as famine reserve, food and cash crop, industrial raw material and livestock feed (Osipira-Patino and Ezedinma, 2015). Across the country, cassava production has undergone a tremendous increase for different reasons, specifically due to introduction of high yielding and disease-resistant varieties, early maturing ones, among other factors (Sanni, Onadipe, Ilona-P, Mussagy, Abssa, and Dixon, 2009). Unfortunately, the conventional white fleshed cassava is not rich in the micronutrient pro-vitamin A to address the double burden of malnutrition, despite the fact that it is a choice food among more than half a billion people around the world and serves over 200 million in Africa; second to maize in its calorie contribution (Talsnia, et al., 2016; FAO, 2011). Cassava has a comparative advantage over other staples and attracts poor resource farmers who constitute the bulk of supplies (Moon et al, 2004; Bamidele et al., 2008) hence the need for biofortification improvement. Biofortification is the practice of deliberately increasing the content of an essential micronutrient (vitamins, minerals including trace elements) in a food, so as to improve the nutritional quality of the food supply and provide a public health benefit with minimal risk to health, through agronomic practices, conventional plant breeding or modern biotechnology (WHO, 2019).

Biofortification is considered to be sustainable because it requires a onetime investment that further allows farmers to continuously grow the micro-nutrient rich planting material for years to come, at no more cost than the regular crop would cost. Biofortification of staple foods such as cassava, rice, beans, wheat, maize and sweet potato indirectly target low-income households who cannot afford a more diverse diet and who live in rural areas where supplementation programmes cannot reach or cannot afford fortified products (Huffman and Mccluskey, 2014; Agunannah, 2021). According to Randall and Sanjur (1981) biofortified yellow cassava contains vitamin A and results in public health gains. Today, bio-fortification provides one of the best ways to achieve improvements in nutrition.

Crop breeders at the National Root Crops Research Institute (NRCRI) in collaboration with International Institute of Tropical Agriculture (IITA) and the International Centre for Tropical Agriculture (CIAT) under the funding from Harvest Plus Programme have worked assiduously to develop cassava varieties that serve as sources of vitamin A. These pro-vitamin A or beta carotene varieties of cassava would go a long way in correcting the deficiency of this nutrient in diets, particularly those of the poor and the vulnerable at the individual and household levels respectively. Presently, it is estimated that over one million Nigerian farm households are growing 'yellow' cassava varieties, which contain significant amounts of pro-vitamin A even after processing. Yellow cassava now represents an additional source of vitamin A in Nigeria diets. (Ilona and Bouis, 2017).

Several varieties of biofortified pro-vitamin-A cassava varieties exist in Nigeria. These include UMUCASS (36, 37, 38, 42, and 43 varieties), NR 0220, TMS 1371, TMS 0593, and TMS 0539 (Ayinde, 2016; Eyinla et al., 2019).

Currently, the newly introduced varieties of pro vitamin A cassava known as UMUCASS 44, UMUCASS 45 and UMUCASS 46 have a pro vitamin A content that averages 10 parts per million (PPM) based on fresh roots. This set of pro vitamin A cassava varieties have increased beta-carotene levels as well as matching agronomic characteristics as an incentive for better farmer adoption and also help to improve cassava products such as *garri, fufu, high quality cassava flour, cassava bread and starch* (IITA, 2014). Bio-fortification can reduce the prevalence of Vitamin-A deficiency, given prominent role of cassava in the diets of rural households in Nigeria (Oparinde et al., 2016; Garg et al., 2018).

PROCESSING PRODUCE INTO PRODUCTS

A well-known Economist, Professor Felix Nweke wrote a book titled "Cassava: Africa's best held secret". He clearly showed that cassava is no longer a subsistence crop, but a commercial crop. A crop that allows you to make *starch, high quality cassava flour, dried chips for exports, livestock feed and ethanol*, is not a poor man's crop but a rich man's crop.. The interest in

cassava is because it is a choice food among Nigerian`s and is important to people's livelihood, with comparative advantages for cultivation than other crops. But producing more food is not enough, we must also ensure that there is enhanced food nutrition and health.
Paul Ilona of Harvest Plus, once said that given the importance of cassava in Nigeria, pro vitamin A cassava can provide more vitamin A in the diets of over 70 million Nigerians and continue to reduce vitamin A deficiency which is widespread in the country (Vanguard Newspaper, 19th. March 2022).
Therefore, processing cassava produce to products will enable us create new markets for cassava and enhance the nutritional content of processed cassava products through the;
Production of high quality pro-vitamin A cassava garri, fufu, lafun, abacha and tapioca, which is rich in vitamin A and low in carbohydrate content using traditional processing methods. Hence serves as excellent meal for the diabetic. Also,pro-vitamin A cassava produce can be processed into high quality pro-vitamin cassava flour to be used in replacing some of the wheat flour being imported to produce bread. Presently we have cassava bread sold in our super markets. Former President Dr. Ebele Goodluck Jonathan, once said that we must eat what we produce and produce what we eat. If we produce enough vitamin A rich cassava flour, the country can be saving over N250Billion naira annually used in wheat flour importation (Adesina, 2011). With the development of the Pro-Vitamin A cassava, the nutritional quality of the cassava bread in Nigeria will be substantially improved. So while you eat cassava bread, you will get more vitamins, reduce child malnutrition, reduce blindness, enhance the cognitive skills of our children, and reduce infant mortality. So, as you choose pro vitamin A cassava bread, you are choosing improved health and nutrition. Thus, effort should be geared towards including pro-vitamin A cassava in the processing of high quality cassava flour. Other products are; high quality fructose cassava syrup that can be used to replace sugar, high quality cassava cake and dried cassava chips, cassava starch, ethanol and the conversion of cassava peels considered as waste into some livestock feed.

.CASSAVA VALUE CHAIN SPECTRUM

Value chain refers to a chain of activities where products pass through in sequence and at each activity the products gain value. It is the whole spectrum of operations from production to consumption.
The Agricultural Transformation Action Plan (ATA), has as its goal the addition of 20million MT of food to the domestic supply. At the same time, it focuses on agriculture as a business, not a development programme, it focuses on developing agricultural values that can allow farmers to make money from what they produce, through greater value addition (Adesina, 2011).
Also, the Anchor Borrowers Programme launched in November, 2015 by President Mohammed Buhari,is capable of boosting agricultural production through private sector investment in the agricultural value chain which will help in attaining the county's price stability goals, while reducing its dependence on imported food items.
Cassava is one of most important crop for Nigerian farmers and is mostly widely cultivated crops that provide food and income to over 30 million farmers, large numbers of processors and traders (Daniel, Udah, Elechi, Oriuwa, Tijam, Grand Sanni, 2011). Hence, cassava crop will play a significant role in the agricultural production, income generation and employment creation in Nigeria, if it's potentials are properly harnessed. The implication of this is that cassava value-chains are essential for economic development and employment generation, which could at the same time foster revolution in the agricultural sectors as well as encouraging in the growth of Nigerian economy.

The key actors in the cassava value chain spectrum can help to generate income, achieve job creation and contribute to food security. The key actors or collaborators in the cassava value chain are:

Producers (cultivator, planters/farmers): Cassava production in Nigeria is carried out mostly by small holder farmers. There are also a few medium and large-scale producers of cassava in the country (Udemezue, Chinaka, and Okoye , 2019). Transporters are also part of value chain spectrum ***w****hose primary assignment is to move the bulky cassava tuber and stems to where it is needed. Other actors are; Processors, who turn the primary produce into finished product, Agricultural Equipment manufacturers, they are manufacturers of processing equipment used in production, and Marketers, whose function is to make the products gets to the final consumers through the process of buying and selling.*

CONCLUSION:

In terms of nutritional value, cassava is a great source of energy due to its high carbohydrate content; however, it has low levels of fat, protein and micronutrients that are essential for normal growth, eyesight and cognitive development. The opportunities of value addition in farm produce has the potential to not only address the issues of nutrition but also the health status of her citizen Hence, the study reviewed pro-vitamin A cassava; processing produce into products for nutrition and health in Nigeria. The reviewer found out that Nigeria is one of the countries in the world with serious micronutrient malnutrition problems, and also has the highest number of stunted children in sub-Saharan African. Thus, processing pro-vitamin A cassava produce into products like garri, fufu, abacha, cassava bread, cake and chips will reduce the level of malnutrition and stuntedness, thus improving nutritional and health status of her citizen. Hence Pro-vitamin A cassava will be a game changer, if it is adequately advertised and financed. Therefore, It is crucial that accelerated efforts and policy measures should be adopted to improve health and nutrition of vulnerable groups, especially women, infants and children, through nutritional supplementation, diversity of diets and bio-fortification. Awareness creation via improved communication networks is important to provide overwhelming product acceptance, adoption and consumption of bio-fortified cassava.

ABSTRACT

Concern for food quality and safety remains imperative to human and national development. This concern is in consonance with postharvest handlings of food crops either in the manners of processing or storage. The study investigated the quality of some common Ready-to-eat (RTE) foods such as roasted groundnuts, smoke-dried fishes and cassava grit ('Garri') collected from open and super-markets in Kano state. They were evaluated for total aflatoxin, polycyclic hydrocarbons and hydrogen cyanide respectively using HPLC, GC-MS and spectrophotometry methods accordingly. Data obtained for each analysis were subjected to statistical tests where mean differences were compared at 5% probability level. There was significant difference ($p<0.05$) between total aflatoxin level of groundnuts from different markets. Total aflatoxin (AF_{Total}) ranged between 39.53 to 104.92 µg/kg in the open markets while those from super-markets ranged between 11.93 to 53.02 µg/kg. while AFB1 accounted for 91% of each total values, the mean concentration levels of AF_{Total} from the open markets samples exceeded the EU (4 µg/kg) and the codex (15 µg/kg) standards, whereas 75% samples from super markets were within the tolerance limit (4 to 15 µg/kg. From among the twenty- four frequently mentioned PAHs as recommended by European Union and the US- Environmental protection Agency, Benzo[a] pyrene had the highest value of 26.28 µg/kg and 20.19 µg/kg only in the BT-1 and SH-1 samples respectively. Despite fewer number of PAHs detected in BT-1, the Σ PAHs was highest (204.42 µg/kg). There was significant difference ($p<0.05$) in PAHs of smoke-dried fishes from both markets except for BT-1 and BT-2 markets. The level of cyanide contents of 'Garri' ranged from 0.0428 to 0.0811mgHCN/10g an equivalent of 4.28 to 8.11ppm. The cyanide contents of all 'Garri samples were relatively low compared to the ≥10ppm LC_{50} of the WHO limit. Based on these findings, there is a need for periodic surveillance of food, capacity development for processors and marketers on improved handling, processing methods in reducing incidence of food poisoning among consumers.

Keywords: Ready-to-eat, food safety, Markets, smoked fish, groundnuts, Garri.

INTRODUCTION

Ready-to-eat (RTE) foods are a group of food products intended by the producer or the manufacturer for direct human consumption without the need for cooking or other processing effective to eliminate or reduce to an acceptable level micro-organisms of concern (Regulation (EC) No. 2073/2005). They are typically pre-cleaned, precooked, mostly packaged and ready for consumption without previous preparation or cooking (Huang, 2012). They could be traditionally or industrially processed, packaged, or unpackaged and are usually considered to comprise, mainly, the publicly vended foods consumed immediately or later (Cerna-Cortes *et al.*, 2015). Generally, most RTEs are adopted and accepted as part of the cuisine of the people, thus giving them an identity and heritage, which are often passed across generations (Kraig & Taylor, 2013). For example, 'Kulikuli', smoked fish, roasted groundnuts, 'suya', 'kilishi' etc are some of the common RTEs delicacies in Nigeria.

World Health Organisation, 2010 reported that that many RTE vendors either in the open or supermarkets in low and middle-income countries often lack knowledge about good hygiene practices, which may predispose the foods to microbial contamination. The condition is further complicated by the practice of vending RTEs in outdoor environments. Therefore, the foods are exposed to air, aerosols, microbes, insects, and rodents, which serve as sources of food contaminants, jeopardizing the essence of food safety. Furthermore, the inherent nutrients (lipids, protein etc) are oxidized when exposed or not packaged appropriately which affects the quality and shelf life of RTEs.

Common non-microbial-related RTE contaminants include heavy metals, pesticide residues, polyaromatic hydrocarbons. On the other hand, incessant daily exposure to single or fusions of these food contaminants via consumption of contaminated RTEs could lead to a surfeit of adverse health effects. Noticeable effects may range from mild to recurrent nausea, vomiting, and diarrhea (Ceuppens *et al.*, 2011) to severe complications such as cancers, neural tube defects, and even human fatalities (Gibb *et al.*, 2015). Thus, improperly prepared RTEs in low- and middle-income countries, where regulations and monitoring for compliance are grossly inadequate, may constitute a huge risk to public health. In a world of accelerating change, the need for food to be safe remains a constant. Ready access to safe and nutritious food is a basic human right. Yet every year around the world, over 420 000 people die and some 600 million people – almost one in ten – fall ill after eating contaminated food. In fact, foodborne hazards are known to cause over 200 acute and chronic diseases from digestive tract infections to cancer (FAO, 2019). Globally, there is a subjective believe/myth that food vended in supermarkets are free from food borne pathogens and are of high nutritional quality but a lot of research work has debunked the myth and further work is being carried out. In order to contribute to the address of food safety in Nigeria, this research has decided to assess the quality and safe levels of dried and RTE foods like smoked fish, groundnut and cassava grit commonly known as '*garri*' sold in both open and supermarkets in Kano city, Nigeria

MATERIALS AND METHODS

Sample Collection and Handling

One kilogram (1kg) sample each of *garri*, groundnut and smoke-dried fish samples were purchased in triplicates from two open markets and two super markets in Kano State and brought to the food laboratory. One hundred gram (100g) each representative sample was measured, pulverized and packaged in zip-lock bags and ready for individual chemical analysis of total aflatoxin, polycyclic aromatic hydrocarbons and hydrogen cyanide contamination levels.

Determination of Total Aflatoxin Contamination

Total aflatoxin was determined according to Official Methods of Analysis (2000) of the AOAC Method 991.31 with slight modification

Determination of Polycyclic Aromatic Hydrocarbon

Five (5g) of each blended fish sample was spiked with d-PAHs and extracted with mixed solvents of 150ml hexane: dichloromethane (1:1) using soxhlet extraction apparatus for 10hours. The solvent was reduced to 1ml using rotary evaporator and nitrogen gas while the extract was passed through a clean-up column filled with 100-150 mesh silica gel followed by 1g of aluminium oxide and anhydrous sodium sulfate. The column was washed with 10ml of hexane and the PAHs were collected by eluting with 8ml of hexane and 5ml of dichloromethane. Thereafter, the extracts were concentrated to 1ml under nitrogen gas flow at ambient temperature. The solution was injected to GC/MS for PAHs analysis. Quantification of individual PAHs was done based on known concentrations of 24 PAHs standard calibrations.

***GC-MS Analysis Conditions*:** GC-MS analysis was carried out on GCMS-QP2010 PLUS SHIMADZU. The column used was Perkin Elmer Elite - 5 capillary column measuring 30m × 0.25mm with a film thickness of 0.25mm composed of 95% Dimethyl polysiloxane. The carrier gas used was Helium at a flow rate of 0.5ml/min. 1µl sample injection volume was utilized. The inlet temperature was maintained as 250°C. The oven temperature was programmed initially at 80°C for 4 min, then raised to 280°C at a rate of 20°C/ minute and maintained at this for 8min. Total run time was 35 min. The MS transfer line was maintained at a temperature of 200°C. The source temperature was maintained at 280°c. Mass spectra were collected by electron impact ionization at 70eV and data was evaluated using total ion count (TIC) for compound identification and quantification. The spectra of the components were compared with the database of spectrum of known components stored in the GC-MS library.

Determination of Hydrogen Cyanide Content

The cyanide content of '*Garri* samples were determined according to alkaline picrate method with modifications according to Williams and Edwards (1980). The cyanide content of each sample was extrapolated from the standard curve of potassium cyanide as shown in Figure 1.

Data Analysis

Data obtained from each analysis were analyzed using the t-test of SPSS 16.0 version 2007 at 95% confidence level ($p < 0.05$) to compare means.

The total aflatoxin contamination levels in the ready-to-eat groundnut sampled from open and super-markets of Kano state is presented in Table 1. Total aflatoxin contaminations were observed to be profound in samples from open markets as it ranged from 39.53 to 69.50 µg/kg. This could be due to the non-selective measures on roasted or ready-to- eat groundnut samples which are usually brought for sale without cleaning up the outer seed cover. However, levels of aflatoxin contaminations in groundnut samples from the super-markets ranges from 10.56 to 53.02 µg/kg. Afolabi et al., 2015 reported the presence of AFB1 at 1.3-59.1 µg/kg in roasted groundnut sold along road side while Bankole *et al*., (2005) reported concentration ranging from 5 to 165 ppb of Aflatoxin B1 in all aflatoxin-positive samples which he sampled from south western part of Nigeria and concluded that they might present potential health hazards to consumers. This might be associated to the fact that ready-to-eat-groundnut supplied to super-markets are usually cleaned up of their outer seed coats and carefully sorted based on the physical observations of any defect. RTE foods are a broad and diverse food category, prepared and stored in different ways and under different conditions, some of which support growth of some selected mycotoxins at specific storage and shelf-life conditions. The level of aflatoxins food contaminations cannot really be compared due to non- homogeneity of climatic conditions and agricultural practices among other factors (Williams, *et al*., 2004). To protect humans and animals from the harmful effects of mycotoxins, especially aflatoxin, the European Commission (EC) and international communities have proposed maximum allowable limits for aflatoxins in foods and feeds. It usually between 4-30ppb, depending on the country, for example, it 20ppb (20 µg/kg) in the USA (Ingenbleek, *et al*., 2019). Contamination by these fungi could have occurred during the removal of the skin of the seeds after roasting or when the snack is being distributed into nylons or by cross infection from other products displayed for sale in the markets.

Table 1: Total aflatoxin contamination of Ready-to-eat groundnut from two open and two super-markets in Kano

Aflatoxin (µg/kg)	Sample Codes							
	OM1 GR1	OM1 GR2	OM2 GR1	OM2 GR2	SM1 GR1	SM1 GR2	SM2 GR1	SM2 GR2
B1	36.46	35.97	63.24	95.48	10.86	13.11	9.61	48.25
B2	0.80	0.79	1.39	2.10	0.24	0.29	0.21	1.06
G1	1.60	1.58	2.78	4.20	0.48	0.58	0.42	2.12
G2	1.21	1.19	2.08	3.15	0.36	0.43	0.32	1.59
Total	40.07	39.53	69.50	104.92	11.934	14.411	10.558	53.020

OM1 and OM2 represent open markets 1 and 2; SM1 and SM2 represent Super-markets 1 and 2; GR1 and GR2 represent groundnut replicate samples

Table 2 presents the level of polycyclic aromatic hydrocarbons in smoke-dried fishes from open and super-markets of Kano state. All PAHs were detected in all samples except for BT-1, JF-2 and SH-1where fifteen, fourteen and twenty-two PAHs were only detected. Polycyclic aromatic hydrocarbons which are formed during incomplete combustion of organic matters are ubiquitous in the surrounding atmosphere and play important role in cancer risk assessments (Rengarajan, *et al*., 2015). Fish smoking is one of the many ways PAHs are formed. These compounds differ in their toxicity and carcinogenicity depending on their respective hydrophobicity.

The highest of any single PAHs of record in this study was the Benzo[a] pyrene with 26.28 µg/kg and 201.9 µg/kg in BT-1 and SH-1 respectively. The EU maximum limit for Benzo[a] pyrene for fish and fish products range between 2 to 10 µg/kg (EFSA, 2008). The high levels of total PAHs in each sample might not only be due to smoking of fishes alone, but also, due to PAHs contaminated fish feeds during aquaculture (Nnaji and Ekwe, 2018). Benzo[a] pyrene is generally used as exposure markers for cancer risk assessments and thus considered one of the most carcinogenic PAHs (Lee and Vu, 2010). Benzo[a] pyrene, benzo[a] anthracene and naphthalene have been reported with embryo toxicity in animals, thus making these PAHs of frontline concerns (Rengarajan, *et al*., 2015). In this study, samples from JF-1, JF-2, YM-1 and YM-2 perhaps had values for PAHs above 2 µg/kg but were all below 10 µg/kg maximum limit. This could affirm the report of Nnaji and Ekwe, 2018 that not only smoking of fishes but also could be from feeds used during aquaculture. In this study, PAHs values of ≥10 µg/kg were naphthalene in BT-1, Acenaphthene and Acenaphthylene in BT-2, S-methyl chrysene in BT-1, Benzo[a]pyrene in BT-1 and BT-2, chrysene, pyrene, benzo[a]pyrene, benzo[j]fluoranthene in BT-1 and SH-1samples, Dibenzo [a, h] pyrene in BT-1, Dibenzo [a, i] pyrene in BT-1 and BT-2, benzo[jhi] perylene in BT-2 and SH-2 samples. Samples from BT-2 and BT-1 followed by SH-1 and SH-2 recorded the highest sum of PAHs than other samples.

Table 2: Polycyclic Aromatic Hydrocarbons (PAH) levels of Ready-to-eat smoke-dried fish from two open and two super-markets in Kano

Polycyclic Aromatic Hydrocarbons (PAHs)	PAHs (µg/kg) in Smoke-Dried Fish samples							
	BT-1	BT-2	JF-1	JF-2	SH-1	SH-2	YM-1	YM-2

BT-1 = open market BT sample 1; BT-2= open market BT sample 2; SH-1= supermarket SH sample 1; SH-2= super market SH sample 2; JF-1= supermarket JF sample 1; JF-2= supermarket JF sample 2; YM-1=, open market YM sample 1; YM-2= open market YM sample 2. *Σ PAHs represent summation of sample PAHs. The levels of PAHs contamination are statistically (P<0.05) different between all market fish samples.*

Table 3 presented the levels of hydrogen cyanide in '*Garri*' samples obtained from both open and super-markets in Kano state. Each value was as extrapolated from figure 1 standard curve equation of $y = 0.0019x+0.019$ where y represented the value of absorbance and x represented the concentration. Samples from super-markets had cyanide contents ranging between 0.0696± 0.15 to 0.0723± 0.50 mg HCN/10g while samples from open markets had HCN range between 0.0428± 0.01 to 0.0811± 0.10 mg HCN/10g. '*Garri* are made from sweet cassava cultivars which are grouped of varieties with less than 50mg HCN /Kg (Ginting, 2011).

These results inferred that the cassava varieties used in the making of these '*Garri*' sample had undergone serious processing which must have precipitated more than 95% of the potential hydrogen cyanide that would be produce by hydrolysis of cyanogenic glycoside (Onabolu, 2002; Bradbury, 2006). The content of hydrogen cyanide in root crops especially cassava is dependent of the variety and the extent of processing into products (Ginting and Widodo, 2012). Hydrogen cyanide formed due to hydrolysis of cyanogenic glycoside become more volatile at temperature ≥25°C when cassava tissues are undergoing processing into products (Cardoso, *et al*., 2005).

Table 3: Hydrogen cyanide Contents of '*Garri*' samples from Open and Super-markets in Kano State.

Garri Sample	Cyanide content (mgHCN/10g)	Equivalence (ppm)	Relative % to LC_{50} (10ppm WHO limit)
SM_1G_1	0.0723± 0.50	7.23	27.7

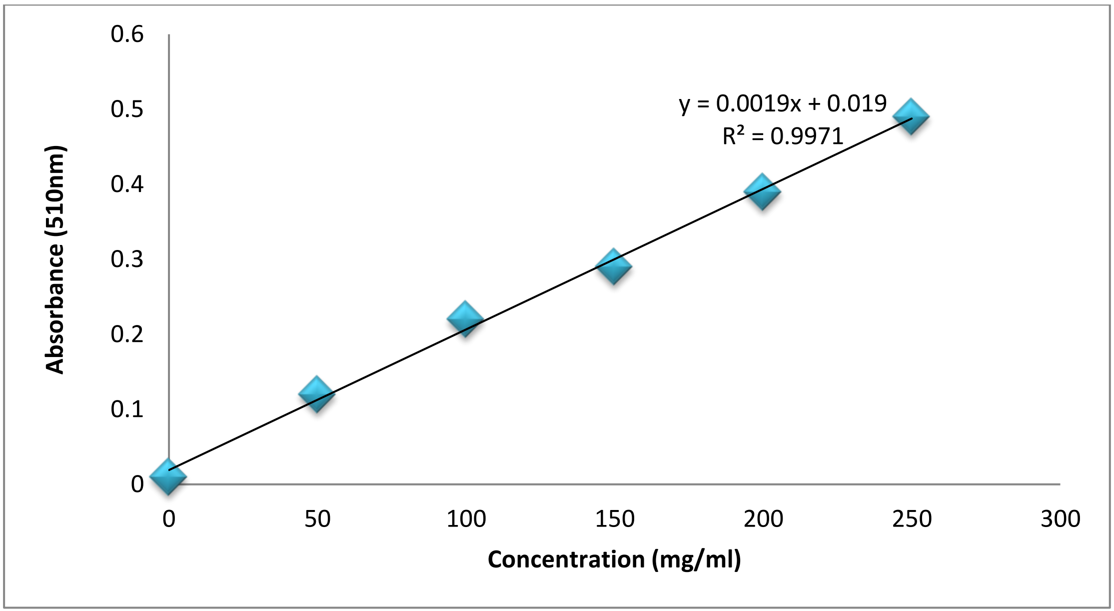

Figure 1. Standard curve of Hydrogen Cyanide

Extremely high dose of HCN beyond which the body can detoxify would result in stomach pains, headaches, dizziness, nausea and many a times diarrhea **(Burns, 2012**). With reference to Burns' assertion (2012), it can be deduced, that the more surface area of cassava products, the lesser the cyanide contents. Therefore, none of the *Garri* sampled for this study have hydrogen cyanide contents of heath concern.

CONCLUSION

Food safety has become more important than ever due to awareness by consumers and ensuring consumption of contaminated foods will go a long way in addressing this issue. PAHs, hydrogen cyanide levels were above safe limits on some instances, however the limits were not exceeded in some commodities. The high level of benzo (α) pyrene observed in one of the samples in open and supermarket is a major concern while the high level of hydrogen cyanide is below safe limit. This calls for training on improved processing and enlightenment on the dangers of consuming contaminated foods. Food safety is best ensured by the shared responsibility of everybody involved with food from the professional to the consumer which if neglected become a very serious public health problem.

ABSTRACT

Arsenic is an environmental toxicant, and the exposure can occur through the workplace and food. Due to Arsenic toxicological effects, exposure to humans can cause degenerative disorders. This study examined the toxic effect of arsenic and the protective roles of Ginger (Zingiber officinale) on experimental rats exposed to arsenic. Animals were divided into three groups: the control group that received the normal feed, the Arsenic group fed with arsenic-contaminated feed, and the Arsenic + Z. officinale group that received arsenic-contaminated feed with Zingiber officinale for 90 days. The animal's percentage weight, hematological analysis, biochemical evaluation, and DNA damage in comet and micronucleus assays were determined. The results were analysed using the Graph pad prism. Results obtained revealed that co-administration of Arsenic contaminated feed with Zingiber officinale decreased the weight of the animals. When compared to Zingiber officinale and control group, the results showed that exposure to Arsenic for 90 days decreased the amounts of white blood cells and red blood cells. The result showed a significant increase in liver enzymes (AST, ALT and GGT), and Arsenic contaminated group also had higher levels of Urea and Creatinine than expected. Normal and arsenic–contaminated groups in the treated group showed a significant difference. Arsenic was shown to affect hepatocytes and caused DNA damage in comet and increased %MNPCE in micronucleus assay however co-administration of Zingiber officinale restored the hepatocytes to normal and decreased the level of %MNPCE. This study demonstrated that eating foods polluted with arsenic has toxicological consequences on the body but adding spices like Zingiber officinale to regular meals can protect us from these effects.

Keywords: Arsenic, *Zingiber officinale*, Body weight, Hematology, Biochemical analysis, Genotoxicity

INTRODUCTION

When compared heavy metals to water, the metallic elements with a comparatively high density of metals are referred to as heavy metals (Alam et al., 2020). Heavy metals also include metalloids like arsenic, which might have low toxicity when exposed to the environment and on the basis of its heaviness and toxicity (Luo *et al.*, 2020). The public health issues brought on by the environmental degradation by these metals have gotten worse in recent years. Due to the exponential rise of a variety of industrial, agricultural, residential, and technical applications, exposure to organisms has also substantially expanded (Proshad *et al.*, 2020).

Heavy metals are divided into two essential and non-essential categories. Essential heavy metals, also referred to as micronutrients, include; cobalt (Co), copper (Cu), chromium (Cr), iron (Fe), magnesium (Mg), manganese (Mn), molybdenum (Mo), nickel (Ni), selenium (Se) and zinc (Zn), and are needed for a variety of biochemical and physiological processes (WHO/FAO/IAEA, 1996)

One example of heavy metal is arsenic. It is a common element that can be found in soil, water, food, air and it comes from both natural and artificial sources, and it is also released into the environment. Arsenic consequences range from immediate death to long-term ones like cancer and cardiovascular disorder. Based on known or suspected toxicants, arsenic is ranked first among toxicants that pose a significant risk to human health (Zheng *et al.*, 2022).

The spice ginger (*Zingiber officinale*) is one of the most popular in the world. It has a long history of use as herbal remedy for conditions like indigestion, discomfort, vomiting, and cold-induced disorders (Zhang *et al* 2021). Ginger is well known for its antioxidant, and anti-inflammatory, and anticancer properties. The volatile oils and different phenolic compounds like gingerols, shogaols, zingerone, and gingiberols are regarded to be the active ingredients in ginger. One potential mechanism for scavenging oxygen free radical and reducing the generation of reactive oxygen species (ROS) has been identified as the antigenotoxic activity of ginger (Celik, 2020). This study was done to determine the toxicological effects of short-term exposure of rat to arsenic and protective role of ginger (*Zingiber officinale)*

MATERIALS AND METHODS

Plant collection and Identification: From the area of Sabo Baptist Church Market, in Ogbomoso, *Zingiber officinale* was gathered. It was blended into a powder at the market and packaged for the animal.

Experimental Animal: Seventeen male Wistar rats (weighing between 120-160grams) were bought from Mama Rat Animal Holding in Ogbomoso, Oyo State. Animals were maintained in polycarbonate cages and placed in the animal house under regular conditions. They have undergone two weeks of acclimatization in a chamber with 12hour light/12hour dark photoperiod schedule at a temperature of 32 ± 2°C. The normal group received only food, the second group received food infected with arsenic and the third group received food infected with arsenic + ginger

Contamination of feed with heavy metal: Feeds + Heavy metal (Arsenic) + Supplement or Spices (ginger)

Feed contamination is accomplished by combining the heavy metal and the feed's raw powder separately. Following the addition of spices, the final combination is then converted into granules for the rats to easily consume at the Ladoke Akintola University of Technology Ogbomoso animal house.

Biochemical analysis: Prior to biochemical analysis, the clot-filled blood in the lithium tubes was spun at 3000 g for 10 min to separate the serum (supernatant) and stored at −70 ◦C. WBC, HGB, HCT, RBC, PLT, and %LYM were the hematological parameters that the obtained blood was examined for using an auto analyzer. Standard techniques were used to evaluate the serum biochemical indicators, according to Constantino, Serum functional test indicators for the liver and kidneys were measured (Constantino, 2017). Utilizing HAICE®, DR 3000, (Germany), the absorbance for each reaction were determined spectrophotometrically. Jiraungkoorskul et al., 2007's protocol for the micronucleus and comet assay was followed.

Statistical Analysis: Microsoft Excel and Graph pad prism 5 were used for the statistical analysis. Analysis of variance was used to analyze the outcome (One way ANOVA).

RESULTS

Percentage change in body weight of rats fed with Arsenic-contaminated feed after 90 days of exposure.

Table 1: As shown in this table, the percentage weight growth of rats fed with arsenic contaminant feed decreased significantly from 30 days to 90 days as compared arsenic-contaminated with *Z.officinale* to normal group. There was a significant difference when compared arsenic to arsenic + *Z.officinale* after 90days of exposure.

	% Body weight gain		
Group	30days	60 days	90 days
Normal	21.66^{a}	4.88^{a}	4.26^{a}
Arsenic-contaminated feed	27.91^{b}	15.64^{b}	12.17^{c}
Arsenic-contaminated feed + Ginger	25.84^{a}	15.39^{b}	8.71^{b}

Value was expressed as mean± SEM and considered significant at P value <0.05 after 30-90days of exposure

Normal control

d- Not significantly difference when compared treated group to normal

e- Significantly difference when compared arsenic and arsenic+ *Z.officinale* to normal

f- Significantly difference when compared the arsenic to arsenic+ *Z.officinale*

The effect of Arsenic and *Z.officinale* on the hematological parameters of Rats.

Table 2: The data from this table below indicated how *Z.officinale* and arsenic affected the rat's hematological parameters. After 90 days of exposure, the arsenic contaminated feed group and arsenic contaminated with *Z.officinale* group showed a significantly lower levels of WBC, RBC and other parameters as compared to the control group (p<0.05). After 90 days of rat exposure, there was no significant difference between the arsenic contaminated feed group and the normal control group in RBC, HGB and PLT (p<0.05). However, there was no significant different when compared arsenic and arsenic with *Z.officinale* in RBC, HCT and HGB.

Parameters	**Duration**	**Normal**	**Arsenic-contaminated Feed**	**Arsenic contaminated feed + Ginger**

%LYM	90 days	75.27±1.91	66.80±11.40[b]	74.80±5.87 [a]

Value was expressed as mean± SEM and considered significant at P value <0.05 after 30-90days of exposure

Normal control

d- Not significantly difference when compared treated group to normal

e- Significantly difference when compared arsenic and arsenic+ *Z.officinale* to normal

f- Significantly difference when compared the arsenic to arsenic+ *Z.officinale*

The Effect of Arsenic and *Z.officinale* on the hepatic function and renal function levels.

Table 3: The results showed that, when compared arsenic contaminated feed group to normal group, the levels of AST, ALT and GGT increased significantly, however, in the arsenic contaminated with *Z.officinale*, the levels of AST, GGT and ALT significantly increased when compared to normal group. The results from this table demonstrated a substantial difference in urea level and creatinine level between normal group, arsenic-contaminated diet and arsenic contaminated with ginger. When compared to the normal group, the arsenic-contaminated group and the arsenic-contaminated with *Z.officinale* group both have higher levels of creatinine. There was a significant difference when compared arsenic-contaminated group and the arsenic-contaminated with *Z.officinale* group in AST and ALT but there was no significant different in GGT.

GROUP	AST(μ/L)	ALT (μ /L)	GGT (μ /L)	UREA	CREATININE
NORMAL	50.93±6.63	69.79±7. 10	56.45±2.65	30.91±1.32	90.00±16.21
Arsenic contaminated feed	123.50±46.07 [b]	156.50±38.75 [b]	60.77±1.94 [a]	50.71±0.56 [a]	125.50±23.67[b]
Arsenic contaminated feed +Ginger	98.80±60.15[b]	104.80±95.22 [b]	58.71±5.93 [b]	45.94±8.52 [b]	107.00±80.67[b]

Value was expressed as mean± SEM and considered significant at P value <0.05 after 30-90days of exposure

The Effect of Arsenic and *Z.officinale* on the %MNPCE and % tail DNA of Rats fed.

Table 4: The results of this study demonstrated that after 90 days of exposure to arsenic, the %MNPCE level in the normal group dramatically increased when compared to arsenic contaminated group but there was little difference when compared to arsenic with *Z.officinale* group, whereas there was no significant different when compared arsenic to arsenic with ginger . According to the comet results, after 90days of exposure, there was a significant difference between the arsenic-contaminated group and the normal group, but not between the arsenic

contaminated + *Z.officinale* group and the normal group, while there was a significant different when compared arsenic to arsenic with *Z.officinale*.

Parameters	Duration	Normal	Arsenic	Ginger

Value was expressed as mean± SEM and considered significant at P value <0.05 after 30-90days of exposure

DISCUSSION

Toxicants are ingested and are carried by the blood to many different organs, including the liver and kidney where they may have negative consequences in the body. In this study, the amount of weight growth experienced by rat fed with arsenic contamination and the healthy control group declines over time. According to recent studies, *Z.officinale* may help people lose weight and prevent obesity-related disorders (Suk *et al*, 2017). Hemolytic anemia, infections, inflammation-tissue necrosis and stress are examples of benign disorders that can result in Leukocytosis and thrombocytosis (Claire *et al.*, 2021). RBC, HTC and HGB levels in the exposed with arsenic rat group and arsenic+ *Z.officinale* group significantly decline with time from 30 to 90 days which is a sign of anemia which could be as a result of gastrointestinal tract bleeding suggesting that arsenic suppresses the immune system. According to Aysel *et al*, (2016), administration of arsenic+ *Z.officinale* result in the preservation of haematological parameters.

Because liver enzymes are secreted into the extracellular space by hepatocytes, they are employed as indictors of liver damage (Zhang *et al*, 2020). When hepatocytes are harmed or eliminated, the liver releases alanine and aspartate aminotransferases. When arsenic poisoning causes hepatocellular damage, the serum activity of these enzymes increases. Apart from the arsenic-contaminated diet mixed with *Z.officinale* in the exposed rat, liver enzymes AST and ALT were higher ($p<0.05$) in the arsenic exposed rat compared to the arsenic+ *Z.officinale* rat. According to Talpur *et al*, (2013), supplementing *Z.officinale* in rat diets as an alternative to antibiotics and therapeutic drugs had significantly as an additive and may improve the immune status of rats, however in GGT the exposed rats are significantly higher compared to arsenic+ *Z.officinale* rat. The arsenic contaminated exposed group shows a significant increase which trend in the exposure period of the rat when compared to arsenic+ *Z.officinale* rats. The micronucleus test is determined using %MNPCE in the blood of exposed rat and normal rat, arsenic-induced toxicity has been linked to a number of mechanisms, including the inhibition of several enzymes involved in DNA repair and expression, which are responsible for the types of genotoxic damage seen in this work (Andersen et al., 2018).

As a sensitive, quick and affordable method for detecting DNA strand breakage, the comet assay is an excellent non-specific indicator of genotoxicity in rats (Andersen et al., 2018). After 90 days, the amount of DNA damage found in the tissue of rats exposed to an arsenic contaminated diet increased. *Z.officinale* played a protective role which could lead to the decrease in the level of arsenic in the tissue which result in repaired DNA, the loss of cells with severely damage DNA, or both (Muller et al., 2021). The toxicology of a contaminant that could interfere with the enzymatic activities in the generation of DNA damage may be the cause of the inverse association between time of exposure and DNA damage (Muller et al., 2021).

CONCLUSION

These findings suggested that care should be given to long-term exposure to feed contaminated with arsenic. In this investigation, arsenic was specifically found in the rat liver as evidenced by the micronucleus assay that was carried out. *Z.officinale*, which has numerous biological properties including antioxidant, anti-inflammatory, antibacterial, anticancer, neuroprotective, hepatoprotective, cardiovascular protection, and antidiabectic, can be used to evaluate the degree of exposure and damage, potentially reverse these effects.

ABSTRACT

The proximate and mineral composition of the commonly consumed fresh and smoked Clarias gariepinus (Catfish) was determined in this study. The fish was purchased from a fish farm in Alimosho area (Lagos) and divided into two parts: fresh fish while the other part was smoked using smoking kiln for 15 hours. The fish was analyzed using the standard methods for proximate analysis (moisture, fat content, ash content, crude fibre, protein content, total carbohydrate (all in %) and energy value (kcal) and Atomic Absorption Spectrophotometer was used to determine the mineral composition (Ca, K, Mg, Na, Zn, Fe, Cr). Analysis of variance (ANOVA) was carried out using F-test to determine the treatments level of significance. The result presented is mean value of each determination± standard error (SE). The results of proximate analysis of the catfish samples shows that there is an increment in the nutrition value of the smoked catfish except with the reduction in the moisture content (58.10±0.17 to 7.74±0.16%) which indicated the stability of the fish. The changes in proximate composition were found to be significant for the smoked catfish. The mineral analysis results ranged from 1.02±0 to 251.52±0.01 ppm in fresh catfish samples while the smoked samples ranged from 1.21±0 to 290.08±0.01ppm with sodium as the highest and chromium as the least mineral. From this study, the proximate parameters and essential minerals in Clarias gariepinus can help in complementing the nutritive values derivable from the consumption of these fish.

Keywords: *Clarias gariepinus*, smoking kiln, fresh and smoked catfish, proximate and mineral Analysis

INTRODUCTION

For many people, fish is a vital part of their diet and frequently delivers the essential elements for a healthy lifestyle. It is a wonderful component of the human diet because of its

characteristic as a cheap source of animal protein, which is now widely acknowledged around the world (Iheagwara, 2013). Currently, fish protein is preferred over other proteins of animal origin since it compares favorably to those found in meat, eggs, and milk in terms of amino acid content (Iheagwara, 2013). In developing countries like Nigeria, where the staple diet predominately consists of starchy foods, fish protein is essential for many individuals as a diet supplement (Idris, 2010). Despite the fact that fish is a necessity, a significant incidence of fish rotting still occurs in Nigeria due to a lack of storage facilities, which severely hampers the development of the fishing business in Nigeria (Akinpelu et al., 2013). Fish spoilage can be decreased using a variety of preservation techniques, including freezing, smoking, drying, brining, and chilling, according to Akinola et al. (2006). This was demonstrated, according to Bellagha et al. (2007) that indigenous methods of preservation, including as salting, drying, and smoking, have evolved over time due to the perishable nature of fish. The artisanal fishing industry places a lot of emphasis on fish smoking as a processing and preservation technique. It improves the flavour and increases utilization of the fish in addition to decreasing wastes when catches are good and influences protein availability to rural people (Ndimele, 2011). According to a review by Kiin-Kabari et al. (2011), smoked fish plays a significant role in the local diet of Nigerians, as evidenced by its delectable flavor and taste. Additionally, it has been observed that the smoked fish improves the product's flavor and aroma, lengthens shelf life due to its antioxidant and antibacterial properties, lowers pH levels, imparts a pleasing colour, hastens drying times, and acts as a preventative against spoiling. Also, it reduces waste, especially during times of abundant catches, enables for storage during the rainy season, boosts the population's access to protein year-round, and simultaneously makes fish preservation easier to pack, transport, and market.
Clarias gariepinus is one of the species of catfish which is highly nutritious. *Clarias gariepinus* is low in carbohydrates and contains high percentage of vitamins, proteins, minerals with low saturated fat, (Idris et al., 2010). It is an economically important freshwater fish and is accepted worldwide. It is cultivated extensively in ponds but is sometimes short-priced (Kumolu-Johnson et al., 2010). *Clarias gariepinus* is a very important fresh water fish in Nigeria as it accepted worldwide in most parts of the country because of its unique taste, flavour and texture (Ayeloja et al., 2011).

The knowledge of their proximate and essential mineral compositions is very important for the determination of their quality and adequacy in the diet of the consumer. Thus, it is recommended to have vital information on the proximate and mineral composition of catfish for human consumption as well as comparing the results with the recommendation limit so as not to pose hazard on human health. This study, therefore, aims to determine the proximate analysis and mineral composition of fresh and smoked catfish species in Alimosho area, Lagos State. This location was chosen based on the fish marketers.

METHODOLOGY

Fish Sample and Preparation: Melunch sizes of Fresh catfish (*Clarias gariepinus*) (20kg) samples were purchased from a reputable fish farm in Alimosho area, Lagos State. Some of the fish samples were immediately transported in an oxygen bag to the Sofunk foods processing unit command Ajasa Alimosho Lagos following the hygienic protocol for smoking while others were transported to Federal Institute of Industrial Research Oshodi (FIIRO) and Nigeria Institute for oceanography and Marine Research (NIOMR) for chemical analysis. The catfish samples for analysis were divided into two (fresh and smoked).

The first part of the samples (fresh catfish samples) were properly washed, cleaned, degutted and blended in an electrical grinder machine to smaller sizes to increase the surface area for further analysis and it was stored in a refrigerator for prior use. For the second part, the clean degutted catfish samples were smoked for 15 hrs using a smoking kiln and was allowed to cool for 8 hrs before being pulverized for further chemical analysis.

Chemical Analysis: The fresh and smoked catfish samples were homogenized after which proximate composition (moisture, ash, crude fibre, fat, protein total carbohydrate and energy value) was determined using the standard methods of AOAC (1994) and mineral composition (Ca, K, Mg, Na, Zn, Fe and Cr) were also determined using Atomic Absorption Spectrophotometer (AAS)

Statistical Analysis: Data obtained were subjected to Analysis of variance (ANOVA) which was carried out using F-test to determine the treatments level of significance. Treatments were separated using Duncan Multiple Range Test (DMRT) to compare mean differences at 5% level of probability. The result presented is the mean value of each determination ± standard error (SE).

RESULTS AND DISCUSSION

The results of the proximate analysis of the fresh and smoked catfish samples are presented in Table 1. From the result, the moisture content of the fresh catfish samples was lower than that of the smoked samples with moisture content of 58.10±0.17 and 7.74±0.16, respectively. The moisture contents of the two fish samples (fresh and smoked) were within the range of the previous finding (Elagba and Rabie, 2010; Ajai et al., 2019). The stability of food substance is usually measured by its moisture content which also affects the composition of both protein and lipid (fat) contents (Olagunju et al., 2012). In this study the crude protein had the highest composition based on dry matter, which is an indication of dietary quality. The protein results is comparable to results obtained by Ajai et al. (2019) (11.65±1.99 and 41.15±1.87 for fresh and oven-dried *Clarias gariepinus*, respectively) and Ayeloja et al. (2015). Increase in fat content in the smoked sample could be as a result of salting and smoking due to the oxidation of the polyunsaturated fatty acids (PUFA) contained in the fish tissue into peroxides, aldehydes, ketones and the free unsaturated fats by these additives (Holma and Maalekuu, 2013).

Table 1: Proximate analysis of fresh *Clarias gariepinus* fish (catfish)

Parameter	Mean ±SE	
	Fresh	**Oven-dried**
Moisture (%)	58.10±0.17^{c}	7.74±0.16^{b}
Ash content (%)	5.32±0.02^{a}.	5.69±0.09^{c}
Crude fibre (%)	0.14±0.02^{a}	3.90±0.12^{c}
Fat content (%)	6.95±0.15^{a}	12.29±0.17^{b}
Protein content (%)	27.39±0.11^{a}	48.53±0.11^{b}
Total carbohydrate (%)	2.11±0.40^{a}	21.84±0.05^{b}
Energy value (kcal)	180.51±0.47^{a}	392.12±1.56^{b}

Results are Mean ± Standard Error of triplicate analysis. Those with different superscripts are significantly different, while those with similar superscripts are not significantly different at p ≤ 0.05.

Table 2: Mineral analysis of fresh *Clarias gariepinus* fish (catfish)

Parameter (ppm)	Mean ±SE	
	Fresh Catfish	**Oven-dried Catfish**
Calcium	74.07 ± 0.03^{a}	162.81 ± 0^{c}
Potassium	74.41 ± 0.01^{c}	63.14 ± 0.01^{a}
Magnesium	41.81 ± 0^{a}	48.91 ± 0^{c}
Sodium	251.52 ± 0.01^{a}	290.08 ± 0.01^{b}
Zinc	2.39 ± 0^{a}	3.07 ± 0.01^{b}
Iron	3.46 ± 0^{a}	3.58 ± 0^{b}
Chromium	1.02 ± 0^{a}	1.21 ± 0^{b}

Results are Mean ± Standard Error of triplicate analysis. Those with different superscripts are significantly different, while those with similar superscripts are not significantly different at p ≤ 0.05.

The result of the ash content concur with the findings by Bhouri et al (2010) and Ajai et al (2015),who reported an increase in ash content in oven dried fish as compared to the fresh fish. The observed range of ash content in this study indicated that the oven dried fish had a good source of minerals since ash is a measure of the mineral content of food item (Oladipo and Bankole, 2013).

Minerals are essential to the body metabolic process in living organisms. Catfish is among the most important sources of these minerals. Table 2 shows the mineral constituents of the studied fresh and smoked fish. From the results obtained in this study, the mineral composition of the samples considered varied from 1.02±0 to 251.52±0.01 ppm in fresh catfish samples while the smoked samples varied from 1.21±0 to 290.08±0.01ppm with sodium as the highest and chromium as the least mineral. Sodium is an essential nutrient involved in the maintenance of normal cellular homeostasis. It regulates fluid and electrolyte balance and blood pressure (Strazzullo and Leclercq 2014). Chromium is an essential trace element needed in the diet in small amount concentration. It helps in brain function, blood sugar control, and the breakdown of fats and carbohydrates. In this study, smoked catfish has a contributory effect on the zinc concentration as it increases its bioconcentration. Zinc serves as cofactors to some important enzymes and is also involved in most metabolic pathway in human, while its deficiency can lead to loss of appetite, growth retardation, skin changes and immunological abnormalities; however, at higher concentration they tend to be toxic (Fawole et al., 2013). Calcium is also an important mineral in the body metabolic process. It helps in the uptake of dietary Vitamin B and activation of lipase; synthesis of neurotransmitter acetylcholine and; lowers blood pressure and helps in building and maintaining bone mass (Olaniyi *et al.*, 2018). Generally, all the minerals analyzed are within the FAO/WHO (2011) recommended limit. Increase in some minerals in the smoked could be as a result of oxidation during the smoking process.

CONCLUSION

The result of this study indicated significant differences ($p < 0.05$) in the proximate composition and mineral contents of both fresh and smoked catfish. The results provided vital information on the proximate and essential mineral compositions of fresh and smoked *Clarias gariepinus* in Alimosho area, Lagos state. The smoking method of drying catfish was found to be more efficient with the reduction in moisture content, making it appropriate for export. From this study, the proximate parameters and essential minerals of *Clarias gariepinus* can assist in complementing the nutritive values derivable from the consumption of these fish.

As a result of this study, it is advised that food regulatory organizations make a valiant effort to conduct routine analyses of the nutritional composition of fresh and smoked catfish to make sure that their essential mineral contents are within the permissible limit and won't be harmful to the health of the consumers.

24 - 28 Oct., 2022

ABSTRACT

Cassava roots can be are processed into different types of products such as gari, lafun, landang, fufu, flour, chips, starch akara, okpokpo garri, meal, ighu, syrups, dextrins, and alcohol

Characterizing the food and industrial potentials of different cassava varieties may be achieved by understanding the pasting properties of the roots and intermidate products such as flour.fourteen (14) elite cassava clones and a preffered land race were harvested from NRCRI cassava programe (TMS13F1160P004, TMS13F1343P0022, NR-14B-218, TMS11TA000070, TMS13F1343P0044, NR-095-F, TME 419, TMS13F1112P0005 TMS13F2110P0008, NR130022, TMS01/136810, TMS01/11412, 98/0505, Nwaocha, TMS130124.) Freshly harvested cassava clones were washed, peeled and cut into chips. The Chipped cassava roots were oven dried at 50^{o}C and milled into flour for pasting properties which was determined using a Rapid visco analyzer (RVA). NR-14B-218 had the highest final viscosity, setback value and a good pasting temperature. The good swelling potential exhibited by all the clones reveals their suitability for both baking and confectioneries.

Key words: Pasting properties, Starch, Confectioneries, Swelling potential and shelf life[

INTRODUCTION

Cassava, Manihot esculenta Crantz is an important staple food in sub-Saharan Africa. Cassava roots are processsed into products such as gari, lafun, landang, fufu, flour, chips, starch akara, okpokpo garri, meal, ighu, syrups, dextrins, and alcohol (Nwabueze and Odunsi, 2007),

Breeders have mostly focused on improving agronomic traits of varieties that could be distributed and promoted among farmers (Acheampong, 2015). However the need to inco-operate food quality attributes into breeding programs has become imperative considering the low adoption of the released improved varieties by farmers, food and industrial processors.

Characterizing cassava varieties for different food and industrial potential is therefore of utmost importance due to rapid urban growth and dynamics in market development in Nigeria. This may be achieved by understanding the pasting properties of the roots and intermidate products such as flour for food and industrial purposes.

MATERIALS AND METHODS

Fourteen (14) elite cassava clones and a preffered land race were harvested from NRCRI cassava programe crossing block experimental field (TMS13F1160P004, TMS13F1343P0022, NR-14B-218, TMS11TA000070, TMS13F1343P0044, NR-095-F, TME 419, TMS13F1112P0005 TMS13F2110P0008, NR130022, TMS01/136810, TMS01/11412, 98/0505, Nwaocha, TMS130124.)Fresh roots of the different cassava clones were washed, peeled and cut into chips. The Chipped cassava roots were sub-sampled, oven dried at 50^{o}C and milled to flour. The pasting properties of the flour was determined using a Rapid visco analyzer (RVA).

RESULT AND DISCUSSION

The table shows that peak viscosity of the cassava varieties ranged from 337.50 RVU for NR-095-F to 547.96 RVU for 98/0505. There was no significant differences (p>0.05) in the peak viscosity of the cassava varieties. Peak viscosity is an index of the ability of starch-based foods to swell freely before their physical breakdown (Adebowale et al., 2008). NR-095-F had the highest peak viscousity and starch content compared to the other clones However, these values obtained for peak variety were lower than 622.50 RVU previously reported Obadina et al., (2014) for yam Values obtained for trough viscosity ranged from 150.80 RVU (TMS13FS110P0008) to 292.88 RVU (NR-14B-218). Apart from the NR-095-F and NR14B-218 trough viscosity did not differ significantly (p>0.05) among the cassava varieties.
The breakdown viscosity of the cassava varieties ranged from 191.33 to 315.92 RVU, no significant differences (p>0.05) was observed among the cassava genotypes. The highest value of breakdown viscosity was recorded in 98/0505 (315.92 RVU). The breakdown viscosity is an index of the stability of the starch and a measure of the ease with which the swollen granules can disintegrate under shear stress (Kaur et al., 2007). A range of 159.63 to 451.84 RVU was obtained as the final viscosity of the cassava varieties. NR-14B-218 had the highest value of final viscosity (451.84 RVU), followed by TMS01/11412 (389.71 RVU) NR-095-F however had the least value for final viscosity (159.63 RVU). TMS/130124, TMS01/136810, NR130022, TMS13FS110P0008, and NR095-F; and NR-14B-218 their values for final viscosity were significantly different (P<0.05) from other cassava varieties in terms of final viscosity. Final viscosity is commonly used to define the quality of particular starch-based flour since it indicates the ability of the flour to form a viscous paste after cooking and cooling. It also gives a measure of the resistance of the paste to shear force during stirring (Adebowale et al., 2008). This study revealed that NR-095-F had the lowest setback viscosity hence a lesser tendency to retrograde indicating long shelf-life and good fridge stability compared to the other cassava varieties. The values of setback viscosity showed that no significant differences (p>0.05) among the cassava varieties apart from NR-095-F and NR-14B-218. The peak time of the cassava varieties ranged from 4.13 to 5.30 min. whereas the peak viscosity of NR-095-F was significantly different (p<0.05). NR-095-F had the highest value of peak time (5.30 min) while the lowest peak time was recorded in TMS/130124 (4.13 min). Pasting temperature is one of the properties which provide an indication of the minimum temperature required for sample cooking (Iwe et al., 2016). The pasting temperature of the cassava varieties ranged from 65.93 to 87.10°C.). Higher pasting temperature recorded in NR-095-F indicated that its starch possess smaller granular size compared to that of other cassava varieties. Zeng et al. (2013) affirmed that pasting temperature is dependent on the size of the starch granules. pasting temperature of TMS13F1112P005, TMSIITA000070, NR-095-F, and NR-14B-218 were not significantly different (p>0.05) from each whereas the pasting temperature of TMS13F1343P0022 was significantly different (p<0.05).

CONCLUSION

The outcome of this research revealed that all clones have a good swelling potential and will be suitable for both baking and confectioneries. NR-095-F had the lowest setback viscosity hence a lesser tendency to retrograde indicating a longer shelf-life and good fridge stability compared to the other cassava varieties. NR-14B-218 is highly recommendable has it's has the perfect pasting quality.

The pasting properties of the flour

24 - 28 Oct., 2022

ABSTRACT

Ogiri was produced using melon seeds to determine quality and consumer acceptability. The proximate composition and functional properties was determined which gives protein content of 12.703±0.172%, moisture content of 4.717±0.041%, fat content of 20.713±0.150%, Crude fiber of 1.1700±0.030%, ash content of 1.7267±0.015% and Carbohydrate content of 59.283±0.067%. The functional properties were determined and it was also subjected to sensory evaluation in terms of taste, colour, texture, aroma and overall acceptability on 9-point hedonic scale ranging from like extremely (9) to dislike extremely (1). The sensory evaluation result shows that the consumer preferred the ogiri produced from melon with an overall acceptability 80%.

Keywords: Melon Seeds; Proximate Composition; Functional Properties; Sensory Evaluation; Ogiri; Overall Acceptability.

INTRODUCTION

Fermented food condiments have constituted a significant proportion of the diet of many people as they give pleasant aroma to soups and sauces in many countries, especially in Africa where protein calorie malnutrition is a major problem (Sarker *et al*., 2003). They also have a great potential as key protein and fatty acid sources, and are good sources of gross energy (Omafuvbe, *et al*., 2004). In Africa, many proteinaceous oily seeds are fermented to produce food condiments (Sanni and Ogbonna, 2011; Baird-Parker, 2014). Therefore, these condiments are basic ingredients for food supplementation, and are named according to the substrate or raw materials employed (Odunfa, 2005) which include "ogiri ugu" produced from fluted pumpkin seeds (*Telferia occidentallis*) and "ogiri egusi" produced from melon seeds (*Citrullus vulgaris*). Previous studies have centred on ogiri egusi (Omafuvbe *et al*., 2004; Ogueke and Nwagwu, 2007; David and Aderibigbe, 2010). Ogiri is one of the condiments consumed in the Eastern and Western parts of Nigeria (David and Aderibigbe, 2010). The seeds of castor oil (*Ricinus communis*) are one of the various substrates accentuated by many authors on the production of ogiri (Odunfa, 2005; Jideani and Okeke, 2001). Other substrates used for the production of ogiri include the seeds of water melon (*Citrullus vulgaris*), creeping melon (*Colocynthis vulgaris*) and seed of fluted pumpkin (*Telfairia occidentalis*) (Odunfa, 2011; David and Aderibigbe, 2010). However, none or little work has been reported on the comparative study and consumer acceptability of ogiri egusi production, a food condiment made from melon seeds. There is therefore the need to study the consumer acceptability of Ogiri production using melon seeds.

METHODOLOGY

Sample Preparation and Procurement

The shelled melon seeds used in this study was purchased from Towobowo market, situated in Ibarapa Central Local Government Area of Oyo state, Nigeria. The raw materials obtained were sorted, cleaned and then washed to remove all extraneous matter. They were then allowed to dry and packaged separately in a plastic bag, ready for processing. All other chemicals used in this research were of analytical grade.

Production of Ogiri from Melon Seeds

Ogiri was produced from melon seeds using the method described by Ifesan, *et al.*, (2019) with a fermentation period of 3 days.

Proximate Analysis and Functional Properties of Ogiri Produced from Melon Seeds

Proximate composition such as protein content moisture content, fat content, ash content, crude fiber and carbohydrate content and functional properties such as water absorption, swelling capacity, solubility and oil absorption were determined using the method described by AOAC (2005).

Sensory Evaluation

Sensory Evaluation was carried out according to the method described by Iwe (2010). On each of the samples using 10 trained panellists to assess the sensory attributes (appearance, aroma, texture, and overall acceptability) of the samples. The panellists were selected using simple random sampling techniques comprising staff of Oyo State College of Agriculture and Technology, Igboora who were familiar with the products as taste panelists in carrying out this research. In selecting the test. The samples were presented in plates with water to rinse mouth after each tasting. The panelists were instructed to rate the sample for the attributes based on a 9-point Hedonic scale ranging from 9- like extremely to 1- dislike extremely.

RESULTS AND DISCUSSIONS

The produced melon seeds ogiri was analyze in triplicate to obtain the proximate composition of the products as presented in table 1. The ogiri produced from melon seeds has a protein content of 12.703%±0.172, moisture content of 4.717±0.041, fat content of 20.713±0.150, crude fiber of 1.170±0.030 and carbohydrate of 59.282±0.067%. the result obtained in this study falls out within the range reported by David and Aderibigbe (2010) who observed that the moisture content of unfermented melon seeds and 4 days fermented *ogiri egusi* samples increased from 7.13% to 35.43%, ash content increased from 2.85% to 3.56%, carbohydrate increased from 11.03% to 24.43%, protein decreased from 32.27% to 29.37%, fat decreased from 50.13% to 33.95% and fibre decreased from 3.53% to2.57%. similarly, a lower value was obtained as compared with the report of Akinyele and Oloruntoba (2013) on average proximate composition of unfermented *ogiri-egusi* with crude fibre 7.14%, crude protein 37.41%, crude fat 29.55%, ash 3.17% and moisture 4.77%; while after five days fermentation, the proximate composition was crude fibre 11.43%, crude protein 33.3%, crude fat 33.54%, ash 3.17% and moisture 8.25%.

Table 1 Proximate Composition of Ogiri Produced from Melon Seeds

variables	Composition (%)
protein content	12.703±0.172
moisture content	4.717±0.041
fat content	20.713±0.150
ash content	1.7267±0.015
crude fiber	1.1700±0.030
carbohydrate content	59.283±0.067

The produced melon seeds ogiri was analyze in triplicate to obtain the functional properties of the products as presented in table 2. The ogiri produced from melon seeds has a water absorption of 78.537±0.015%, swelling capacity of 2.930±0.020%, solubility of 17.317±0.101%, and oil absorption of 84.747±0.081%.

Table 2 Functional Properties of Ogiri Produced from Melon Seeds

Variable	Composition (%)
water absorption	78.537±0.015
swelling capacity	2.930±0.020
Solubility	17.317±0.101
oil absorption	84.747±0.081

Sensory evaluation was carried out on the produced ogiri from melon seeds and the results obtained were presented in table 3 below.

Taste: From the result shown in table 3, 70% of the respondents like the taste of the ogiri produced from melon seeds extremely while the remaining 30% of the respondents like the ogiri produced from melon seeds taste very much.

Colour: The result presented in table 3 shows that 60% of the respondents like the colour of the ogiri produced from melon seeds exteremely, 30% of the respondents like the colour of the ogiri produced from melon seeds very much while the remaining 10% of the respondents moderately like the melon ogiri.

Texture: In terms of texture, 70% of the respondents like the texture of the ogiri produced from melon seeds extremely and 30% of the respondents like the texture very much as presented in table 3.

Aroma: 70% of the respondents like the aroma of the ogiri produced from melon seeds exremely, 20% of the respondents like its aroma very much, while the remaining 10% of the respondents show that the ogiri made from melon seeds is moderately like as presented in table 3.

Overall acceptability: The result presented in table 3, shows that 80% of the respondents accepted the ogiri made from melon seeds extremely while the remaining 20% of the respondents says the acceptance of the ogiri made from melon seeds with the hedonic rating of like very much.

Table 3 Sensory Evaluation of Ogiri from Melon seeds

Ranting	**Taste**	**Colour**	**Texture**	**Aroma**	**Over Acceptability**
Like extremely	70	60	70	70	80
Like very much	30	30	30	20	20
Like moderately	0	10	0	10	0
Like slightly	0		0	0	0
Neither like nor dislike	0	0	0	0	0
Dislike slightly	0	0	0	0	0
Dislike moderately	0	0	0	0	0
Dislike very much	0	0	0	0	0
Dislike extremely	0	0	0	0	0
Total	100	100	100	100	100

CONCLUSION

Food condiments are made from protein based foods and oil-seeds in which ogiri is included. Ogiri was produced from melon seeds. The proximate composition and functional properties were determined and was found to be rich in nutrients needed by human body for normal growth and development. It was later subjected to sensory evaluation using well trained panelists who are familiar with the consumption of ogiri to rate the produced ogiri from melon seeds on a 9-points hedonic scale. It was found out that, 80% of the consumer accepted the products with a rating of like extremely and 20% accepted the product with like very much rating base on the hedonic scale.

ABSTRACT

African locust beans seeds with an initial moisture content of 8.04% was obtained and preconditioned to moisture content of 6%, 12%, and 18% and extraction temperature of 40^0, 50^0C and 60^0C as stated in the experimental design. Oil was extracted from the seeds using solvent extraction method, the process of extraction was investigated to check the effect of the varied moisture content and extraction temperature, maintaining a constant extraction time of 8hrs. The highest percentage oil yield of 21.05% was obtained at seed moisture contents and extraction temperature of 6% and 60^0C respectively. While, the least value of 6.51%. was obtained at seed moisture contents and extraction temperature of 18% and 40^0C respectively. The response obtained as the percentage oil yield were subjected to statistical analysis to understand the significant effect of the factors considered, a p-value lesser than 0.05. This indicated that, the moisture content of the seed is inversely proportional to the oil yield while the extraction temperature is directly proportional to the oil yield obtained from African locust bean seeds.

Keywords: Locust beans; Moisture Content; Extraction Temperature; Oil Yield.

INTRODUCTION

Natural vegetable oils and fats are increasingly becoming important in nutrition as well as the manufacturing industry worldwide. Nutritionally, vegetable oils are important sources of dietary energy. Vegetable oils account for 80% of the world's natural oils and fat supply (Okullo et al., 2010). Vegetable oils are sourced from diverse varieties of leguminous plants. With an ever increasing demand for vegetable oils for food and industrial applications, there is need for considerable expansion of oilseed crop production (Çamaş et al., 2007). This expansion can be achieved by exploring other sources of vegetable oils, especially underutilized oilseeds (Popoola et al., 2016). Locust beans (*Parkia biglobosa*) is a wild legume known for its inexpensive proteins, but the exploration of its oil content (Bhat & Karim, 2009). Its oil is suitable for consumption since it contains very low acid and iodine contents; it has essential acids and vitamins and serves as a protein supplement in the diet of poor families and has been reported to be non-toxic.

Currently in Nigeria, the focus is on groundnuts, soybeans and cotton as the main oil seeds. These sources of vegetable oil have not been able to meet the increasing demand of vegetable oil for both human and industrial use. Hence, there is need to supplement the supplies with other sources, especially underutilized oilseeds (Popoola et al., 2016). It is worthwhile to investigate the effect of process parameters that affects the yield of oil obtained from oil bearing seeds. Hence, this study was carried out to extract oil from African locust beans (*Parkia biglobosa)* by examine the effect of moisture content and extraction temperature through the use of solvent extraction method.

METHODOLOGY

Sample Collection and Preparation

African locust beans (*Parkia biglobosa)* seeds were obtained from local market in Igboora, Oyo State, Nigeria. The seeds were handpicked to remove stones and deteriorated ones. All samples were milled to fine particle size, packaged in an air tight container and then stored in the refrigerator at 4^{o}C prior to extraction.

Experimental Design

After the locust beans seeds were obtained and prepared, the experiment to be carried out were designed with the aid of Minitab 18 software using full factorial design. In designing the experiment, the factors considered were the moisture content and extraction temperature keeping a constant extraction time of 8hr while the response of each experiment was chosen to be the percentage oil yield obtained from the seed. The levels used for the factors is given in table 1. A total of nine experimental runs were obtained and the extraction was carried out using soxhlet apparatus.

Table 1 Factors and their Levels for Full Factorial Design

Variables	Symbol	Levels		
Moisture content (%)	X_1	6	12	18
Extraction temperature (◦C)	X_2	40	50	60

Moisture Content Variation

The initial moisture content determination and moisture content variation of the seeds was achieved using method described by Siyanbola, *et al.*, (2020) and Ogunsola, *et al.*, (2021).

Oil Extraction from African Locust Beans Seed Using Solvent Extraction Method.

Thirty grams (30g) of the conditioned seeds at various moisture content levels were poured and wrapped inside a filter paper of known weight. The samples were carefully inserted inside the extraction chamber which is being suspended above a round bottom flask containing 300ml of ethanol solvent and below a condenser. Heat is being applied to the flask with the aid of a

heating mantle at the desired extraction temperature. The solvent evaporates to the condenser where it is cooled and converted into liquid and falls back into the extraction chamber containing the sample.
The flask containing the solvent and oil was removed at the end of the extraction process after completing 8hr extraction time. The procedure was repeated for other sample at the specified moisture content and extraction temperature in the experimental design. The mixture of the oil and solvent were poured back into the soxhlet apparatus. Heat is being applied to the flask with the aid of a heating mantle at the temperature of 50^0C. The Solvent evaporates to the condenser where it is cooled, converted into liquid and before it falls back into the extraction chamber containing the mixture, it was then poured out into a separate container. The procedure was repeated for other sample until the solvent was completely evaporated from the oil.

Determination of Percentage Oil Yield Obtained from Locust Beans Seeds

The weight of the sample before extraction was recorded as W_i and the residue of the sample after extraction was oven dried at a temperature of 50ºC for about 1 hour in order to evaporate excess solvent present and later weighed and recorded as W_r. The percentage oil yield of each of the sample was obtained.

The percentage oil yield was calculated as follows;

% oil yield= $\frac{\text{Wi}-\text{Wr}}{\text{Wi}} * 100$ (Siyanbola, *et al.*, 2020)

Where;

W_i is the weight of sample before extraction.

W_r is the weight of the residue after extraction.

Analysis of Data

The results obtained from the experiment were analyzed with the aid of Minitab 18 software to develope response equation for analysis of variance (ANOVA) in other to determine the effects of moisture contents and extraction temperature on oil yield of African locust bean seeds.

RESULT AND DISCUSSION

The results obtained after the extraction of the oil from locust beans seeds with initial moisture content of 8.04% is presented in table 2. The two parameter factors, moisture contents and extraction temperature were combined in the experiment to obtain the percentage oil yield as the response. The variation of percentage oil yield obtained indicated that the parameters considered have effects on the extraction of oil from locust bean seeds. It was observed that the highest percentage oil yield of 21.05% was obtained at an extraction temperature of 60ºC and moisture content of 6%. While the least percentage oil yield of 6.51% was obtained at a moisture content of 18% and extraction temperature of 40ºC. The results indicate higher oil content as compared to oil yield reported by Talabi and Enujiugha (2014), Mweta and Magombo (2017) and *Olowokere et al. (2018)* for African locust bean as 20.68±0.71%, 12.06±0.26 % and 11.41±0.03% respectively. It was discovered that the variation of moisture contents with extraction temperature affected oil quantity as reported by Siyanbola, *et al.* (2020) and Ogunsola, *et al.* (2021). The higher the moisture content, the lower the percentage oil yield. This is as a result of the solvent not being soluble in water, with high moisture content, the extraction efficiency of the solvent will be reduced leading to low oil yield. Also, an increase in temperature led to increase in oil yield. This is because as the temperature increases, there is a breakdown of oil cells leading to decrease in oil viscosity and increasing the number of oil siphons which allow oil to flow more readily through. It can be deduced that the combined effects of moisture content and extraction temperature has effect on the oil quantity from African locust bean seeds. The higher result obtained in this study indicated that moisture content and extraction temperature are part of the process parameters that affect the quantity of oil obtained from African locust beans seeds.

As shown in Table 3, the p-value was used to measure how significant the effect of the factors on the percentage oil yield obtained from African locust beans seeds. From the results obtained, it was discovered that each of the factors experimented has a significant effect on the percentage oil yield of African locust beans seeds as the result of the obtained p-value was less than 0.05. The results obtained revealed that variation of moisture content and extraction temperature have a significant effect on yield of locust beans seeds.

Table 2. Factors Considered and Responses

Run Order	Moisture Content (%)	Extraction Temperature (hr)	% Oil Yield
1	12	50	11.65
2	6	40	12.37
3	18	50	9.23
4	6	60	21.05

Total	8	195.342			

CONCLUSION

African locust beans (*Parkia biglobosa)* with an initial moisture content of 8.04%(wb) was obtained and preconditioned to the various moisture content of 6%, 12%, and 18% and extraction temperature of 40^0, 50^0C and 60^0C as stated in the experimental design. Oil was extracted from the seeds using solvent extraction method, the process of extraction was investigated to check the effect of the varied moisture content and extraction temperature, maintaining a constant extraction time of 8hrs. The highest percentage oil yield of 21.05% was obtained at seed moisture contents and extraction temperature of 6% and 60^{0}C respectively. While, the least value of 6.51% was obtained at seed moisture contents and extraction temperature of 18% and 40^{0}C respectively. This indicated that, the parameters varied has effect on the oil quantity. With a higher oil yield obtained in this study using solvent extraction method, this shows that solvent extraction method is more effective in removing oil from oil bearing seeds, makes the industrial practice of the oil recovery a profitable venture and will reduce the level of waste that is obtained from oil extraction.

ABSTRACT

In the Era of Global warming, this study was carried out to establish and obtain empirical data on the level of aflatoxin B_1 (AFB_1) contamination of Nigerian groundnut cake (GNC). It could also bring resurgence of interest in Nigerian groundnut pyramid and a re-focus of interest in nationally sourced GNC for poultry feeding which would be rewarding to the Nigerian feed sub-sector. One hundred and twenty samples of the Nigerian GNC were collected from five locations of two States from each of the six geopolitical zones of Nigeria both in the dry and rainy seasons. The levels of AFB_1 contamination of Nigerian GNC were determined using the Enzyme Linked Immunosorbent Assay (ELIZA) method. It was observed that samples from the Southern geopolitical zones recorded the higher (450.00, 500.00 and 620.00 ppb) levels of AFB_1 contamination compared to the Northern geopolitical zones with (220.00, 190.00 and 241.00 ppb). Meanwhile, the lowest (not detectable) level of AFB_1 contamination were obtained within samples from the North-East (N-E) geopolitical zone. However, the highest (620.00 ppb) level of AFB_1 contamination recorded was among samples from the South-South (S-S) geopolitical zone. Thus, with the right applications of the technological advances in transportation and storage, couple with adequate enlightenment of handlers of GNC on the best management practices, could further reduce the levels of AFB_1 contamination of Nigerian GNC.

Keywords: groundnut cake; aflatoxin B_1; contamination; enzyme-linked immunosorbent assay; not detectable; geopolitical zones.

INTRODUCTION

Groundnut is one of the plant protein source in which Nigeria has comparable advantage of production over other oil seed crops with comparable crude protein content with some other plant proteins. The northern part of Nigeria is famous for groundnut pyramids in the 1960s and early 1970s, and GNC could be easily available for livestock feeding after extraction from the groundnut. In the recent times, the cost of locally available feed ingredients such as maize, GNC and soya bean meal (SBM) have become sky-rocketed due to obvious reasons such as crop failures occasioned by climatic change (Ezihe *et al.*, 2017, Siamabele and Moral, 2021). The direct impact of these on the poultry industry is shortage of the major raw materials needed for feed production. Pre- and post-harvest infection by storage moulds and subsequent mycotoxin accumulation in groundnut seeds are serious problems in the tropical hot and humid areas of the world (Mohammed *et al.*, 2016). The mycotoxins produced by these moulds are toxigenic contaminants of food and feeds that are frequently responsible for health and economic concerns in many countries (Bhatnagar *et al.* 2003). Aflatoxins (AFs) are a group of naturally occurring highly carcinogenic compounds which are mainly produced by *Aspergillus flavus, Aspergillus parasiticus* and *Aspergillus nomius* (Strosnider *et al.* 2006). There are different variants of aflatoxin of which the most abundance and importance are aflatoxin B_1, B_2, G_1 and G_2. Among these, AFB_1 is the most toxic (Lalah *et al.*, 2019).

Medina *et al*. (2014) observed that at a particular interacting situations of two environmental stress factors, there are meaningful influences on the relative amounts of AFB_1 produced. These authors further stressed that one of the associated features of climate change that promote AFB_1 contamination in groundnut, and maize is drought stress in developing countries when water period occur, which might affect their nutritional values. According to Kos *et al*. (2013) prolonged hot and dry weather of 2012 caused AFs contamination of 69% of samples examined. Doboyi *et al*. (2013), as well revealed that climate change could lead to increased AFs contamination. Some reports have also implicated few cases of AFs contamination due to climate change factors (Magan *et al*., 2011). AFB_1 contamination could be stimulated under drought stress at 37^0C and 630 and 1000 ppm CO_2 exposure (Medina *et al*., 2014). Study also predicted that, on a global scale, pests and diseases are moving to the poles at the rate of 3-5 km / year (Bebber *et al*., 2013). This implies that more pest multiplication rates which could cause more harm and promote more infestation of *A. flavus* and contamination with AFs. History have also proved that with an increase in ambient temperature and decrease in rainfall, there can be increase in AFs contamination of peanut in Australia (Medina *et al*., 2014). These authors also noted Africa and Asia as risk regions, where AFs contamination could increase as a result of climate change conditions and a threat to foods / livestock feeds. Availability of water and temperature are known to influence life cycle of mycotoxigenic fungi and mycotoxin production (Sanchis and Magan; Magan Alched, 2007). AFs growth and toxin production could be enhanced by ecological conditions of water available and temperature, for instance, increased temperature (37^0C and water stress (0.95, 0.90 $_{aw}$). The mode of transportation, geographic origin, and the area where the feedstuff is stored, and length of storage in conjunction with certain climate conditions may affect aflatoxins concentration (Peterson and Lima, 2010; Donald *et al*., 2017). Since, climate change could lead to completive interactions among some terophilic fungi during dry and hot periods which could make secondary metabolites to increase, resulting to aflatoxins contamination of stable foods (Leong *et al*., 2010). Thus, there is need to periodically survey and re-verify the level of AFB_1 contamination of Nigerian GNC. Therefore, this study was designed to provide reliable data on the level of AFB_1 contamination of the Nigerian GNC from the six geopolitical zones of Nigeria.

MATERIALS AND METHODS

Preparation of GNC samples for aflatoxin B_1 quantification

The samples collected were prepared according to the manufacturer's (AgraQuant® Aflatoxin B_1 Assay (2-50 ppb) Competitive ELISA guidelines. The following procedures were followed:

i. Representative samples (20 grams) of GNC were put in conical flasks labelled according to the sampling location. The sample was milled so that 95% was able to pass through a 20-mesh screen and thoroughly mixed (homogeneous).
ii. 25 ml of 70% methanol extraction solution (70/30 (v/v) methanol/water) was added to the ground sample and the jar was sealed. Five (5) g of the ground GNC sample was measured using a sensitive scale that can measure in grams.
iii. It was blended for 3 minutes.
iv. Samples were allowed to settle, filtered the top layer of extract through a Whatman No 1 filter paper and the filtrate was collected. Proceeded to the test procedure. Note**:** extracts were allowed to have a pH of 6 – 8 preventing excessive alkaline or acidic condition which might affect the test result, therefore was adjusted before testing.
v. The filtrate was diluted in ratio 1: 2 with the assay buffer provided. Note: the sample in the filtrate served as the antigen.

Quantification of aflatoxin B_1 in GNC samples

The concentration of aflatoxin B_1 was analyzed by a competitive Enzyme-Linked Immunosorbent Assay (ELISA), which is based on an antigen-antibody reaction. For the enumeration, extracted samples were diluted into dilution wells by adding 200 ml of conjugate solution (provided with the kit) with 100 ml of extracted samples. After proper mixing, 100 ml conjugate mixed extract samples were transferred into antibody-coated wells and incubated for 15 minutes at room temperature. Following incubation, the wells were washed 5 times with deionized water (provided with the kit) and later kept dry. Then 100 ml substrate solution was pipetted into the antibody-coated wells and incubated at room temperature for another 5 minutes. Then, 100 ml stop solution (provided with the kit) was added into antibody-coated wells which changed the colour of the solution from blue to yellow. Finally, photometric measurement of aflatoxin B_1 was done by putting the antibody-coated wells in an ELISA aflatoxin B_1 reader (Chromate Plate Reader-4300 / USA) at 405nm, 450 nm and 630nm.

Calculation

To calculate the sample concentration, the curve had been obtained according formula used to calculate the %absorbance. The concentration of AFB_1 was calculated from the calibrated curve and software of the ELIZA machine directly.

Statistical analysis

Data collected from ELIZA were analyzed by the statistical analysis of variance (ANOVA) using the SPSS statistical package version 16.0.

RESULTS

Table 1 shows the AFB_1 contamination levels of the Nigerian GNC samples from the six geopolitical zones of Nigeria. In the rainy season, there were highest (450.00, 500.00 and 620.00 ppb) AFB_1 contamination levels among the samples of Nigerian GNC collected from the three Southern zones, compared to the three Northern zones (220.00, 190.00 and 241.00 ppb). However, during the dry season highest (300.00, 300.00 and 320.00 ppb) AFB_1 contamination levels were reported in samples from South-South (S-W), South-East (S-E) and

S-S respectively. While the highest values (189.00, 162.00 and 235.00 ppb) AFB_1 contamination levels were obtained in samples from North-West (N-W), N-E and North-Central (N-C) respectively. Specifically, the highest mean AFB_1 contamination was recorded in the South-South during the dry season (171.00 ppb), the rainy season (358.00 ppb), and in both seasons (264.50 ppb); while the least mean level of AFB_1 contamination was recorded in the North-East during the dry season (80.18 ppb), in the rainy season (97.25 ppb), and in both seasons (88.72 ppb).

Table 1: Aflatoxin B_1 Level (ppb) of GNC from the Six Geopolitical Zones

	Season								Both	
	Dry				Rainy					
Geopolitical zone	Lowest	Highest	Mean	CV	Lowest	Highest	Mean	CV	Mean	CV
North-west	ND	189.00	95.88	1.33	12.00	220.00	116.00	1.45	105.94	1.39
North –east	ND	162.00	80.18	1.43	4.50	190.00	97.25	1.48	88.72	1.45
North-central	ND	235.00	124.07	1.34	22.00	241.00	131.50	1.42	127.79	1.38
South-west	1.80	300.00	140.19	1.50	61.00	450.00	255.50	1.38	197.85	1.44

production. Therefore, transportation process and storage techniques may also be among the factors that contributed to the relatively higher levels of AFB_1 contamination of Nigerian GNC in the Southern zones of Nigeria (Abass *et al*., 2017). Since, climatic and storage conditions play vital roles in the growth of aflatoxin B_1 producing fungi (Mutegi *et al*., 2013).

CONCLUSION

Generally, the study established that the AFB_1 contamination of Nigerian GNC was higher in the Southern zones compared to the Northern zones of Nigeria. This is evident that AFB_1 contamination levels in most especially Southern Nigeria requires more attention. It is suggested that extension officers should take up the task of adequately creating the awareness of AFB_1 contamination of GNC, its possible effect on the value of the GNC and well-being of poultry as well as its economic effect among the farmers. Also, levels of AFB_1 contamination of Nigerian GNC can be reduced by intensifying surveillance at various points of GNC production, and ensure that infected groundnut seeds are not used in the production of GNC.

ACKNOWLEDGEMENTS

The authors sincerely appreciate the supports (in terms of samples collection and analysis) of Animal Care Consult and Hybrid Feed through my friend and brother, Sir. Clement Adebija (-a former staff of Animal Care Consult).

ABSTRACT

The World Health Organization recognized foodborne illnesses and occurrences as a foremost public health threat globally. Personal hygiene practices are keys to making street food and snacks safe to consume and the perception its handlers on personal hygienic practices rank high amongst the major concerns that may potentially lead towards food not being safe. This study therefore primarily examined the perception of the street food and snacks vendors in the study area on personal hygiene viz-a-viz safe food for the consumers. Using a 2-stage sampling procedure, 60 respondents were selected and relevant information collected from them using a well-structured questionnaire. Data collected were analyzed using simple descriptive statistics. The results shows that majority (53%) of the respondents were not registered with NAFDAC; most of them (53%) are engaged in the street food and snacks business full time. About 70% of the respondents sell only snacks and most of them are new entrants into the business with less than 5years experience. Furthermore, the study revealed that 45% of them do not really see washing of hands as a compulsory practice and 67% of the respondents do not agree with the use of hand gloves in selling their snacks. The study concluded that the respondents have poor perception about personal hygiene as a food safety measure in street food and snacks selling business. The study therefore recommends that the relevant agencies beam their light on the study area to educate the stakeholders in the sector.

Key words: Food-Safety, Hygiene, Perception Snacks

INTRODUCTION

World Health Organization (WHO) recognized foodborne illnesses and occurrences as a foremost public health threat globally of the 21st Century (World Health Organization (WHO), 2015). Unsafe food handling increasingly results in bacterial food poisoning cases in Saudi Arabia (El Sheikha, 2015). It is therefore imperative that safe foods are consumed. Food safety is a vital issue both in developed and developing countries; given that food borne illnesses contribute to millions of illnesses and thousands of deaths annually (Pilling, et al., 2008). A vital aspect of food safety is good knowledge and right perception of good personal hygiene measures. This is more critical for those who handle food and or snacks consumed by the public. Snacks and street foods or fast foods are "ready-to–eat" foods and beverages that are prepared and sold by vendors and hawkers especially in the street and other similar public places (Food and Agricultural Organization, 1997). Preparing and selling food on the streets provide a constant income for millions of unenlightened people in fact; approximately 2.5 billion people around the world consume street-food (snacks) every day (Food and Agricultural Organization (FAO), 2011). Personal hygiene according to (Rahman, Tosepu, Karimuna, Yusran, & Junaid, 2018) is a way of caring for humans to maintain their health. Maintenance of individual hygiene is needed for individual comfort, security, and health. It is also very important that public food handlers keep basic rules of hygiene so to ensure the safety of their customers. The perception of the respondents about personal hygienic practices of food handlers' rank amongst the major concerns that may potentially lead towards food not being safe. In this study, some basic occupational traits of street food and snacks vendors and their perception of personal hygiene as food safety measures in the study area was assessed.

METHODOLOGY

The study was carried out in Dutsin-Ma town, the Dutsin-Ma Local Government Area headquarters which hosts the Federal University Dutsin-Ma as well as the Isah Kaita College of Education with several secondary and primary schools as well as other government and private agencies. The Local Government lies between latitude 120 17.00ʹN to 120 17.84ʹN and longitude 0070 26′ E. It has a land size of about 552.323km^2. Although the indigenes are predominantly crop farmers, cattle farmers and traders, the town plays hosts to thousands of students and workers that are not indigenes. The community comprise of Hausa and Fulani ethnic groups while Islam is the predominant religion.

A two-stage sampling procedure was used to select 60 street food and snack vendors interviewed for the study. In the first stage, Purposive selection of six (6) locations where street food and snacks vendors were concentrated (Wednesday market road, FUDMA take-off site environs, Hospital road, Wednesday market, Old market and Gangere Motor Park) was made. The street food and snacks vendors were counted to be 505. In the second stage, 60 samples were proportionately selected and used as samples for the study. The 60 sample size was selected using raosoft calculator using 10% margin error, 90% confidence level, and 50% response distribution (www.raosoftcalculator/samplesize.html). A well-structured questionnaire was used to collect relevant information from the respondents. The data was analyzed using simple descriptive statistics.

RESULTS AND DISCUSSION

Basic occupational traits of the vendors of the street food and snacks vendors in the study area

Basic occupational information of the vendors is shown in Table 1. Majority of street food vendors (93%) are not registered with National Food and Drug Administration and Control (NAFDAC). However, seven percent (7%) vendors are registered members with the agency. This implies that there is probably no monitoring of what the vendors are selling to the public in the study areas. Majority (53%) of the responses are full time street food and snacks vendors while 47% are part-time with other things they do for a living. A good majority (70%) of the respondents sells snacks only, 25% sells food only while 5% sells both food and snacks. This probably is because the study area is a community dominated with many students of tertiary institutions who prefers fast food most of the times. About 25% of the street and food vendors have between 6 and 16 years' experience while 12% have between 17 and 22 years' experience. Most of the respondents have less than 5 years' experience. This might be due to the fact that most of the respondents are also young. Only 8% have years of experience greater than 22 year.

Level of perception of food safety measures among the street food and snacks vendors in the study area

The respondents were confronted with some basic personal hygiene measures and their perception on each were documented in table 2. The result revealed that only 33% of the food and snacks vendors strongly believed that hands should be washed before handling food items. Furthermore, 22% agreed to this assertion but 45% are careless about washing of hands. It shows that a good number of these vendors have poor perception about hand washing before and after food and snacks handling. According to (Abdalla, Abdalla, Suliman, & Bakhiet, 2009), hand washing is an important aspect of personal hygiene expected to be strictly adhered to by food and snacks vendors because the organisms such as *Salmonella typhi*, non-*typhi salomnella*, *Compylobacter* spp. and *E. coli* can survive on fingers tips and other surfaces for varying periods of time and some cases after hand washing. On the issue of washing of utensils, a good majority have a good perception to it as 38% and 50% of the respondents strongly agreed and agreed to it respectively. Those who are indifferent, those that disagreed and those who strongly disagreed to this assertion were 8%, 2% and 2% of the respondents respectively. The vendors' perception on covering of wounds during the process of handling food items is fair, about 75% of them agreed/strongly agreed to the assertion. On the issue of staying back at home, 26% of them did not see much need to that assertion. The vendors have a good perception about using clean containers for storing food items. According to Table 2 also, 84% of the respondent agreed that deteriorated food should be disposed properly. This implies that most of the respondents are not adding deteriorated food or snacks to newly prepared ones in order to maximize profit. Those who disagreed with this assertion are just 2% while 15% are indifferent. Covering of mouth/nose while sneezing is a hygienic practice that some people might take lightly. According to the result presented in Table 6, 7% disagreed on the need to practice it as food handlers while 48% said they are indifferent. This implies that more than 50% have the probability not to imbibe the practice. This definitely will expose consumers of snacks and food from such people to communicable diseases. From the result also, less than half of the respondents (46%) agreed with the assertion properly covering of food/snacks after preparation. Furthermore, 3% did not see the need for that practice while 51% are indifferent meaning that practicing it for them is by chance and not deliberate. From personal observation of the researcher during data collection, many food and snacks vendors do not cover their items properly.

Similarly, 10% of the food and snacks vendors never agreed to the need for the use of hand gloves/fork to pick food items. They probably see that as luxury and not needed. On the other hand, 57% are indifferent on the use of hand glove or fork implying that they will only use such by chance. On the vendors' consideration for the neatness of their selling points, the result in Table 2 shows that 65% of the respondents agreed that it is a very important factor to consider. On the other hand, 17% are indifferent while 18% out rightly disagreed on the need to consider the neatness of their selling points. This might be the reason why some of them as observed are located in indecent places selling snacks.

From the results discussed, it is obvious that the perception of the street food and snacks vendors in the study area is weak to make them serve safe foods to the consumers. Similar studies like (Wafa, Anushree , & Amit, 2018) highlighted poor knowledge of mothers in Saudi Arabia with regard to food handling and poor knowledge of food handling among women in Saudi Arabia was reported. (Farahat, El-Shafie, & Waly, 2015).

Table 2: Level of perception of food safety measures among the street food and snacks vendors in the study area

Safety Measure	*Level of perception				
	S.A	A	I	D	S.D
Hand washing before and after food preparation	20 (33)	13 (22)	27 (45)	0	0
Washing of utensils before and after use	23 (38)	30(50)	5(8)	1(2)	1(2)
Covering of wound properly during food/snacks preparation	19(32)	25(42)	14(23)	2(3)	0
Staying back at home when indisposed or sick	19(32)	25(42)	13(21)	3(5)	0
Using of good and clean containers for storing food/snacks after processing	21(35)	30(50)	9(15)	0	0
Properly disposing of deteriorated food/snacks	19(32)	31(51)	9(15)	1(2)	0

Covering of mouth/nose while sneezing/coughing	15(25)	13(22)	28(46)	4(7)	0
Covering of food/snacks after preparation	14(23)	14(23)	30(50)	2(4)	0
Use of hand gloves/fork for dispensing food	14(23)	6(10)	34(57)	6(10)	0
Neatness of selling point location	19(32)	20(33)	10(17)	11(18)	0

Source: Field Survey, 2021

CONCLUSION AND RECOMMENDATION

Based on the findings of this study, it was concluded that the street food and snack vendors in the study area has poor perception about personal hygiene as a measure of food safety. It therefore recommends that the relevant agencies should pay attention to the sector in the study area to curb impending health consequences.

Agricultural Society of Nigeria
24 - 28 Oct., 2022

ABSTRACT

The study was carried with a view to evaluating the proximate constituents of some fruits sold in Abraka, Delta State, Nigeria. Selected fruits were velvet tamarind (Dalium guineensis), soursop (Anona muricata), pineapple (Ananas comosus) and avocado (Persea americana). The fleshy parts were oven dried, blended and analysed. The results showed variations in the proximate content of the fruit species P. comosus has the highest moisture composition (86.76) followed by A. Muricata (75.00%) and P. Americana (67.87%) while D. guineensis had the least value (10.30) for moisture content. Ash was highest in A. muricata (3.43%) followed by D. guineensis (2.52%) and least in A. comosus (0.34%). Crude fibre was higher in A. comosus (7.00%) followed by P. americana (4.65%). Carbohydrate was significantly higher (P$\leq$0.05) in D.guineensis when compared with values recorded for A. comosus (9.87%). The study indicated that D. guineensis can be used as a source of protein as it could help in body building and cells repair. Fat is a good source of energy and a medium for dissolving vitamins A, B, C and K hence P. americana could be taken as a source of fat beside the fibre ash and other mineral contents. The study has confirmed the presence of numerous mineral chemicals and nutrients in the fruit studied hence, should be included in our daily diets for optimum body metabolism and maintenance of good health.

Key words: Fruits, proximate compounds, good health.

INTRODUCTION

Fruits are excellent sources of nutrients and are antioxidants packed. They are rich in vitamins, minerals, fibres, water and organic acids (Agbogidi, 2019). Dieticians have encouraged the eating of fruits to maintain good health and protection against heart diseases, cancer, kidney stones and type 2 diabetes (Ekpete and Edori, 2013). Fruits are also low in calories hence, useful in weight management (Li, 2008; Adeputu, 2009). Everyone including children need adequate fruits to stay healthy and for optimum body metabolism. Fruits are rich in carbohydrates, vitamins; A, B1, B2, C, and E, and minerals such as Ca, Mg, Zn, Fe, K, and other organic compounds and anti-nutrients (Panda, 2010; Terry, 2011). It is also common that fruits vary in their nutrient contents hence the need to assess the proximate analysis of some fruit species sold in Abraka, Delta State with a view to recommending the very nutrient rich ones to the rural populace of Abraka and its environs.

MATERIALS AND METHODS

Study area: The study was carried out in Abraka, Delta State. Abraka is located in Ethiope East Local Government Area of Delta State and is situated between latitude 5^0 45' and 5^0 5^{0}' N and longitude 6^0 and 6^0 15'E in an agglomeration of several communities that are aligned linearly along the New and Old Sapele-Agbor highway. The Abraka area is a typical coastal plain terrain, monotonously lowland and flat with a gentle slope towards the Ethiope River. The climate is equatorial, hot (23 to 37^0C) and humid (relative humidity, 50 to 70%). There is dry season from about November to February and a wet season that begins in March, peaks in July and October. Vegetation is rainforest, most of which has been decimated and replaced with farmlands and secondary forest (Efe and Aruegodor, 2003).

Collection of fruit samples: Selected fruits (velvet tamarind, soursop, pineapple and avocado) were purchased from Abraka main market. The fleshy parts were oven dried and blended to fine powder using mechanical blender. The samples were stored in clean polythene bags and taken to the laboratory for analysis of proximate composition.

Proximate analysis: Moisture contents was determined by the gravimetric method described by Kjeldahl method, total ash content was by the furnaces incineration gravimetric method following the procedure of James (1995) and AOAC (2003). Crude fibre was determined by the method of James (1995), crude fat was by solvent extraction gravimetric method described by Kirk and Sawyer (1980) and carbohydrate was determined using the method of James (1995).

Results obtained were subjected to one-way analysis of variance while the significant means were separated using SAS (2006). Stored in clean polyethylene bags and transferred to the laboratory for analysis of proximate contents.

RESULTS AND DISCUSSION

The scientific information of the fruit species used are described in Table 1.
Proximate composition of fruits sold in Abraka, Delta state, Nigeria is described in Table 2.

Table 1. Scientific information of the fruit species used

S/n	Common name	Scientific name	Family
1.	Velvet tamarind	*Dialium guineense* Willd	Fabaceae
2.	Sour sop	*Annona muricata* L	Annonaceae
3.	Pine apple	*Ananas comosus* L. (Mere)	Bromeliaceae
4.	Avocado	*Persea americana* Mill	Lauraceae

Table 2. Proximate composition of fruits sold in Abraka, Delta State

Fruits	Proximate composition %					
	Moisture	Ash	C.Fibre	C.Fat	C.Protein	C .Carbohydrates
D. guineensis	10.30d	2.52b	1.18c	5.66b	3.71a	77.79a
A. ***Muricata***	75.00b	3.43a	0.19d	3.25c	2.91b	15.41b
A. comosus	86.78a	0.34d	7.00a	0.26d	2.77c	9.87d
P. americana	67.87c	1.05c	4.65b	14.63a	2.76c	13.69c

Means with different letters in the same rows are significantly different at (P≤0.05) using the Duncan's Multiple Range Tests (DMRT).

The results showed variations in the proximate content of the fruit species *P. comosus* has the highest moisture composition (86.76%) followed by *A. muricata* (75.00%) and *P. Americana* (67.87%) while *D. guineensis* had the least value (10.30%) for moisture content. Ash was highest in *A. muricata* (3.43%) followed by *D. guineensis* (2.52%) and least in *A. comosus* (0.34%). Crude fibre was higher in A. comosus (7.00%) followed by *P.americana* (4.65%). Carbohydrate was significantly higher (P≤0.05) in *D.guineensis* when compared with values recorded for *A. comosus* (9.87%). The study indicated that D. *guineensis* (77.79%) can be used as a source of protein as it could help in body building and of cells repair. Fat is a good source of energy and a medium for dissolving vitamins A, B, C and K hence *P. Americana* could be taken as a source of fat beside the fibre ash and other mineral contents (Ganny, 2008). The high source of water in *A. comosus* is similar to the water content of paw paw (Aravind *et al*., 2013). Apart from its sweetness and high water contents, pineapple and some chemical composition that protects the kidney against kidney stones and excessive blood pressure (Ekpete and Edori, 2013).

CONCLUSION

The study has confirmed the presence of numerous mineral chemicals and nutrients in the fruit studied hence, should be included in our daily diets for optimum body metabolism and maintenance of good health.

24 - 28 Oct., 2022

ABSTRACT
Postharvest fungal rot is one of the major constraints to sweet potato production. Combined methanolic extracts of *Allium sativum* and *Zingiber officinale* and *Allium sativum* and *Moringa oleifera* were evaluated for efficacy in inhibiting postharvest rot of sweetpotato using preventive and curative methods, with Mancozeb 80WP (0.2%) used as a positive control. The design was CRD with 3 replications. Data was analyzed using Analysis of Variance and differences between means were compared using Duncan's Multiple Range Test (P=0.05). The result showed that combined methanolic extracts of *A. sativum* and *Z. officinale* or *M. oleifera* were effective in reducing rot of sweet potato when applied in both preventive and curative methods. Mancozed, *Allium sativum/Zingiber officinale* extract combination and *Allium sativum/Moringa oleifera* extract combination exhibited rot inhibitions that ranged from 85.9333 ± 0.4099 to 100%, 39.4133 ±0.3099 to 97.8367±0.0876 % and 31.9400±0.0971 to 99.0467 ±0.5374% respectively. There was significant (P=0.05) interaction between the control methods and treatments for all the pathogens. Control treatments were more effective when applied as a preventive measure than in curative form, shown by a significantly higher rot inhibition exhibited in the sweet potatoes pre-inoculated and pre storage treatment tests in both plant extract combinations than those of post-inoculated treatments in 14 days of storage at room temperature. Therefore, combined methanolic extracts of *Allium sativum* and *Zingiber officinale* or *Allium sativum* and *Moringa oleifera* holds promising prospect for use in the development of novel bio-fungicide for management of postharvest rot of sweet potatoes.

Keywords: *Zingiber Officinale*, In vivo, Postharvest Rot, Sweet Potato, Extract Combinations, Control

INTRODUCTION
Sweet potato roots are susceptible to many microbial infections at different stages including field stages including field, harvest, storage (if they are not properly harvested and stored) and marketing stages (Alum *et al*., 2019a). In a previous study, three hundred and fifty-two fungi were isolated from 200 sweet potato samples from Ebonyi State. Seven species of fungi including

Botrydiplodiae theobromae, Rhizopus oryzae, A. niger, A. flavus, F. solani, P. expansum and *A. awamori* have been implicated with sweet potato rot causation in Ebonyi State; inciting four categories of rot (dry rot, soft rot, java black rot and blue green mold) (Alum *et al.*, 2019a). Fungi rot on roots of sweet potato significantly (P=0.05) depletes carbohydrates, crude fibre and moisture contents (Alum *et al*, 2019b).

Due to the negative economic importance of the fungal pathogens, their control on sweet potato is needed. Given the drawbacks associated with the orthodox rot control approaches based on chemicals, focus in recent times, has shifted toward exploitation of plant extracts as novel fungicides in plant protection (Akueshi *et al.*2002; Okigbo and Nmeka, 2005). Two plant extract combinations (Combination of *Allium sativum* and *Zingiber officinale* extracts and combination of *Allium sativum* and *Moringa oleifera* extracts have been reported to inhibit mycelia growth of postharvest rot-inducing fungi in vitro with no antagonism {Alum and Umeh, 2020). According to Ranasinghe *et al.* (2002), the antimicrobial activity of plant extracts that is observed in *in-vitro* conditions is quite different from its effect in complex food systems. In most cases, antimicrobial activity is decreased due to interactions with food components (Ranasinghe *et al.* 2002).

Despite this recognition, there was however, paucity of information on the ability of the said plant extract combinations (Combinations of *Allium sativum* and *Zingiber officinale* and *Allium sativum* and *Moringa oleifera*) to inhibit sweet potato fungal rot in vivo. Against this back drop, the present study was therefore aimed at testing the sweet potato postharvest rot inhibitory capability of combinations of *Allium sativum* and *Zingiber officinale* and *Allium sativum* and *Moringa oleifera*.

MATERIALS AND METHODS

To determine if the antimicrobial-producing plant extracts combinations have a potential application in bio-preservation of sweet potato roots, a food trial was undertaken using the methods of Tijjani *et al.* (2013). Fresh, healthy sweet potato roots of the Tupiaochi cultivar were purchased from Ebonyi sweet potato farmers and used for the evaluation. Seven fungi including *Botryodiplodia theobromae, Fusarium solani, Aspergillus flavus, Aspergillus niger, Penicillium expansum, Rhizopus oryzae* and *Aspergillus awamori* isolated from symptomatic sweet potato roots and confirmed responsible for postharvest spoilage of sweet potato in Ebonyi State in a previous study (Alum *et al.*, 2019a) were employed in the study. The treatments included negative control (sterile distilled water), positive control (Mancozeb), *A. sativum* and *M. oleifera* extract combination and *A. sativum* and *Z. officinale* extract combination. Evaluation was done via two methods- preventive and the curative methods. This evaluation was based on the method of Tijjani *et al.* (2013) with modification in the quantity of applied inocula (3 x 104 sporangia/ml of sterile distilled water according to Suleiman and Emua (2009). The negative control set up consisted non-treated, wounded and inoculated while the positive control setup was sweet potato roots treated with Mancozeb 80WP (0.2%). The inoculated sweetpotato roots were incubated at room temperature (28 ± 2^{o}C) for 14 days. After the incubation period, the tubers were incised horizontally with sterile knife. The length of rotted portion from each hole was measured over the total surface length with a metre rule and fungitoxicity determined in form of percentage growth inhibition which was calculated according to the formula of Okigbo and Nmeka (2005)

$$\text{Growth inhibition (\%)} = \frac{(LC - LT) \times 100}{LC}$$

Where: LC = average length of unrotted portion of control and LT = average length of unrotted portion with treatment.

The Experimental set up was Completely Randomized Design with 3 replications. All data were analyzed by Analysis of Variance (ANOVA) using SPSS 20.0 Version. Differences between the treatment means were tested using Duncan's New Multiple Range Test. Significance was considered at P=0.05.

Results and Discussion

Results on the effect that mancozeb and the combined plant extracts exhibited against the postharvest rot caused by the test fungi on sweet potatoes is presented in Table 1. The results showed that all treatments significantly inhibited rot development by all the fungi compared to the negative control (non-treated, wounded and inoculated root) that gave zero inhibition. Furthermore, the results showed significant (P=0.05) interaction between method (preventive and curative) and treatments for all the pathogens. Inhibition of rot exhibited by all the treatments was significantly (P=0.05) higher with the preventive method than with the curative method across all postharvest pathogens except in only *A. niger* where percentage inhibition (100%) recorded by mancozeb was the same in both preventive and curative methods. This lends credence to the report that effective disease management strategy is proactive and prophylactic rather than curative (Amaeze *et al.*, 2009). Mancozed, *Allium sativum/Zingiber officinale* extract combination and *Allium sativum/Moringa oleifera* extract combination exhibited rot inhibitions that ranged from 85.9333 ± 0.4099 to 100%, 39.4133 ±0.3099 to 97.8367±0.0876 % and 31.9400±0.0971 to 99.0467 ±0.5374% respectively. The highest percentage rot inhibition (100 ± 0.00%) was recorded by mancozeb against *A. niger*; however, inhibition of *B. theobromae* by mancozeb (88.8267±0.0807%) was significantly lower than that of *Allium sativum/Zingiber officinale* extract combination (91.1233 ±0.1510%) on the same pathogen.

The in vivo effects of the single plant extracts was not evaluated in this study, therefore there were no values with which to compare the in vivo effects of the combined extracts so as to ascertain potentials for synergism or otherwise. However, when comparing the in vivo effects of combined plant extracts to them in vitro effects as well as the in vivo effects of Mancozeb, a parallel may be drawn between results from the in vivo study and those achieved by the in vitro study, in that the results of the in vivo effects showed a similar trend (above 50% inhibition) with those in the in vitro assay.

CONCLUSION

Combinations of *A. sativum /Z. officinale extracts* and *A. sativum/ M. oleifera* extracts hold promising prospect for use in the development of novel biofungicide for management of postharvest fungi/rot of sweet potatoes. For optimum results however, the treatment regimens should be applied as a prophylactic measure. The plant extract combinations however, need to be subjected to further evaluations.

ABSTRACT
This study analyzed food insecurity and coping strategies among female headed households in Abia State, Nigeria. 0ne hundred and twenty (120) female headed households were randomly selected from the study area using multi stage random sampling techniques. Primary data were obtained using structured questionnaire. The objectives of the study were analyzed using percentages responses and probit regression model analysis. The result obtained showed that most of the female headed households were aged, high literacy level (87.5%) and moderate household size (1 – 6 persons). Also, the household size and level of education were the determinant factors to attainment of food security by female household. The result also indicated that the most common coping strategies for food insecurity were engagement in off-farm income (68.33%), while the least was migration (20%). There is need to enhance farmers' access to adult education and labour-saving devices at subsidized cost.
Keyword; Food insecurity, Coping strategies, female headed households, Abia State, Nigeria

INTRODUCTION
Agriculture is Nigeria, single largest industry apart from oil sector with smallholder farmers being in the helm of the affairs, just like many parts of the world (IFAD, 2013). In, Nigeria and many countries in sub-Saharan Africa, women constitute about 70 – 80% of the farming population, and play important roles in food and agriculture (World Bank, 2013). Despite the efforts of this farming class in enhancing food sufficiency to the world population, but in many developing countries, this farmers have limited access to land; credit facilities farm input training and advice, technology and crop insurance among other things. The worse-off among the women is female headed households, who run their own farms without male assistance. (Ume, *et al;* 2018). Studies show that compare to the male counterpart, this class of household is poorer and continue to grow due to socioeconomic characteristics and among others (Sepahvand, 2019). Studies show that when women farmers have the same access to productive resources as men, they can increase yields by 20 to 30 percent (Sepahvand, 2019). In developing countries, this could potentially increase overall agricultural output by 2.5 to 4 percent and lift 100 to 150 million people (IFAD, 2012).
In Nigeria, successive governments have instituted varied programmes to cushion the effects of food insecurity through enhancing the farmers' access to improved farm inputs and tools and technical support, traditional thrift and saving and value-added access to credit as a way of alleviating poverty (Dauda, 2014). However, the success of the poverty alleviation programmes as asserted by World Bank (2013) had been hampered by inadequate financial support, corruption, inability to board the essential population and human resources, war, and community dissension. In effect, food insecurity continually spreading like wide fire and, studies revealed that the household structure both in urban and rural areas have devised several coping strategies in averting maximally

food insecurity ((Burvinic and Gupha, 2013) This study tends to bridge the research gap in the study area, as regards the determinant factors influencing the attainment of food security and coping strategies adopted by the female headed households.

MATERIAL AND METHODS

The study was carried out in Abia state. Abia State lies between latitudes $04^0$45'and 04º41' North and longitudes $7^0$5' and $08^0$04' East. It occupies a total land area of 6,420square kilometer with a population of approximately 284.104 million people (NPC, 2006). It has annual rainfall of 1800-2000mm and temperature range of 22^0C-38^0C during the year. The people in the area are predominantly farmers, although engage in other economic activities.120 female headed households were randomly selected from 12 Local Government Area out of 17 that made up the state for detailed study. Structured questionnaire and oral interview were used to collect the data. Percentages responses and probit model analysis were used to address the objectives of the study.

Model Specification

Probit Analysis

The probit analysis was used to capture the determinants of poverty among the rural farming household. The model can be stated as:

$1*_i = \beta Tx_i + ei$ ………………………………………………………………… (1)

$Y_i = 0$ if $1*_i = T$ ……………………………………………………………… (2)

$Y_i = 1$ if $1*_i > T$……………………………………………………………… (3)

Where Yi represents a limited dependent variable which simultaneously measures the level of poverty and the level of is an underlying latent variable that indexes adoption. T is an observed threshold level, X is the vector of independent variables affecting poverty level, β^T is a vector of parameters to be estimated, and ei is the error term. If the non-observed value of 1* is greater than T, the observed variable Ti becomes a continues function of the independent variables and O otherwise. The model is specified in an implicit form as follows:

$Y = F (X_1, X_2, X_3, X_4, X_5, X_6, X_7, X_8 + ei)$

Y = Food security status (Secure; 1; insecure; 0. X_1= Age of the respondents(years), X_2= Off- farm income (N), X_3 = Educational Level (Years), X_4 = Farming experience(Years), X_5= Household Size (No).

RESULTS AND DISCUSSION

Table 1: Socioeconomic Characteristics of Female Household Heads

Variable		Frequency	Percentage

Source: Field Survey, 2021

Table 1 shows that the mean age of the respondents was 52 years old. This implies that most of the female headed households have dependents and could adopt technologies to enhance their food security status (Burvinic and Gupha, 2013). Also, 54.17% of the respondents had household size of 1- 6 persons, followed by 41.67%; 7- 12 persons, while the least 4.17%; 13-18 persons. Amber, *et al;* 2014) reported that large household size that is dependent population tends to exert more pressure on consumption than the labour it contributes to production. Besides, 12.5% of the respondents had no formal education, 87.5% had formal education. Educational status of the farmer makes her to be more objective in evaluating innovations which could positively influence their food secure status through attainment of high productions targets (World Bank, 2013). Table I moreover shows that 83.3% of the respondents had years of farming experience above 10 years, while 16.7% had less than 11 years. The average year of experience was 27. This implies that most of the female headed households are well experienced in farming In order to diversify her production and minimize risks of food shortages (FAO, 2019). Furthermore, majority (83.3%) of the sampled population engaged in off farm income and only 16.7% do not. Off -farm income could be used for family consumption and to offset market risks (World Bank, 2013).

The result in Table 2 indicated that the most common coping strategy of food insecurity in the study area was employment in off- farm activities.

Table 2: Distribution of female household heads according to coping strategies adopted by

Strategy	Frequency	Percentage
Decrease in meal frequency	78	120
Sale of farm assets and land	45	37.5
Over reliance on remittance	74	61.67
Withdrawal of children from school	38	31.67
Reduction in other expenditure	50	41.67
Off farm income	96	80
Food aid	65	54.27
Migration	24	20

*** Multiple responses**

Source: Field Survey, 2021

Literatures show that reasons for this observed income diversification include declining farm incomes and the desire to insure against agricultural production and market risks (Ogbonna, 2018). Also, female household, in particular pulled into the off-farm sector, especially when returns to off-farm employment are higher or less risky than in agriculture, resulting in "demand-pull" diversification. The result also showed that the least, (20%) adopted coping strategy was migration. This strategy is common among herders in the far northern part of Nigeria, who are often confronted with scarcity of fodder and water during certain periods of the year. To that effect migrate southwards where these resources are abundance to caution the effect (Ume, *et al*, 2018).

****, **, * Significant at 1.0%, 5.0% and 10.0% levels respectively*

The coefficient of the age of the female headed household was positive and significant at 5% probability level. This implies that as age of the household advances, there is likelihood of decrease in being food secure especially where they have many dependent populations. Furthermore, as expected, the coefficient of level of education of the respondents had positive relationship with food security attainment and significant at 1% alpha level. This could be attributed to the fact that educated female headed households have the likelihood of attaining improved financial resources, which in turns raises their farm productive capacity (Ume, *et al*; 2018). Moreover, the coefficient of the female headed household size was positive and in line to apriori knowledge and significant at 5% probability level. The sign identity of the variable could be linked to the use of members of the household in farming for increased output which turn out for higher income. Nevertheless, Amber; *et al*; (2013) found negative relationship between household size and food security. They were of the view that increase in one additional member per head, generally reduces income per head, expenditure per head, and per consumption increases with a rise in household members.

CONCLUSION AND RECOMMENDATION

Based on the finding, the following conclusions were deduced; First, most of the respondents were aged, educated, had moderate household size and well experienced. Second, the educational level of the farmer and household size were the determinant factors to attainment of food security.

Based on the conclusion, the following recommendations were proffered

Government and non-governmental organizations (NGO) should intensify efforts on importance of family planning and advocate for small family size. As well, Farmers with large household size should be encouraged to be actively involved in adoption of technologies since large household size would provide the much needed labour requirements in food production activities at low cost, compared to hired labour. Also, there is need to strengthen the current policies on education such as the universal basic education, adult education and nomadic education. Furthermore, policies aimed at improving farmer's access to education through aggressive awareness campaign and mass mobilization are needed.

ABSTRACT

To understand the varietal traits that attract cassava seed users and their willingness to buy the cassava varieties that possess the desired traits, a study was conducted in four selected states in southeast and south-south geopolitical zones of Nigeria where the activities of Building a Sustainable and Integrated Cassava Seed System (BASICS Project) is currently going on. The study adopted a combination of purposive and random sampling techniques to select 44 cassava farmers who have patronized the cassava seed entrepreneurs. Data obtained were subjected to descriptive statistics and probit regression analysis. Results of the study revealed three distinct trait categories that attracted the interest of the users. These categories include: Agronomic traits, product characteristics and marketability traits. Also, the probit regression output shows that farmers who planted local varieties previously were more likely to be willing to buy improved cassava varieties. Also, there is a varietal preference for TME 419 due to its high starch content and whitish colour including high dry matter content. It was therefore recommended that the identified traits should guide breeders in further varietal developments and the preferred variety (TME 419) should be massively multiplied and distributed to ensure that farmers have access to it at all times.

Key words: Cassava, seed, improved, varieties, farmer, preferred, trait

INTRODUCTION

Cassava is one of the important tropical root crops in Nigeria and Africa as a whole, considering that over 30 million Nigerian farmers, traders and processors are engaged in cassava value chains and agribusiness. Undoubtedly, Nigeria is the world's largest producers of the crop (FAO, 2020). Despite these achievements, cassava production is characterized by over 80% of smallholder farming outlay and dominant use of old and local varieties with traditional production technologies. These account for low yields experienced by the farmers.

National Root Crops Research Institute (NRCRI) Umudike and International Institute for Tropical Agriculture (IITA) Ibadan have developed varieties to meet the needs of the end users and increase demand. Such traits as high dry matter, high yielding, disease resistant, early maturing, high beta carotene content etc., constitute the quality demanded by the farmers. However, quality content of these traits differs according to variety, therefore will form a major consideration for the farmer to buy such variety. Before now, Teeken et al (2018) had opined that Nigerian cassava breeding programs prioritize traits in setting breeding agenda so as to impact the largest possible number of people through improved varieties. Furthermore, IITA (2021) reported that improved cassava varieties have been subjected to years of preference studies with rural women who plant, process and eat cassava. These varieties resist pests like cassava mosaic disease (CMD), have the right color and texture when prepared as meals.

Willingness to buy certified improved cassava seed is a measure of the ability and preparedness of a farmer or user to exchange a commodity with money payment due to certain accepted criteria that the variety possesses. Certainly, for a farmer to be willing to pay for a preferred variety, his or her perception of the seed should be better than what the farmer is already using and have the ability to give a positive return on investment. The expectation is influenced by quality traits of the variety that meet the criteria for selection by the farmer and at an affordable price. Deal breaker traits are those attributes (phenotypical and genotypical) of a cassava variety that qualifies it for acceptability by the farmer and end users. Such traits include agronomic, processing and marketability qualities of the variety that distinguishes it from other varieties and thus attracts demand from users. In other words, deal breaker traits are those traits that the variety possess as a sufficient condition for a buyer to take decision to buy. This study therefore seeks to identify those traits that a cassava variety should possess that will facilitate farmers' preference and willingness to buy the variety.

METHODOLOGY

The study was carried out in south-east and south-south geopolitical zones of Nigeria. Two states were purposively selected from each zone based on BASICS activities in the states. In South-East, Abia and Imo states were selected while in South-South; Cross River and Akwa Ibom states were selected. The respondents were selected from a list of customers who purchased stems from the key CSEs that sold cassava seed during the 2018 planting season. A total of 44 cassava farmers who are customers to the CSEs were identified and selected. The researchers adopted a snowball method to trace the respondents whose distribution is presented in Table 1 below.

Table1: Distribution of respondents according to states

States	Number
Abia	7
AkwaIbom	20
Cross River	5
Imo	12
Total	44

Data collected were analysed using simple descriptive tools such as percentages and a probit regression analysis.

RESULTS AND DISCUSSION

Deal -Breaker Traits of Preferred Improved Cassava Varieties in the study area.

Preference to cassava varieties is pivotal to adoption, utility and commercialization of cassava. Since the varietal traits contained in the seeds cascades down through the product value chain from primary outputs (roots) to secondary products (*gari, fufu*, etc). These traits were characterised into three distinct groups based on farmers' responses as shown in Table 2 below. They include the agronomic traits indicating cassava stems physical features at farm level which forms sources of attraction and a measure of farm level performance of plants amidst diverse climatic conditions. These certified improved cassava varieties show resilience to climate change, soil nutrient and water use efficiency especially during late season farming, they mature early, visibly show good stem architecture which is a good trait for cassava stem entrepreneurs, giving them more value for their labour, good root formation, shape and sizes are some of the best traits identified at farm level as quality agronomic traits.

In addition to this, the second classification of the deal breaker quality traits that leads to increased demand for product is product characteristics at processing level. These varieties show low water content during processing (a proxy for high dry matter), swelling property which is commonly referred to as less-for-better for commercial producers and households with large number of members. For a farmer who is also a processor, an important trait which these improved varieties are renowned for is underground storability. They have proven to have slow deterioration on the field which enables a farmer plan its product marketing regime and possibly take advantage of the off-peak market demand for cassava roots.

Finally, the market-level leading traits as identified from the survey include; brightness of product colour which is a leading property for marketing the product. Products of improved cassava varieties (*Gari, fufu, Abacha*) does not change colour under the sun or extreme conditions or over time. Its swelling property, draw ability of *gari* and *fufu* (a proxy for good starch content) is a market level leading trait of preference that meets consumer demands. Products of certified improved cassava varieties demonstrates visual and textural satisfaction for consumers and the popularization of these qualities leading traits are a yardstick for increased production and sales to attain maximum utility and overall consumer satisfaction. These findings justify previous findings (Bentley et al 2017, Bechoff, et al 2019).

Table 2. Deal -Breaker Traits of Preferred Improved Cassava Varieties in Southern Nigeria

Agronomic traits	Product characteristics	Marketability traits
High yield	Higher dry matter content	Bright colour of products (garri and fufu)
Early maturity	Considerable starch quantity	Swelling property of processed product
Soil nutrient-use-efficiency	Easy to process (Softens quickly) for fufu	Colour (yellow, Off-white)
Resilient to harsh weather and diseases	Yellow root	Very high demand market for product (stem and roots)
Excellent stem architecture	Underground storability of roots post maturity	Good starch quality for fufu (draw ability)
Good root size and formation	Good for garri processing	Products meet consumers visual and textural preference
Newness of product	Nutritional added advantage	Popularity of products in the area

Source: Field Survey, 2020

Willingness to buy certified improved cassava stem in South east and South-South Nigeria

The result of the probit regressions analysis presented in Table 3 reveals a pseudo-R squared value of 0.4148 and chi square value of 31.35 statistically significant at 1% level of probability indicating the goodness of fit of the regression equation. Three (3) out of the eleven (11) independent variables were statistically significant at different probability levels. These include planting of local varieties which had a direct relationship with willingness to buy the certified improved cassava varieties at 5% level of probability. This shows that majority of farmers who are willing to buy improved varieties are those who plant local varieties and are willing to try something new. Furthermore, purchase of variety TME 419 had a positive relationship with willingness to buy, statistically significant at 10% level of probability reflecting an increased demand for the variety. The more they purchase this variety, the higher their willingness to buy more. Those who had purchased TME 419 cassava varieties earlier are more willing to buy, having seen the performance of the cassava variety. This could be because the variety has become popular due to its deal-breaker traits that meets the diverse needs and preferences of different categories of consumers. Conversely, the variable purchase of TMS 01/1368 had an inverse relationship with willingness to pay at 10% level of probability. Which reflects a decline in willingness to purchase the cassava stems. This means that any farmer that purchased the variety will not be willing to pay for it any more, thereby confirming the position of Ayinde (2017) that adoption and consumption of bio-fortified pro vitamin A cassava varieties remain low in Nigeria. Also, in a related study, Onyeneke

(2020) identified some constraints to adoption of bio-fortified cassava to include among others, quick root deterioration and high moisture content. These are poor processing qualities that may discourage purchase of seed of the yellow root variety.

Table. 3. Parameter estimates of the Probit regression on willingness to buy certified improved cassava stems in Southern Nigeria

Source: Probit result computed from STATA14.0* is significant at 10%, ** significant at 5%

CONCLUSION

Deal breaker traits in a cassava variety plays an important role in determining the preference and willingness to buy such varieties. From the study, cassava varieties that possesses certain agronomic traits (high yielding, early maturing, soil nutrient -use efficiency, resilient to harsh weather and diseases, excellent stem architecture and good root size), product characteristics (high dry matter, considerable starch quality, easy to process (ferments quickly) for fufu, root colour, and nutritional added advantage) and marketable traits (bright colour, good swelling property, high market demand, good starch quality, good visual and textural quality and popularity of product in the area) are considered to possess deal breaker traits that determines the preferences and willingness to buy such varieties. The TME 419 variety is the most preferred variety. The probability of farmers to buy and continue to use TME 419 is significant whereas there is high probability for farmers who have used TMS 01/1368 to stop using it. It is therefore recommended that seed producers should increase the multiplication of TME 419 to meet its increasing demand.

Determinants of adoption of information and communications technology (ICT)-based market information services by smallholder farmers and traders in Benue State, Nigeria

Chimaroke, O.C and Nwafor S.C.
Extension services unit, National Root Crop Research Institute, Umudike, Nigeria.
Solomonnwafor8@gmail.com

ABSTRACT
Market access is increasingly relying on Information and communications technologies (ICTs) like telephony and internet that are only adopted haphazardly. Despite the need for ICTs in Market Information Services (MIS), ICT usage in Africa is low. Little is known about ICTs for use in MIS including, technology, its potential users and characteristics of both entities. The study examined ICT components used and factors influencing the adoption of the components used. Stratified random sampling was used to select respondents and data were collected from them using structured questionnaires. The data collected from 150 farmers and 50 traders were analysed using descriptive and influential statistics with the aid of STATA statistical package. Radio was the most used old ICT, whereas mobile phones were most used new ICT. Expensive handsets, poverty, poor power supply, lack of expertise and poor network coverage limited ICT use. Farmers with knowledge of ICT groups and those thinking that ICTs benefited agriculture were the more likely adopters of ICT-based MIS. Family size and land farmed influenced farmers' adoption, whereas age, trading experience, family size and monthly expenses influenced traders' adoption. Farmers and traders who majorly used ICTs for making profit were more likely to use mobile phone whereas those who stayed further from towns were less likely to use the component.

INTRODUCTION
Access to markets has been one of the major factors that have influenced smallholder agriculture in developing countries. Accessing markets allows smallholder farmers buy inputs and sell surplus of their subsistence and semi subsistence agriculture to enhance household incomes (Barrett, 2008). These markets can be between communities, villages, sub counties or countries. Markets that are often accessed by smallholder farmers who form majority of the poor in developing countries are characterized by poor infrastructure and limited investment capital (Barrett and Swallow, 2006). Market access helps alleviate poverty through commercializing agriculture and result in uniform distribution of incomes in developing countries (DCs).
Income distributions in DCs are biased by corruption tendencies which have hindered improvement in household welfare (Dao, 2008). Progress in household welfare is dependent on increments in productivity of household stocks of land, labour and capital through adoption of better agricultural technologies that foster economic growth and alleviate poverty (Barrett and Moser, 2003). Even though important innovations continuously occur in many developing countries globally, Africa inclusive, new technologies are only adopted at a slow pace and haphazardly (Singh, 2006). The slow pace of new technological adoption has kept household incomes low.
However, increase in incomes would enable poor households save more financial resources and consequently gain required financial ability to invest in new technologies that are needed in commercial agriculture (Okello, 2005). Most developing countries like Nigeria are characterized by poor infrastructure in roads and poor administrative systems that are ethnic based and usually marginalize sections of poor farmers and traders, hence restricting smallholders' access to markets (Nwafor et al 2019).

ICTs are generally defined as a combination of activities that enhance capture, storage, processing, transmission and display of information by electronic means (Rao, 2004). These Information and Communication Technologies (ICTs) include cellular phones, internet/email, World Wide Web, Print media, and digital radio receivers. Sustainable information exchange in agricultural markets, technology and knowledge is becoming a critical area of agricultural development. Information exchange seems to be given limited priority and in agriculture the bulky load of agricultural information exchange between farmers and agricultural experts and advisors has been left to extension agents. The effectiveness and efficiency of these extension agents have been declining partly due to limited funding from support organizations like government and donor agencies, and the high costs required in maintaining and sustaining the physical movements of these agents between the rural areas where farmers are found, and the urban areas where agricultural experts are mostly stationed (Nwafor *et al.*, 2019).

Majority of factors affecting adoption of ICTs for MIS are generic in nature. For instance cost effectiveness and speed of information transfer, organizational characteristics like business size, system characteristics like availability and access to ICT services, and internal and external characteristics of the business household like education, past experience in using ICTs, attitude towards ICTs, business objectives and incomes among others (Windrum and Berranger, 2002; Dholakia and Kshetri, 2004). Galloway and Mochrie (2005) further opined that usage of ICTs by smallholder households that inhabit mainly rural areas is constrained by limited education and poor technological infrastructure.

With the current need of efficiency in understanding market price trends, accessing inputs and support services, farmers and traders need to use more efficient and appropriate new ICTs to take advantage of the existing opportunities. Timely access to market information, inputs and other necessary information services like weather changes, pest control techniques and others would increasingly enable small-scale farmers and traders make timely, reliable, realistic and economically viable decisions concerning what crops to grow, when to grow them, what products are for sale when and where, what inputs to use and how to use them. The main objective of this study was to assess the adoption of ICT-based market information services (MIS) by smallholder farmers and traders

MATERIALS AND METHODS

This study was conducted in Benue State, Nigeria. The state has a population of about 5,741,800 National Bureau of Statistics (NBS) (2016); its total land area is 34,059km^2 and it is the 11th largest land mass in the country. Benue State falls within longitude $7^{0}47^{1}$, 10^{0}0E and latitude $6^{0}25^{1}$, $8^{0}8^{1}$N, the state shares boundaries with five other states in Nigeria. Benue State is divided into three senatorial districts, namely, North East senatorial district (Zone A) North West Senatorial District (Zone B) and Benue South Senatorial district Zone (C). Stratified random sampling was used to select the respondents used for the study and data were collected from them using structured questionnaires. The data collected from 150 farmers and 50 traders across the three senatorial zones were analysed with descriptive and inferential statistics with the aid of STATA statistical package.

RESULTS AND DISCUSSION

.

Table 1 presents a focus on some characteristics of the sample considering two broad sample strata; adopters and non-adopters. Means of education, experience in using ICTs, monthly income and distance to nearest town were statistically significantly different between adopters and non-adopters of ICT-based MIS. The class of households' monthly income, costs and distance covered to and from the nearest town were statistically different across groups

Logit model estimates of the determinants of traders' adoption of ICT-based MIS.

Logit model are presented in Table 7 and show that knowledge of existence of ICT groups perceived benefit of ICTs to agriculture and family size and land farmed in previous season significantly influenced adoption of ICTs for MIS by farmers. A one person increase in family size increased the probability of farmers to adopt ICTs for MIS by 60%.

Contrary to *a priori* expectations, an acre increase in land farmed previous season reduced probability to adopt ICTs for MIS for farmers by 15.3%. Farmers who had positive perception towards ICTs and those who had knowledge of existence of ICTs were more likely adopters than their counterparts. Though had a low participation in ICT usage (Table 1), women were more likely to likely to adopt ICTs for MIS than males. Table 8 presents Logit model results of factors influencing Traders' adoption of ICT-based MIS. Age of the trader, trading experience and monthly costs, family size, asset base, later age and better education significantly influenced the probability of adopting ICTs for MIS by traders. A one person increase in the family size of traders' household increased the probability of adopting ICTs for MIS by 0.09%, as a one year increase in age and trading experience reduced such adoption by 0.08 and 0.03%, respectively. At later age, adoption of ICTs reduced more rapidly. A one shilling increase in monthly costs increased probability of ICT adoption by 0.18%.

Much of small-scale household farming in the study area was mostly practiced by women who had the primary responsibility of farming for household food security as mothers. Therefore males were less likely to devote to the use of ICTs in agricultural market information exchange. Having knowledge of ICT groups' existence availed farmers with an opportunity that attracted them to use and adopt ICTs for MIS. ICT groups were the sources of information and learning on how to use ICTs and benefits of ICTs, thus the positive influence is consistent with (Pickernell et al., 2004). ICTs enabled farmers to access general agricultural information like weather patterns, pests control, mobile money and others that were required in crucial decision making. That was consistent with Opata et al. (2011) and Peansupap and Walker (2005) who found positive perception towards ICTs being positively associated with expansion in ICT use.

Households mainly farmed for household food supply and mainly used rudimentary tools like hand hoes, knives and family labour. The average family size of farmers was small; below six persons (Table 3). Household average incomes were also very small and majority earned below 30 US $ per month (Table 3). Findings were consistent with Njuki et al. (2008) who found that large output proxied by large farm size in this research markets itself hence limiting need for market searches that were largely done using ICTs. However, Warren (2003) found that there was a positive association between farm size and ICT use. Increase in monthly costs on ICTs implied increased use and realisation of economic purpose of ICTs to traders hence traders' attraction to ICT-based MIS as costs increased. Whenever monthly costs increased, traders shifted to more efficient ICTs like mobile phones that gave them quick and more reliable information per unit cost, thus an increase in costs positively influenced adoption of ICTs. Nevertheless findings were contrary to *a priori* expectations and conclusions of Kovacic and Vukmirovic (2008) who found monthly costs to be negatively associated with the likelihood to use and adopt ICTs.

With more age and trading experience, traders mastered business patterns, the trends and tactics of the business environment, thus reduction in need and use of ICTs for MIS. +-Varying locations of family members necessitated more the need of communicating with each other using a more mobile device, thus increasing likelihood of using a mobile phone as compared to pay phone. Knowledge of ICT groups attracted households to gain membership to these groups in which they were more likely to be advised on using modern ICTs like mobile phones, thus a decreasing likelihood to use pay phone as compared to mobile phone. Having ICT groups' knowledge constituted a human capital and consequently a social asset as defined by (Parkinson and Ramirez, 2006). Increased experience in using ICTs enabled households acquire better skills and interest to use more complex ICTs like WWW and internet/email, consistent with Bailey (2009) who established that experience in using ICTs was positively associated with use of modern ICTs particularly the internet. With increasing incomes, households were less likely to use www, CD-ROM and internet/e-mail compared to mobile phone because these components were more capital intensive than mobile phones. Using internet or www required buying a computer and internet services.

CONCLUSIONS

Mobile phone was one of the most important ICT components used by households to access market information services. Family size significantly and positively influenced ICT-based MIS adoption for both small-scale farmers and traders and having knowledge of ICT groups' existence availed farmers with an opportunity that attracted them to use and adopt ICTs for MIS. Therefore, innovation on ICTs should be stended to farmers via ICT groups and farmers organization

ABSTRACT

This study sets out to examine the frequency, reasons for patronizing supermarkets and factors that determines the patronage among women in Ibadan metropolis. A total of 300 respondents were selected using multi-stage random sampling techniques. The result of the analysis shows that about 30.7% of the respondents had never shopped in a supermarket while 39.4% patronizes supermarket once in a month. The major reason for patronizing supermarket in order of importance is convenience. Factors that determine patronage of supermarkets are income, distance to the nearest supermarket, perceived quality of the products and ease of shopping. The study therefore concludes that there is growing importance in roles that supermarkets play in the economy of the nation. Therefore, factors that encourage its patronage should be advocated by all relevant stakeholders. Supermarkets owners should also ensure that they continue to sell products that are of high quality as it is one of the major factors that determine its patronage.

INTRODUCTION

The retail food outlets including supermarkets, hawkers, and open-air markets connect consumers to their food choices and there is an increase in competition among types of modern stores: grocery stores, supermarkets, discount stores, department stores, catalog showrooms Retailing is an essential service industry as it provides an important service to customers, making products available when and where customers want them. Extant literature shows that retailing can take many forms, both store and non-store forms Oghojafor et al 2012. Whatever the form, the customer is called upon to make a choice. Thus, consumer decision-making involves not only the choice of product and brand but also the choice of retail outlet (Jobber, 2009). Retail choice and patronage are hardly a single factor phenomenon (Verhallen & de Nooij, 1982; and North & kotze, 2004).

Supermarkets play a crucial role in introducing new processed foods or nutritious products, such as exotic out-of-season fruits or conveniently packaged vegetable snacks (Hawkes 2008) and there has been an increase in competition among types of modern stores: grocery stores, supermarkets, discount stores, department stores, catalog showrooms; they are competing for the same customers. (Kotler and Keller 2006). However, there are also some critics of different food outlets (i.e., supermarket, open-air market, and hawkers). For instance, supermarket expansion may be related to modern health problems such as obesity (Michimi and Wimberly 2010). Also, it has been shown that low food quality is often closely related to food products offered by hawkers (Hanashiro *et al.* 2005; Rane 2011). Similarly, practicing appropriate sanitation guidelines and periodic bacteriological control is necessary in open-air markets to reduce food contamination (Filiousis *et al.* 2009). Also, retail shopping behavior has been predicted by means of objective variables like distance, traffic patterns, population density and store size (Alpert, 1971).

Growing incomes, expanding retail outlets, and changing consumer preferences in developing countries especially Nigeria calls for an examination of the choice of retail outlets by consumers, frequency of visits to modern retail outlets, reasons for patronizing supermarkets and factors that determine patronage of supermarkets are examined in order to generate policies for stakeholders in the industry that will bring about the desired growth for the industry through advocating for its patronage by promoting factors that drives its patronage .

METHODOLOGY

The study was conducted in Ibadan metropolis area of Oyo state. Ibadan is the capital city of Oyo State and the third largest metropolitan area, by population, in Nigeria, with a population of over 3 million. Ibadan is also the largest metropolitan geographical area. At Nigerian independence, Ibadan was the largest and most populous city in the country and the third in Africa. Ibadan is located in south-western Nigeria, 128 km inland northeast of Lagos and 530 km southwest of Abuja, the federal capital, and is a prominent transit point between the coastal region and the areas to the north. The city ranges in elevation from 150 m in the valley area, to 275 m above sea level on the major north-south ridge which crosses the central part of the city. The Heritage Mall and Coco mall in Ibadan houses several local and international retail stores The 2 malls contain International South African retail shop SHOPRITE, Pep store, dines and wines, restaurants, electronic outlets, Mr price, Cash n Carry, LG electronics, e.t.c. The metropolis also has other supermarkets such as Foodco, Feedwell, Extra miles.

A multi-stage sampling technique was employed in the selection of the respondents. The first stage was the random selection of three Local Government out of the five Local Governments that are classified as urban centers. Stage two was the random selection of five enumeration areas as stratified by the government during the 2006 population census. Stage three was the random selection of 20 housing units from each of the enumeration area to give a total of 300 respondents. A total number of 244 questionnaires were retrieved which served as the sample size.

Frequency of visits to supermarkets and their reasons for patronizing supermarkets were analyzed through the use of descriptive statistics and Probit regression analysis were implored to identify the factors that determines the probability that household will patronize supermarkets.

The model is specified as

$$Y(\beta X_i) = \int_{-\infty}^{\beta \chi i} 1 \Big/ \sqrt{2t} \;\; \exp\left(-t^2 \Big/ t\right)^2 dt$$

Where Y is the dependent variable, which is if the respondents patronize or do not patronize supermarkets.

0 =Patronize

1 = Do not patronize

t is the random variable, which is distributed as a standard normal deviate. β is a vector of unknown coefficients. X_i is the vector of characteristics of the i^{th} individual and are the independent variables, which are defined as follows.

X_1= Age (in years)

X_2=Income (₦)

X_3=Spouse Income (₦)

X_4=Household size (In numbers)

X_5=Distance to nearest supermarket (In Km)

X_6=Years of formal education (in Years)

X_7=Perceived quality of products (1 = products bought are genuine when compared with open market 0 = otherwise)

X_8=Perceived prices of products (1 = prices of supermarket are comparable or cheaper than other retail outlet 0 = otherwise)

X_9=Ease of shopping (1=shopping at supermarket is convenient when compared with other outlet 0= otherwise)

Constant term

RESULT AND DISCUSSION

Patronage of Supermarkets

Figure one shows the respondents patronage or not of supermarkets. The result shows that while 30.7% of the respondents do not patronize supermarkets and shopping malls 69.3% of the respondents purchase goods from supermarkets. This implies that there are some respondents who still adhere to the traditional open market system/hawkers for the purchase of their goods.

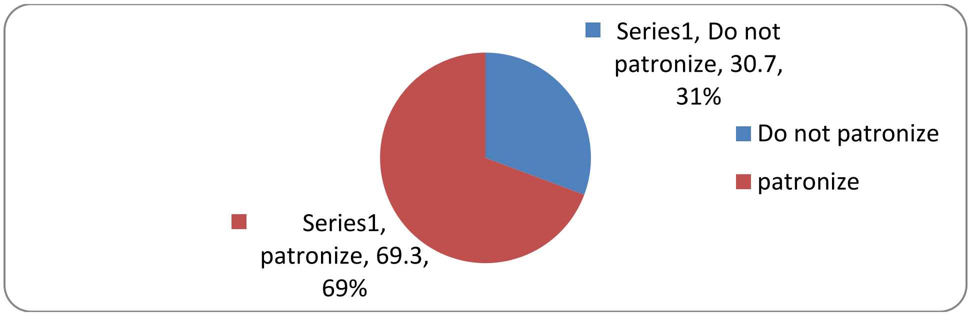

Figure one: Patronage of Supermarkets

Frequency of Patronizing Supermarkets

Figure one presents the result of the frequency of patronizing supermarkets. It was observed from the result that 30.7% of the respondents have never visited a supermarket for shopping. The result further indicates that majority of the respondents (40.2%) patronizes supermarkets only once in a month. This is expected as majority of the respondents are salary earners and they get paid only once in a month. Furthermore, most women receive housekeeping allowance once a month. They therefore tend to shop on a monthly basis when they receive their remunerations.

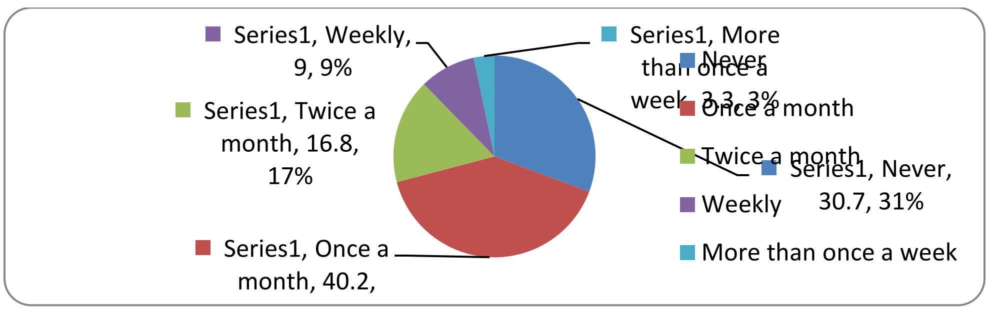

Figure two: Frequency of Patronizing Supermarkets

Reasons for Patronizing Supermarkets as Retail Outlets

The major reason for patronizing supermarket in order of importance is presented in table 1. The result shows that majority of the respondents (36.1%) identified convenience as their major reason for patronizing supermarket. This is followed by the quality of the products sold in the supermarkets that was ranked second by 32% of the respondent.

Table 1: Reasons for Patronizing Supermarkets

Reasons for Patronizing Supermarkets	Rank					
	1st	2nd	3rd	4th	5th	6th
Price mechanism	28 (16.6)	16 (9.5)	15 (8.9)	45 (26.6)	49 (29.0)	16 (9.5)
Quality of the Product	24 (14.2)	54 (32.0)	21 (12.4)	32 (18.9)	11 (6.5)	27 (16.0)
Convenience	61 (36.1)	22 (13.0)	09 (5.3)	08 (4.7)	30 (17.8)	39 (23.1)
Cleanliness	14 (8.3)	30 (17.8)	53 (31.4)	11 (6.5)	12 (7.1)	49 (29.0)

***Figures in parenthesis are in percentages**

Reasons for not patronizing supermarkets

Table two presents the reasons why respondents doss not visit supermarkets. The outcome of the analysis indicates that the major reason why most of the respondents (40%) do not shop at supermarkets are due to the fact that they do not have provisions for credit facilities. This is followed by the fact that they engage in bulk purchasing (37.3%) and due to the large quantities, that they require they prefer to do their shopping at open-markets.

Table 2: Reasons for not Patronizing Supermarkets

Reasons for Not Patronizing Supermarkets	Rank			
	1st	2nd	3rd	4th
Bulk purchasing	15 (20)	28 (37.3)	17 (22.7)	15 (20.0)

Determinants of patronizing Supermarkets by Women

Factors that determine patronage of supermarkets are income, distance to the nearest supermarket, perceived quality of the products and ease of shopping. Income was a positive significant factor that women will likely patronize supermarket at $p<0.05$. Distance to the supermarket also had a positive effect on the likelihood that women will patronize supermarket which was also significant at $p<0.01$. Perceived quality of the products also had a positive and significant effect on the likelihood that households will patronize supermarket at $p<0.01$. Ease of shopping was significant at $p<0.05$ level and positively related to the probability that urban women will patronize supermarket.

Table 3: Determinants of Patronage of Supermarket

Variables	Parameter Estimate	Marginal Effect	Standard Error	Parameter
Age	-0.03	-0.00	0.35	0.93
Income	2.17	0.11	1.11	0.04

Ease of shopping	0.35		0.12	0.03
Constant term				

CONCLUSION AND RECOMMENDATION

This study examined the patronage of supermarkets, frequency of visits, reasons for patronizing and not patronizing of supermarkets among women in Ibadan metropolis of Oyo State. The study shows that while some women patronize supermarkets some still adhere strictly to the traditional open market system. The result of the analysis identifies convenience, quality of the products sold at supermarkets and cleanliness of the environment of the supermarkets as the major reasons while they patronize supermarkets. Factors that determine patronage of supermarket are income, distance to the nearest supermarket, perceived quality of the products and ease of shopping.

Supermarket owners should therefore endeavor that they continue to ensure that attributes such as convenient shopping procedures, high quality products and cleanliness of environment that endears customers to patronize them is maintained. In addition, supermarket owners should look inwardly on how to have facilities for credit purchase so as to enhance their level of patronage.

24 - 28 Oct., 2022

ABSTRACT
The reliance on agriculture for food production and food security at domestic, regional and global levels depend on youth productive force. While their contribution towards attaining food security cannot be underestimated, yet their apparent lukewarm effect towards agriculture is a source of concern. This study assessed youth participation in Commercial Agricultural Development Programme in Ekiti state.

Interview schedule were conducted on one hundred and eighty-four (184) of both active and non-active youth participants using structured questionnaire. Data analyses were through the use of frequency, percentages, means and t-test were used to test the hypothesis of the study. The findings revealed that the majority of youth sampled were male (92% and 88.1%), majority between the ages of 31-35 years (56%) with mean age of 35 years. Most of them were married (93.3% and79.8%) Also, majority of them were illiterate (86.7% and79.85%) and had been farming for a period of 6-10 years of active participant also, non-active (50.5%) had farming experience of less than 5years. Majority of active participants (76%) were full time farmers while (68%) of non-active were part-time farmers. The result revealed that youth have positive attitude towards the YCAD programme. Also 89% of active and non-active 79% of variations in the dependent variable (output level) was explained by the independent variable (socio-economic characteristics). It is concluded that the youth commercial agricultural programme have positive effects on youth participation in the programme.

Keywords; Effect of Youth in commercial Agriculture Development programme, Youth participation, Agricultural production,

INTRODUCTION
The role of Agriculture remains significant in Nigeria economy despite the strategic importance of the oil sector. Agriculture primarily provides employment for Nigerians and accounts for more than one third of total gross domestic product (GDP). More than 70% of the working populations in Nigeria are employed in the agricultural sector directly or indirectly and over 90% of Nigeria's agricultural outputs come from peasant farmers who live in rural areas (Abubakar, 2016). The reliance on agriculture for food production and food security at domestic, regional and global levels depend on youth productive force. This is the generation which is expected to rise in the coming years for food production and food security (Proctor and Lucchese, 2017). Agriculture in Africa has untapped potential to create jobs both directly and indirectly in order to attract young people, agriculture will need to be more dynamic and appealing than it is now and young people will need to view the sector more positively than they do now (Institute of development studies, 2012) and Fayemi, 2012 noted that without effective policies and agenda on youth development, the benefits

of economic growth will continue to by-pass a significant proportion of Nigerians, including our teeming population of youths.

Globally, youth is described as the period in an individual's life, which runs between the end of childhood and entry into the world of work (Onuekwusi and Effiong 2007). Youth is seen as universal stage of development, according to Nigeria's National Youth Development Policy, the youth comprises all young persons of age 18-35 who are citizens of the Federal Republic of Nigeria. A major concern of the Nigerian Government is how to tackle the problem of unemployment among the youths in the country. Various regions in Nigeria have designed and executed several self-empowerment programmes to enhance the economic empowerment of youths (Umeh and Odo 2002). One of such programmes is Youth Commercial Agricultural Development Programme (YCAD) which was initiated in 2012 to accelerate the process of Agriculture commercialization in Ekiti State and help to increase employment opportunities for youths, value addition of specific agriculture products and increased Internally-Generated Revenue (IGR). It is crafted to systematically mobilize the youths into sustainable commercial agriculture, generate employment opportunities to potential young entrepreneur by promoting High Value Crop (HVC) production, processing and marketing under a holistic value development agenda. The programme focuses on youth who are graduates, Diploma and school certificate holders. It focuses on Arable crops, Nursery, Processing, Livestock and Aquaculture.

MATERIALS AND METHOD

Sampling Procedure and Sample size

The study was conducted in Ekiti state, population count was 239 registered participants of the YCAD programme. The list was further segregated into two; active participants and inactive participants. And samples were randomly selected

A simple random technique was used to select of 70 % of 83 active participants.

In addition, 70% of the 156 non-active Participants were also randomly selected to give a total sample size of 184 respondents. And data were collected using a structured questionnaire.

Measurement of Variable Dependent Variables

The dependent variable for this study was youth participation in commercial agriculture

Independent variables: The independent variables used for this study was; Age, gender, marital status, Level of education, level of youth participation,

Dependent variables include:

To examine the effect of the socio economic factors on youth participation in YCAD programme, thirteen-item statements was presented and assessment based on a 5 – point Likert scale of Strongly Agree (SA), Agree (A), Undecided (U), Disagree (D) Strongly Disagree (SA) and scores of 5, 4,3,2,1 was assigned to the corresponding responses for positive statement and the reversed scores for the negative statements.

Assess the youth perception of the extent to which the objectives of the programme met was measured using a 4- point likert-type scale of Highly satisfied=1, satisfied =2, Dissatisfied =3, highly Dissatisfied =4. This was asked from the respondent maybe the programme has influenced them positively or negatively.

Data Analysis

The statistical tools that were used for data analysis for this study include both descriptive and inferential statistics. Descriptive statistics involving frequency counts, percentage, and mean and ranking were used to analyze objectives 1, 2, 3 and 4 While Regression Analysis and t-test were used to test the hypotheses of the study.

RESULTS AND DISCUSSION

Socio – Economic Characteristics of Youth

Table 1 Distribution of Respondents according to their socio-economic characteristics

Variables	A n=75		N.A n=109	
	%	Mean	%	Mean
Age: 31-35 35-40	 37.3	 35	30.3	36
Gender: M F	92 8		81.1 11.9	
Education: Sec Tert	13.3 86.7		20.2 79.8

Source: Field Survey 2021

Key: A=Active, N.A=non-active, M=male, F=female, Sec=secondary, Tert=tertiary, H.size=Householdsize, NP=Nature of participation, M.S= marital status.

Table 1 revealed the socio economic characteristics of active participants about'56% of the respondents were within the age of 31 – 35 years, with 86.7% while the non-active participants about 51.4% of respondents were within the age of 36-40 years, the active participants are in line with the study conformed to the United Nation (2019) definition of youths as people within the mean age of 35 years.

Majority of the respondents both active and non-active attained basic level of education while (86.7%) and (79.8%) attained tertiary education. This finding is confirmed by Muhammad-Lawal et al (2009) whose study showed that a greater percentage of the participants (93.64%) in youth agriculture programme in Nigeria had some form of formal education.

93.3% of the active participant were married while 79.8% of non-active participant was married, also revealed that a high proportion of the active respondents (93.3 %) have a household size of 1-5 while the non-active respondent (90.8%) of the same household size.

The field results also showed that about (33.3%) of active participant have had farming experience of 6-10 years and non-active (50.5%) had farming experience of less than 5 years in farming.

Majority of the youths interviewed (76%) of active participant were full-time farmers, while majority (68.4%) of non-active were part-time farmers. These show maybe non active participants have something doing somewhere that is more profitable than agriculture.

Assess Youth Perception of the Extent to which the Objective of the Program has been met

Table 2. Youth Perception towards the Objective of the YCAD Program

Source: Field Survey 2021

KEY: A= Active, NA=Non-Active, 1=highly satisfied. 2=satisfied, 3=Dissatisfied, 4=Highly Dissatisfied

Table 2 shows the effects of YCAD on youth's participation in agriculture. A great number of active participants agreed that the programme should continue because it has reduced their poverty level while most of non-active disagreed with this perception with the mean ratio of 4.25 and 3.77. Majority of the active participants agreed that the programme has been the source of employment while non active participant strongly disagreed with this with the mean ratio of 4.38 and 3.56. This implies that Agriculture primarily provides employment for Nigerians and accounts for more than one third of total gross domestic product (GDP). More than 70% of the working populations in Nigeria are employed in the agricultural sector directly or indirectly. (Abubakar, 2016).

Table 2. **s**hows that perception of youth towards the objectives of the programme. Majority of the youth are highly dissatisfied with the Marketing of agricultural products for both active and non-active participants as this occupied the second and third position on the ranking with Mean ratio of 3.13 and 3.16, also a great number of respondents dissatisfied with this perception of not giving incentives from government as this occupied the first and ninth position on the ranking with Mean ratio of 2.44 and 2.78.Majority of youth were dissatisfied with the storage facilities for both active and non-active participants as this occupied the third and second position on the ranking with Mean ratio of 3.10 and 3.22. This implies that Lack of infrastructure and essential input also hinders youth to participate in agricultural and rural development activities. (Onuekwusi and Ottah (2006)

Hypothesis Testing

The mean effects scores of active and non-active participants were compared by the use of t-test (Table 3).

TABLE 6: Summary of t-test Analysis Mean active participants	**Mean non active participants**	**t-cal**	**Sig.**
3.071	2.103	0.05	P = 0.05

Source: field survey, 2021

Hypothesis 1: The result showed that there was no significant difference in compared the mean effects scores of active and non-active to YCAD programme. The youth in the study area have positive effects to agricultural development intervention programmes**.**

CONCLUSION

Based on the findings of this study, it can be concluded that level of participations among active participants is high because they spent more time and days in farming activities of their chosen enterprise while non active participants spent less time and days in farming activities

Furthermore, both active and non-active participants were faced with the challenges of storage facilities, transportation, marketing of agricultural products and incentives. Majority of the participants were still in their active age and they have school education which would assist them to communicate and make them to participate more actively in the programme.

ABSTRACT

Forest constitutes important component of the environment. It covers about one third of the world's land area and provides vital environmental services. It plays valuable roles on food security and sustainable livelihood. This paper therefore looked into the relationship between forest and environment and their influence on food security. The environmental protection role of trees and their direct contribution to food security are examined. It is concluded that forest immensely contributes to the sustainable livelihood of rural and urban dwellers and enhances environmental sustainability.

Keywords: Environment, Food security, Sustainable livelihood, Trees

INTRODUCTION

The word forest

Forest is a renewable natural resource characterized bycomplex ecosystem and consists mainly of trees that cover the earth and support a myriad of life forms (Adeyoju, 2005)**.** The trees help create a special environment which, in turn, affects the kinds of animals and plants that can exist in the forest. Trees are important component of the environment. Forests cover roughly one third of the world's land area and provide vital environmental services such as climate regulation, soil protection and water management (FAO, 2007). They also produce food and raw materials, which sustain hundreds of millions of people and support economies. By and large, a plant community is categorized as a forest when is occupying an area of land more than 0.5 hectares with trees higher than 5 meters and a canopy cover of more than 10 percent, or trees able to reach these thresholds at that particular time in that area (FAO. 2007). Invariably, it does not include land that is

predominantly under agricultural or urban land use (FAO, 2001). There are three main different types of forests in the world: tropical forests, temperate forests and boreal forests.
Man lived inside the forest in the very distant past, and was hundred percent dependent on it for shelter, clothing, food, medicine and aesthetic functions (Famuyide, 2005). The practice and art of managing forestlands and other natural resources associated with them such as trees, other plants, wildlife, soil, water, air and the climate, for human benefit, is referred to as forestry which is the major component of the environment (Faleyimu and Arowosoge, 2011)

The environment

The surroundings or the circumstances, in which human beings, other animals and plants live or grow, constitute our environment. It is from the environment that all resources essential for our survival and development are to be found (World Bank, 2011). These resources include non-living parts such as soil and air, and the living organisms. The non-living and living organisms influence and support each other in such a way that they form a community. When the area is large and similar organisms interact with the non-living parts, they work together as an ecosystem (Arongol and Dachomo, 2007). The variety of living things and the non-living parts that sustain them is called biodiversity or the diversity of life. The Nigerian environment is warm and rainfall is important in determining organisms that are found in any location. Nigeria is said to have several ecological zones ranging from lush forest vegetation in the south, Guinea savanna in the middle belt, Sudan savanna in the north and Sahelian vegetation in the far north. Overall, Nigeria is rich in the variety of living organisms (biodiversity) and the systems that support them for sustainable livelihood. (Mailumo *et al*, 2011; Aiyeloja and Faleyimu, 2011).

The word food security

Food Security can be defined as access to adequate and quality food at the individual, household, national and international levels at every given time. The Food and Agricultural Organization (1997), states that Food Security exists when all people, at all times and all levels have access to sufficient, safe and nutritious food to meet their dietary needs for an active and healthy life. Food security, according to the United States Department of Agriculture (USDA), connotes a steady supply of safe and nutritious food for human consumption. An assured ability to acquire acceptable food in socially acceptable ways (that is, without resorting to emergency food supplies, scavenging, stealing or other coping methods or strategies).Food security is associated with food intake at the individual level and its availability at household, sub- national and national levels (World Bank, 1996). A food secured household can be defined as a home which has adequate food for the required intake of its members. Availability of food at the household level depends on many variables. These include, net food production, land, labour, capital, knowledge and technology, food prices and food supply in the market, cash flow, farm rents, and per capita income of consumers (Mailumo *et al*, 2011; FAO, 1997).

The link among forest, environment and Food security

Forest and environment are inseparable. The environment could be conspicuously not in existence without trees and other resources that make up the forest (Aiyeloja and Faleyimu, 2011; Akachukwu, 1997). In the ecosystem environment, forests provide a large proportion of rural households' food needs. The provisions are in two forms: (i) the environmental protection role of trees and forests that enhance water and soil conservation to maintain high levels of productivity; (ii) the direct food commodity contributions which can supplement normal farm yields or serve as substitute products in the event of crop failures due to floods, droughts or insect infestation (Akande *et al*., 2007; Hoskins 1990). Also of major importance are the socioeconomic contributions of forestry to food security.

The environmental protection role of trees

The interception and reduction of air pollution for health and Social well-being
One of the most key values for human health that trees can provide is the interception and reduction of air pollution (McPherson*et al*., 2016; McDonald *et al*., 2016). Air pollution (such as particulate matter (PM), ozone, carbon monoxide, polycyclic aro-matic hydrocarbons, nitrogen dioxide, sulfur dioxide, and so on) is linked to bronchitic symptoms that leads to several ailments in both old and young.(Nwanaji-Enwerem*et al*., 2019; Di *et al*., 2017). Trees remove a tremendous amount of these air pollutants (Nowak *et al*., 2006).
Educational values
Forest serves as a laboratory for several environmental students. It increases literacy and numeracy among the students having had access to the nature. The botanical rambling, forest enumeration and other studies in the forest add to educational values of the students. (Kuo*et al*., 2018).
Economic and Resource value
Trees provide many ecosystem services that can benefit a city environment, ranging from erosion control, soil nutrients conservation, reducing energy use and removing pollution to increasing property values, developing the local economy, and supporting tourism (Nowak and Greenfield, 2018). It has been estimated that trees provide $18.3 billion in annually in United States of America due to air pollution removal, reduced building energy use, carbon sequestration, and avoided pollutant emissions just in an enclosed forest of a country (Nowak and Greenfield, 2018).
Climate change Amelioration
Climate change directly affects where people live. In fact, heat-related deaths from diseases and infectious diseases are one of the most pressing risks for human health associated with a changing climate. The increase in heat and heat-related health problems is especially prevalent in cities, where the urban heat effect increases the impact of heat waves (Ward *et al*., 2016). Properly placed trees can mitigate temperatures in the forest and built environments. Not only do trees provide shade through intercepting and absorbing light, but through evapotranspiration trees actively cool the air of cities (Ward *et al*., 2016).

Roles of trees as source of food
The tree food potential
As reported by Powell *et al*. (2013) a larger percentage of all fruit cosumed by human beings are from trees, most of which come from trees that were planted. Many of these cultivated trees still have "wild" or "semi-wild" stands in "native" forest that are also harvested and which form important genetic resources for the improvement of planted stocks (Dawson *et al*., 2014). Although, quite a reasonable numbers of forest fruit tree species have been domesticated to support more efficient production, via increase in yields and quality and of course ease their harvesting.
According to FWM, (2021) forest food are keys to ensuring the availability of nutrient-dense foods and important vitamins and trace elements in many communities. They have been estimated to represent less than 0.6% of global consumption.. Forests and treesdo not meet human consumption alone but support food availability by providingfodder for domestic animals. Trees provide animal fodder, enabling communities to keep livestock that provide them with nutritionally important milk and meat. Provision of green manure that replenishes soil fertility and supports annual crop production is not left out, as well as fuelwood that provides energy (Jamnadass *et al*., 2013). In the case of fodder production, for instance, a recent initiative in East Africa involved more than 200,000 smallholder dairy farmers growing mostly introduced fodder shrubs (especially, *Calliandra calothyrsus*) as supplementary feed for their animals (Franzel *et al*., 2014). The typical increase in milk yield achieved enabled smallholders to raise extra revenue from milk sales per

cow per year and allowed them to provide more milk more efficiently to urban consumers (Franzel *et al*., 2014). Such tree-and shrub-based practices for animal fodder production increase farmers'resilience to climate change and many of the tree and other forest products are also used in ethnoveterinary treatments that support animal health and hence human food production (Jamnadass *et al*., 2013).

Food supply stabilization

Local communities derive income from timber and non-timber products (NTFPs) in forests through out the year as different fruit tree species mature at different time. In addition to providing food directly, several NTFPs harvested from natural or plantations provide a range of resources that are used by human directly or sold for income that can be used to purchase a variety of products, including food. The increased demand for forest products in low-income nations, prompted by population growth and urbanisation, provides particular opportunities to enhance rural livelihoods (Arnold *et al*., 2006).

Forest consumable food

Despite the fact that trees and other forest plants can provide edible fruit, nuts and leaves, that are often good potential sources of nutrients and are sometimes used in this regard, it does not mean that all of them are used by humans for food. There may be long lists of edible NTFPs but it does not imply that they can be consumed(Arnold *et al*., 2006).

Nuts

Nuts are a very important part of our diet in the whole world. Irrespective of one's feeding style or pattern, comsumption of nuts are are always enjoyable.They can be eatean as snacks or serve as an important component of cooking ingredients. Some of them are gotten from fruits as seed, while others grow by themselves.Some nuts support subsistence for rural communities and forest dwellers, while others, such as the *Azanzagarckeana*, Walnuts are of considerable commercial importance. Trees and shrubs bearing edible nuts are often left standing on farmlands and homesteads after land clearance (FWM, 2021).

Bushmeat

Bushmeat (wild meat), fish and insects are all be important food sources. Bushmeat is often the main source of animal protein available to forest and forest-boundary communities, serving as an important source of iron and fat, and diversifying diets (Golden *et al*., 2011). It plays a particularly important role in diet where livestock husbandry is not a feasible option and where wild fish are not available. The hunting of animals and eating of bushmeat also play special roles in the cultural and spiritual identity of indigenous peoples (Sirén, 2012).

Insects

Edible insects have been part of the human diet from time immemorial. Despite changing of feeding habits over the year, and while insect consumption was largely lost in some part of globe after the classical antiquity, the tradition lingered on in Africa. There are hundreds of insect species consumed in Africa as food or as traditional medicine. Some years ago, the FAO (Food and Agricultural Organization of the United Nations) recognized the potential of edible insects as one possibility to mitigate hunger and the effects of the climate change (Tchibozo and Lecoq, 2017).

CONCLUSION

Forest is the major components of environment, it is not only the main constituent of ecosystems but it tremendously contributes to its existence. The Forest immensely contributes to the sustainable livelihood of rural and urban dwellers and enhances environmental sustainability.

24 - 28 Oct., 2022

ABSTRACT
This study examined the effects of gold mining activities on arable crop production in Atakunmosa East Local Government Area, Osun State. A 2-stage sampling technique was used to select 120 arable crop farmers using structured questionnaire. Descriptive statistics, Cost and returns analysis and Multiple regression analysis were employed to analyze the collected data. Results showed that the mean age of farmers and household size were 42.9 ± 10.1 years and 4 members respectively. Majority (93.9%) of arable crop farmers were males and had spent at least 10 years in school. Mean farm size was 17.3 acres and farmers had 10.3yeras of experience. An average arable farmer's total income losses to gold miners activities amounted to ₦17131.47 per acre per cropping season. The result indicates that yam farmers recorded the largest difference in income (₦51896.50) before and after mining activities. The coefficients of farm size, water pollution, farming experience and number of dug pits significantly influenced revenue loss of arable crops farmers. The study recommends that gold mining activities should be regulated by the government.

Keywords: Arable crop farmers, Gold extraction, Multi-stage sampling, Total income, Water pollution,

INTRODUCTION
Agriculture and mining have played instrumental roles in shaping the patterns of economic development in most countries in Africa (Ericsson and Löf, 2019). According to Alison-Madueke (2009) Nigeria is richly endowed with natural resources that are widely distributed across the country left bare, naked and untouched. Among these are; solid

minerals, petroleum and natural gas. Nigeria loses huge amount of money to illegal mining of solid mineral resources. It was alleged that two companies robbed the country of over ₦100 billion while the total loss was put at about ₦400 billion in 2017. In its effort to revive the sector, the Federal Government of Nigeria introduces a lot of reforms in the solid mineral resource sector which culminated in the 2007 Minerals and Mining Act. The Act vests entire right and control of all Mineral Resources in, under, or upon any land in Nigeria, its contiguous continental shelf and all rivers, streams and water resources throughout Nigeria, any area covered by its territorial waters or constituency and the exclusive economic zone in the Federal Government of Nigeria (Gbite, 2004).

The mining sector of the economy has been regarded as key drivers of economic growth and the development process, also has lead sectors that drive economic expansion which can lead to higher levels of social and economic well being (Bridge, 2008; Addison and Roe, 2018). In February 2017, President Muhammadu Buhari's administration published its Economic Recovery Growth plan (ERGP) 2017-2020. One of the plans was to create an enabling environment to enhance private investment targeting energy minerals, iron/steel and gold/ gemstones and decrease value leaks/loss by formalizing informal mine activities. The government plan emanated from billions of Naira that is lost annually to illegal mining activities and economic resources that are left untapped and decried the horrible state of exploited land and promised to regulate the activities of the miners (Tende et al. 2021).

Gold mining has many adverse effects which can lead to soil degradation that destroys the soil profile for agricultural production and livelihood. Agricultural farmlands were lost to gold mining activities in areas where gold mining activities are done. Mining has led to loss of agricultural farmlands in most mining areas; thereby adversely affecting farmers' means of livelihood. Apart from this, agricultural labour is moved from food production to mining thereby creating wide gap between demand and supply. Labour is being shifted from farming to mining when miners attract labourers with good pay than farmer. Mining activities also encourages leaching of soil nutrients and accelerates surface run-off. It generally leads to reduction in the overall production of farm produce in the area when there is scarcity of farmland. Contamination of surface and groundwater in gold mining communities is also a serious environmental problem in many countries, Nigeria inclusive (Aslibekian and Moles, 2003, Gilbert & Albert, 2016). Rapid deforestation including wild economic trees, reduction of soil fertility through erosion, effect on the health status of people in the mining communities which reduce the productivity of farmers. Garba (2003) and Tende et al. (2021) opined that, gold mineralization is present in alluvial and primary veins from several parts of supra crustal (schist) belts in the northwest and southwest of Nigeria. Also, most of the northwest Nigeria schist belts that have been studied are poly metallic and are endowed with mineralization such as gold (Garba, 2000). From the problems identified in the literature review, this study attempts to provide answers to the following questions: What are the economic effects of gold mining on arable crop farming in the study area? What are the effects of gold mining on arable crop farmers' production and the constraints?

The main objective of this study is to investigate the effects of mining on agricultural production Atakumosa East Local Government Area in Osun state. The specific objectives are to examine the economic effects of gold mining on arable crop farming in the study area; determine the effects of gold mining on arable crop farmers' production output and identify the constraints to arable crop production.

MATERIALS AND METHODS

The study was carried out in Atakunmosa East Local Government Area (LGA) in Osun State, Nigeria. Its headquarters are in the town of Iperindo in the east of the area at latitude of 7°30′00″North and longitude of 4°49′00″East. It has an area of 238 km² and a population of 76,197 at the 2006 census. The LGA was chosen because of the heavy concentration of gold in the area and it is part of the areas where gold mining is mainly practiced in the southwestern part of Nigeria. The climate can generally be described as tropical with two seasons - the rainy season (April – October) and dry season (November – March). The major occupation of the residents of the people is farming. Primary data used for this study were collected with the aid of well-structured questionnaire administered to the arable crop farmers in the area. Two stage sampling techniques were used in selecting the respondents. The first stage involved a random selection of 5 communities in the study area and in the second stage, 24 farmers were randomly selected from each community making a total of 120 farmers. The collected data were analyzed with both descriptive and inferential statistics. The descriptive statistic that was employed include: the mean, frequency counts, ranking and percentages while the inferential statistics that was used include: cost and returns and multiple regression technique.

- Cost and Return is specified as:

GM=TR-TVC……………………………………… (1)

Where GM = Gross Margin, TR = Total Revenue and TVC = Total Variable Cost

- Multiple regression model specification

$Y=F(X_1,X_2,X_3,X_4,X_5,X_6,X_7,et)$

The explicit equation is:

$Y = b_0 + b_1X_1 + b_2X_2 + b_3X_3 + b_4X_4 + b_5X_5 + b_6X_6 + b_7X_7 + e_t$ ……. (2)
Where Y= Farm income
X_1 = Farm size in hectares, X_2 = Age of respondents in years, X_3 = Years of formal education, X_4 = Household size in numbers, X_5 = Water pollution in numbers, X_6 = Farming experience in years.
X_7 = Number of dug pits, et = Error term

RESULTS AND DISCUSSION

Socioeconomic characteristics of the arable crop farmers is presented in Table 1. The result shows that the mean age of arable crop farmers was 42.9 ± 10.1years. This result implies that vast majority of the arable crop farmers are still in their economically active age. The household size of farmers indicated that their household had an average of 4 persons per household. The years of farming experience of the arable crop farmers showed that the farmers had put in about 10.28 years. This result affirms that the arable crop farmers are highly experienced in the arable crop production enterprise. Results shows revealed that the mean farm size of the arable crop farmers in the study area was 17.26 acres.
Table 1: Profile socio-economic characteristics of the arable crop

Variables	Mean	SD
Age (years)	42.9	10.1
Household size (persons)	4.0	2.0
Years spent in school (Years)	10.0	4.0
Farming experience (years)	10.28	2.07
Farm size (Acres)	17.26	6.59

Source: Field Survey, 2020

The values of the crop lost to mining activities is per cropping season in naira is shown in Table 2. The result shows that level of destruction to arable crops was highest (₦6193.97) in the plantain farms (representing by 36.2% of the total losses suffered by the arable crop farmers by the activities of the miners). Cocoyam is next to plantain with a mean income loss of ₦3614.22, constituting 21.1% of the total losses of arable crop farmers per cropping season. Arable farmers' income losses to cassava, yam and maize amounted to ₦3012.09, ₦2805.17 and ₦1506.03 respectively. An average arable farmers total income losses to gold miners activities amounted to ₦17131.47 per acre per cropping season.

Table 2: Values of crop lost to miner's activities per cropping season in Naira

Crops	Income generated from sales of crop (₦)/acre	Percentage (%)
Cassava	3012.09	17.58
Maize	1506.03	8.79
Cocoyam	3614.22	21.10
Plantain	6193.97	36.16
Yam	2805.17	16.37
Total	17131.47	100

Source: Field Survey, 2020

The effects of gold mining activities on farm income of the arable crop farmers per cropping season is presented in Table 3. The result indicates that yam farmers recorded the largest difference in income before and after mining activities with ₦51896.50 which constituting 15.5% total farm revenue. Cassava farmers was the second arable crop with mean difference of ₦38879.30 in income before and after mining activities (7.9%) while plantain had a mean difference of ₦40862.20 in income (4.0%). Maize and cocoyam suffered a mean income differences of ₦59827.60 and ₦319914.00 which constituted about 6.5% and 5.6% differences in income respectively. On average, an arable crop farmer incurred a mean difference in income of ₦238103.00 in farm income. The result of the t-test showed significant differences in income before and after mining for all the crops. These results imply that arable crop farmers' income from their farming activities is significantly reduced by the activities of gold miners in the study with the attendant consequences on their household welfare.
Table 3: Effects of gold mining activities on farm income of arable crop farmers per cropping season (n = 116)

Crops	Income before mining activities (₦)	Income after mining activities (₦)	Difference in income (₦)	Percentage loss in income	T Value
Cassava	491465.50	452586.20	38879.30	7.90	45.34***
Maize	918448.30	858620.70	59827.60	6.50	36.05***
Cocoyam	3534396.60	334482.80	319914.00	5.62	13.83***

Yam	335517.20	283620.70	51896.50	15.50	0.07***
Total	3113103.00	2875000.00	238103.00	7.65	

Source: Field Survey, 2020 ***Significant at 1%, **Significant at 5% level and *Significant at 10% level

that the F value (5.20) is significant at 5% level and adjusted R^2 was 0.520 indicating that the model has a good fit and a strong explanatory power. The coefficients of farm size, water pollution, farming experience and number of dug pits significantly influenced revenue loss of arable crops farmers. ($P < 0.05$). The result shows that the coefficient of farm size has positive sign and significantly affected arable crop farmers' revenue loss due to gold mining activities. A unit increase in hectare of farm size cultivated by the arable crop farmer increased the likelihood of crop losses by 1.18%. This result implies that arable crop farmers with large farm size would be willing to sell significant portion of their arable crop farm to the gold miners for gold explorative activities. In case of water pollution, the variable has a positive coefficient and significantly determined income losses by arable crop farmers. The result reveals that the more the amount of water pollutants released to the soil due to activities of gold miners and uptake by the crops to the more the enormous of revenue losses from arable crop farms. However, farming experience of arable crop farmer indicates that an additional year of experience of the farmer increased the likelihood of revenue loss as a result of gold miners' activities by 6.5%. It implies that farmers that are highly experienced in arable crop farming has the tendency of sell farmlands with declined productivity to miners for gold mining and exploration. The coefficient of the number of dug pit by gold miners increased the likelihood of revenue losses of arable crops farmers by 6.4%.

Table 4: Effects of gold mining activities on arable crop farmers' production

Variables	Coefficients	Standard error	t-value	P value
Farm size in hectares (X_1)	1.81	0.11	16.45	0.000***

F value = 5.20**,R-squared = 0.543, Adj R-squared = 0.520
*significant at 1% level, ** significant at 5% level

The perceived consequences of gold mining activities on arable crop farmers in the study area is shown in Table 5. The result indicates 78.5% of arable crop farmers in the study area were faced with direct conflict with the gold miners as result of the destruction that comes from their mining activities. However, 72.4% of the arable crop farmers opined that kidnapping is a serious problem created gold mining activities and 71.9% of the farmers experienced some sort of assaults coupled with prevalent crime. Similarly, a high (64.7%) proportion of the arable crop farmers agreed that incessant murder are common serious consequence of gold mining activities in the study area. Others include, water pollution (63.8%), removal of arable crops (50.9%) and soil degradation (50.0%) that gold mining activities had triggered.

Table 5: Consequences of gold mining activities on arable crop farmers in the area

Consequences	Frequency (n = 116)	Percentage
Soil degradation	58	50.0
Water contamination	74	63.8
Removal of arable crops	59	50..9
Conflict with miners	91	78.5

Kidnapping	84	72.4
Assault	82	71.9
Murder	75	64.7

Source: Field Survey, 2020

CONCLUSION AND RECOMMENDATIONS

This study examined the effects of gold mining activities on arable crop production in Atakunmosa East Local Government Area, Osun State. The study found that majority of the arable crop farmers were literate middle-aged men, with a mean age of 42.9years. Most of the arable crops farmers had been into arable crop farming for over 10.3 years and with farm size of 17.26±6.59 acres. Average arable crop losses of farmers amounted to ₦17131.47 while the total income from arable crops was ₦238103.00 per cropping season. Farm size, water pollution and farming experience are the factors significantly determining revenue loss by arable crop farmers. The study recommends that Gold mining activities should be regulated by the government in order to minimize farm revenue loss in areas where mining activities is taking place.

ABSTRACT
This study identifies farmers' production constraints and preferences for leafy and exotic vegetables and the implications of policy for increased productivity. Multistage sampling procedure was used to select 200 farmers from 6 local government areas in both Oyo and Imo States. Data was analyzed using descriptive statistics. Result confirmed vegetable farming as an important agribusiness enterprise that offers opportunities especially for the young and unemployed youth. To fully tap the economic benefit of vegetable production, it is recommended that government's ongoing policy drive give vegetables much greater priority than is currently receiving.

Key words: Leafy vegetable, Exotics,Production Constraints ,Southern Nigeria

INTRODUCTION
In Nigeria, agriculture remains the largest sector that contributes to the nations Gross Domestic Product (GDP). The sector contributed an average of 24% to the nation's GDP over a seven period ,(2013 – 2019 (Taiwo, 2020 and between January and March 2021, the agriculture sector contributed 22.35 percent of the total GDP (FAO/David Tsokar 2022). Agribusiness is a large part of Nigeria's economy, directly providing more than 50 percent of jobs and contributing more than 35 percent to the national GDP. It has enormous potential for transformation because primary agriculture is much larger than off-farm agribusiness. Primary agriculture accounts for 21 percent of the national GDP,whereas off-farm agribusiness contributes 14 percent.

As the largest employer of labour in the country, the sector employs more than 36% of the country's labour force. More than 80% of Nigeria's farmers are smallholder farmers and accounts for 90% of Nigeria's agricultural produce. Crop production remains the largest segment and it accounts for about 87.6% of the sector's total output. This is followed by livestock, fishing and forestry at 8.1%, 3.2% and 1.1% respectively (Taiwo2020) .Vegetables can generate higher profits than staple crops, especially when land is relatively scarce and labour is abundant (Ibeawuchi *et al.*, 2015).

Over the last 20 years, value-added per capita in agriculture has risen by less than 1 percent annually, with the effect of rising food and raw materials import bills and declining levels of self-sufficiency in food production. Low mechanization of agricultural production and technologies appropriate for small, medium and large scale farming remains an important challenge to greater productivity, especially in enhancing agricultural extension delivery system. There is low capacity building and poor enlightenment of farmers to achieve mass acceptance and adoption of modern technology in farming. In addition, budgetary allocations to the agro- sector does not encourage enough production to guarantee increased food production and sufficiency in the country. The share of Agriculture in Federal Government's annual budget has consistently fallen below the Maputo Declaration of 10% share of total country budget for agriculture, an indication of the low priority previous governments had placed on agriculture. Out of the total 2020 budget size, agriculture budget represents 1.8% (or N183 billion) of the total 2020 budget size.
In spite of the performance of the agricultural sector in recent times, productivity remains low when compared with the global average. There are however enormous opportunities to design policies and investments to accelerate transformation and create more and better jobs. The current National Agricultural Technology and Innovation Policy (NATIP), 2022- 2025 is designed to fast track the agricultural revolution in Nigeria. The policy is expected to boost extension service delivery, create access to finance, ensure the security of Agricultural land and other related investments that are Agro- based.

METHODOLOGY

The study was carried out in the south eastern and western part of Nigeria. A multi-stage sampling procedure was used. The first stage involved the selection of one state from South West (Oyo) and Imo State from South East. In the second stage, local government areas prominent in vegetable production.in the states were selected. The third stage was the selection of villages from the identified Local Government Area (LGA). In the final stage, vegetable farmers were randomly selected and interviewed with the aid of semi -structured questionnaires. The Participatory Rural Appraisal (PRA) technique was also used to evaluate constraints. Analysis of data collected was done using descriptive statistics.

RESULTS AND DISCUSSION

Socio-economic characteristics

With respect to sex, in the study area, there are more women than men in vegetable production. The average household size of vegetable farmers is 9 members and this implies that there is enough family labour for vegetable production. The significance of household size in smallholder agriculture, hinges on the fact that, the availability of labour, total area cultivated, the amount of farm produce retained for domestic consumption, and the marketable surplus are all determined by the size of the farm household. Farming is the primary occupation and main source of livelihood most respondents.

Enterprise characteristics

Farm size cultivated by most farmers is between 1- 2.5 acres as they operate basically as smallholders while the mean farm holding is 1.24 acres. Years of farming experience is a main factor in agricultural productivity. The mean farming experience is 13 years.
In the study area, land ownership structure is mostly through inheritance. Land ownership structure indicate that land is mostly owned by men .With respect to land topography ,most cultivatable land for vegetable production is within the valley bottom in the Imo while most land area in the Oyo, are flat grounds.

Farming Systems

In both Imo and Oyo states, the main farming system practiced is mixed cropping production. Farmers also keep livestock like poultry, sheep, and goat. Maize and cassava are the crops that are usually inter-cropped with vegetables. This diversification into different crops is done to mitigate the risks of crop failure. While most farmers make use of the natural rain as the main source of water, a few use irrigation system in addition to rain to complement water requirements on the farm. Those with farms located close to the river use pumps to channel water into the fields.

Farmers have access to and cultivate different types/ varieties of indigenous leafy vegetables and exotics .Vegetable planted in the Imo state (South East), include Telfaria, Okra, Amaranth, Cucumber and Watermelon. Also planted are bitter leaf and water leaf. In Oyo State (South West), vegetables grown include Okra, Amaranth, Celosia, Corchorus, as well as cucumber and watermelon. The exotic ones include cucumber, cabbage, lettuce and watermelon. In both states, improved varieties of these vegetables are sourced mainly from retail seed outlets.

There are various factors that influences choice of vegetable varieties produced. Some vegetable are planted for their leaves and others for their fruits. In Oyo state, most farmers still grow more of the traditional vegetables still available since most of the consumers preferred these ones to the newly introduced varieties. In Imo State, farmers reported that egg plants with small size fruits often exhibit more tolerance to pest and disease. As such, a nursery is usually cultivated and seedlings are drawn from there to replace dead or diseased plants on the field. Similarly, consumers of okra in Okigwe, Imo state were not bothered by the outward appearance of the fruits (such as fruits being spiny or not) as the most preferred trait is viscosity, whereas in Orlu senatorial zone, spineless and size of okra is a big determinant of acceptability and consumption. The farmers in these areas therefore cultivate vegetables with preferred traits.

The farmers in Imo state use inorganic fertilizers and manure to boost the soil fertility but those in Oyo (specifically in Igagan/Ibarapa) do not use inorganic fertilizer at all. They however have dedicated areas for cultivation of vegetables alone. Most vegetable farmers in across the all agricultural zones plant vegetables for their leaves. The methods of storage are mostly traditional.

Constraints Analysis

Land ownership

A key constraint is agricultural production in Nigeria generally, is the absence of a clear title to land. Group ownership of land is associated with such problems as limited tenure security, restrictions on farmers' mobility, and the inevitable fragmentation of holdings among future heirs. This also limit access to formal credit, since the farmer cannot use land as collateral. There are however some land owned by government which is sometimes leased out to farmers.
The pattern of land ownership for vegetable farmers is basically by inheritance. This followed by ownership through rentage or lease while few percentage of the cultivated land is acquired through outright purchase. Because most vegetable farmers are poor and without customary access to inherited land, they cultivate and remain on depleted lands and further degrade these resources leading to declining productivity.

Fertilizers usage

Although improved crop varieties exist, low fertilizer use is a serious constraint to agricultural productivity growth. An important factor is low and unstable domestic production. There has been no domestic production of fertilizer since the early 2000s. Other issues which affect domestic supply of fertilizer, even till date, include high transport costs from port to inland destinations, poor distribution infrastructure, the absence of capital for private sector participation in distribution, significant business risks facing fertilizer importers, and inconsistencies in government policies. As a result, most vegetable farmer use animal waste as fertilizer because it is relatively cheap and readily available. Some farmers also use NPK and urea. Only very few use organic folia fertilizer.

Access to water

Challenges faced by vegetable farmers in Imo (SE) and Oyo (SW) states in particular is the problem of inadequate water due to irregular rainfall pattern as agriculture in these parts of the country is still majorly rain-fed. Other challenges which cuts across all the zones include insect/pest infestation, inadequate access to information, limited access to improved varieties and inadequate access to finance.

Access to extension services

The extension workers are important stakeholders in the farming community as they are the middlemen responsible for taking farmers concerns to the researchers just as they take developed technologies to the nooks and crannies of the farming communities. Most respondents had no access to extension services and this is a major constraints to farmers' productivity in general and to vegetable in particular.

Access to credit

As is the case with all businesses, farming activities or agribusiness require money. Access to agricultural credit is positively linked to agricultural productivity. Most farmers do not have access to formal credit facilities and this remains a major limiting factor even in vegetable production.

Banks with large loan funds are generally difficult for smallholder farmers to access. Problems of collateral and high interest rates appear to frequently screen out most potential rural smallholder beneficiaries.Apart from high rate most these farmers are practicing subsistence farming, with low income. That is, they are very poor and lack assets that can be used as collateral for accessing required amount enough to boost their productivity. Besides, farming is full of risk that rendered it not suitable for conventional loan repayment policy. Agricultural loans are often short-term with fixed repayment periods, a loan structure that is not suitable for annual cropping or livestock production.

Sources of credit
Most do not belong to any farmers' cooperative mainly as a result of lack of trust As such, purchase of improved seeds, land clearing, purchase of fertilizes and agrochemical and others expenses is done using personal money. The few that are members of a cooperative, are able to do so, access credit through informal sources like cooperatives and friends, and those that source credit from banks and micro finance houses are very few.

Incidence Pest and disease
Farmers in both states experience similar vegetable insect/pest infestation. The common insect pests are grasshoppers, white flies and podagrica spp, resulting in stunted growth of affected plants. The infested plants are usually removed and buried.

Climate changes
Apart from man-made constraints, farmers' output and income were also negatively affected by climate. Changes in weather affected planting period. Different coping strategies were employed by farmers in order to cope with changes in the climate. These included use of irrigation, planting of improved drought -tolerance plants and changing of planting and harvesting times.

CONCLUSION

Vegetable farming is a major enterprise among smallholder farmers as well as opportunities for attracting the young and unemployed if cultivatable lands, inputs, credit and social overheads that will make the farming communities liveable are provided.

ABSTRACT

The study investigated farm households' response to beef price increase in Tai Local Government Area. Data were collected from 83 respondents drawn from the study area using multi-stage sampling techniques. A set of structured questionnaires were used for the study. Data were analyzed using descriptive statistics and 4-point likert scale. The findings of the study showed that 38.6% of the sampled respondents were within the age of 40-49 years. About 80.7% of the respondents were males while, 19.3% were female and 71.1% of the respondents had household size of 1- 4 persons while 28.9% of them had household size of 5-10 persons. Findings from the study also showed that 87.95% used periwinkle, 97.59% used fish, as alternative source of protein to beef. The major factors which were responsible for price increase of beef during the pandemic; lockdown; transportation cost, high cost of production and few suppliers/inadequate supply of beef. The study recommended that at moments of lockdowns, government should give free and uninterrupted passage to agricultural commodities across the country so that prices of these commodities will not increase drastically.

Key words: Farm household, Beef, Protein, Price increase

INTRODUCTION

Beef is a major source of protein in an average Nigerian family. This is necessitated due to its wide acceptability devoid of religious and sociocultural constraints (Oladejo, 2012). The supply of cattle and its product have been declining while the demand has been increasing. The short fall in supply of cattle has often been linked to the high cost of cattle marketing, because the cattle are brought from the northern part of the country to the South, usually there is high cost of transporting the cattle considering the long distance that the traders have to travel with them (Mafimisebi *et al*., 2013). More worrisome, is that the advent of COVID-19 has further led to an increase in the price of beef. According to FAO (2021) World food commodities prices such as vegetable oils, meat (including beef), cereal is reducing global food demand after COVID-19 outbreak compared to the pre-COVID-19 period when people spent more on food.

COVID-19 poses as a threat to food systems as it reduces food supply and increases the price tagged to foods (Egwue *et al.,* 2020). Meat and livestock prices have been extraordinarily volatile during the COVID-19 pandemic (Lusk *et al*., 2020). The volatility and rise in the price of meat/beef could threaten household food security as wages and income remain unchanged (Obaye *et al.*, 2020). An average man/woman is supposed to consume 10-30% of calories from protein sources daily (Yvette, 2020). With the tediousness of farming activities, household farmers would require sufficient amount of protein if they must carry out their farm operations effectively. Schönfeldt *et al.*, (2013) observed that an insufficient supply of nutrients to the human body restricts and retards physical and cognitive development, and both manifest as financial and social burdens on society. Furthermore, they mentioned that animal source foods are valuable sources of complete, high-quality, easily digestible protein and many essential micronutrients such as iron, zinc, calcium, vitamin A and vitamin B12. Thus, in the face of rising beef prices owing to the incidences birthed by the COVID-19 pandemic, farm households who consume this commodity may have to look for alternative protein sources if they must meet the sufficient amount of protein required to carry out their farming operations. On this standpoint, the study was poised to analyze the following objectives:

i. describe the socioeconomic characteristics of the farm household heads;
ii. ascertain the substitutes to beef;
iii. identify factors that were responsible for price increase in beef during the pandemic.

MATERIALS AND METHOD

The study was conducted in Tai Local Government Area (LGA), Rivers State Nigeria. Tai has an area of 159km^2 and a population of 117,797 and a projected population of 142,602 in 2011 (NBS, 2012; NPC, 2006). The LGA lies between latitudes 4° 43' and 7° 18'N of the equator and longitudes 4.72°and 7.30°E of the Greenwich Meridian. The LGA is within the tropical climate and experiences two distinct seasons, the rainy season and the dry season. The primary occupations are farming, and fishing to a lesser degree.

Multi-stage sampling was used in selecting the sample size of the study. In the first stage, the purposive selection of ten (10) communities out of the seventeen (17) communities in Tai LGA was employed. This was owing to the fact that there were more farmers concentration in the selected communities because they engage more in farming, The second stage involved the simple random selection of ten (10) household heads (household heads was the medium of contacting the farm households) from Botem, Kpite,, Korokor, ueken, Bunu and Nonwa, eight (8) was chosen from Sime and five (5) from Kira, Borobara and Gbene-ue, thus making a total of 83 respondents.

METHOD OF DATA ANALYSIS

Objectives (i) and (ii) were achieved using descriptive statistics. Objective (iii) was achieved viz., 4 point Likert scale.

Likert Scale Rating Technique

Likert scale rating technique was used particularly in measuring the factors that were responsible for price increase in beef under the pandemic. This was done on a four-point basis. According to Umoinyang (2014) the 4-point scale rating technique does not give room for the respondents to be indifferent. The rating is presented in the following order:

Strongly agreed (SA) = 4; Agreed (A) = 3; Disagree (D) = 2; Strongly disagree (SD) = 1.

The mean scores of the respondents based on the 4-point scale will be 4 + 3 + 2 + 1 = 10, 10/4 = 2.50. Using the interval scale of 0.05, the upper limit cut-off point will be 2.50 + 0.05 = 2.55. The lower limit was 2.50 – 0.05 = 2.45. On this basis, any mean score (MS) below 2.45 (i.e. MS < 2.45) will be regarded as not important. Those between 2.45 and 2.55 will be considered as important (i.e. $2.45 \geq MS \leq 2.55$). Mean score greater than 2.55 (MS>2.55) will be considered very important.

RESULTS AND DISCUSSION

Socio-economic characteristics of the respondents

Table 4.1 shows that majority (38.6%) of the farmers were of the age range of 40-49 years and 36.1% of them were within the age 30-39 years of age. This finding agrees with the argument of Ogundari and Ojo (2005) who mentioned that middle aged people constitute the working force of the populace (31-50 years) as they are still active in terms of agricultural production and marketing. Entries on sex shows that 80.7% of the respondents were male while 19.3% of them were female. It therefore implies that most males were faced with responsibility of catering for their families. Meanwhile, results on household size shows that 71.1% of the respondents had household size of 1-4 persons while 28.9% of them had household size of 5-10 persons. Furthermore, results from table 1 demonstrates that, 4.8% of the respondents had no formal education, 9.6% of them had primary education, 72.3% of them had secondary education and 13.3% of them had tertiary education, establishing that a good proportion of them are educated. Education accounts for why farmers are able to manage their finances since education facilitates the capacity of individuals to understand, manage, and work with new ideas (Ewuola and Ajibefun, 2000). On income, result shows that 67.5% of the respondents earned 5000 – 10000 naira per week while 32.5% of them earn 11000 – 15000 naira per week. On this premise, it is less debated that household consumption pattern can be enormously influenced by their income levels. Entries on Marital status shows that 55.4% of the respondents were married, 8.4% of them were divorced, 24.1% of them were widowed and 12% of them were single. Results on the type farming indicated that 96.4% of the respondents engaged in crop cultivation while 3.6% of reared livestock. Showing that the study area would poses more crop produce than livestock.

Table 1: Frequency distribution table showing summary statistics of respondents according to their socio-economic characteristics (n=83)

Variables	Categories	Frequency	Percentage(%)	Mean
Age (years)	30 – 39	30	36.1	
	40 – 49	32	38.6	44.5yrs
	50 – 59	12	14.5	
	60 and above	9	10.8	
	Total	**83**	**100**	
Gender	Male	67	80.7	
	Female	17	19.3	
	Total	**83**	**100**

Alternative sources of protein by farm households

The alternative sources of protein by the farm households served as a response to the increase in the price of beef, the result is presented in Table 2 which shows on that basis of frequency that 30 of the respondents ate pork as substitute to beef, 47 of them ate chevon (Goat meat), 49 of them ate bush meat, 76 ate crayfish, 73 of them ate periwinkle, 81 of them ate fish, 33 of them ate chicken and 43 of them ate snail. The results above indicate that majority of the respondents ate fish as their alternative source of protein during COVID-19 owing to the high cost of beef Special attention is given to fish product consumption as a meat substitute because fish products are important sources of protein (Jione and Won, 2002).

Table 2. Frequency distribution of respondents according to their substitutes to beef

Items	Frequency	Percent
Pork	30	6.84
Chevon	47	10.76
Bush meat	49	11.21
Crayfish	76	17.39
Periwinkle	73	16.70
Fish	81	18.45
Chicken	33	7.55
Snail	48	10.98
Total	**437**	**100.00**

Factors for Increase in Beef Price during COVID-19 Pandemic

The factors that influenced the supply of beef as identified by the respondents were ranked as shown in table 4.3. Lockdown, transportation cost, high cost of purchase and few suppliers/inadequate supply of beef were agreed by respondents to have influenced beef supply (with mean scores greater than 2.50). On the other hand, respondents disagreed that future expectation (with mean score 2.00) of prices had influence on beef supply. This result, agrees with the submission of Serpil and Mehmet (2020) who asserted that rise in food prices under the COVID-19 outbreak was related to lockdown restrictions

Table 3: Factors that influenced beef supply during the pandemic

S/NO	FACTORS	SUM	MEAN	REMARKS
1	Lockdown	327	3.94	Agree
2	Transportation cost	253	3.05	Agree
3	High cost of purchase	254	3.06	Agree
4	Few suppliers/inadequate supply of beef	253	3.00	Agree
5	Future expectation	166	2.00	Disagree

Criterion mean score ≥ 2.50
Source: Field survey, 2021

CONCLUSION AND RECOMMENDATIONS

The study showed that the widely used substitute to beef by farm households in the study area during COVID-19 was fish and that lockdown was the most prevailing factor which influenced increase in the price of beef in the COVID-19 pandemic.

On the basis of the findings, the study made the following recommendation:

i. At moments of lockdowns, government should give free and uninterrupted passage to agricultural commodities across the country so that prices of these commodities will not increase drastically.

ii. Government should encourage fish production as it serves as a veritable substitute to beef.

ABSTRACT

This study examined the determinants of artisanal fishermen access to micro-credit in Andoni L.G.A of Rivers State. About 90 artisanal fishermen were sampled in the study area. Logistic regression and descriptive statistics e.g. frequency, simple percentage, mean ratings were employed as data analysis techniques. The results showed that 67.78% (more than half of the sample) of the respondents were male, 82.22% were married and 56.67% completed secondary education The findings also showed that the sampled the respondents affirmed that deposit money banks, microfinance banks, cooperative societies, local money lenders, government agencies and friends and relatives were sources of micro-credit. The results showed that collateral requirements and availability of loan guarantor increased the probability of micro-credit access by 5.67% and 4.96% respectively. Similarly, it was found that each additional year of age and educational qualification increased the probability of micro-credit by 1.66% and 2.29% respectively. The results, however, showed that the interest rate charged and years of farming experience decreased the probability of micro-credit access by 0.128% and 5.2% respectively. Based on the findings, it was recommended that the government should ensure that banks and other micro-lending agencies do not impose difficult collateral conditions and high interest rates on micro-credits to enable artisanal fishermen to increase their funding for higher productivity.

Keywords: **Artisanal fishermen, micro-credit, cooperative societies, money lenders and government agencies**

INTRODUCTION

There has been a growing interest in improving the access of small-scale farmers including artisanal fishers to micro-credit in developing countries. This is part of the efforts to address their credit needs and constraints so as to improve their access to credit. Essentially, access to micro-credit has been described as the strategy to improve the financial inclusion of small-scale and low-capital farmers. According to Offor *et al.* (2021), micro-credit is imperative for meeting the financial needs of the poor as they do not have the required collateral conditions for borrowing from the conventional financial institutions. Thus, micro-credit is fundamental in helping the low-capital and poor-technology smallholder farmers to improve their financial position. Access to microcredit connotes the ability and willingness to borrow and repay the lender at the price that will cover his cost (Mukherjee, 2014). It reflects how comfortable an individual or enterprise can make optimal use of the financial services (Gehringer, 2014).

The concept of microcredit or microfinance development is based on the fact that the poor possesses the ability to generate wealth through the "income generating economic activities" but is handicapped by the lack of credit, savings and insurance facilities. Okidim and Obe-Nwaka (2021) posit that micro credit access by small-scale fish farmers are being encouraged through the formation of co-operatives to improve their access to micro-credit. This is also expected to provide opportunities for increased and affordable access to credit for profitable growth. Dzadze *et al.* (2012) described access to micro-credit as a fundamental resource that creates opportunity for farmers to expand their agriculture activities or adopt innovative farming methods through the use of new technology. The lending procedures provided by the formal financial institutions have limited the access of farmers to credit. This tends to pose a threat to the process of agriculture development.

Furthermore, Kolapo *et al.* (2021) observed that the availability of credit is essential for the development of the agriculture sector. They further explained that the socioeconomic characteristics of the farmers are the important determinants of their access to credit. In addition, Emerole et al. (2013) identified years of farming experience, membership of cooperative society and savings of farmers as the factors that determine their access to credit. While Obisesan (2009) outlined age as the major determinant of credit access, Ololade and Olagungu (2013) as well as Okidim and Obe-Nwaka 2021 argued that high interest rate and delay in government loan approval are the factors that determine micro-credit access among rural farmers. It is also argued that improvement in the micro-credit access procedure among small-scale farmers as well as their prompt access to credit facilities have the potential of fostering the productivity capacity of small-scale fish farmers. Udoka, Bassey and Okorie (2019) argued that income is an important consideration in credit access because lower income earners rarely save and as such do not have tangible assets that can be mortgaged as security for loan.

Okidim and Obe-Nwaka (2021) investigated access to micro-credit acquisition among small-scale fish farmers in Obio-Akpor Local Government Area of Rivers State, Nigeria. Descriptive statistics and multiple regression analysis were used in data analyses using semi-structured questionnaire. The findings showed that majority of the respondents are male (65.0%), 35.0% were between 20 – 30 years, 71.0% were married and 94% had formal education. The results further showed micro-credit from cooperative societies is an important source of finance for majority (47.0%) of fish farmers. The result of the multiple regression analysis showed that sex, household size, fish farming experience and income were determinants of micro-credit acquisition. The results further revealed that high interest rate charged, delay in processing loan application and age, farm size, lack of awareness/proper communication and insufficient available credit and experience are major constraints to micro-credit acquisition among the fish farmers. Based on the findings, the study recommended that financial institutions should provide single digit interest rate for fish farmers. Despite the efforts geared at improving the access of artisanal fishermen to micro-credit, there has been growing controversies on the factors that determine their access to credit. While majority of the argument identify the socioeconomic characteristics of the artisanal fishermen as major factors affecting their access to micro-credit, it is also argued that interest rate, government policy and collateral conditions of lending institutions among others are determinants of micro-credit access by artisanal farmers. As the controversy continues to grow, this study sets out to assess the determinants of artisanal fishermen access to micro-credit in Andoni LGA, Rivers State.

1.2 OBJECTIVE OF THE STUDY

The broad objective of this study is to assess the determinants of artisanal fishermen access to micro-credit in Andoni LGA, Rivers State. However, the specific objectives were to:

i. describe the socio-economic characteristics of the artisanal fishermen in Andoni LGA.
ii. determine the sources of micro-credit among artisanal fishermen in the study area.
iii. examine the determinants of micro-credit access among artisanal fishermen in the study area.

METHODOLOGY

Study Area

The study on determinant of fishermen access to Micro credit was conducted in Andoni Local Government Area in Rivers State. The LGA was created in the year 1991with its headquarters located at Ngo town. It has a land area of over 233 km^2 and an estimated population of 311,500 people as at the last census. (NPC, 2006). The postal Code is 504, and coordinate of 4.487N, 7.4087E. Andoni LGA has a latitude of 4028121.811 North and a longitude of 7022157.511 East, 4° 32′ 57″ north, 7° 26′ 47″ East. Geographically, Andoni LGA shares boundaries on the North with Khana LGA, on the South with the Atlantic Ocean, on the East with Opobo/Nkoro LGA and on the West with Bonny LGA. The Local Government Area has many towns, villages and Fishing settlements which are either separated from each other by seas, rivers, creeks and as well as land boundaries. The popular economic activities for the people of Andoni LGA include Artisanal fishing and farming. (Okuduwor, Oretan and Morris 2022).

Research Design

In this study, survey research design was employed. According to Collis and Hussey (2003), survey research design is imperative for gathering data, study sample and generalizing the findings obtained to the entire population.

Population of the Study

The population of the study comprised all the artisanal fishermen in various fishing communities in Andoni LGA.

Sampling Procedure and Sample Size

A multi-stage sampling technique was employed to purposively select four (4) fishing landing settlements/communities that are known for artisanal fishing activities. They were: Oyorokoto, Ekede, Ebukuma and Asarama. Random sampling method was used to select 20 fishermen from each settlement/community and 30 from Oyorokoto to give a total of 90 respondents. This formed the sample size for the study.

Data Collection

The data required for this study were collected using well-structured questionnaire.

Data Analysis

Descriptive statistics, mean rating and logit regression were used to measure the objectives percentage distribution, logit regression was applied to estimate the likelihood of micro credits acess based on the socio-economic determinants. Logit regression method was applied because the dependent variable (Access to micro credit) was measured as a discrete variable and depicts non linear relationship.

The model specification is:

$Y = bo + b1X_{1,+} b2X_{2,+} B3X_{3\,,+} B4X4_{,+} B5X_{5\,+,}B_6 + X_{6,+}B_{7+}X_{7\,+,}B8X8 + B9X9_{,+} B_{10}X_{10} + U_t$ .equ 1

Where: Y = Access to Credit, X_1 = Interest Rate, x_2 = Ownership Of bank account, x_3 = Membership of cooperative society, x_4 = Years of farming experience, x_5 = Collaterial requirements, x_6 = Ownership of fishing boat, x_7 = Availability of laon guarantor, x_8 = Type of occupation, x_9 = Age and x_{10} = Education, ut = error term

The formal specification of the logistic regression model is as follows

$\ln\{P_j/(1-P_j)\} = \alpha + \alpha_1x_1 + \alpha_2x_2 + \alpha_3x_3 + \alpha_4x_4 + \alpha_5x_5 + \alpha_6x_6 + \alpha_7x_7 + \alpha_8x_8 + \alpha_9x_9 + \alpha_{10}x_{10} + U_t$ (3.2)

Where: $\ln\{Pj/(1-Pj)\}$ = natural log of the odds in favour of access to micro-credit, α = constant parameter, $\alpha_1 - \alpha_{10}$ = vector of coefficients of the factors of access to micro-credit, $x_1 - x_{10}$ = determinants of access to micro-credit and U_t = error term

RESULTS AND DISCUSSION

2.1 Socio-economic Characteristics of Respondents

The socio-economic characteristics of the respondents were shown in Table 1

Table 1.: Socio-Economic Characteristics of Artisanal Fishermen in Andoni LGA

Variables	Freq. (n =90)	%	Cumulative %
Sex			
male	61	67.78	67.78

Source: Field Survey 2022

Table 1. shows the socioeconomic characteristics of artisanal fishermen in Andoni in Rivers state, bellow are some of the socioeconomic characteristics.

Sex:

The results showed that about 67.78% (about 61 respondents) and 32.22% (29 respondents) were males and females respectively. In other words, more than half of the respondents were males, implying that artisanal fishing is a male dominated business. The study portrayed that males are more involved in the means of livelihood of the family. This is in line with the findings of Okuduwor, Oretan and Morris (2022) which showed that artisanal fishery in Andoni LGA is dominated by the male folks. Okidim and Obe-Nwaka (2021),

Age:

The results in table 4.2 also showed that about 1.11% (1 respondent), 8.89% (8 respondents) and 23.33% (equivalent 21 respondents) were between the ages of 18 and 25years, 26 and 31years and 32 and 40years respectively. The results further showed that about 28.89% (i.e26 respondents), 21.11% (equivalent 19 respondents) and 11.11% (about 10 respondents) were between the ages of 41 and 45years, 46 and 50years and 51 and 65years respectively. It was also found that about 5.56% (5 respondents) of the respondents were 66years and above. In summary, the results showed that majority of the respondents were between the age group of 41 and 45years. The economic implication of this result/ findings is that the age bracket fell within the work force and the fishermen were still energetic and highly productive .The result agrees with the findings of Okuduwor et al (2022) that ascertains that farmers between the ages of 30-49 years are willing and able to take risks with the expectations of a larger profit than old farmers.

Marital Status:
It was evident from the results that about 8.89% (8 respondents), 82.22% (equivalent 74 respondents) and 3.33% (equivalent 3 respondents) were single, married and widow/widower respectively. The results further showed that 5.56% (5 respondents) were divorced. In other words, the results showed that majority of the respondents were married. The result aligns with the findings of Okuduwor et al (2022) that married people constitutes the larger population of artisanal fishing business in Andoni LGA of Rivers State and Okidim and Obe-Nwaka (2021) that majority of the fishermen in their study area were married and would therefore have greater family responsibility.

Level of Education: The results from Table 1 above further showed that about 10.00% (9 respondents) of the respondents do not have access to formal education. It was also found that about 13.33% (12 respondents), 56.67% (51 respondents) and 20.00% (18 respondents) completed primary, secondary and tertiary education respectively. The study showed that majority of the respondents having access to secondary education is an implication that Micro credit lending agencies tend to consider level of education in granting loans. In summary, the results showed that more than half of the sampled respondents completed secondary education contradicting the findings of Okuduwor et al (2022) that majority of the artisanal fishermen in Andoni LGA had access to only Primary education.

Household Size:
Table 1.2 as well showed the household size of the respondents and it was found that about 24.44% (22 respondents) and 32.22% (29 respondents) had family size of 1 to 3 persons and 4 to 5 persons respectively. The results further showed that about 43.33% (39 respondents) had family size of 6 persons and above implying not too large household sizes. In summary, the distribution of the households based on their sizes showed that most of them have households of about 6 persons, an indication that family labor is beneficial in artisanal fishing. This result agrees with Okidim and Obe-Nwaka (2021) that fishing families with large households will not have to spend much on hiring laborers.

Annual Income
As observed from Table 1.2 about 33.33% (30 respondents), 31.11% (28 respondents) and 14.44% (13 respondents) had annual income of less than NGN100,000, between NGN100,000 and NGN150,000, and between NGN151,000 and NGN200,000 respectively. The results further showed that about 21.11% (equivalent to 19 respondents) had annual income of more than NGN200, 000. In summary, the results showed that the annual income of majority of the respondents about NGN100, 000 net income ie after household consumption and expenditure This suggests that most of the respondents were low-income earners because artisanal fishing in Andoni LGA o is a low income-earning means of livelihood, corresponding with the findings of Okuduwor et al (2022). Although, artisanal fishing is a means of livelihood

Table 2 Analysis of the respondents views on sources of micro-credit

Sources	SA	A	D	SD	Mean Score	S.D
Deposit Money Banks	41	32	12	5	3.21	0.88
Microfinance banks	23	34	23	10	2.77	0.958
Cooperative societies	38	43	9	0	3.32	0.650
Local money lenders	47	32	7	4	3.36	0.812
Government agencies	23	23	22	21	2.54	1.119
Non - Government organizations	3	19	28	40	1.83	0.877

Friends and Relatives	51	30	6	3	3.43	0.765

Source: Field Survey 2022

From table 2 the results showed that the respondents affirmed that deposit money banks, microfinance banks and cooperative societies were sources of micro-credit. This is based on the fact that the corresponding mean scores of these sources were greater than the critical mean value of 2.5. It is also evident from the results that the respondents agreed that local money lenders, government agencies and friends and relatives were sources of micro-credit. This is established from the corresponding high mean scores (3.36 and 3.43) which are greater than the critical mean value of 2.5. In summary, the findings showed that the major source of micro-credit to artisanal farmers was friends and relatives given that it had the highest mean score of 3.43. It therefore followed from the results that majority of the artisanal farmers rely on informal financial sources for funding. This implies that the volume of credit might be low compare to other sources.

Table 3: Summary of the respondents' Perception on determinants of access to microcredit

Determinants	SA	A	D	SD	Mean Score	S.D
Interest rate charged	30	33	11	16	2.911	1.002
Ownership of bank account	44	28	14	4	3.244	0.878
Membership of cooperative society	14	37	33	6	2.655	0.823
Years of farming experience	19	63	6	2	3.1	0.601
Collateral requirements	32	46	10	2	3.2	0.722
Ownership fishing boat	66	19	4	1	3.67	0.618
Availability of loan guarantor	78	10	2	0	3.84	0.422
Type of occupation	21	21	36	12	2.57	0.995
Age	12	21	40	17	2.31	0.932
Educational Qualification	6	7	9	68	1.47	0.927

Source: Field Survey 2022

Table 3 above, shows the determinants of access to credit with critical mean value of 2.5. However, it was established from the results that the respondents failed to agree that age and educational qualification were determinants of access to micro-credit amongst artisanal fishermen. Overall, availability of loan guarantor was identified as the major determinant of loan access given that it is associated with the highest mean score of 3.84. This agrees with the findings of Obe-Nwaka, Okidim and Agbagwa (2020) The findings showed that interest rate charge decreased the probability of micro-credit access among artisanal farmers in the study area.

Table 4 Summary of logic regression results for micro-credit access determinants

Regressor	Odds Ratio	Std. Err.	z	P>|z|	[95% Conf. Interval]	
Interest rate charged	.9828921	.358586	-0.05	0.962*	.4807989	2.009316
Ownership of bank account	1.780481	1.0771	0.95	0.340	.543994	5.827475
Membership of cooperative	1.1555	.5394653	0.31	0.757*	.4627771	2.885149
Years of fishing experience	.4991381	.3786942	-0.92	0.360	.1128281	2.208128
Collateral requirements	2.14689	1.336668	1.23	0.220	.633645	7.274006
Ownership of fishing boat	.6202197	.3296131	-0.90	0.369	.218866	1.757571
Availability of loan guarantor	1.950771	2.251149	0.58	0.563*	.2032063	18.7273
Type of occupation	.7365212	.2806922	-0.80	0.422	.3489698	1.554471
Age	1.249751	.5932789	0.47	0.639*	.4928822	3.168866

_cons	.0026636	.0165822	-0.95	0.341	1.34e-08	530.5085
Pseudo R2	0.3141					

Source: Field Survey 2022

The results showed that the possibility of artisanal fishermen micro-credit access decreases by 1.6% [(.984-1)*100] as interest rate increases holding other variables constant. The results also showed that the possibility of micro-credit access increases by 78% [(1.780-1)*100] and 15.5% [(1.155-1)*100] due to ownership of bank account and membership of cooperative respectively while controlling for other variables. Similarly, the likelihood of micro-credit access also increases by 114.6% [(2.146-1)*100] and 95.1% [(1.951-1)*100] as a result of increase collateral requirements and availability of loan guarantor while holding other factors constant. Again, as age and educational qualification increases there was possibility of micro-credit access by 24.97% [(1.2497-1)*100] and 36.1% [(1.361-1)*100] respectively. On the other hand, it was found that years of farming experience, ownership of fishing boat and type of occupation decreased the likelihood of access to micro-credit by 50.1% [(.499-1)*100], 38% [(.620-1)*100] 26.3% [(.737-1)*100] respectively.The Pseudo R^2 (0.3141) showed that the explanatory variables jointly explained 31.41% of the total variation in micro-credit access. This finding provides appreciable evidence for the reliability of the estimated logistic model.

CONCLUSION AND RECOMMENDATIONS

CONCLUSION

The study concludes that interest rate charged, years of farming experience, boat ownership and occupation type deceased the probability of micro-credit access. Based on the findings, it is concluded that collateral requirements and availability of loan guarantor were the major determinants of micro-credit among artisanal farmers.

5.2 RECOMMENDATIONS

1 That Government should ensure that banks and other micro-lending agencies do not impose difficult collateral conditions on micro-credits to enable artisanal fishermen increase their funding for higher productivity.

2. The study recommended that artisanal fishermen should open bank account and frequently do bank transaction since the study showed that ownership of bank account increases access to micro credit.

3 Government should ensure the formation of cooperative since cooperative membership increases access to micro credit.

24 - 28 Oct., 2022

ABSTRACT

Gender responsiveness in agricultural technology is germane to food needs of future populations and it will ensure that agricultural productivity translates into improved welfare for the poor. Using gender friendly technologies for agricultural based activities will not only lead to food production but it will also ensure that women are recognized as key stakeholders in agricultural value chain not only in Nigeria but also in Africa. This will bring about efficiency and development that can benefit everyone in the society. It is worthy of note that successful development interventions are by their nature transformative because they create opportunities. Creating a gender inclusive agricultural technology is such a transformative intervention. By critically analyzing and understanding constraints facing women in agriculture, it will be possible to develop the new ways to addressing their needs and thinking of a way of enhancing their contributions in order to improve agricultural productivity with the aim of reducing hunger and alleviating poverty. This paper review how gender responsive technology in agriculture could help to tackle the incessant food shortage which women are mostly at the receiving end in Nigeria and describe some gender issues that influence technology usage. It was observed that women are not usually given adequate attention in technology development and transfer as they are seen as farmers' wives and not as farmers. Thus, the reason behind food shortage in Nigeria.

Keywords: gender, technology transfer, engender, self-reliance.

INTRODUCTION

A strong and efficient agricultural sector will enable a country to be food secured, creates foreign earnings, generate employment and above all supply raw materials for the various agricultural based industries in such countries. Agricultural sector has the potential to be the industrial hub of any country, especially in Nigeria where it was once served as the mainstay of the economy, generating as high as over and above 60% to the total Gross Domestic product (GDP) (Oji-Okoro, 2011). At this time, food insecurity was never a problem as every household was food secured and Nigeria as a country was industrial and economic springboard for other countries in Europe as many of their companies were situated in Nigeria due to the availability of raw materials obtained basically from the country's agricultural sector. Shortly, after 1960s and specifically, in the 1970s during the oil boom, gradual decline in agricultural sector sets in. Ukeji (2003) submitted that in the 1960s agriculture contributed up to 64% to the total GDP but gradually declined in the 70s to 48% and it continues in 1980 to 20% and 19% in 1985 ad this was largely attributed to oil glut of the 1980s.

\

The significance of the high contributions of agriculture to the GDP of Nigeria was evidenced in her position being the world's largest exporter of groundnut, the second largest exporter of cocoa and palm produce and an important exporter of rubber, cotton in the 1960s (Sekunmade, 2009). More recently, agriculture employs about two-thirds of Nigeria's labour force, contributes significantly to the total GDP and provides a large proportion of non-oil earnings (Anyanwu, Ibekwe and Adesope (2010). Despite the decline in the GDP contribution, the sector has several untapped potentials for growth and development. This is manifested in the availability of natural resources like land, water and fertile soil and human factors like labour as well as the economic factor like large internal markets (Sekunmade, 2009). It is estimated that Nigeria has about 84 million hectares of cultivable land mass but as at 2011, only about 40% of this was under cultivation (FMARD, 2012). Productivity in the cultivated lands is also low due to small farm holdings capacity and crude methods farming as lack of technology advancement in Nigerian agriculture is one of the reasons for food shortage (Olatunji, 2002).

Owning to the food shortage experienced, Nigeria has therefore become heavily dependent on food imports. In addition to diverse and rich vegetation that can support crop cultivation and heavy livestock population, it also has potential for irrigation with a surface and underground water of about 267.7 billion cubic meters and 57.9 billion cubic meters respectively (Chauvin, Mulangu and Porto, 2012; Lipton 2012). Nigeria's large and growing population provides a potential for a vibrant internal market for increased agricultural productivity. These enormous agricultural related resources have the capacity to enable a country feed its growing population, earn foreign exchange, generate employment and provide raw materials for industries. Ordinarily, at both micro and macro levels, the agricultural sector is strategically positioned to have a high multiplier effect on the Nigeria's quest for socio- economic and industrial development. However, inability to use technology for farm operations and put gender at the center of technology development may be responsible for the current status of Nigeria in terms of food production. This paper critically looks at the trends in technology utilization in agriculture in Nigeria, reviews literature on gender inclusiveness in the development of technology for farm operations and describe gender issues in the usage of agricultural technology.

METHODOLOGY

The study is based on review of literature that were relevant to the main title. Therefore, **s**econdary data from literature were used for this documentation.

RESULTS

Food Production in Nigeria and Trends in Technology Usage

Sub-Saharan Africa is adjudged the poorest region in the world (Chauvin, Mulangu and Porto, (2012). Average real per capita income in 2010 was $688 compared to $1,717 in the rest of the developing world. Over the past 30 years, GDP growth per capita in SSA has averaged 0.16 percent per year. This failure of growth over the long term has resulted in high levels of poverty in the region. One finds the same picture of stagnation when one looks at the structures of African economies. In almost all of them production is dominated by the primary sector, mostly agriculture. This sector is marked by low productivity with little application of science and technology (Dercon and Beyrouty, 2009).

In Nigeria, the low application of technology in the agricultural sector has made foreign trade to mirror the production structure and exports dominated by primary commodities incorporating little application of science and technology while the bulk of manufactures and knowledge-based services are imported (Olajide, Akinlabi and Tijani (2012). Although, for the majority of African countries, the agricultural sector still provides a relatively large share of GDP but productivity in the sector has lagged considerably behind that of other continents and the potential that Africa can reach in the sector. While on average agriculture employs 65 percent of Africa's labor force it accounts for about 32 percent of gross domestic product, reflecting the relatively low productivity in the sector (Olajide*et al.*, 2012). For Africa therefore, the rural population has been unable to move out of poverty principally because they have not been able to transform their basic economic activity which is agriculture through technological utilization which is basic to the development of agriculture. Adopting and utilizing technology is not even enough but gender consideration in the technology development is a prerequisite to the development of agriculture. This is because women constitute significant proportions among the stakeholders in agricultural sector (Bilkisu and Ibrahim, 2016). In addition, owing to the importance of agricultural sector to the livelihoods of the poor, the World Bank in her 2008 World Development Report, devoted to Agriculture and Rural Development, that the sector must be placed at the center of the development agenda if the Millennium Development Goals of halving extreme poverty and hunger by 2015 are to be met. In view of this, appropriate technology that is gender inclusive and sustainable must be disseminated to farmers with a view to improving production.

Regrettably, the rate of hunger continues to increase after 2015 in Nigeria when the MDG target was to half hunger by 2015 in Sub-Saharan Africa. This connection between hunger and poverty was established by Janvry and Sadoulet (2002) and (Bilkisu and Ibrahim, 2016). The authors opined that efficient use of technology will lead to an improved in production and the implication is that the users will live above the poverty line of any country of the world. A technology becomes gender responsive when the needs of both sexes are considered in the usage (Deji, 2011) while its sustainability involves its usage over generations (Ogunsumi, 2010).

Karanyo (2002) affirmed that new technology in all areas of agriculture has improved production, hence, its sustainability. Today's Agriculture is using best management practices (BMP's), by targeting many of its applications, not broadcasting as was done in the past. New disease resistant hybrids, biological pest control, reduced pesticide use, cultural practices that reduce the incidence of pests and diseases, and better placement and reduced amounts of fertilizers are all being employed without any gender specific approach. Insect specific chemicals and biological insect controls are now being utilized, instead of broad-spectrum pesticides that actually reduce the number of sprays needed along with costs (Munyi, 2000). Nigerian agriculture needs to adopt specific gender approach to the above identified technologies for sustainability due to the contribution of women in food production. This will promote our reliance on safe domestic supply of food rather than relying on foreign imports which could affect our security if cut off and not be able to guarantee its safety in terms of the types and nature of technologies used in producing the foreign foods. Technologies have been developed by different research institutions and universities to improve the lots of farmers in Nigeria (Degrande and Duguma, 2000). These technologies are usually transferred through the ADPs to the target farmers and the extension agents are responsible for disseminating them using appropriate techniques for farmers to adopt. The extension agents also have a specific role of getting a feedback from the clientele to the origin of the technologies (with a view to improving on the weakness if there is any.

The Need for Gender inclusiveness in Technology Development and dissemination in Agriculture

Agriculture plays a significant role in poverty reduction in Africa. The high percent of people who engage in it may be used to explain this assertion. In rural area of Africa, Nigeria inclusive, agriculture employs over 75% of the population (IFAD, 2015), thus, it is an important livelihood source to many of these people in rural areas. It is estimated that 70% of sub-Saharan Africa's labour force works in agriculture (Maxwell, 2001). But the argument in favour of agriculture as *the* poverty alleviating sector *par excellence* rests on more than population statistics. Improvements in agriculturalproductivity have a powerful knock-on effect to the rest of the economy by: creating jobs in neighboring sectors such as food processing and input supply as well as directly in farming; increasing the supply of affordable food; and stimulating and supporting wider economic growth and development. However, women constitute the bulk of labour force in agricultural sector and they must be the target of any technology in agricultural production.

Generally, technology usage raises agricultural productivity and it is the major factor in creating positive effects which agriculture has on the economy of any nation. Thirtle, Lin and Jennifer (2003) explored the relationship between agricultural productivity and poverty in developing countries and established that a 1% improvement in crop yields reduced the proportion of people living on less than US$1 per day by between 0.6 and 1.2%. therefore, no other sector has demonstrated such a comparably high impact on poverty. This is in-line with the report of Lipton (2001) who argues that no other sector than agriculture offers the same possibilities in job creation and poverty reduction among people. Indeed, the adoption of new technologies and subsequent increases in agricultural productivity in different parts of the world explain, in large part, the regional differences in the reduction of poverty over the last few decades. Nkamleu, Gokowski and Kaziangor (2003) submitted that technological change was the main cause of the differences in the productivity.

Technological change in agriculture began at least 10,000 years ago, when the first cultivators selected wild plants and experimented with different growing environments. From those early beginnings, the technical performance of agriculture in the great civilizations remained roughly equivalent for centuries until the middle of the nineteenth century, where, principally in Europe and North America, the introduction of new machinery and sources of power (Grigg, 1974), the rediscovery of Mendel's experiments leading to the development of scientific plant breeding, and the development of artificial fertilizers, resulted in rapid increase in agricultural productivity (Doss, 2001).

Gender issues in Agricultural Technology design and usage

Gender issues can be understood with adequate understanding of some gender concepts as described by Deji (2011). Some of these concepts that may enable us to understand gender issues are: sex, gender roles and sex roles. Thus, understanding of gender roles is premised on the sound knowledge of the following concepts as described below:

Sex

Sex refers to the biological differences between male and female. These differences are congenital, unchanging/permanent, universal and most of the time, they are physical. They are natural and biological features and attributes that an individual is born with, which distinguish males from females in the society. Sex is genetically determined. Only a very small proportions of the difference in roles as to men and women can be attributed to biological or physical differences based on sex. For example, pregnancy, childbirth and differences in body physiology can be attributed to sex-related characteristics. This takes us to differentiate between gender and sex.

Differences between gender and sex

Specific differences between gender and sex

Gender	**Sex**
Rooted in the society	Natural/biological
It can be influenced by culture	It cannot be influenced by culture
It varies from culture to culture	It does not vary from culture to culture
It can be changed	It cannot be changed/congenital
Gender may be biased	It cannot be biased
It is time specific	It is not time specific
It is learnt through socialization	It doesn‘t need socialization to learn sex

Source: National Open University Module, 2015.

Gender role

Roles are functions performed by individuals in the social positions they occupy. Gender roles are those functions that are culturally allotted to individuals on the basis of their gender but are not related to biological functions of that individual. They are roles that can be carried out by a man or a woman. The assigning of such roles varies from societies to societies and from culture to culture and over a period of time. Gender roles relates to what a man or a woman should do and how a person of a particular gender walks, talk, dresses and relates with outsiders (Deji, 2011). All these are culturally determined. For example, child caring is allotted to women. Its therefore becomes a female gender role but not a female sex role since a man or a woman can carry out the function. Also, household chores such as washing of plates, fetching of water among others are women's works in many societies but a man can equally perform these roles as well. However, sex roles like carrying a pregnancy or breast-feeding that are exclusively for female require some specialized organs. This is why such roles are exclusively for the females. Therefore, in gender roles, no specific organ is required for it to be performed. For example, a man needs his hands and his brain to work as a medical doctor. Also, a woman also needs the same thing to perform the same function. Therefore, both men and women can be medical doctors. Medical profession becomes what both men and women can do. It is not a sex role but rather a gender role. Hence, gender roles are also a set of expectations as to what ought to be the appropriate behaviour for men and women under particular circumstance.

Sex role

These are naturally endowed duties given to the women. These duties require certain biological characteristics in order to perform them. For example, a woman requires a womb to carry a pregnancy, a breast to breastfeed her baby and a man requires a specific and specialized organ to impregnate a woman. These are sex roles which a member of a given sex can perform (Deji, 2011). Sex roles are permanent as they cannot be changed by culture or society. A man cannot carry pregnancy because he has no womb to do so. However, child rearing is a gender role and not a sex role since both men and women can carry out these functions.

Gender Issues

Gender issues arise where an instance of gender inequality is identified. In most cases, it arises as a result of misinterpretation of gender roles and sex roles. This becomes manifest where there is discrimination and oppression against a particular sex leading to a gender gap or inequality among male and female. For example, the involvement of female children in household chores such as washing of plates, cooking of foods, fetching of water while the male children will be allowed to play football and read their books deny the female children from studying and subsequently, affects their performance in schools. This discrimination and oppression becomes a gender issue. This is applicable to the development of technologies for farm operations. Usually, technologies are developed for farmers and in Africa, whenever a farmer is mentioned, male picture comes to mind. This is the picture in which planning of programmes for farmers is usually based upon.

Therefore, gender-related effects of technology change are often important in determining the impact of adoption on poverty. Technology generation tends to favour even crops traditionally grown by men, who frequently have greater access to labour, markets, credit and other inputs than women to a degree that may impact negatively on the intra-household distribution of income and consumption (Doss, 2001). Addressing these challenges goes well beyond technology design, as male dominated societal rules and norms, and a complex household environment of 'joint decisions, multiple objectives and mutual dependence' (Bonnard and Scherr, 1994) make it difficult to target, or predict the gender-related outcomes of technology development. Simply targeting technology to women's crops is not necessarily the answer (Von Braun and Webb, 1989) but technology that meets the needs of both gender will probably provide a sustainable platform to meeting the food needs of Nigerians.

CONCLUSION

The focus of technology development will, at its most fundamental level, need to be guided by an understanding of the future direction of agriculture in Nigeria and an appreciation of the changing ways in which it will contribute to growth and poverty reduction. While the initial nomenclature of farmers as males has changed but the packages and programmes meant for them still remain unchanged. The men are still better favoured in access to technology and other productive assets than the women. The consequence of this unchanging approach to increasing food production may be responsible for the huge cost of importing food from other countries into Nigeria. Therefore, for Nigeria to be food reliance and sustained, gender must be put at the center of deliberations when technology is to be developed for farmers.

RECOMMENDATION

1. Technology developers must factor in gender considerations while developing farm-based technologies targeted at improving agricultural productivity in Nigeria
2. The usually nomenclature of farmers being men must change to include men and women when designing agricultural technologies for farmers.

ABSTRACT
Laboratory studies was conducted at Entomology Laboratory of University of Maiduguri under ambient laboratory conditions to assess the efficacy of diatomaceous earth (DE) against *C. maculatus* infesting bambara groundnut. The bioassays were conducted on treated seeds of Bambara groundnut variety *Farin ngangala*. *C. maculatus* adults was bioassayed on 50g seed samples using CRD replicated three (3) times at the following dose rates; DE (250, 500, 750, 1000, 1500 mg/kg of seeds) The effects of treatments on seed germination was conducted on freshly treated seeds and at 90 days after treatment (DAT). The results showed that DE applied at 1000mg/kg and 1500mg/kg completely suppressed ovipostion, adult emergence, damage and weight loss. DE only affected germination at the highest dose rate of 1500mg. It was concluded that DE could be used to manage *C. maculatus* populations in stored bambara groundnut.

Keyword: Diatomaceous earth; Cowpea; Oviposition; Mortality; Germination

INTRODUCTION

Bambara groundnut, (*Vigna subterranea* L. (Verdcourt)), is a leguminous crop of the order Fabales, family Fabaceae and sub family, Faboidea, with creeping stems and branching just above ground level. The seeds are variously colored from white to cream, red, black or brown, sometimes mottled; blotched or striped (Bamshaiye *et al*., 2011). The seeds are used in many types of foods, some of which are an important part of human diets. Mature, dry seeds are boiled and eaten as a pulse. Seeds can be milled to make flour. Ripe seeds are very hard and must be cooked for longer than those of other legumes. Like other legume plants, *V. subterranea* is a good soil fertilizer and a good rotation crop. It does not require any additional fertilizer. It is generally intercropped with cereals (maize, sorghum, and pearl millet), other pulses (cowpea, groundnut), root and tuber crops, or vegetables. Cream-coloured seeds are often preferred to red and black seeds, because they are less bitter and take less time to cook. Large seeds are preferred to smaller ones, especially for use as a snack. Smaller seeds are ground into flour for use in various recipes. The processing of *V. subterranea* results in by- products (shells of offals) that can be fed to animals. Seeds can also be fed to animals if surplus to human requirements. The leafy shoots are used as fodder (Brink *et al.*, 2006). The seeds are used for food and beverage because of their high protein content and for digestive system applications. The entire plant is known for soil improvement because of nitrogen fixation. According to Mazahib *et al*. (2013), high carbohydrate (65%) and relatively high protein (18%) content as well as sufficient quantities of fat (6.5%) make the Bambara groundnut a complete food. According to Bamashiye *et al*. (2011), Bambara groundnut seeds have been found to be richer than peanuts (groundnuts) in essential amino acids such as isoleucine, leucine, lysine, methionine, phenylalanine, threonine and valine. This is an important trait for the potential of bambara groundnut to be used to complement foods lacking in these essential amino acids. The fatty acid content is predominantly linoleic, palmitic and linolenic acids, (Minka and Bruneteau, 2000). The major bruchid species that infest bambara groundnut in storage are: *Callosobruchus maculatus* Fabricus, *C. subinnotatus* Pic, *C. chinensis* Linnaeus and *Zabrotes subfasciatus* Bohemian (Ayamdoo *et al.,* 2013). Of these, *C. maculatus* is the major storage pest of Bambara groundnut seeds (Ayamdoo *et al*., 2013; Magagula and Maina, 2012). They are field to store agricultural pests of Africa and Asia (Beck and Blumer, 2014) and are the most destructive on account of their shorter life cycle (Maina and Lale, 2004). The weevil can cause as much as 99% yield or weight loss in susceptible grain legumes.

The damage results in quantitative and qualitative losses. To combat these debilitating storage pests, farmers and traders in west Africa use storage structures and other available materials like earthenware pots, gourds, mud silos, jute sacks, bagco bags, metal drums, plastic containers and local granaries for grain storage. These are most often, integrated with synthetic pesticides (Aviara *et al*., 2013 and Ayamdoo *et al*., 2013). However, the unabated use of toxic synthetic chemicals has given rise to problems of toxicity, pest resurgence and elevation of secondary pests, development of pesticide resistant populations, deleterious effects on population of non–target organisms, residues in food chain, high costs of most of the chemicals, contamination of the environment, non–availability and the falsification and adulteration of pesticides (Bloch, 2012; Grzywacz and Leavett, 2012).

In this effect, the increased awareness and concern for biorational alternatives, which are effective, economically sound, feasible, and user friendly, have gained an important position in the protection of stored products. They are safe, effective, and relatively simple prevention and control methods available to manage populations of stored-product insect pests without the use of chemical insecticides. The use of biorational approach provides practical economical and safer ways to managing stored-product insect pests. These approaches are either directly take advantage of key aspects of the pest's biology to eliminate or manage pest populations through manipulation of the physical and biological environments of the target species. Control of stored-product insects by desiccation can be facilitated by treatment of infested commodity and spaces with diatomaceous earth (DE). DE represents the fossilized silicon dioxide skeletons of diatoms, which are unicellular aquatic algae. DE kills insects following contact exposure by absorbing the hydrocarbons from their cuticles, which causes dehydration and ultimate death (Korunic, 1998). The activity of DE is increased under low humidity and higher temperatures. An enhanced DE was developed that utilizes added silica gel, a finer and more homogenous source of silicon dioxide (Korunic and Fields, 1998). DE is nontoxic to vertebrates and is even a common food additive and food-processing agent with the designation GRAS (generally regarded as safe). The efficacy of DE varies significantly among its geographic source locations where it is mined, so users must follow label instructions closely to ensure control (Korunic, 1998). Application of DE at effective rates to an entire grain mass can cause a significant loss in bulk density, thus lowering the quality and value of the treated grain (Korunic *et al*., 1996); care should be taken to use minimal effective rates or to treat problem areas only (e.g., the top or bottom layers of the grain mass). The objective study was to evaluate the efficacy of Diatomaceous earth on management of *Callosobruchus maculatus* infesting stored Bambara groundnut.

Materials and method

Study Site

The study was conducted at the Entomology Laboratory of the Department of Crop Protection, Faculty of Agriculture, University of Maiduguri. All experiments were conducted under ambient laboratory conditions. Temperature and relative humidity ranged from 28 to 34°C and 22 to 58% respectively. The study was conducted during the period of March – June.

Source of the Insects

Cowpea Bruchid; *Callosobruchus maculatus* adults were collected from cultures maintained on cowpea in the laboratory and was used to establish new cultures on Bamabara groundnut. The insects were then reared for two generations on Bambara groundnut for the experiments. Culturing entailed placing a hundred unsexed adult insects onto 300 g of sterilized Bambara groundnuts seeds placed in 1-liter capacity jar for seven days and then sieved out and discarded. The resulting F_1 generation aged 1 – 2 days old were used for the experiments.

Handling of Bambara Groundnut Seeds

The seeds, after acquisition, were cleaned and placed in deep freeze refrigerator for 2 weeks to kill all life stages of the insect that might be present. The seeds were conditioned to room temperature for at least ten (10) days before commencement of the experiment.

Source of diatomaceous earth (DE)

Diatomaceous Earth was provided by the Department of Crop Protection, University of Maiduguri, from samples obtained from Diatom Research Consulting Incorporation, Canada.

Bioassay Procedures for Determination of Efficacy of Diatomaceous Earth against *C. maculatus.*

The bioassays were conducted on treated seeds of the variety *Farin ngangala*. The choice of application rates were based on published literature, largely on studies arising from control of pest infesting stored cowpea. The application rates used in the present study were: D.E (250, 500, 750, 1000, 1500 mg/kg of seeds)

Grain treatment, bioassay and experimental design

Fifty grams of *Farin ngangala* cultivar seeds were placed in a 150 ml jar and the appropriate treatments were applied on the seeds. The jars were shaken vigorously to ensure proper mixing after which they were infested with newly emerged (1 – 24 h old) adult bruchids from the culture. Five pairs of the newly emerged adult *C. maculatus* were introduced per jar. The jars were covered and then arranged on the laboratory bench using CRD. Each treatment combination (insecticidal material x dose) was replicated three (3) times. The adults were allowed to oviposit for seven (7) days after which they were sieved out and discarded.

Observation and data collection

Egg counts were carried out seven (7) days post treatment. This was done by random draw of 20 seeds from each jar in each concentration per treatment. The seeds were observed with a magnifying glass (x 100) and the number of eggs on the seeds was counted. The number of adults produced in each jar was counted forty (40) days after infestation. The percentage damage and percentage weight loss was determined by randomly taking 50 seeds from each jar, and then separated into holed (damaged) and whole (undamaged) grains. The seeds in each category were counted and the numbers used to calculate the percentage damage:

$$\text{Percentage seed damage (SD) (\%)} = \frac{\text{Number of damaged grains}}{\text{Total number of grains}} \times 100$$

For percentage weight loss, the grains in each of the above categories were weighed, and the weights used to calculate the percentage weight loss according to Golob *et al*. (1982).

$$\text{Weight loss (\%)} = \frac{(Und) - (Dnu)}{U\,(nd + nu)} \times 100$$

Adult emergence inhibition rate

Adult emergence inhibition rate (AEIR) was calculated according to Kabir (2011) as:

$$AEIR\% = \frac{Ne - Na}{Ne} \times 100$$

Hatching rate

$$\text{Hatching rate was calculated as: } \frac{\text{Number of emerged } F_1 \text{ progeny}}{\text{Number of eggs produced}} \times 100$$

Determination of Treatment Effect on Seed Germination

Germination test was conducted according to the methods described by the International Seed Testing Association, 2015. Two germination tests were conducted. The first was carried out at the beginning of the experiment with freshly treated seeds. Whereas the second test was performed on treated seeds described earlier and infested with the insects ninety (90) days after treatment (DAT). From each treatment combination (insecticidal material x dose), ten (10) seeds were selected randomly from each jar and placed on moistened plastic Petri dishes, lined with Whatman's No. 1 filter paper. The petri dishes were labeled and arranged on a laboratory bench using CRD for seven days. There were four replicates per treatment combination. Germinated seedlings were counted after seven (7) days. And percentage germination was calculated using the formula.

$$\text{Germination percentage} = \left[\frac{\text{Number of seed germinated}}{\text{Total number of seeds in each petri dish}}\right] \times 100$$

Data Analysis

The data were subjected to analysis of variance (ANOVA) using statistical software (Statistic 8.0). Differences in mean values of treatment were separated using Tukey Kramer's honestly significant difference (HSD) at 5% level of probability. Data on germination test were subjected to T- test to determine any differences between the freshly treated seeds and those treated and stored for 90 days.

Table 1: Effect of diatomaceous earth on ovipostion, adult emergence, hatching rate and inhibition rate of *Callosobruchus maculatus* on Bambara groundnut seeds

Application rate (mg/kg)	Oviposition	Adult Emergence	Hatching rate (%)	Inhibition rate (%)
0.0	193.7 ± 9.8[a]	144.3±4.7[a]	74.7±1.8[a]	-
250	33.7 ±2.3[b]	13.7± 4.1[b]	39.4± 9.9[b]	90.5
500	22.7 ± 4.3[bc]	7.7 ±2.7[bc]	32.0± 5.7[b]	94.7
750	11.0 ±4.6[bc]	2.0±0.6[bc]	20.0± 2.9[bc]	98.6
1000	2.0 ±1.0[c]	0.0± 0.0[c]	0.0 ± 0.0[c]	100
1500	0.0 ±0.0[c]	0.0± 0.0[c]	0.0 ± 0.0[c]	100

Effect of diatomaceous earth against *C. maculatus* and seed germination of Bambara groundnut.

The effect of diatomaceous earth on ovipostion, adult emergence hatching rate and inhibition rate of *C. maculatus* on stored Bambara nut at different dose rates is shown on Table 1. Compared to control, there was a drastic decrease in the number of eggs even at the lowest dose rate 250g. Oviposition further decreased with increase in dose rate as low as 0.0 in the highest dose. The result shows that there was significant difference P=<0.0001 between dose rates and control. Treatment also showed significant effect P=<0.0001 on adult emergence. Adult emergence reduces with increase in dose rate up to 0.0 at dose rate 1000 g and 1500 g. The results on hatching rate and progeny inhibition showed significant difference between dose rate and control, there was 0.0 % hatching rate and 100% inhibition rate at dose rates 1000g and 1500g due to 0% adult emergence. Dose rates varied significantly with the control, hatching rate decreased with increase in dose rare while inhibition rate increased with increase in dose rate.

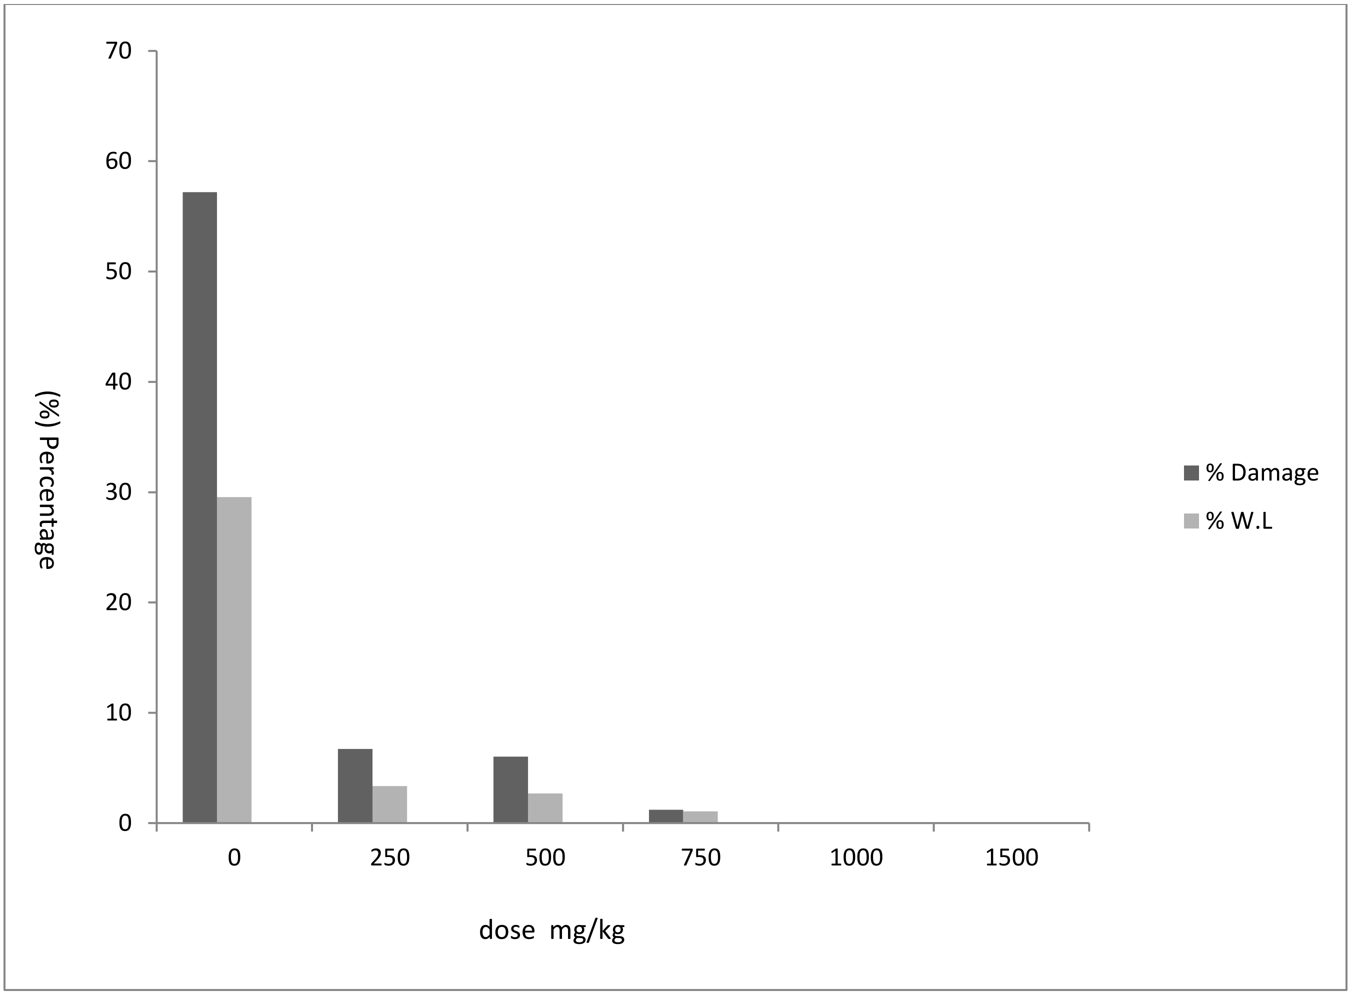

FIG 1: EFFECT OF DE ON PERCENTAGE DAMAGE AND WEIGHT LOSS OF STORED BAMBARA GROUNDNUT CAUSED BY *CALLOSOBRUCHUS MACULATUS*

Effect of diatomaceous earth against *C. maculatus* on percentage seed damage and weight loss of Bambara groundnut.

Percentage damage and weight loss decreased with an increasing dose rate (Fig 1), with decrease of 0% at dose rates 1000 and 1500mg/100g.

Table 2: Effect of diatomaceous earth on seed germination of bambara groundnut

Application rate (ml/kg)	% germination 0 days after treatment	% germination 90 days after treatment	T-test
0.0	100.00a	100.00a	Nd

250	100.00a	100.00a	Nd
500	100.00a	100.00a	Nd
750	95.00ab	100.00a	0.0917
1000	92.50bc	98.75a	0.0154

Nd – not determinable

Effect of diatomaceous earth on seed germination of Bambara groundnut

The effect of diatomaceous earth on Germination rate of Bambara groundnut at 0 DAT showed that treatment did not differ with control at 250, 500 and 750g; 750g and 1000g did not vary; and 1000g and 1500g do not vary with each other. At 90 DAT dose rates did not vary with each other except the highest dose. T-test showed no significant difference P=<0.0001 between germination at 0 DAT and 90 DAT at dose rate 0.0, 250mg and 500mg (Table 2).

DISCUSSION

The findings from this study indicated that Protect-It can be used successfully as a protectant against adults of Cowpea bruchid *Callosobruchus maculatus*. Regardless of the synergism of other factors, the effect of DEs is dose-dependent (Fields & Korunic, 2000; Athanassiou *et al*., 2003; Stathers *et al*., 2004; Mahdi & Khalequzzaman, 2006), as in the case of residual insecticides used as grain protectants. The overall efficacy depends upon different factors such as type and concentration of DE, grain moisture content, temperature, insect species, insect density and type of grain commodity (Korunic and Fields, 2006). Among these factors, temperature and relative humidity plays an important role in determining the efficacy of DE against stored insect pest (White and Loschiavo, 1989). However, the dose rate is more important in the case of inert dusts, given that the presence of dust in seed highly affects the physical properties of seed (Korunic *et al.*, 1996). In addition, dust formulations that are effective at high application rates (Subramanyam & Roesli, 2000). In the present study, the rates of 1500mg/kg produced high mortality levels, 100% was achieved in most of the cases examined. However, given that *C. maculatus* cannot survive at application rates higher than 1000mg/kg and are effective against other stored-grain beetle species (Fields & Korunic, 2000), higher dose rates or longer exposure intervals are needed to achieve 100% mortality for adults of this species. Moreover, this insecticide has a long persistence after treatment (Kabir and Lawan, 2016). Fields and Korunic (2000) have confirmed the effectiveness of several DE-based formulations on adults of *Tribolium castaneum*. As proven in this work, *C. maculatus* express susceptibility to DE due to morphological, physiological and ecological characteristics.

The efficacy of diatomaceous earth on the mortality of insect pests of stored products is usually affected by several factors among which stands out the temperature (Chanbang *et al*., 2007). Generally, the increase in temperature favors the increase in the effectiveness of this product by stimulating the movement of insects within the grain mass, providing an increased contact of them, with the diatomaceous earth (Vayias *et al*., 2009). In addition, the insects have higher respiration rates at higher temperatures and consequently the greater water loss via spiracles promoting desiccation (Zachariassen, 1991). However, it was shown in some studies that the insect mortality can vary between species (Vayias *et al*., 2009).

Increased exposure time is highly important for DE efficacy, since surviving individuals may disperse from the treated substrate and colonize untreated parts of the product mass (Subramanyam and Roesli, 2000). This fact must be seriously taken into account in cases of partially treated grain masses with DE, such as the surface treatment in grain bulks, when DE in the surface is used alone, as a barrier to infestation (Korunic and Mackay, 2000). Earlier studies have shown that stored grain insect pests can be controlled by commercially available DE formulations. For example, Kavallieratos *et al*. (2005) used DEs Insecto and SilicoSec on eight different grain commodities, at 750 mg/kg and recorded mortality after 14 days of exposure ranging from 63 to 97%. Similarly, Vardeman *et al*. (2006) reported that Protect-It at the same exposure found that 400 mg/kg gave 85% adult mortality for *R. dominica*. However, our findings are consistent with the results reported in other studies (Fields and Korunic, 2000; Athanassiou and Kavallieratos, 2005). Athanassiou *et al*. (2006) reported 100% mortality of the exposed *R. dominica* adults after 14 days in wheat. However, longer exposure interval suppresses the progeny emergence in the treated substrate provided the dry condition prevails (Athanassiou *et al.*, 2005). Also, Paula (2001) reported that the higher dose rate was negatively correlated with the production of F_1 of *Sitophilus* spp. The present trial undoubtedly supports the statements of other researchers as there was less progeny at high dose rates and longer exposure intervals, which practically prevented damage and weight loss.

CONCLUSION

Conclusively, DE proved to be effective in managing *C. maculatus* on stored bambara groundnut. The treatments significantly reduced oviposition and progeny emergence, which varies significantly with control. Similarly, treatments decreased damage and weight loss significantly compared to the untreated control. Treatments increased effectiveness with increase in dose rate. All treatments did not significantly reduce germination both at 0 DAT and at 90 DAT except in control treatment.

RECOMMENDATIONS

It is recommended that DEs should be adopted by farmers as alternative for synthetic insecticides, as they have proven effectiveness in the management of *C. maculatus* on stored Bambara nut. DE could be used at 1000 mg/kg. The use of DE as a safe control method against stored pests is highly recommended. The results obtained indicate the potential of non-chemical method development.

PROCEEDINGS
56th Annual Conference
Agricultural Society of Nigeria
24 - 28 Oct., 2022

ABSTRACT

The need for indigenous developed sugarcane varieties cannot be over emphasized as the sugar estates in Nigeria depends more on exotic cultivars that succumb to pests/diseases and suffer quick yield decline due to non-adaptability in their new environment. Sugarcane production is very important in the country, as its plays a vital role in food and income security. A study was conducted to evaluate the performance of sixteen sugarcane hybrid clones at NCRI Badeggi. The clones were planted on Randomized Complete Block Design (RCBD) with three replications. Analysis of variance reveals significant differences among the clones for some traits. Highest cane yield (175.7 tha^{-1}) was recorded in BD 1098-003m. BD1098-001m clone gave the best brix (21.4%) and sugar yield (17.47 tha^{-1}) among the studied hybrids. BD 1098-005m, BD 441-007m and B 47419 possess better fibre and such materials can be manipulated for energy cane variety.
Brix percent also varied among the clones with increase in crop age, which can be used as indicator for maturity. This evaluation has revealed the performance of some hybrid clones and they will be nominated for further evaluations (yield trials).

INTRODUCTION

Sugarcane is one of the most important commercial and cash crop cultivated for sugar production across the world. It contributes about 75% of the world sugar production, while sugar beet produces 25% (Mani *et al*., 2019). It is grown in Nigeria on small scale for home uses and on large industrial scale for refined sugar production and it's by products (Takin *et al*., 2019). Sugarcane production is vital for Nigeria economy diversification as huge resources is invested in sugar importation annually. Its production in Nigeria is profitable with a return of ₦1.88 for every naira invested as documented by Aina *et al*., (2015). Africa contributes only 5% to the current global sugarcane production and 83% of this is in Sub-Saharan Africa. The Sub-Saharan African region, with its tropical and subtropical climate, is well-suited in many ways to expanding the production of sugarcane.

Nigeria annual raw sugar production averages is 80,000 metric ton despite annual consumption of 1.7 million metric ton. According to Nigeria Sugar Annual (2019), the country imports about 1.6 million metric ton of raw sugar from Brazil, Thailand and the United States to meet its demand.

Ishaq *et al*., (2019) has highlighted lack of improved high yielding and adaptable sugarcane varieties as major setback for sugar production in the region. Olaoye (1999) has sighted the need for locally improved sugarcane varieties which will also be adapted to our ecology as part of constrains to sugar production in the country. The goal of sugarcane (*Saccharum species*) breeding is to develop genetically improved varieties with high sugar yield (cane yield and sucrose content) that will be economically sustained over several ratoon crops. Sugarcane yield can be improved in Nigeria through, hybridization, evaluation and adoption of promising clones to the country ecology. Increased cane yield is a function of higher genetic potential of the clones (Nazir *et al*., 1994) and can only be reveal through a progeny performance evaluation. The remedy for less cane yield and sugar recovery problem relies on cultivation of improved cane varieties (Chattha *et al*., 2006). Sugarcane cultivars varies in juice quality characteristics, cane yield, maturity, flowering and and yield per hectare arising from inter-species hybridization involving four species (S. *officinarum*, S. *barberi*, S. *sinense* and S. *spontaneum*) of the genus Saccharum (Moore *et al.*, 2014).

Performance of various clones and their agronomic traits studies are paramount before a variety is accepted for commercial cultivation (Maqbool *et al*., 2001).

Therefore this study was conducted to evaluate and revealed the performance of some sugarcane hybrid clones at National Cereals Research Institute, Badeggi Nigeria.

MATERIALS AND METHODS

This study was carried out by sugarcane research program of the National Cereals research Institute, Badeggi, Niger State, Nigeria (NCRI). Fourteen promising clones (obtained from fuzz raising) were advance from progeny testing II series to preliminary yield trial. The fourteen clones with two commercial varieties (B 47419 and N 27) were planted in a randomized complete block design (RCBD). Each clone was planted on a 5 m x 5 m plot and replicated three times. Sixty cane setts (three budded) were planted per plot. The Preliminary Yield Trial was established 09th October, 2018 and all cultural practices for sugarcane production were adopted according to recommendations of NCRI Badeggi. Juice analysis was carried out at the NCRI laboratory for qualitative traits.

Table 1: List of Sugarcane Hybrid Clone and their Parentage

Genotypes	**Parents (Female X Male)**	**Status**
BD 140-02m	M 1551/80 X F77790	Progeny of Mauritius fuzz
BD 140-011m	M 1551/80 X F77790	Progeny of Mauritius fuzz
BD 140-014m	M 1551/80 X F77790	Progeny of Mauritius fuzz
BD 1098-001m	M 2256/88 X POLYCROSS	Progeny of Mauritius fuzz
BD 1098-003m	M 2256/88 X POLYCROSS	Progeny of Mauritius fuzz
BD 1098-005m	M 2256/88 X POLYCROSS	Progeny of Mauritius fuzz
BD 1098-014m	M 2256/88 X POLYCROSS	Progeny of Mauritius fuzz
BD 441-004m	M 1489/91 X POLYCROSS	Progeny of Mauritius fuzz
BD 441-007m	M 1489/91 X POLYCROSS	Progeny of Mauritius fuzz
BD 575-007m	M 422/91 X R570	Progeny of Mauritius fuzz
BD 1354-20m	M1672/90 X R570	Progeny of Mauritius fuzz
BD 1576-31m	M2256/88 X R570	Progeny of Mauritius fuzz
BD 1576-07m	M2256/88 X R570	Progeny of Mauritius fuzz
BD 1576-14m	M2256/88 X R570	Progeny of Mauritius fuzz
N 27		Commercial Variety
B 47419		Commercial Variety

Data was collected on germination and establishment (%) at 21 and 42 days after planting respectively, tiller count at 3 months after planting, stalk girth, plant height at 6 month, stool per plot, stalk per plot, milleable cane per plot and cane yield ton/ha at maturity. Brix (sugar content) was measured with the aid of refractometer at 8th, 9th, 10th and 12th months after planting.

Recoverable Sucrose percent (RS)

$$\text{RS (\%)} = \left[\text{Pol \%} - \frac{(\text{Brix} - \text{pol})}{2} \right] \times \text{JF.}$$

Juice Factor = 0.65

$$\text{Sugar Yield (t/ha)} = \frac{\text{Cane Yield tha}^{-1} \times \text{Recovery Sucrose}}{100}$$

(Islam *et al*., 2011).

RESULTS AND DISCUSSION

Result from the table below significantly reveals differences among the hybrid clones for some growth traits. BD 140-014m has higher germination than other clones except BD 1098-014m. The result on germination percent is in conformity with the report of Mohammed *et al*., 2019. According to the table below, 1098-014m has more established plants (68.3) than some studied clones (BD 1098-001m, BD1098-005m, BD441-004m, BD 575-007m, BD 1354-20m, BD 1576-31m, BD 1576-07m and BD 1576-14m) and lowest establishment was recorded in BD 1576-31m. BD 1098-014m has the highest number tillers which was significantly superior to the number of tillers recorded for all the studied clones.

Table 2: Mean values for growth performance of selected hybrid sugarcane genotypes evaluated at NCRI Badeggi (2018/2019)

GENOTYPE	SPROUT	TILLER	ESTAB	PLH 6
BD 140-02m	52.7	70.7	62.7	161.9
BD 140-011m	39.7	70.0	57.0	196.1
BD 140-014m	64.0	106.3	62.7	223.3
BD 1098-001m	37.0	59.0	51.0	188.5
BD 1098-003m	46.0	100.3	59.7	204.5
BD 1098-005m	43.0	26.7	44.0	145.9
BD 1098-014m	58.0	161.7	68.3	165.6
BD 441-004m	41.7	71.3	40.0	186.3
BD 441-007m	54.0	127.0	66.3	158.9
BD 575-007m	19.0	73.3	47.7	151.0
BD 1354-20m	18.0	59.0	26.0	162.3
BD 1576-31m	12.3	27.3	22.0	157.6
BD 1576-07m	20.3	82.3	39.7	159.8

CV%	13.3	12.8	16.1	7.9

Means were separated using SE± at P<5%.
Note: sprout (%), Tiller= number of tillers per plot, Estab= establishment count, PLH 6= plant height at six months after planting

There was no significant different recorded among the studied sugarcane hybrids clones for number of stalk per stool (Table 3). However BD 1098-014m has more number of milleable stalks (140.6) per plot and 1576-07 BD has the lowest milleable cane per plot. Maximum stalk girth (2.8 cm) was recorded for BD 140-014m and BD 1098-005m, which compare significantly better than the girth of B47419 (commercial check). The variation noted in the stalk girth was in conformity with the result of Soomro *et al*., (2006), that documented differences among twelve promising sugarcane varieties in Thatta, Pakistan. The highest cane yield (186.5 t/ha) was recorded in BD 1098-003m which was significantly the same with the yield recorded for N 27 and the lowest yield was noted in BD 441-004m. Khan *et al*., (2004) had also reported higher cane yield of 174.4 t/ha. Higher cane yield exhibited by some studied clones might have been inherent genetic potential of the progenies and higher cane yield is also known to be the function of higher genetic potential of a variety as documented by Nazir et *al.* (1997). Variability among the clones for yield per hectare is in agreement with report of other researchers (Getaneh et al., 2015, Ali et al., 2017 and Islam et al., 2011)

Table 3: Mean values for yield performance of selected hybrid sugarcane genotypes evaluated at NCRI Badeggi (2018/2019)

GENOTYPE	STK/STUL	MIL/PLT	STL/PLOT	GIRTH (cm)	YIELD (ton/ha)

Note: STK/STUL= stalk per stool, MIL/PLT= milleable stalk per plot, STL/PLOT=stool per plot

The result on table 4 shows significant different among the studied clones for Brix percentage at 10 and 12 months after planting. BD 1098-001m and 1576-31 BD gave the best Brix (21.4% and 21.1%) and the lowest brix was noted in BD 441-007m. In some studied clones (BD 140-02m, BD 140-011m, BD 1098-001m, BD 1098-003m, BD 1098-005m, BD 1098-014m, BD 441-004m, BD 575-007m, BD 1576-31m, BD 1576-07m, BD 1576-14m, B 47419) the brix percent tend to increase as the age of the crops increases. Most of the studied genotypes exhibit higher brix percent than the check (B47419) nd is in conformity with the result of Ali *et al*., 2020 that studied the performance and stability analysis of some sugarcane genotypes across different environments in Egypt. It has also been suggessted that brix accumulation of genotypes depends on crop-age and environment (Mebrahtom *et al*., 2017).The time of highest Brix percent of a sugarcane clone can serve as an indicator for crop maturity in non-flowering condition.

Table 4: Trend of sucrose (brix) accumulation for hybrid sugarcane genotypes evaluated at NCRI Badeggi (2018/2019)

GENOTYPE	BRIX 8	BRIX 9	BRIX 10	BRIX 12

CV%	19.8	11.2	9.1	7.8

Means were separated using SE± at P<5%.

The juice qualitative analysis reveals differences among the studied clones (Table 5). Highest fiber was recorded in some clones (BD 1098-005m, BD 441-007m, BD 1576-31 and B 47419) and the lowest fibre percent (5.37) was noted in BD 1098-003M. Those genotypes that possess high fibre can further be utilized as source for energy cane varieties since none variety had been release for such purpose in the Nigeria.

Variation among the studied hybrids for juice purity is in agreement with the report of Khan *et al*., (2017) on differences in juice purity of sixteen varieties. Juice purity above 85% with relatively high pol percent noted in some varieties indicated that these varieties attained maturity earlier than other varieties with lower purity percent. Maximum purity percent of 93.6 was obtained in BD 1576-14 and BD 1098-014m gave a lower purity level (72.6).

The disparity in the recovery sucrose of evaluated clones confirms the report of Khan *et al*., (2017). Sugar yield differs among the hybrid clones, BD 1098-001m, BD 1098-003m, and BD 1354-20m gave better sugar yield than the checks varieties (N 27 and B 47419). The family of BD 1098m clone performs better in sugar yield per hectare, which can be related to higher genetic potential of their parent for the trait. Several workers had also reported significant difference among sugarcane varieties for sugar yield per hectare (Khan *et al.*, 2017, Getaneh *et al*., 2015 and Islam *et al*., 2011).

Table 5: Juice quality of selected hybrid sugarcane genotypes evaluated at NCRI Badeggi (2018/2019)

Genotypes	Moisture (%)	Fibre (%)	Brix (%)	Sucrose (%)	Glucose (%)	Polarity (%)	Purity (%)	Recoverable Sucrose	Sugar Yield (t/ha)

N 27	69.79	9.21	21.00	17.09	21.43	16.09	76.40	8.86	14.97
B 47419	63.59	15.21	21.20	18.37	22.98	16.91	79.70	9.59	9.33

CONCLUSION

Those clones with high fiber and good sugar yield can be dedicated for dual purposes (for sugar and ethanol production). The promising hybrids will be advance for more evaluation at diverse location for yield and juice quality stability studies.

ACKNOWLEDGEMENT
The team of researcher that carried out this study extend their appreciation to National Cereals Research Institute for providing enabling working environment and supporting the Sugarcane Research activities. We are highly thankful to National Sugar Development Council for their support on sugarcane breeding projects in NCRI.

ABSTRACT

In most parts of Africa where crops are grown, fertilizers and irrigation are applied to improve soil fertility status and reduce plant water stress. This is essential to reduce losses and requires effective approach in achieving adequate crop use. Application of both methods are beneficial if the value of increase in crop yield due to climatic change is sustained and improved. This study investigated the effects of urea and irrigation on the performance of *Amaranthus viridis* in the humid rainforest and savanna agroecological zones within southwestern Nigeria during two planting seasons. The experimental design was a randomised complete block design with four replicates. The treatments compared two methods of irrigation (sprinkler and capillary) with urea fertilizer application rates of 0 and 40 kg N/ ha by fertigation, broadcast, drilling and spot placement. 40 litres of water was applied at intervals during the cultivation seasons of the vegetable. In the two agroecological zones, 40 kg/ha urea-N combined with capillary irrigation significantly improved its fresh yield and other growth parameters. This method did not constitute negative effect on the vegetable quality and other agronomic parameters in both zones.

Keywords: Capillary irrigation, Agroecological zones, Fertilizer, *Amaranthus viridis*

INTRODUCTION

Irrigation is the artificial application of controlled amount of water to the soil to support crop production. Irrigation water may be applied in drops, flooding soil surface and beneath the soil.

Irrigation water may be applied to supplement the water available through irregular rainfall as a result of climatic change. It also contributes to soil moisture from groundwater. Worldwide, the amount and timing of rainfall is not adequate to meet water requirement of crops thus making irrigation important to raise crops necessary to meet food requirement in Africa. Sprinkler and capillary irrigation systems are examples of surface and subsurface irrigation methods, respectively. In the sprinkler system, water is sprayed in the air and allowed to fall on the soil by gravity. It is suitable to all types of soil and irrigate crops where the plant population per unit area is very high (Mikkelson *et al.,* 2015). Capillary irrigation as a subsurface irrigation system with the aid of capillary pipe is effective as it reduces drudgery, serves as water reservoir for plant, supplies water directly to the crop root zone and saves time (Egbebi, 2021). It will also reduce soil compaction and improve aeration which could have occurred from the effects of soil tillage. It reduces saturation and waterlogging in soil (Million *et al.,* 2007) as it provides water directly to the root zone of the soil. Irrigation practices are threatened due to increasing demand for water and its scarcity in Africa. Climatic changes and its effects is a serious challenge to agricultural development (Poonia *et al.,*2021) as increasing water demand for agricultural and industrial use has become competitive due to limited water resources (Luo *et al.,,* 2018). Many studies are also ongoing to identify the management practices which will reduce environmental threat as a result of climate change. These will be aimed to increase food production with limited and available water by improving irrigation technology as a strategy to conserve and save water. (Auci and Vignani, 2021).

METHODOLOGY

The study investigated water management under manual sprinkler (watering can) and capillary irrigation methods using *Amaranthus viridis* as test crop. It covered two successive dry planting seasons in the rainforest and savanna Agroecological zones of Nigeria. Vegetable seedlings were transplanted at spacing of 0.1 m within rows and 0.2 m between rows. Urea fertilizer was applied at two rates (0 and 40 kg N/ ha) by four different methods: fertigation, drilling, spot placement and broadcasting. 40 kg N/ha is the recommended fertilizer microdosing rate. The capillary irrigation method was combined with fertigation while the watering can sprinkler irrigation method was combined with other methods of fertilizer application and fertigation adopted for this study. Forty (40) litres of water was applied at two days interval. The treatments were as follows: **1.** 40 kg N/ ha (broadcasting) + sprinkler irrigation **2**. 40 kg N/ha (fertigation) + capillary irrigation **3**. 40 kg N/ha (spot placement) + sprinkler irrigation **4**. 40 kg N/ha (drilling) + sprinkler irrigation **5**. 40 kg N/ha (fertigation) + sprinkler irrigation **6**. 0 kg N/ha + sprinkler irrigation (control). Data on fresh biomass weight at harvest was monitored. The water required and saved to produce one kilogram of the vegetable was also determined by the irrigation methods at both locations. The data collected were analysed separated with Duncan's New Multiple Range Test with the SAS software package (SAS, 2003).

RESULTS AND DISCUSSION

The volume of water required to produce one kilogram of the vegetable reduced under the capillary irrigation method at the two locations (Table 1) compared with watering can irrigation method which was higher. This is important for vegetable production especially during this period of climate change, water scarcity, the dry season and in savanna regions (Kijazi *et al.,* 2013) where water is usually in short and limited supply. The device reduced water loss to evapotranspiration and regulated water supply to the soil root zone in response to crop demand. The control plots utilized more volume of water in this study at the two zones due to little or no application of fertilizer. However, the water used at the savanna through the manual watering can method of irrigation was significantly higher than water used at the rainforest. More water was required to produce one kilogram of the vegetable in the savanna compared with the rainforest as a result of differences in climatic variables of both locations. The is as a result of loss of some volume of water to the environment in the savanna from high solar radiation during cultivation period and water stress encountered by the vegetable. This agrees with the findings of Oyedele and Tijani (2010), who observed that temporal variation in soil water content is mainly dependent on weather conditions. This result was also influenced by the level of water applied according to Li *et al.* (2020) and the capillary irrigation device which responded precisely and actively to the vegetable root uptake with equal volume of water applied through both methods of irrigation considered. The innovation also supported water retention in the vegetable which was enough to produce optimum yield unlike the sprinkler system that encouraged runoff and fertilizer volatilization in both zones associated with climate change. The higher water requirement in the savanna is also due to higher temperature in the savanna which was in accordance to crop demand. Early shade, root and canopy development from fertigation with the capillary device combined and soil surface sealing caused by the impact of water droplets on soil surface from the sprinkler irrigation method could have reduced and increased evapotranspiration rate respectively as timely water supplied through the capillary device into the soils of these zones might have been trapped within the rhizosphere and made available for the amaranth growth and development (Table 1). These results shows that water have been saved for future agricultural and industrial use (Figure 1).

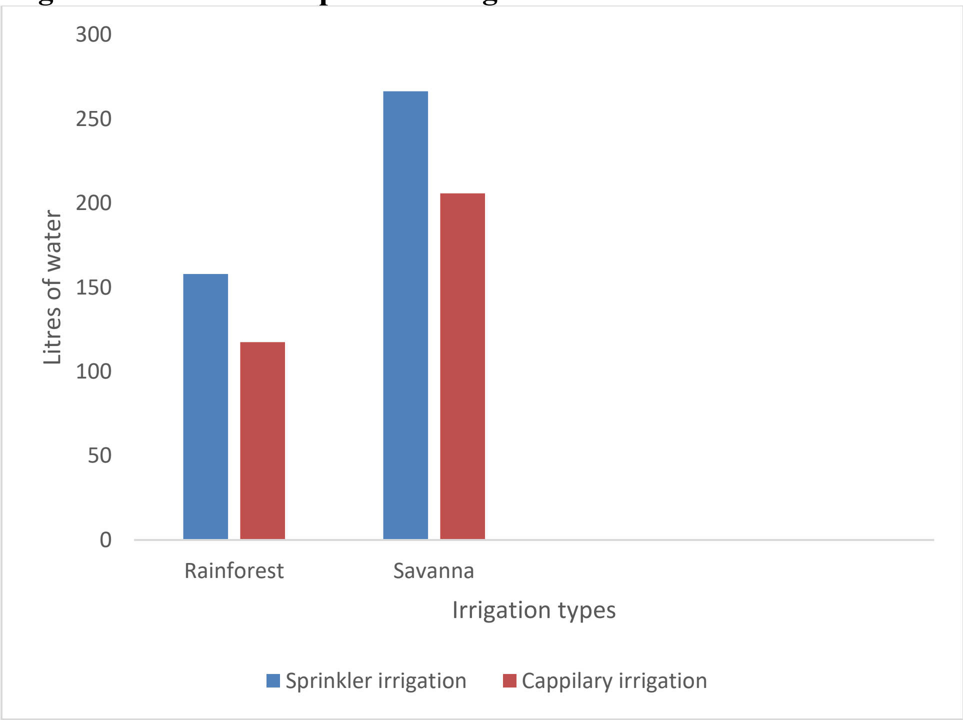
Table 1: Water required per unit weight of fresh *Amaranthus viridis*

	Rainforest	Savanna
	…...Litres…..	
1	125.32ab	234.81a
2	117.43b	205.83ab
3	133.27ab	252.43a
4	141.48ab	256.84a
5	139.32ab	261.45a
6	250.04a	326.61a

1. 40 kg N/ ha (broadcasting) + sprinkler irrigation 2. 40 kg N/ha (fertigation) + capillary irrigation 3. 40 kg N/ha (spot placement) + sprinkler irrigation 4. 40 kg N/ha (drilling) + sprinkler irrigation 5. 40 kg N/ha (fertigation) + sprinkler irrigation 6. 0 kg N/ha + sprinkler irrigation (control).

60.59 litres of water was conserved through the capillary irrigation device at the savanna while 40.45 litres was conserved at the rainforest in cultivating the green amaranth (Figure 1). Water was significantly saved through the capillary device at both zones. Climate change factors such as excessive evapotranspiration and higher temperature in both zones which could have affected and resulted to high soil infiltration rate and percolation combined with increased soil erosion from possible deforestation could have led to loss of significant amount of water from the sprinkler irrigation method adopted in the study. Higher volume of water saved at the savanna could have resulted from lower rate of decomposition of plant residue which would have retained and made water available within the root zone and reduced crop demand for water (Pregitzer and King 2005) from the capillary irrigation device. This is an advantage in this period of climate change and challenge.

Figure 1: Water saved per unit weight of fresh *Amaranthus viridis*



CONCLUSION

The capillary irrigation device has the ability to sustain and improve food production, this is evident through its water use, management and low cost of operation.

ABSTRACT
A comparative analysis of the nutritional and chemical composition of the rind, pulp and seeds of *Citrullus lanatus* Thunb. (Watermelon) and *Cucumis melo* L. (Sweet melon) was conducted with a view to ascertain the most nutritive fruit part, and to encourage whole fruit consumption and utilization. The rind, pulp and seeds of *C. lanatus* and *C. melo* were screened for their proximate, mineral, ascorbic acid and secondary metabolites contents using standard protocols while the antioxidant activity of the samples was analyzed against 1,1 – diphenyl – 2 picrylhydrazyl (DPPH) radicals and the data were subjected to variance analysis and statistically different means were separated by Duncan Multiple Range Test at $p < 0.05$. The results revealed that secondary metabolites were highest in the rind, proximate content was highest in the seeds while minerals and antioxidants activity were highest in the pulp of both fruits. The mineral composition and inhibitory antioxidant activity was discovered to be in rich amounts in Sweet melon fruit (rind, pulp and seed) which suggests that regular consumption could regulate enzyme, hormone production and control cell damage caused by free radicals. Appreciable amount of phytochemicals was recorded in the pulp of Watermelon fruit which justify its reported therapeutic potentials when consumed regularly. Therefore consumers are encouraged to consume whole fruit (rind, pulp and seed) of both fruits in enhancing health. Also Sweet melon fruit could serve as a very good substitute to Watermelon fruit when it is out of season or not readily available.

Keywords: Watermelon, Sweet melon, Rind, Pulp, Seed, Phytochemicals, Proximate, Minerals

INTRODUCTION
In Nigeria, Watermelon (*Citrullus lanatus* Thunb.) is mainly cultivated in the Guinea, Sudan and Sahel savanna vegetations and then distributed to other parts of the country. It is mostly grown for its sweet juicy taste and high water content - about 92% total weight (Okrikata and Ogunwolu, 2017). The fruit are an excellent source of vitamins having many smooth black, yellow or white compressed seeds thickened at the margin. Their seeds and pulp have been reported to contain phytochemical constituents like alkaloids, flavanoids, tannins, cardiac-glycocides, terpenoids and saponnins (Siti *et al*., 2018). The whole fruit possesses useful nutritive properties which enhance the improvement of human health and its pulp has been reported to possess high lycopene and carotenoid which are very good source of antioxidants (Adewale *et al*., 2015). Its therapeutic effects employed in the management of cancer and cardiovascular diseases has been attributed to the presence of beta carotene, lycopene, antioxidants and certain phytochemical compounds (Adewale *et al*., 2015).
Sweet melon (*Cucumis melo* Linn.) is extensively cultivated for their fruits, eaten as vegetable and sometimes naturalized in open scrub forest. The melon is reported to be rich with important vitamins such as riboflavin, thiamin, folic acid and a good source of provitamin A and C (Laur and Tian, 2011). The seed of *C. melo* are commonly used as diuretic while its pulp is used as anthelmitic while its peels has anti-hyperlipidemic effect (Naveed *et al*., 2015). The reported therapeutic, pharmacological and antioxidant properties of *C.melo* may be due to the presence of phytochemicals like tannins, saponnins, flavinoids (Alagar *et al*., 2015).

In Nigeria, the rind and seeds of *C. lanatus* and *C. melo* are largely disposed as wastes. Proper utilization of these parts (rind and seeds) could meet and improve the nutritional and therapeutic needs of consumers as well as improving environmental hygiene. Therefore this study aims to comparatively assess the proximate, phytochemical, mineral, vitamins and antioxidant constituents of the rind, seed and pulp of *C. lanatus* and *C. melo*.

MATERIALS AND METHODS

Collection, Identification and Preparation of Plant Materials

Whole fresh fruit samples of *C. lanatus* and *C. melo* were harvested from the Research Farm of Federal University Wukari, Nigeria. The pulp, seed and rind were separated, sliced to small pieces and crushed to paste using milling machine (Miller's blender) and then evaporated to dryness using water bath (model: Vega 81404).

Phytochemical Screening

The evaporated extract of *C. lanatus and C. melo* were evaluated for alkaloids, flavonoids, tannins, saponins, polyphenols, cardiac glycoscides, proximate constituents, mineral content and vitamin contents and antioxidant activity through DPPH (1, 1–diphenyl–2–picrylhydrazyl) assay using standard procedures as described by AOAC, 2005.

Statistical Analysis

Data were subjected to variance analysis using SPSS version 23 and significantly different means were separated by Duncan Multiple Range Test (DMRT) at $p < 0.05$ or 95% confidence interval.

RESULTS AND DISCUSSION

Table 1 shows that the phytochemical constituents displayed in the fruit parts were highest from rind > pulp > seed in the descending order. It further shows significantly higher secondary metabolites in Sweet melon than Watermelon fruits in most analytes. The phytochemical analysis of the rind (Table 1) showed that the rind of Sweet melon (SM) displayed significantly higher constituents except for terpenoid (576.67±6.00 mg/100g) present in the rind of Watermelon (WM), while the seed and pulp of both plants displayed appreciable amount of secondary metabolites.

Table 1: The phytochemical composition of the rind, pulp and seeds of sweet melon and watermelon fruits

	Phytochemical composition (mg/100g)					
Variable	**Alkaloid**	**Flavonoid**	**Cardiac glycosides**	**Saponins**	**Tannins**	**Terpenoids**
RIND (SMR)	$1718.30±7.26^{a}$	$188.33±4.41^{b}$	$76.67±1.67^{a}$	$328.33±4.41^{b}$	$246.67±6.00^{b}$	$51.67±1.77^{e}$
(WMR)	$1695.00±7.63^{b}$	$105.00±2.89^{c}$	$11.67±1.65^{c}$	286.67±3.41c	$241.76±7.26^{b}$	$576.67±6.00^{a}$

(WMS)	$186.67±5.36^{f}$	$33.33±4.41^{d}$	$11.76±1.46^{c}$	$386.56±5.99^{a}$	$131.57±6.10^{d}$	$468.34±4.00^{c}$
P- value	<0.01	<0.01	<0.01	<0.01	<0.01	<0.01

Values are expressed as Means ± SE; Means with same alphabet across the column are not significantly different at $p<0.05$; **SMR** = Sweet melon rind; **WMR** = Watermelon rind; **SMP** = Sweet melon pulp; **WMP** = Watermelon pulp; **SMS** = Sweet melon seed; **WMS** = Watermelon seed.

The proximate analysis revealed that their quantitative nutrient composition (carbohydrates, proteins and fats) was highest from seeds > rind > pulp in the descending order as shown in table 2. Generally the result from this study shows that Sweet melon fruit displayed an overall higher significant nutrient composition than Watermelon. The nutrient composition of SMR had significantly higher carbohydrate (5.07±0.04%), ash (0.97±0.01%) while WMR displayed significantly higher moisture content (94.12±0.02%), lower ash (0.69±0.01%) contents (table 2). The carbohydrate (6.08±0.03%), ash (0.60±0.02%) and crude fat (0.03±0.00%) of SMP displayed higher composition than WMP except for its moisture content (95.03±0.12%) as shown (table 2). Except for moisture content (67.29±0.03%) and carbohydrate (18.02±0.54%) composition in WMS was significantly ($p < 0.01$) higher than SMS, the other proximate parameters were higher in SMS vis-à-vis WMS (Table 2).

Table 2: Proximate composition of the rind, pulp and seeds of sweet melon and watermelon fruit

Variable	Proximate composition (%)					
	Moisture Content	Protein	Fat	Ash	Fiber	Carbohydrate

The scavenging property of fruits was highest from pulp › rind › seed in the descending order as shown in table 4. The Ascorbic acid (22.53±0.24 mg/100g), Phenols (87.43±0.12 mg/100g) of WMP were significantly ($p < 0.01$) higher than those in SMP. The antioxidant inhibitory potential (69.70±0.14%) SMP was also significantly ($p < 0.01$) higher than that of WMP (table 4). The amount of phenol, ascorbic acid and antioxidant inhibition in the peel and seeds of both fruits shows promising potentials of all fruit parts in scavenging free radicals.

Table 4: Antioxidants and ascorbic acid composition of rind, pulp and seeds of sweet melon and watermelon fruits

Variable	Ascorbic (mg/100g)	Phenols (mg/100g)	Antioxidant inhibition (%)
RIND (SMR)	25.90±0.38^{b}	87.80±0.21^{a}	72.60±0.15^{a}

P-value	<0.01	<0.01	<0.01

Values are expressed as Means ± SE; Means with same alphabet across the column are not significantly different at p<0.05; **SMR** = Sweet melon rind; **WMR** = Watermelon rind; **SMP** = Sweet melon pulp; **WMP** = Watermelon pulp; **SMS** = Sweet melon seed; **WMS** = Watermelon seed.

Generally, Sweet melon (*C. melo*) and Watermelon (*C. lanatus*) pulp are consumed for their sweet taste while their seeds and peels discarded. This study evaluated the rind, pulp and seeds of these fruits and found that they possess appreciable amount of phytochemical, proximate, minerals contents with promising antioxidants potentials. The quantitative phytochemical screening of the rind, pulp and seeds of Sweet melon (*C. melo*) and Watermelon (*C. lanatus*) fruits revealed that they possess significant amount of alkaloids, flavonoids, cardiac glycoscides, tannins and terpenoids that are known to exhibit therapeutic and pharmacological properties as reported by Anandhi and Revathi (2013). The consumption of these plant chemicals may help to prevent some cancer ailments, as well as other serious ailments such as heart diseases, kidney disorders, liver damage and promote better blood functions.

Generally the rind and seeds of Sweet melon and Watermelon are discarded because they are regarded as waste but the highest fiber content from this study was observed in the seed followed by the rind and least in the pulp which suggest that a wide range of useful macromolecules, secondary metabolites and nutritional components that could be harnessed from these plant parts. Therefore, the consumption of the seed, rind with the pulp of Sweet melon and Watermelon have the potential to increase the numerous dietary fiber benefits of these fruits such as protection against colon cancer, maintaining blood lipids within the normal range, reducing the risk of obesity by lowering cholesterol level, hypertension, cardiovascular diseases as well as aid smooth functioning of intestinal tissues (Khan *et al*., 2013). It was observed that a rise in the phenol content showed a corresponding rise in inhibition against DPPH free radicals in Sweet melon rind, Watermelon pulp and Sweet melon seeds. Therefore regular consumption of plants with appreciable antioxidant activity or potentials such as Sweet melon and Watermelon could reduce the reactive oxygen species (ROS) capable of causing decrease in membrane fluidity, loss of enzyme receptor activity, damage to membrane protein, cancer, cardiovascular diseases, diabetes, rheumatoid arthritis, epilepsy, degradation of essential fatty acids and death (Li *et al*., 2007).

CONCLUSION

This study revealed that Sweet melon (*C. melo*) and Watermelon (*C. lanatus*) rind, pulp and seeds possess beneficial phytochemical, nutritional and mineral components and that Sweet melon had higher nutrients, secondary metabolites and minerals than Watermelon. Also, the rinds of the fruits housed highest phytochemicals, its seeds; the proximate and the pulp; mineral contents and antioxidant activity. The fruit could thus exhibit therapeutic function due to the high phytochemicals present (alkaloids, flavonoids, tannins) in the rind, serve as nutritional supplement because of the proximate constituent (crude fibre, protein, carbohydrate) present in the seeds while the presence of appreciable minerals (calcium, potassium, magnesium) and high antioxidant activity (phenol, ascorbic acid) in the pulp could neutralize ROS and improve body metabolism. Therefore consumers are advised not to discard peel and seed but encouraged to consume whole fruit in order to harness the total nutritional and medicinal benefits from these fruit.

ABSTRACT
Investigations were conducted to study the assessment of stem portion on the yield of cassava (NR 8082) under Umudike agro ecology during the 2019/2020 and 2020/2021 cropping seasons. In each year, the experiment was a 3 x 3 factorial laid out in a randomized complete block design (RCBD) with three replicates. Treatments comprised three stem portions (top, middle and tail) and three numbers of stakes per stand (1, 2 and 3). The top portion of the stem gave the best stem portion for storage root yield. However, the top portion produced the highest yield on average. The use of 1 stake per stand increased number of storage roots per plant, root weight and storage root yield in 2020/2021 cropping season. Number of stakes per stand did not significantly influence storage root yield across the two cropping seasons. Findings from this study showed that the use of 1 stake per stand is recommended for high root yields of NR 8082 cassava variety in Umudike agro ecology.
Key words: portion of stem, yield, cassava, Umudike, agro-ecology.

INTRODUCTION
Cassava, (*Manihot esculentus* Crantz) is a very important crop in Nigeria and many countries of the world. According to Food Safety Network (2014), it is known as the third most important source of calories in the tropics after rice and maize. It is also a raw material based for some industries in the production of many finished products. It can be processed into different forms of food for human consumption and in feeding livestock. The demand for cassava is expected to increase as consumers changes with the development of new cassava products (Alacho *et al.*, 2013) but farmers' fields are low due to inappropriate agronomic practices and poor or low soil fertility (Okpara *et al.*, 2010
Number of shoots per stand of cassava is likely to influence growth, development and the yield stability in cassava either by competitions between these shoot for nutrients and space. When cassava stakes are been planted, they produce many shoots which gives rise to nutrient competition. This competition may lead to reduction in shoots. This study seeks to explore ways of integrating the best stem portion and number of stakes per stand to maximize yield. The objective of this study was therefore to investigate the assessment of the portion of stem on the yield of cassava (NR 8082) under Umudike agro-ecology.

MATERIALS AND METHODS
The study was conducted during the 2019/2020 and 2020/2021 cropping seasons at the National Root Crops Research Institute (NRCRI), Umudike farm, Southeastern Nigeria. Umudike is located on Latitude 5^{o} 29$^{'}$ N, Latitude 7^{o} 32$^{'}$ E and altitude of 122meters above sea level.
The study was a 3 x 3 factorial experiment laid out in a randomized complete block design (RCBD) with three replicates. Three levels of cassava stem portions (top, middle and tail) and three levels of number of stakes per stand (1, 2 and 3 stakes). Each plot size measured 5m x 6m (30m^2). The cassava stems were cut and separated into different stem portions (top, middle and tail). The cassava stakes were planted on the crest of the ridges, using the inclined or slanting method at an angle 45^0 to the ground level. While planting, buds faced upwards and two-third buried into the ridges. The planting space at 1m x 1m which gave a plant population of 10,000 plants per hectare for 1 stake per plant, 20,000 plants per hectare for 2 stakes per plant and 30,000 plants per hectare for 3 stakes per plant. After planting,

the field was sprayed with pre- emergence herbicide (EL-TARAZINE), 150mls diluted in 20L of water and post emergence herbicide (TACKLE), 200mls in 20L water to check weeds. Data for yield parameters were taken on number of storage roots, storage root weight per plant (kg) and root yield (t/ha) at 12 MAP in both cropping seasons. The data obtained were subjected to analysis of variance (ANOVA) using GenStat Discovery (2007) edition and the treatment means were separated using Fisher's Least Significant test at 5% probability level.

RESULTS AND DISCUSSION

In **Table 1,** there were no significant effects of stem portion on number of storage roots in both cropping seasons**.** The number of stakes per stand had significant effect, such that 1 stake gave higher number of tuberous roots than 2 or 3 stakes per stand. 2 and 3 stakes per stand maintained statistically similar number of storage roots in both cropping seasons. There were no significant interactions between stem portion and number of stakes per stand on the number of storage roots produced. In **Table 2** in both cropping seasons, top stem portions had significantly higher storage weight per plant than the middle or tail stem cuttings. The middle and tail stem cuttings did not vary in tuberous root weight. In both seasons, interactions were not significant on root weight per plant. In both cropping seasons in **Table 3**, storage root yield in tons per hectare followed similar trends in response to stem portion**.** However, in 2019/2020, the top stem portion produced a significantly higher root yield than the middle and tail cuttings. Storage root yields of the middle and tail stem cuttings were not significantly different in both seasons. There were no differences in storage root yield with respect to number of stakes in 2019/2020, but in 2020/2021, 1 stake per stand had significantly higher root yield than planting 2 and 3 stakes per stand. The 2 and 3 stakes per stand maintained comparable root yields.

Stem portion had effect on storage root yield, with gave the highest yield that was obtained from the top portion. According to Legese *et al.,* (2011), he also reported similar trends. In order to improve the rooting and consequently the establishment of the top portion which produced optimum yield, Onwueme and Sinha (1991) stressed that it is needed to allow tender shoot tips root in mist chamber before transplanting them to the field. The yields of fresh storage root were also the highest with 1 stake per stand in one year. However, the root weight and the number of storage roots decreased as the population density increased. This tells us that number of tubers and tuber weight per plant were dictated by competiting with neighboring plants for light and nutrient. According to Okpara *et al*, (2014) it was observed that when competition became intense in yam, it limits the availability of environmental resources to individual plants. It also leads to high intra plant competition for assimilates which leads to reduction in the number and the weight of tubers.

CONCLUSION

Form this investigation, the soil type makes us to know that the use of more than one stake per stand is not necessary since because there is no improvement in the yield. Conclusively, under the condition of this study, the results showed that stem portion had significant effects on cassava storage root weight and yield. However, the top stem portion produced the highest root yield and is recommended. Therefore, it is recommended that 1 stake per stand should be adopted for cassava production under Umudike agro-ecology.

ABSTRACT
Insecticides are chemicals used in the controlling of insects to prevent them from destroying our farm produce. Some are systemic while some are toxic to our crops. An insect can be defined as a small animal of class **Insecta** or **hexapoda** of arthropods like bugs, ants, beetles, butterflies or bees with well-defined head, thorax, and abdomen. Pesticide covers a wide range of compounds which are insecticides, fungicides, herbicides, rodenticides, molluscicides and nematicides. Some pesticides are beneficial to our crops while some are hazardous to our crops. Due to this, instead of using chemical insecticides, there are many alternative options available now that can protect farmers from major economic losses such as breeding crops resistance, using chemical control like pheromones, integrated pest management and pull push technique methods must be adopted.
Key words: insecticidal, effects, benefits, crop production, Nigeria.

INTRODUCTION
Insecticides are chemicals used to control insects by killing them or preventing them from engaging in undesirable or destructive behaviors. They are used to kill insect. Insecticides are classified based on their structure and mode of action, many of them act upon the insect's nervous system such as cholinesterase, inhibition etc while others act as growth regulators. Insecticides are commonly used in agricultural, public health and industrial applications, as well as household and commercial uses in the control of roaches and termites. The most commonly used insecticides are the organophosphates, pyrethroids and carbamates . The USDA (2001) reported that insecticides accounted for 12% of total pesticides applied to the surveyed crops. Insecticides are applied in various ways, formulations and delivery systems that influence their transport and chemical transformation. Insecticides can be done through runoff , atmospheric deposition, or sub-surface flow (Moore and Ramamoorthy 1984). This study aims to know the way we can control our farm crops in order not to be affected or destroyed while applying insecticide to it.

Types of insecticides
There are two types of insecticides, namely: Systemic insecticides and the contact insecticides.

Systemic insecticides: It become incorporated and distributed systemically throughout the whole plant. When insects feed on the plant, they ingest the insecticide. Systemic insecticides produced by transgenic plants are called plant-incorporated protectants (PIPs).

Contact insecticides: They are toxic to insects upon direct contact and can be inorganic insecticides, which are metals and include the commonly used sulfur, and the less commonly used arsenates, copper and fluorine compounds. Contact insecticides can also be organic insecticides, i.e. organic chemical compounds, synthetically produced, and comprising the largest numbers of pesticides used today.

THE TABLE BELOW SHOWS INSECTICIDE TYPES AND THEIR MODE OF ACTION

Insecticide	Mode of Action
Organophosphate	Cause acetylcholinesterase inhibition and accumulation of acetylcholine at neuromuscular junctions causing rapid twitching of voluntary muscles and eventually paralysis. A broad-range insecticide, generally the most toxic of all pesticides to vertebrates.
Organosulfur	Exhibit ovicidal activity (i.e., they kill the egg stage). Used only against miteswith very lov toxicity to other organisms.
Fumigants	Act as narcotics that lodge in lipid-containing tissues inducing narcosis, sleep or unconsciousness; pest affected depends on particular compound.
Benzoylureas	Act as insect growth regulators by interfering with chitin synthesis. Greatest value is in the control of caterpillars and beetle larvae but is also registered for gypsy moth and mushroon fly. Some types are known for their impacts on invertebrates (reduced emergent species) ar early life stages of sunfish (reduced weight) (Boyle et al. 1996).
Antibiotics	Act by blocking the neurotransmitter GABA at the neuromuscular junction; feeding and eg laying stop shortly after exposure while death may take several days. Most promising use c these materials is the control of spider mites, leafminers and other difficult to control greenhouse pests.
Organosulfur	Exhibit ovicidal activity (i.e., they kill the egg stage). Used only against mites with very lov toxicity to other organisms.
Pyrethroids	Acts by keeping open the sodium channels in neuronal membranes affecting both the peripheral and central nervous systems causing a hyper-excitable state. Symptoms include tremors, incoordination, hyperactivity and paralysis. Effective against most agricultural insect pests; extremely toxic to fish.
Carbamates	Cause acetylcholinesterase (AChE) inhibition leading to central nervous system effects (i.e rapid twitching of voluntary muscles and eventually paralysis). Has very broad spectrum toxicity and is highly toxic to fish.

From Radcliffe et al. (2009).

A crop duster airplane spraying a field with insecticides. Aerial drift of insecticides can cover long distances depending on wind and other factors.

Some biological effects of insecticides

- Developmental effects, especially in aquatic insects (Kreutzweiser 1997).
- Sudden, massive kills of aquatic life (e.g., fish kills)
- Fish exhibiting cough, yawn, fin flickering, S-and partial jerk, nudge and nip; difficulty in ventilation and aberrant behavior (Alkahem 1996)
- Reduced biological diversity (Relyea 2005), especially among aquatic insects.

- More natural insecticides have been interesting targets of research for two reasons, one of it is that the most common chemicals are losing effectiveness, and also, due to their toxic effects upon the environment, many organic compounds are already produced by plants for the purpose of defending the host plant from predation and can be turned toward human ends.

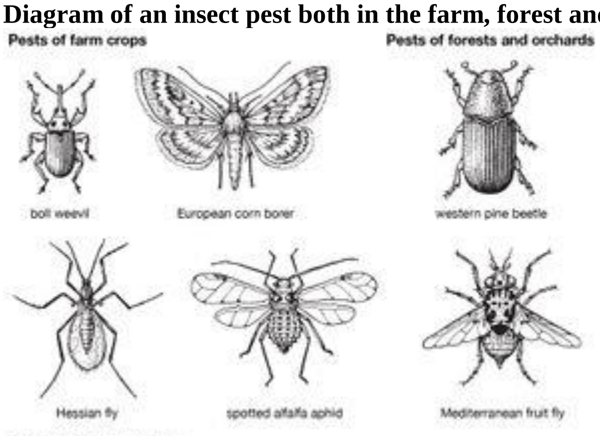
An Insect: An insect can be defined as a small animal of class **Insecta** or **hexapoda** of arthropods like bugs, ants, beetles, butterflies or bees with well-defined head, thorax, and abdomen. The legs are only three pairs (six legs) and with one or two pairs of wings. They are usually refered to as disease carriers but some of them are beneficial to plants. In adaptability, insect is the most successful group of animals. Also, the insect orders that have the greatest numbers of species are the beetles, wasps, bees, butterflies etc. They are adapted to any habitat or environment either land or fresh waters.

Importance of insect: It plays many roles on our crop and for we human being. Some insect like bees produces honey, wax, silk and dyes and they are of a good benefit to the human being. Some insects also serve as food for some people such as termite swams, large palm weevil grubs are source of protein. Some insect can also cause damage to our agricultural products because of their feeding on different types of organic matter. Insect pests affect our food crops both in the field and while storing them and it makes them convey infective micro organisms to the crops.

ENVIRONMENTAL HARM OF INSECT PEST DAMAGE TO CROPS AND COMMERCIAL PRODUCTS.

Some insecticides kill or harm other creatures in addition to those they are intended to kill. For example, birds may be poisoned when they eat food that was recently sprayed with insecticides or when they mistake an insecticide granule on the ground for food and eat it. (Palmer *et.al*., 2007). Sprayed insecticide may drift from the area to which it is applied and into wildlife areas, especially when it is sprayed aerially. In hot and dry areas, as in Southeastern Nigeria, matured tuber crops in the fields is affected by beetles and moths and when it is been harvested, these insects multiplies in the store. They can be carried throughout till the next cropping season. Disinfecting is the best method used to control the insect pest. Some insects feed on the plant and when the plants are of agricultural importance, humans are often forced to compete with these insects. In some agricultural sector, insect pests were introduced along with a crop while planting in the field.

Diagram of an insect pest both in the farm, forest and ochard.



Pesticide: Pesticide covers a wide range of compounds which are insecticides, fungicides, herbicides, rodenticides, molluscicides and nematicides. Among all, insecticides are used in the control of insect diseases. Other systemic insecticides called organophosphate (OP) was introduced in the 1960s, carbamates 1970s and pyrethroids in 1980s. A pesticide is used to target a particular pests and not to non-target pests. Pesticides can be absorbed by plants through the leaves and roots. The ones that are taken up by plants can move (translocate) to other parts of the plant.

Benefits of pesticides

The main benefit of pesticides is the positive effect of it on the agricultural crops.

- For instance, it improves the productivity by killing caterpillars that are feeding on the crop in order not to reduce the yield during harvesting period.
- It also improves the productivity of the farmers such as grains, roots and tuber crops, legumes.
- Food grain production increases from 50million tons (1948-1949) from 169 million tons (1996-1997). This was achieved by making use of high yielding seed materials, advanced irrigation techniques as well as agricultural chemicals (Employment Information: Indian Labour Statistics, 1994).
- Other benefits are: By protecting crop losses, controls of vector diseases and provision of good quality food. In the environment, most of the pesticides undergo photochemical transformation to produce metabolites which are not harmful to human beings and the environment (Kole *et al*., 1999).

Hazard effect of pesticides

- One of it is by contact direct to man and his environment. While applying the pesticides to the infected plant, it can also affect the person that is spraying it and the entire environment. According to Environews Forum, (1999), it was stated that the world-wide deaths and chronic diseases was due to pesticide poisoning number which is about 1 million per year in which the production workers, formulators, sprayers, mixers, loaders and agricultural farm workers are exposed to the high risk of the pesticides.

- **The effect of Pesticide on the environment: It can also contaminate the soil, water and other vegetation by killing weeds. It can be toxic to other organisms host like: birds, fish, beneficial insects, and non-target plants.**

- **Effect of pesticide on soil fertility: According to soil scientist, Dr. Elaine Ingham, it was stated that the soil will be degrade if we lose the bacteria and the fungi present in the soil. This will happen due to the over use of pesticides which had effect on the soil organism.**

- **Runoff and Percolation: Solid bait and liquid insecticides, especially if improperly applied in a location, get moved by water flow. This happens through nonpoint sources where runoff carries insecticides in to larger bodies of water. As snow melts and rainfall moves over and through the ground, the water picks applied insecticides and deposits them in to larger bodies of water, rivers, wetlands, underground sources of previously potable water, and percolates in to watersheds. This can effect the quality of water sources, harming the natural ecology.**
- Insecticides can kill bees and may be a cause of pollinator decline, the loss of bees that pollinate plants, and colony collapse disorder in which worker bees from a beehive or Western honey bee colony abruptly disappear.

CONCLUSION

Pesticides are very easy and quick solution for controlling weed insect pests in our farms. However, it has contaminated almost every part of our environment. The residues are still present in the soil, air and in ground water across the countries. Pesticide contamination had a great risk to the environment and non-target organisms ranging from beneficial soil microorganisms, to insects, plants, fish, and birds. Therefore, Instead of using chemical insecticides to avoid crop damage caused by insects, there are many alternative options available now that can protect farmers from major economic losses. They are:

- Breeding crops resistant.

- Releasing predators, parasitoids, or pathogens to control pest populations as a form of biological control.

- **Chemical control like releasing pheromones into the field to confuse the insects into not being able to find mates and reproduce.**
- **Integrated Pest Management: The act of using multiple techniques in tandem to achieve optimal results.**
- **Push-pull technique: Intercropping with a "push" crop that repels the pest, and planting a "pull" crop on the boundary that attracts and traps it.**

ABSTRACT

Field trial was carried out during the early growing season of 2019 and 2020 at Benin City in Tropical rainforest of Nigeria, to evaluate the agronomic performance of maize varieties to varying rates of nitrogen fertilization. The experiment was laid out in a randomized complete block design, with a split-plot arrangement. Main plot treatment was nitrogen (N) rate (0, 30, 60, 90 and 120 kg N ha^{-1}) and subplot treatment was maize variety (TZEE-Y POP STR C4, 2008 DTMA - Y STR, BR. 9928 DWRSR and TZL COMP.4 C4). Results showed lack of significant N rate × variety interactions for traits except 1000-seed weight. Maize performance was influenced by N rate and variety. Grain yields were higher by 32, 57, 56 and 61% at 30, 60, 90 and 120 kg N ha^{-1} respectively compared to 0 kg N ha^{-1}. Optimum performance was achieved for grain yield at 60 kg N ha^{-1} beyond which rate, additional N did not cause any significant increase. TZL COMP.4 C4 and BR.9928 DWRSR out-yielded TZEE-Y POP STR C4 and 2008 DTMA-Y STR. Therefore, in the Tropical rainforest agro-ecology, TZL COMP.4 C4 and BR.9928 DWRSR should be grown at 60 kg N ha^{-1} for optimum yield.

Keywords: Nitrogen (N) rate; maize variety; grain yield; rainforest agro-ecology

INTRODUCTION

Maize (*Zea mays* L.) is a major cereal crop cultivated in Nigeria. Owing to its high demand, maize is the most widely grown staple food crop in sub-Saharan Africa (SSA), occupying more than 34 million hectares each year (Food and Agriculture Organisation, 2012). Despite the vast land and number of maize farmers in Nigeria, the crop harvest is low due to poor yields. The Tropical rainforest zone of Nigeria has a great potential for maize production, but this is not often realized because the soils are particularly poor in available nitrogen (N).

The high demand of maize for N and other major nutrients such as phosphorus (P) and potassium (K) makes it impossible to achieve high maize yield without fertilization (Havlin et al., 2013). Nitrogen is typically the nutrient of most concern because it has a strong influence on cereal crop yields (Havlin et al., 2013). However, N deficiency is common in the Tropical rainforest zone of Nigeria due to N losses through excessive run offs, leaching and volatilization. Therefore, soils in this region cannot support meaningful maize yields without proper N fertilization. Continuous and excessive application of N fertilizer has negative effects on crops, and as such, hindering agricultural and environmental sustainability. However, Kamara et al. (2004) suggested that one strategy for improving the productivity of maize is to select varieties that perform well under suboptimal N conditions.

A sustainable approach, such as assessing maize varieties that does well at an applied N level maybe the best agronomic practice for the sustainability of maize and the environment with the growing human population. Maize varieties of different maturities are recently being introduced into the Tropical rainforest zone. The Tropical rainforest is traditionally known to be a zone where late maturing maize varieties are grown. Most of the farmers use single rate of N for all maize maturities since there is little or no information available on the rate of N application for various maize maturity groups. Availability of maize of different maturities can change the optimum or recommended rate of N. Thus with the introduction of maize of diverse maturities into the rainforest, there is need to know how these varieties will perform under varying rates of N fertilization. This may result in identification of correct nitrogen rate for particular varieties for optimum yields. Therefore, the objective of this study was to determine the agronomic performance of contrasting maize varieties to varying rates of nitrogen fertilization in a Tropical rainforest agro-ecology.

MATERIALS AND METHODS

The study was conducted during the rainy seasons of 2019 and 2020 at the Teaching and Research Farm of the Faculty of Agriculture, University of Benin, Benin City, in the Tropical rainforest of Nigeria. The physical and chemical properties of the soil at the experimental site were determined at the beginning of the experimentation in 2019 according to procedures of International Institute of Tropical Agriculture (1982).

Maize varieties evaluated in this study were: TZEE-Y POP STR C4, extra-early maturing; 2008 DTMA - Y STR, early maturing; BR. 9928 DWRSR, intermediate maturing and TZL COMP.4 C4, late maturing. The experiment was laid out in a randomized complete block design with a split-plot arrangement replicated three times. Treatments were nitrogen rate (0, 30, 60, 90 and 120 kg N ha^{-1}) and the four maize varieties. Nitrogen rate formed the main plot and maize varieties the subplots. A subplot measured 3.0 m x 5.0 m having four rows. Treatment plots and replications were separated by 0.75 m.

After land preparation, three seeds of maize were sown per hole at a depth of about 4 - 5 cm at a plant spacing of 75 cm x 25 cm. Seedlings were thinned to one plant per stand, two weeks after planting.

At one week after planting, phosphorus was applied as single super phosphate (SSP) at a rate of 60 kg ha^{-1} P_2O_5 and potassium was applied as muriate of potash (MOP) at a rate of 60 kg ha^{-1} K_2O, to all plots. Urea was used as a source of nitrogen. Half of each nitrogen treatment rate was applied one week after sowing and the remaining half at three weeks after the first application. Weed and insect pest were properly managed.

Data were collected from the two middle rows per plot (net plot). At full tasselling, plant height (cm) was determined on five randomly selected plants, by measuring the height from ground level to the node, where the last top leaf (flag leaf) attached itself to the stem just before the tassel using a measuring rule. The average plant height was recorded. At maturity, plants in a net plot were harvested for the determination of yield and yield components. Harvested ears were de-husked and air-dried for one week. Grains were threshed from the dried cobs and, weighed. Grain yield was expressed in kg ha^{-1}, adjusted to 15 % moisture content using Farmex MT-16 grain moisture tester. 1000-seed weight was determined by weighing 1000 seeds per net plot.

Data obtained were subjected to analysis of variance (ANOVA) using the PROC GLM procedure of SAS for Windows Release 9.2 (SAS Institute, 2011). Means were separated using LSD test at 5% level of probability.

RESULTS AND DISCUSSION

Growing condition:

Results showed that the soil of the experimental site had 886 g kg^{-1} sand; 56 g kg^{-1} silt; 58 g kg^{-1} clay. It also contained organic carbon of 14.3 g/kg, total nitrogen content of 1.1 g/kg, available phosphorus of 2.11 mg kg^{-1}, potassium content of 0.21 cmol kg^{-1} and pH (H_2O) of 5.2. The chemical properties of the soil were inherently low in their natural fertility in respect to N, P and K which could not support any meaningful maize yield without fertilization. The climatic condition during the cropping period was adequate for maize production.

Plant height:

Plant height was influenced by N rate ($p=0.0081$) and variety ($p<.0001$). Maize plants grew taller when N was applied at the rates within 30-120 kg N ha^{-1} compared to 0 kg N ha^{-1} (Table 1). This highlights the importance of applied N to maize production. Nitrogen deficiency reduces cell division and growth of plants. Haque et al. (2001) indicated that at sub-optimal level of N, growth is reduced. Mean plant height of the various varieties was in the following order: BR. 9928 DWRSR > TZL COMP.4 C4 > TZEE-Y POP STR. C4 > 2008 DTMA-Y STR (Table 1). These differences may be due to the genetic constitution of the varieties. Study conducted by Bello et al. (2012) reported that most of the late or intermediate varieties evaluated were late to maturity, and higher in plant and ear heights compared to early maturing group. Ewansiha et al. (2020) reported that varietal differences in plant height were real to the point that even in the presence of high N fertilization, the extra-early and early maturing varieties remained shorter than the late maturing varieties. There was no significant interaction between nitrogen rate and maize variety for plant height at different levels of N (Table 1).

Seed weight:
Significant varietal differences occurred in 1000-seed weight (p=0.0092). Mean seed weight of varieties TZEE-Y POP STR. C4, BR. 9928 DWRSR and TZL COMP.4 were heavier than 2008 DTMA-Y STR (Table 1). This may be that, the varieties have better N utilization. The significant nitrogen rate × variety interaction for seed weight (p=0.0186) suggests that the maize varieties varied in their response to levels of applied N for seed weight (Table 1). This was in corroboration with Anjorin (2013) who reported varietal differences in response to varying soil fertility. At 0 kg N ha^{-1}, seed weight differed only between 2008 DTMA-Y STR and BR. 9928 DWRSR as well as between 2008 DTMA-Y STR and TZL COMP.4 C4. At 30 kg N ha^{-1}, differences among the varieties were not significant. At 60 kg N ha^{-1}, differences occurred only between 2008 DTMA-Y STR and BR. 9928 DWRSR. At 90 kg N ha^{-1}, the trend was similar to that obtained at 30 kg N ha^{-1}. At 120 kg N ha^{-1}, differences in seed weight occurred only between BR. 9928 DWRSR and TZL COMP.4 C4. However, 2008 DTMA-Y STR had low seed weight at 0 and 60 kg N ha^{-1}. This may be due to the fact that the variety is early to maturity, had shorter plants and probably have a narrow genetic potential for nutrient utilization for yielding.

Grain yield:
Nitrogen rate (p=0.0006) and variety (p=0.0156) influenced mean grain yield. Grain yield increased with increase in applied N (Table 1). Grain yield was 32, 57, 56 and 61 % higher at 30, 60, 90 and 120 kg N ha^{-1} respectively, compared 0 kg N ha^{-1}. However, grain yield was optimum at 60 kg N ha^{-1} beyond which rate, increase in grain yield was minimal. This means that application of N above 60 kg N ha^{-1} to maize plants may result in fertilizer wastage and soil contamination. Reduced grain yields obtained at 0 and 30 kg N ha^{-1} might have resulted from nutrient insufficiency as little or no N was available. Kamara et al. (2012) reported that N is a major limiting nutrient in the Nigeria Savannas as shown by the significant yield reduction under low N conditions. Ewansiha et al. (2019) suggested that farmers will need to add N to the soil as to improve yields of maize, whether extra-early, early or late maturing varieties. Varieties TZL COMP.4 C4 and BR.9928 DWRSR had comparable grain yields; similarly TZEE-Y POP STR C4 and 2008 DTMA-Y STR had comparable grain yields; but the former had higher yields than the later (Table 1). This may be due to their lateness to maturity and deeper roots to absorb more nutrients. Ewansiha et al. (2019) reported that the late maturing varieties had superior yield compared to the early maturing maize varieties because of better utilization of soil nutrient. There was no significant interaction between nitrogen rate and maize variety for grain yield (Table 1).

CONCLUSIONS
Maize performance was influenced by N rate and variety. Maize plants grew taller when N fertilizer was applied at 30 - 120 kg N ha^{-1} compared to zero N application. Mean grain yield was approximately 2.2, 2.9, 3.5, 3.4 and 3.6 t ha^{-1} at N rate of 0, 30, 60, 90 and 120 kg N ha^{-1}, respectively. Optimum performance was achieved for grain yield at 60 kg N ha^{-1} beyond which rate, additional N did not cause any significant increase in grain yield. Variety BR.9928 DWRSR grew taller than other varieties. Mean seed weight of varieties TZEE-Y POP STR. C4, BR. 9928 DWRSR and TZL COMP.4 were heavier than 2008 DTMA-Y STR. Varieties TZL COMP.4 C4 and BR.9928 DWRSR out-yielded varieties TZEE-Y POP STR C4 and 2008 DTMA-Y STR. Therefore, in the Tropical rainforest agro-ecology, variety TZL COMP.4 C4 and BR.9928 DWRSR should be grown with nitrogen fertilization at 60 kg N ha^{-1} for optimum yield. This will lead to reduction in fertilizer wastage.

ACKNOWLEDGMENT
The authors thank the International Institute of Tropical Agriculture (IITA), Nigeria, for providing the maize seeds evaluated in the trial.

ABSTRACT

Atrazine and nicosulfuron are persistent herbicides widely used for weed management in maize. The persistence of these herbicides extends the duration of weed control but may injure associated and follow-up crops of maize. Hence, soil amelioration may be necessary to deter the phytotoxic effect of herbicide residue on these crops. A screenhouse experiment was conducted to investigate the effect of sawdust on atrazine and nicosulfuron residue in the soil using *celosia argentea* as a test crop. A 4 x 5 factorial experiment was laid out in a completely randomised design with four replicates. The first factor comprised four herbicide levels: herbicide-free (control), atrazine at 3.0 kg a.i ha^{-1}, nicosulfuron at 40 g a.i ha^{-1}, and a mixture of atrazine and nicosulfuron at 750 g a.i ha^{-1} and 60g a.i ha^{-1}, respectively. The second factor comprised five levels of sawdust; 0% (control), 5%, 10%, 15%, and 20% by volume in the potting soil. The number of celosia leaves per plant and the plant heights were recorded weekly from 3 weeks after transplanting (WAT) to 6 WAT. The fresh and dry weights of the celosia plants at 6 WAT were also recorded. Findings indicated that residues of the herbicide levels in the soil did not significantly ($P<0.05$) reduce the number of leaves, plant height and fresh weight of celosia. However, nicosulfuron impacted the dry weight of celosia shoots negatively. Sawdust at a low proportion of 5% and 10% improved celosia growth, whereas a 20% proportion reduced celosia growth. The interaction of atrazine and nicosulfuron with 5% sawdust resulted in enhanced growth and yield of celosia over untreated soil. Hence, for the follow-up crops of maize, the addition of 5% sawdust is recommended within the rooting depth of atrazine and nicosulfuron-treated soil.

INTRODUCTION

Atrazine and nicosulfuron are selective herbicides used for weed management in maize production (Akadiri et al., 2017). The persistence of these herbicides in the soil may negatively affect the growth of vegetables cultivated in maize plots in a relay cropping system or as catch crops (Aladesanwa, 2001; Mamnoie, 2021). Increasing the pre-plant interval to avoid reduced vegetable yield in atrazine and nicosulfuron-treated plots may invalidate the fitness of vegetables for the relay cropping system. Hence, it is imperative to alleviate the harmful effect of herbicide residue by reducing its availability to sensitive vegetable crops without significantly disrupting the sowing dates.

Organic matter is an important absorbent for herbicides (Spark & Swift, 2002). Applying soil organic amendments may increase herbicide persistence by increasing the sorption process (Mehdizadeh et al., 2019). However, the sorption of herbicides by organic matter makes them less available for plant uptake (Williams et al., 2001). Celosia (*Celosia* *argentea*) is a commonly cultivated vegetable in Nigeria and has been reported to be sensitive to atrazine and nicosulfuron (Aladesanwa et al., 2001; Mishra et al., 2016). Hence, this study investigated the effect of sawdust on atrazine and nicosulfuron residues using celosia as a bioassay.

MATERIALS AND METHODS

Collection of materials and preparation of potting media

Seeds of *Celosia argentea* (TLV 8) were sourced from the National Horticultural Research Institute (NIHORT), Ibadan, Nigeria. The seeds were stored in a paper bag and kept in a dry environment before planting. Topsoil within 0-15cm depth was collected from the Faculty Garden of Adekunle Ajasin University, Akungba-Akoko, Ondo State, Nigeria. The soil was air-dried, sieved with 2mm mesh, and used to fill polythene plant pots measuring 5 cm x 3 cm. In preparing the potting media, ratio-based volume mixing of topsoil and sawdust was adopted. Each sawdust level (0%, 5%, 10%, 15%, and 20%) was used to fill sixteen pots. Hence, eighty filled pots were arranged 1 m apart in the screenhouse. The topsoil used is a sandy clay loam with a neutral pH, 0.96% organic carbon, 1.65% organic matter, 0.08% nitrogen, 3.5 mg kg^{-1} phosphorus, and 0.61 mg kg^{-1} potassium. The soil's sodium, calcium and magnesium contents were determined to be 0.81, 1.4 and 0.7 cmol kg^{-1}, respectively. The sawdust had 94.82% organic carbon, 5.24 mg kg^{-1} phosphorus, and 2.77 mg kg^{-1} potassium. The sawdust's sodium, calcium and magnesium contents were analyzed to be 2.61, 3.21 and 1.86 cmol kg^{-1}, respectively.

Experimental design and treatments

A 4 x 5 factorial experiment in a completely randomised design (CRD) was laid out in a screenhouse at Adekunle Ajasin University, Akungba-Akoko, Nigeria and replicated four times. The first factor comprised four herbicide levels; herbicide-free (control), atrazine at 3.0 kg a.i ha^{-1}, nicosulfuron at 40 g a.i ha^{-1}, and a mixture of atrazine and nicosulfuron at 750g a.i ha^{-1} and 60g a.i ha^{-1}, respectively. The second factor comprised five levels of sawdust in the potting topsoil; 0% (sawdust-free control), 5%, 10%, 15%, and 20%.

Herbicide application in the screenhouse

For per hectare herbicide application proration, four plots measuring 1 m x 1 m each were marked out in the screenhouse. Twenty pots were arranged within each plot such that the five levels of sawdust were replicated four times. Thereafter, different herbicide levels were singly applied to each plot using a knapsack sprayer. Only water was applied to the herbicide-free control.

Transplanting of celosia seedling

Two weeks after sowing (WAS), celosia seedlings at a two-leaf stage were transplanted from the nursery to the potted soil in the screenhouse. The seedlings were transplanted six weeks after herbicide application. The bed was watered thoroughly before transplanting to avoid root damage. Transplanting was done in the morning to reduce water loss through transpiration.

Data collection and analysis

The height and number of leaves of celosia were recorded weekly, starting from 3 weeks after transplanting (WAT) and continued till 6 WAT. Celosia plants were uprooted and analyzed for fresh and dry weight at 6 WAT when the plants had attained commercial maturity. Data obtained were subjected to Analysis of Variance using SPSS version 23 software. The treatment means were separated using Duncan Multiple Range Test at a 5% probability level.

RESULTS

Effect of herbicide residue on growth and yield of celosia

Generally, the number of leaves per plant and height of celosia increased progressively with plant age. There was no significant difference ($P<0.05$) in the number of leaves at the herbicide levels at 3 WAT and 6 WAT, unlike 4 WAT and 5 WAT (Figure 1a). Atrazine had the highest number of leaves per plant at 4 WAT (11 leaves) and 5 WAT (25 leaves). Its number of leaves was significantly ($P<0.05$) higher than herbicide-free control and all herbicide levels at 4 WAT and 5

WAT, respectively. The number of celosia leaves recorded per plant in the herbicide-treated soil was not significantly ($P<0.05$) lower than in the herbicide-free soil throughout the trial.

Celosia plant heights were significantly ($P<0.05$) different across the herbicide levels at 3, 5, and 6 WAT (Figure 1b). At the aforementioned stages in the trial, atrazine had the highest celosia plant height (3.44 cm, 8.78 cm and 14.39 cm) and its celosia plant heights were significantly higher than the herbicide-free control (2.47 cm, 6.09 cm and 9.82 cm) which had the least.

There were no significant differences ($P<0.05$) in the fresh weights of celosia among the herbicide levels at 6 WAT (Figure 1c). Hence, the effect of herbicide residue on the fresh weight of celosia was insignificant. Celosia plants in potted soil treated with atrazine had the highest fresh weight of shoot (11.4 g) and root (2 g), while nicosulfuron had the least (5.6 g and 1 g, respectively). The dry weights of celosia shoot and root were significantly different ($P<0.05$) at 6 WAT (Figure 1d). Celosia plants in herbicide-free control had the highest dry weight of celosia shoot and root (1.05 g and 0.35 g). Herbicide-free control had a significantly higher weight of celosia shoot and root than nicosulfuron (0.42 g and 0.18g), which had the least. The dry shoot and root weight of celosia in nicosulfuron-treated soil were significantly reduced ($P<0.05$) compared to herbicide-free control. However, the atrazine-nicosulfuron mixture and atrazine had comparable celosia dry weights with the herbicide-free control.

Effect of sawdust on growth and yield of celosia

The number of leaves and plant height of celosia were significantly different ($P<0.05$) among the sawdust levels from 3 WAT to 6 WAT (Figure 2a&b). Throughout the trial, the highest number of celosia leaves (8, 14, 31, and 49 leaves) were recorded from 5% sawdust. Contrarily, 20% sawdust had the least number of celosia leaves (4, 5, 7 and 14 leaves), and it was significantly ($P<0.05$) lesser than 5% sawdust throughout the trial. Notably, 20% sawdust resulted in a significantly ($P<0.05$) reduced number of leaves at 3 WAT and 4 WAT compared to sawdust-free control (0% sawdust). However, it had a comparable number of celosia leaves per plant with sawdust-free control at 5 WAT and 6 WAT. Judging by the sawdust-free control, the 10% sawdust and 15% sawdust resulted in a significantly increased and a comparable number of celosia leaves, respectively.

Similarly, weekly results from 3 WAT to 5 WAT showed that 5% sawdust had the highest celosia plant height (4.09 cm, 6.94 cm, 10.77 cm and 17.71 cm). It was significantly ($P<0.05$) different from 20% sawdust which had the least plant height. The 5% sawdust and 10% sawdust resulted in celosia plant height significantly higher than the sawdust-free control (0% sawdust), whereas 15% sawdust and 20% sawdust resulted in a comparable plant height and a significantly reduced ($P<0.05$) celosia plant height, respectively.

The fresh and dry weights of celosia across the sawdust levels were significantly different at 6 WAT (Figure 2c&d). The 5% sawdust had the highest shoot, root and total fresh weight (15.94 g, 3.06 g and 19 g), whereas the lowest shoot, root, and total fresh weights were recorded in 20% sawdust (1.94 g, 0.06 g and 2 g). The shoot, root and total fresh weights that resulted from 5% sawdust were significantly higher than the sawdust-free control, whereas 10%, 15% and 20% sawdust had a comparable shoot, root, and total fresh weight. The dry weight of the celosia plant followed the same trend as the fresh weight across the sawdust levels.

Interaction of herbicide residue and sawdust on growth and yield of celosia

The number of celosia leaves differed significantly ($P<0.05$) among the herbicide and sawdust interactions. (Table 1). Based on weekly results, atrazine and 5% sawdust (A+S5%) recorded the highest number of celosia leaves from 3 WAT to 6 WAT (9, 21, 47, and 64 leaves). In contrast, atrazine and 20% sawdust (A+S20%) had the lowest number of celosia leaves at 3 WAT and 4 WAT (3 and 5 leaves). The interaction of nicosulfuron and 20% sawdust (M+S20%) resulted in the lowest number of celosia leaves at 5 and 6 WAT (7 and 11 leaves). Remarkably, the number of celosia leaves from atrazine and 5% sawdust (A+S5%) interaction was significantly higher (P<0.05) than in untreated soil (C+S0%) and herbicide-free soil with 5% sawdust (C+S5%). Also, untreated soil (C+S0%) had a comparable number of celosia leaves with all other interactions, except for the significantly increased number of celosia leaves at 4 WAT and 5 WAT by nicosulfuron and 5% sawdust (N+S5%) and interaction of atrazine and 10% sawdust (A+S10%) at 5 WAT.

The plant height of celosia differed significantly (P<0.05) with respect to herbicide and sawdust interaction. The interactions of atrazine and 5% sawdust (A+S5%) and nicosulfuron and 5% sawdust (A+S5%) had the highest celosia plant height at 3 WAT (5.25 cm) and 6 WAT (22.85 cm). Also, atrazine and 5% sawdust (A+S5%) resulted in the highest celosia plant height at 4 WAT (9.18 cm) and 5 WAT (14 cm). Notably, throughout the study, atrazine and 5% sawdust (A+S5%) had a significantly higher height of celosia plants than untreated soil (C+S0%). A similar trend was also found in nicosulfuron and 5% sawdust (N+S5%). None of the interactions had significantly (P<0.05) reduced celosia plant height compared to the untreated soil (C+S0%).

The fresh and dry weight of celosia per plant differed significantly (P<0.05) among the interactions of herbicide and sawdust. Atrazine and 5% sawdust (A+S5%) had the highest fresh shoot, root and total weight (26.75g, 5g and 31.75g) among the interactions. The least fresh shoot, root and total weights (1.25g, 0.10g and 1.35g) were found in nicosulfuron and 20% sawdust. However, the least fresh shoot, root and total weights were comparable with untreated soil (3.50g, 0.75g and 4.25g).

Herbicide-free and 5% sawdust (A+S5%) had the highest dry shoot, root and total weights of celosia (2.97g, 1.06g and 4.03g) among the interactions. The interaction of nicosulfuron and 20% sawdust had the least dry shoot, root and total weight of celosia (0.08g, 0.02g and 10c), and it was comparable with the untreated soil (C+S0%).

DISCUSSION

This study showed that celosia could be transplanted into atrazine-treated soil six weeks after treatment without a decrease in yield. The transient increase observed in the growth parameters of celosia plants in atrazine-treated soil might have resulted from the hormetic effect (low dose stimulation and high dose inhibition of growth) of atrazine residue. Lytle & Lytle (2005) observed stimulatory growth in *Sesbania vesicaria* and *Vigna luteola* exposed to low concentrations of atrazine. The absence of atrazine phytotoxicity in this study might have resulted from the mitigated concentration of atrazine through decomposition and sorption. Atrazine catabolism and sorption by soil components reduce the concentration of atrazine in the soil, thus causing the stimulatory effect at a low concentration.

The reduced dry weight of celosia in nicosulfuron-treated soil was probably due to the phytotoxicity of nicosulfuron residue. Rahman et al. (2011) reported that nicosulfuron residue reduced the dry weight of mustard plant (*Sinapis alba*), unlike atrazine applied on the same day. The use of herbicide mixture for weed management is justified in this study as soil residue of atrazine and nicosulfuron mixture was not phytotoxic to celosia even at a higher concentration of nicosulfuron, which solely reduced celosia dry weight.

For a longer duration of this trial, the improved growth of celosia in soil treated with 5% and 10% sawdust was probably due to the ability of sawdust to decrease the soil bulk density and increase the soil organic carbon content. The decrease in celosia growth caused by 20% sawdust could be attributed to nitrogen immobilization commonly associated with soil amendments with a high carbon-to-nitrogen ratio (Iroegbu et al., 2020). This study corroborates the findings of Siddiqui & Alam (1990) that sawdust as soil amendment improves the growth of plants.

The comparable growth of celosia in atrazine-treated soil without sawdust and untreated soil disagrees with Aladesanwa et al. (2001), who reported reduced growth of celosia sown within twelve weeks pre-plant interval on atrazine-treated soil. It is opined that the difference in the soil textural class used for this study may be responsible for this different outcome. Further studies on the role of the higher clay content in the soil may provide more helpful information. The improved growth of celosia resulting from the interaction of atrazine and nicosulfuron with 5% sawdust over the interaction of herbicide-free and 5% sawdust indicates the synergistic effect of 5% sawdust and residues of atrazine and nicosulfuron.

CONCLUSION

The soil residues of atrazine and atrazine-nicosulfuron mixture are not injurious to celosia transplanted at a pre-plant application interval of six weeks. Using a mixture of atrazine and nicosulfuron for weed management in maize mitigates the phototoxic effect of sole nicosulfuron residue on follow-up celosia. Applying 5% sawdust to atrazine and nicosulfuron-treated soil improves celosia growth.

56th Annual Conference
Agricultural Society of Nigeria
24 - 28 Oct., 2022

ABSTRACT
Little or no information on pedological characterization and classification of soil developed over Igboora is known. The objective of this study is to provide invaluable information on how pedogenic processes along the different land use affect the soil properties, aim to gauge the soil potential. Difference in soil properties in five land uses (cassava, maize, maize inter-planted with cassava, fallow and orchard) were observed on many soil properties as they influence crop growth. Soil profiles with varies depths in centimetres were described and sampled horizon-wisely for morphological, physical and chemical analysis. The results of laboratory analysis revealed that the soil reaction is strongly acidic. The soil organic carbon, total nitrogen, available phosphorous showed increasing trend with depths of pedons along the land uses, this suggested that these soil properties were affected by the land uses. There are existence of two different soil order (ultisol and inceptisol). Farmers in the study area were advised not only required to adopt integrated soil fertility management but also embrace soil conservation measures to maintain soil physio-chemical properties.

Key words: Pedological, interplanted with, morphological and chemical characteristics.

INTRODUCTION
Climate and geological history are important factors affecting soil properties on regional and continental scales. Also, land use and soil management practices influence the soil nutrients and related soil processes, such as erosion, oxidation, mineralization, and leaching, etc. (Liu *et al*, 2010). Land use may change the processes of transport and distributions of nutrients.

In non-cultivated land, the type of vegetative cover is a factor influencing the soil organic carbon content. In addition, soils through land use change also caused considerable alterations and resulted in soil quality diminishes after the cultivation of previously tilthed soils (Neris *et al*, 2012). Thus land use and types of vegetation must be taken into account when relating soil nutrients with environmental conditions (Liu *et al*, 2010).

The capacity of soil to function may be determined by measuring soil physical and chemical properties (Buol *et al*, 2011), majority of soil properties were vulnerable to degradation as a result of poor land use management practices.

To come out with sound and reliable information about the soil in relation to land uses pedological classification is the best option. Pedological classification is gathering of vital information on soil by systematic identification, grouping and delineation of different soils in the locality (Kebency *et al*, 2015; Mswanya *et al*, 2016).

Pedological characterization provides valuable information and knowledge on soil characteristics and gives clear understanding on soil genesis, morphology, classification and spatial distribution of soil in an area as observed by Karuma *et al.*, 2015; Kabenay *et al.*, 2015. The information gathered through pedological characterization is needed by soil fertility experts to carry out fertilizer trial and establish meaningful fertilizer recommendations (Msanya *et al.*, 2003). Crop production in Igboora are still being carried out through deforestation on steep slopes, marginal lands and fragile soil with inadequate investment in soil conversation measures which also aggravates soil erosion. The farming system is traditional; modern agricultural technology is not applied in most part of Igboora. As a result, many agricultural soils in igboora have reached a critical point. The situation of the study area is worse and the soil resources have degraded at alarming rate due to continuous cropping. With these practices, the sustainability of agriculture and the livelihood of the community are under severe threat. To come up with sound management practices, investigating the impacts of the interaction of these factors is imperative. This study, therefore, was carried out at the Oyo State College of Agriculture and Technology (OYSCATECH) Teaching and Research Farm and its surrounding farms in igboora area with the objective to characterize and classify the soils of the area in terms of their morphological, physical and chemical properties in order to generate needed information for land use planning.

MATERIALS AND METHODS

The study area is approximately 120 hectares of land located between Igboora and Jakata village in Ibarapa central Local Government area of Oyo state, Nigeria. It is defined within longitudes of $3^0\ 57^1$, 10^1 and $3^o\ 59^1$ E and latitudes 7^o, 15^1 and 7^o, 33^1 of the equator. Base on physiographic, climatic and vegetation characteristics, soil morphological, physical and chemical properties were observed at 0-20, 20-35, 35-65, 65-95 and 95-125cm depth with the aid of Dutch auger for identified, characterization and classification. Five selected units and their respective soil profiles are: pedon-1 (cassava plot), pedon-2 (maize plot), pedon-3 (maize interplanted with cassava), pedon-4 (fallow) and pedon-5 (orchard).

The soil samples were air dried, crushed and passed through 2.0 mm sieve. Particle size analysis was conducted using the modified Bouyoucous hydrometer method. Soil p^H was determined in two solutions, using the follow procedure p^H in water and potassium chloride. The soil were also classified using key to soil taxonomy (soil survey Staff 2006).

RESULT AND DISCUSSION

Morphological properties

The soil morphological characteristics of the studied pedons were shown in Table 1. Distinct horizons layers and argellic–B horizons were observed in the pedons expect for the orchard area that had Bw horizon. Four of the pedons, cassava, maize, maize ipw cassava and fallow had Ap, B and Bt horizons, whereas the pedons at orchard had Ah, Bw and Bhs horizons sequences. Depth and horizons of the profiles were highly variable along the five pedons. Pedon-2 and 3 were characterized by truncated surface layer (20/18 cm), whereas pedon-1 have a moderate shallow depth at B_2 to Bt_2. Contrast, relatively shallower solum and fewer amounts of coarser materials in pedon-3 suggesting that the rate of weathering process were increased with humans activities such as prolong intensive tillage. Surface soil colour (moist) range from light brown (7.5YR$^3/_3$) to commons medium faint light brown (7.5 YR$^5/_2$) lime mattles and lime coating Table 1. Variation in soil colour is due to organic matter which tends to coat minerals particles, darkening and masking the brighter colours of the minerals themselves, and water content which affect the oxidation state of iron and manganese, Munishi,. (2010). Soil structure of the surface horizons of pedons was generally crumb with some variation in size of peds.

Physical Properties

The soil of the different land use at 0 – 20cm horizons were found to be almost the same with loamy sand expect for that of orchard field with silt loam Table 1. The individual soil properties considered silt and sand contents were the most highly correlated with erodibility.

Chemical Properties

The chemical properties of studied pedons were presented in table 1

Topsoil of cultivated field was rated as moderately acidic to slightly acidic whereas uncultivated was rated as acidic to medium acidic. Topsoil organic carbon contents of the studied pedons were higher in the fallow and orchard but lower in the cultivated land.

Total nitrogen followed the trend of organic carbon. An increase in available phosphorous content in the orchard field followed by fallow land could as a result of relative higher organic matter content present in Ap horizons, which strongly associate with organic carbon.

Classification

Field description and laboratory analytical data were used to classify the soils of the stury area according to the United States Department of Agriculture (USDA) soil taxonomy and the world reference base for soil resources. The soils units with ultic properties in the topsoil (A horizon) and argillic – B horizon were classified as ultisol. Long time cultivation and erosion cause the destruction of this dark topsoil in some of the ultisol profiles (pedon – 1, 2, 3 and 4). Pedon 5 that had inceptic properties in the subsurface (Bt horizon) was classified as inceptisol. Pedon – 1, 2, 3 and 4 was further classified at great group (kandiultisol), subgroup (Typic kandiultisol).

CONCLUSION

The low values and high chromas of some colour observed in cultivated land are indicative of low organic matter contents. At the surface horizons, they suggest loss of humified organic matter content mostly through surface wash as organo-mineral complexes of the clay-size fraction. The particle-size data show silt depth functions that reflect parent material origin. The physical and the chemical properties of the soil of the study area indicate that of chemical weathering and, therefore mineralogical alteration have proceeded translocation. The slightly acidity observed in pedons attest to the influence of pre-weathered parent materials on the chemical properties of some soil within the tropics. It is possible that the land used pattern affects morphological, physical and chemical status of soil in the study area. Therefore, their placement in classification systems using soil Taxonomy were made easy. '

ABSTRACT
A fifty-six (56) days study was conducted to determine the effect of varying levels of *Bambusa vulgaris* leaf meal (BLM) inclusion in the diets of broiler chickens exposed to heat stress. A total of one hundred and fifty Arbor Acres broilers were allotted randomly into five (5) dietary treatments (T1-T5) of thirty per treatment and ten per replicate. T1, T2, T3, and T4 were fed 0%, 1%, 1.5%, and 2% BLM included diets respectively, while T5wase fed 200g/mg of Vitamin C included diet. The experimental birds were exposed to a temperature of 50±1°C between the hours of 12-4pm daily for four weeks. Data collected on growth performance, and stress indicators were subjected to one way analysis of variance. The result showed that birds on T4 had the highest ($p<0.05$) feed intake (267g), body weight gain (1504g), and the best FCR (3.64). The serum corticosterone (3.4865U/ml) and glutathione peroxidase (230.3U/ml) levels decreased with an increase in BLM inclusion in the diet with birds on T4 having the lowest ($p<0.05$) values. However, malondialdehyde and superoxide dismutase values increased with an increase in BLM inclusion in the diets with birds on T4 having the highest values (1.7618nmol/ml and 1865.7U/ml respectively). In conclusion, *Bambusa vulgaris* leaf meal inclusion up to 2% in the broiler diet could ameliorate heat stress conditions and improved broiler chicken performance.

INTRODUCTION
Among poultry meats, broiler chickens have assumed great global recognition (Seifi *et al*., 2018) because the production cycle is short and the meat is universally acceptable with little or no restrictions. Over the decades, genetic tools have been used to develop broiler chickens to meet demands (Athrey, 2020) however, heat stress especially in the tropics has constrained the effectiveness and efficiency of broiler chicken production (Sugiharto *et al*., 2017a). Heat stress is a physiological state whereby an animal is subjected to temperatures that are higher than 30 ^{0}C (Seifi *et al*., 2018) resulting in concurrent physiological difficulties, poor growth, the spread of diseases, and death (Sugiharto *et al*., 2017b). Authors have used plant materials like *Moringa oleifera* (Mona *et al.* 2017), bamboo, pawpaw, and

neem leaf (Oloruntola *et al.* 2018) as a dietary supplement, antioxidant or as a feed additive in broiler chicken production.
The bamboo plant found in many parts of the world, and used culinary and medicinal purposes for long, contains antioxidants and free radical scavenging properties (Shen *et al.*, 2019). Research has shown that *bamboo* leaf contains polysaccharides, polyphenols, and flavonoids, these active ingredients contain anti-inflammatory and antioxidant properties which could lower lipids, thereby reducing heat stress both in animals and in humans (Yu *et al.*, 2019). Little research has been carried out on the use of bamboo leaf meals to alleviate heat stress in broiler chickens, therefore, this study investigated the use of bamboo leaf meal as a feed additive in combating heat stress in broiler chickens.

MATERIALS AND METHOD

The experiment was carried out at the poultry unit of the Teaching and Research Farm of Landmark University, Omu-Aran Kwara state, Nigeria. A total of one hundred and fifty (150) day old unsexed broiler chickens were distributed, using a completely randomized design (CRD), into five treatments of 3 replicates each. The birds were kept in an electrical heated pen house on deep litter with wood shavings as litter material, they were given standard vaccinations and medications. The birds were fed with broiler starter diets for three weeks after which they were fed the experimental broiler finisher diets from week four to week eight. Birds were exposed to excess heat between 12pm-4pm at 50 ± 1^0C on days 29-56. Thermometers were provided in each pen to measure the heat generated. All experimental birds were placed under the same environmental condition. Bamboo leaf meal (BLM) was included into the broiler finisher diets at 0%, 1.0%, 1.5% and 2.0% inclusion levels for birds in treatments 1, 2, 3 and 4, respectively, while the broiler finisher diet for birds in treatment 5 contained 0.2% (200mg/kg) vitamin C and fed to the birds **as** shown in Table 1.
The proximate analysis of broiler diets was conducted using the AOAC procedure (AOAC, 2005), photochemical screening: alkaloids, phytate, flavonoid, saponin, and tannin were carried out by standard procedure of Kokate, (1994). All chemical analyses were done in triplicates. On day 56, blood sampling was performed by randomly selecting two birds per replicate. The collection of blood samples was achieved through the brachial veins of the birds. Superoxide dismutase (SOD), serum glutathione peroxidase (GPx), corticosterone (CORT), and malondialdehyde (MDA) were determined using the method described by Akhavan-Salamat *et al.*, (2015).
The means of the samples were compared using analysis of variance (ANOVA), with the level of significant difference set at (p-0.05). The Duncan multiple range test was used to separate the means and the SAS program was used to conduct this analysis (version 9.4)

Total	100	100	100	100	100

[1]Contain the following: vit A 10,000IU, vit D_3 1500 IU; vit E 10,000mg, vit k_3, 1500mg, vit B_1 1600mg, vit B_2 4000mg, pentothenic acid 10mg; nicotinic acid 2.5mg chlorine 3.5mg; folic acid 1mg; magnesium 56mg; lysine 1mg; iron 20mg; zinc 50mg; cobalt 1.25mg, biotin 7.5mg copper 30mg, manganese 40mg, selenium 2mg antioxidant 1250mg.

RESULTS

The proximate composition and phytochemicals of the experimental diets is shown in Table 2. The result indicates that the CP, CF and ash values of Diets T4 (187.21g, 375.50, and 110.01g respectively) were higher ($p<0.05$) than CP, CF and ash values for the other diet while the lowest ($p<0.05$) CP (135.01g), CF (261.55g) and ash (105.20g) values were recorded for diet T1, T5 and T5 respectively. The CP, CF and ash levels were noted to increase with increase in the BLM inclusion level in the diet. The phytochemical results showed the phytate, flavonoids, tannin, and saponin values increased with the increased addition of BLM in the diets. Flavonoids contents were similar and higher ($p>0.05$) for diets T4 and T5, whereas it is low ($p>0.05$) for T1 compared with the other diets.

The growth performance of broiler chickens fed BLM at different inclusion levels in the diet is shown in Table 3. The feed intake and weight gains of the birds increased as BLM increased in the diet, however, it was observed birds fed diet 1 had the lowest ($p<0.05$) feed intake and weight gain compared to birds fed the other diets while birds fed diet 4 had the highest ($p<0.05$) values for these parameters. The FCR values were comparable ($p>0.05$) for birds fed diets1, 4, and 5 with the best FCR from birds on diet 4.

Table 4 indicated that there was no significant difference ($P>0.05$) between glutathione peroxidases (GPx), corticosterone (CORT), and malondialdehyde (MDA) in all the diets. However, the range of glutathione peroxidase and malondialdehyde reported in this study is high (226.5-419.6U/ml and 1.2854-1.7618nmol/ml respectively). The superoxide dismutase is higher in diet 1 with 0% BLM (4477.6 U/ml) and diet 5 with 0.20% vitamin C (8955.2 U/ml) compared with other diets with BLM inclusion (1492.5, 1726.4, and 1865.7 U/ml), but much higher in diet 5.

DISCUSSION

The high phytochemical contents in diet 4 (2.0% BLM) appears better to alleviate heat stress and this is contrary to the report of Abubakar *et* al., (2021) and El-Wardany *et al.,* (2015). The increase in feed intake and weight gain with increasing BLM in the diet may be of positive value since inclusion of BLM at 2% level seems to improve the appetite of the broiler chickens with a resulting increase in weight gain comparable with and better than results from broiler chickens fed diet 5 (0.2% Vit. C). This observation is corroborated by the report of Li *et al*. (2017) who stated that the inclusion of *bamboo* leaves in broiler chicken diets improved body weight gain by 17.6% because of the presence of flavonoids. it has been hypothesized that flavonoids might play the role of growth hormones in animals (Havsteen, 2002), since flavonoids hydroxyl groups of aglycone are positioned in space in the same manner as estrogen's hydroxyl groups. This seems to indicate that the inclusion of BLM at of 2% level is the most efficient, and this dose-dependent impact may be the result of increase in concentrations of flavonoids in the diet. Earlier reports have shown that when birds suffer from challenges such as heat stress and immune suppression, growth performance would be affected (Yang *et al*., 2010). Authors have demonstrated that supplementing broiler chicken diets with bamboo leaf flavonoids at a concentration of 1.6% could mitigate the growth-inhibiting effects of heat stress and immunological suppression in broilers (Qi *et al*., 2014). It could be inferred that flavonoids in bamboo leaves may have been responsible for the observed growth improvement observed as seen in this study. The high feed conversion ratio of the diet contained 2% bamboo leaf that comparable with the diet containing vitamin C suggesting that the bamboo leaves enhanced the feed conversion ratio of the birds with little or no stress and is in line with the report of El-wardany *et al*. (2015) that bamboo leaf can be fed to reduce stress. The inclusion of the bamboo leaf in the diets fed in this study regardless of the level did not affect the percent mortality across the treatment groups and suggesting that it is non-detrimental to the health of the bird, though this is contrary to the report of Krzyszt *et al*. (2011).
The non-significant difference among glutathione peroxidases (GPx), corticosterone (CORT), and malondialdehyde (MDA) in all the diets may indicate less-observable stress within the birds during the study**.** Earlier authors have demonstrated that exposure to the bamboo leaf can remarkably raise the levels of the enzyme superoxide dismutase and glutathione peroxidase, and corticosterone hormone in birds that have been subjected to heat stress, and can enhance the birds' antioxidant potential (Liu *et al*., 2014). Research shows that the ability of flavonoids to stimulate antioxidant enzymes, chelate metal catalysts, transfer electrons to free radicals, and suppress oxidases seems to be responsible for the antioxidant effects that flavonoids have in living systems (Wan *et al*., 2016). We postulated that with the increasing the BLM in the diet, increased the antioxidant capacity of the diets since bamboo leaf has a peroxide scavenging capacity (Ni *et al*., 2011). Inhibition of the synthesis of thiobarbituric acid-reactive compounds can be attributed, in part, to flavonoids and polyphenols (Niu *et al*., 2016). In addition, research has demonstrated that broilers given plant extracts high in flavonoids, polyphenols, and polysaccharides are able to increase their capacity to scavenge free radicals (Yu *et al*., 2019).

CONCLUSION

This study concludes that bamboo leaf meal inclusion at 2% in the broiler feed was able to improve performance, alleviated heat stress and had no adverse effect on health of broiler chickens. Furthermore, broiler chickens fed 2% BLM inclusion showed improvement in terms of growth performance despite being reared under heat stress. This improvement in performance may not be unconnected to the induction of the excessive release of glutathione peroxidase (GPx) and superoxide dismutase (SOD), and reduced levels of corticosterone (CORT) and malondialdehyde (MDA) which positively influenced performance.

ABSTRACT

Biosecurity protocols are often poorly managed on fish farms. This study explored biosecurity practices on 96 fish farms, examining the demographic and management factors related to good biosecurity measures in some southern Local Government Areas in Lagos State, Nigeria. A structured and pretested interviewer-administered questionnaire was used to obtain information on demographic and management factors, and on the procedural biosecurity plans in these farms. A scoring system was developed to assess biosecurity measures, bivariate and multivariable analyses were done to determine forecasters for good biosecurity score on the fish farms. The bivariate analysis of factors associated with biosecurity compliance shows that the majority of the fish farmers are between the ages of 45-50 (30.12%), 78.13% had Tertiary Education as qualification, a group that showed more biosecurity observance, 85.43% are full time farmers with over 10 years of experience. In the multivariate logistic regression, the education status of the fish farmer/manager (OR = 3.6, 95% CI = 1.0 – 4.1, p = 0.01), and fish farmers' occupation (OR = 1.8, 95% CI = 0.2 – 3.7, p = 0.04) are the only significant forecasters of good biosecurity compliance. Factors such as age of farmer/ farm manager, many years of experience and tertiary educational achievement should be considered in the design and implementation of biosecurity measures on fish farms. Mortality rates on fish farms could become a good indicator to maintain practical biosecurity levels.

Keywords: Biosecurity, Southern Lagos, Education, Experience, Fish Farms

INTRODUCTION

Biosecurity measures are set of health controls and activities taken to prevent entry of new infectious diseases into animal herds and to avoid their spread through exit of the disease agent (Barcelo & Marco, 1998). FAO (2008) defines it as the implementation of measures that reduce the risk of the introduction and spread of disease agents; it requires the adoption of a set of attitudes and behaviors by people to reduce risk in all activities involving domestic, captive/ exotic and wild animals and their products or infection from a premise

Aquaculture loses millions of dollars in revenue annually due to aquatic animal diseases. Disease outbreaks continue to threaten profitable and viable aquaculture operations throughout the world. As a result, aquaculture biosecurity programs that address aquatic animal pathogens and diseases have become an important focus for the aquaculture industry. (O'Bryen.2006Aquaculture increasing global importance is directly related to the contribution it makes in reducing the gap between supply and demand for fish products. According to Faturoti (2010). Aquaculture has been clearly demonstrated to be an economically viable, private enterprise in Nigeria. Aquaculture has great potential for food production and the alleviation of poverty for people living in coastal areas, many of who are among the poorest in the world (Tisdell, 1999).

In Nigeria aquaculture is a potential economic investment but different challenges resulting to numerous losses affect the final fish product and returned on investment.

The general objective of this paper is to assess the level of aquaculture biosecurity compliance of fish farms in the southern area of Lagos State, Nigeria. It will also suggest measures which will strengthen aquaculture through the development of aquaculture biosecurity regulations in Nigeria to meet international standard.

MATERIALS AND METHODS

Study Design

Ninety-six (96) registered fish farms were randomly sampled across four local governments (Epe, Eti-osa, and Ibeju -Lekki), in Lagos-Nigeria.

Questionnaire Design and Administration

A structured questionnaire was designed to assess biosecurity measures (n = 34) on the fish farms based on three key areas as described by Barceló & Marco (1998) which are the locations, isolation of replacement stock, and the conditions of the farm. The questionnaire was interviewer-administered to fish farmers or the farm manager on their various farms. Compliance with biosecurity measures relating to distances were adjudged based on the farmers' responses and direct non-participant observation.

Data Analysis

The data were entered into Microsoft Excel. Analysis was done in Statistical Package for Social Sciences (SPSS). A scoring system was developed for the 34 variables to determine the biosecurity level on the fish farms. An equal weight was ascribed to all the biosecurity components, with a score of 0 and 1 for each variable. The presence of each variable was given a score of 1, while its absence was given a zero-score based on the risk effect of such variable. The total obtainable score was 34, and the higher the score, the higher the indication of a better biosecurity level. A score greater than 18 was graded good, the cut off score which addressed our interest on those who implemented a little above 50% of all set of items. Descriptive statistics was done and the associations between the considered demographic and management factors with biosecurity compliance level on the fish farms were assessed by finding the odds ratios. Statistical significance was computed by the Fisher's exact test at the 95% confidence interval. Multivariate logistic regression was used to decide predictors for good biosecurity score. Collinearity among predictors was also checked using Chi-square test for binomial variables. A forward selection method was used. The goodness of fit of the model was checked using the Pearson goodness of fit test. In the final models, only variables that were found to significantly affect the outcome at $P < 0.05$ were kept.

RESULTS

Demography and Management Parameters

Most of the fish farmers were between the age-groups of 40-45 (21.88%) and 46-50 (30.21%). Majority (60.34%) of the farmers were married. There are more male farmers (80.21%) than female (19.79%). A high number of them had tertiary education (78.13%), while just a few of them (17.71%) had secondary education as their highest level of education. Only a few (14.58%) had fish farming as their secondary occupation, while the rest (85.43%) were fulltime fish farmers. Several of them (43.75%) had more than 11 years' experience in fish farming, while the rest (56.25%) had lesser years of experience. Out of all 96 fish farms visited, over half (52.08%) of them were practicing the earthen pond system, while the other half (47.92%) had concrete, plastic, and re-circulatory system. Similarly, over half (53.13%) of the fish farms were practicing intensive culture system, while the rest were semi-intensive (27.08%), and extensive culture system (19.79%).

Table 1: *Bivariate analysis of factors associated with biosecurity compliance on 96 fish farms in Lagos-Nigeria, 2021.*

Variables	Good Compliance n = 20 (%)	Poor Compliance n = 76 (%)
Age of fish farmer/ manager (years)		
16 – 21	0 (0.0)	4 (5.26)
22 – 27	1 (5.0)	3 (3.95)
28 – 33	3 (15.0)	14 (18.42)
34 – 39	3 (15.0)	10 (13.56)
40 – 45	5 (25.0)	16 (21.05)
46 – 50	6 (30.0)	23 (30.26)
> 52	2 (10.0)	6 (7.89)
Marital status

Tilapia	0 (0.0)	14 (18.4)
Others	0 (0.0)	0 (0.0)
Pond System		
Earthen	11 (55.0)	39 (51.3)
Concrete	2 (10.0)	11 (14.5)
Plastic	0 (0.0)	17 (22.4)
Re-circulatory system	7 (35.0)	9 (11.8)
Cage culture	0 (0.0)	0 (0.0)
Tarpaulin	0 (0.0)	0 (0.0)
Others	0 (0.0)	0 (0.0)
Culture system		

Intensive	13 (65.0)	38 (50.0)
Semi-intensive	5 (25.0)	21 (27.6)
Extensive	2 (10.0)	17 (22.4)

Table 2: *Logistic Regression of factors associated with biosecurity compliance on 96 fish farms in Lagos-Nigeria, 2021.*

Variable	**OR**	**95% CI**	**P value**
Education status			
Secondary education	Ref.		
Tertiary education	3.6	[1.0 , 4.1]	0.01
Fish farmers' occupation			
Secondary occupation	Ref.		
Main occupation	1.8	[0.2 , 3.7]	0.04

In the multivariate logistic regression, the education status of the fish farmer/manager (OR = 3.6, 95% CI = 1.0 – 4.1, p = 0.01), and fish farmers' occupation (OR = 1.8, 95% CI = 0.2 – 3.7, p = 0.04) are the only significant predictors of good biosecurity compliance (Table 2).

CONCLUSION:

In the multivariable analysis, the age of pig farmer or manager and higher level of education are significant predictors for good biosecurity score. Farmers or managers who were average age (i.e. between age 45 and 50) were much more likely to have good biosecurity score than those who were younger (i.e. less than 45 years). This finding is similar to that reported by Schemann *et al*. (2011) who reported lower compliance in younger people (less than 25years) involved with fish farming in Australia. This, however, is contrary to the findings of Sayers *et al*. (2013); that younger dairy farmers had higher likelihood to implement biosecurity measures than their middle-aged counterparts. The difference in the age categorization may explain the contrast in the compliance level.

RECOMMENDATION:

Good biosecurity measures on fish farms will always reduce the risk of losses from infectious pathogens. It is important to know the fish and water sources to ensure that specific pathogens do not enter farm facility in any way. Quarantine measures, testing and continuous monitoring of fish health protocols throughout the production cycle are key. Good husbandry, biosecurity designs should carefully be designed with the facility's sanitation, disinfection, system's management schemes and personnel compliance in mind. Record keeping for traceability purposes and continuous educational seminars to upgrade the status quo are important.

56th Annual Conference
Agricultural Society of Nigeria
24 - 28 Oct., 2022

ABSTRACT:

Microflora contamination in laboratories and hospitals is becoming a serious problem worldwide, and the characterization of such contaminants offers hope for the treatment of some infections acquired in hospitals and laboratories. Microflora contamination in benches, floors, media and equipment can be affected by temperature, humidity and nutrient media in laboratories and media storage conditions. This study was carried out to isolate and characterize air microflora in selected clinical laboratories at Igboora (Ibarapa Central) based on morphological, biochemical properties and persistent bacteria in laboratory sites after disinfection with sodium hypochlorite. The samples were collected from four laboratories. The isolation of pure cultures was performed on the basis of morphological differences, using the shape of the colony, elevation, pigmentation and size to distinguish bacterial and fungal contaminants. The results showed that; the laboratory sites examined were contaminated with different microbes. Macroscopic and microscopic observations of fungi confirmed the presence of Aspergillus niger, Fusarium oxyporum, Aspergillus ochraceus and Alternaria alternata on sink and biosafety cabinets, the persistent bacteria identified were Bacillus cereus, Pseudomonas aeruginosa and Staphylococci aureus. The contaminants were similar to the standard strains, but there was a significant difference in contamination in the four selected laboratories (analysis of variance (ANOVA $P<0.05$). Bacterial and fungal contaminants remain a threat on laboratory surfaces and equipment. Therefore, the need to either increase the concentration or change the disinfectant commonly used.

Keywords: Isolates, Microflora, Bacteria, Fungi, Contaminant, Laboratories, Disinfectant

INTRODUCTION

Microflora is a term that refers to a community of bacteria/fungi that exist on or inside the body, and possess a unique ecological relationship with the host. This relationship encompasses a wide variety of microorganisms and the interaction between microbes. These interactions are often a mutualistic relationship between the host and autochthonous flora. Microflora responsible for harmful diseases are often allochthonous flora (Shiva et al., 2010). Microflora contamination in laboratories and hospitals is becoming a serious problem worldwide, characterization of such contaminants helps in treating some laboratory-acquired infections (LAI). There are laboratory quality and biosafety practices that are overlooked, which lead to microflora contamination in large numbers in the cell cultures and in the laboratory environment which may lead to (LAI) to people. The contamination risks pose danger to laboratory personnel as well as increase the costs of in-house cell culture procedure. LAI are the infections symptomatic or asymptomatic acquired through laboratory or laboratory related activities (Traxler et al., 2013). This work determined the microbial contaminations in microbiology laboratories that could cause laboratories acquired infections so as to assist personnel in laboratories to be careful when performing standard manipulations of microbiological specimens in cell cultures and training the personnel on capacity development in monitoring and evaluation of microflora contaminants in laboratories so that the upgrading policy on standard operating procedures could be developed in the laboratories (Negi et al., 2011)

Media preparation and sample collection

The study was carried out in the research laboratory of Oyo State College of Agriculture and Technology, Igboora, Ibarapa Central, Local Government. Nutrient agar (28 g), MacConkey (17 g), Mannitol Salt agar (15 g) and Potato Dextrose agar were weighed and dissolved in 1000 ml of distilled water. The agars were sterilized at 121°C for 15 min. Nutrient broth (with the same ingredients except agar) was prepared by suspending 13.0 g of nutrient Agar in 1000 ml ((Traxler et al., 2013). The media were cooled to a little below 45°C and were poured on plates to solidify. Plates were taken to the laboratories (Mak Mercy, Oluyole, Olugbon, World Health), and were opened and exposed at chosen location (cabinet and sink) for a period of 5-10 mins for contamination by laboratories environmental microflora.

Isolation of bacterial and fungal contaminants

The inoculated Potato dextrose agar (PDA) plates were incubated at a temperature of 25 °C for 72 h while Nutrient Agar plates and MacConkey plates were incubated at 37 °C for 24 h for fungal growth and bacterial growth respectively. The fungi and bacteria that grew on the media were sub-cultured into pure culture.

Identification of bacterial contaminants using biochemical methods

Bacteria identification was done based on results obtained from Gram staining, morphology and motility test, catalase production, oxidase test, indole production, citrate utilization, urease activity, hydrogen sulphide production, gelatin hydrolysis, starch hydrolysis and carbohydrates utilization.

Isolation of bacterial strains persistent to sodium hypochlorite disinfection

Three and half percent of sodium hypochlorite disinfectant (jik) used in the biosafety labs was used to sterilize the biosafety walls, benches and floor of incubating rooms in the laboratories for ten minutes to determine the viable bacteria after which opened plates were positioned in areas mostly used frequently used by the laboratory personnel. Jik is mostly used as it has carbonates, silicates, polyphosphates and chlorine water which decontaminate surfaces therefore leaving the place sterile.

RESULTS AND DISCUSSION

Table 1 and 2 revealed the rate of occurrence of bacterial and fungal isolates at chosen sites in the hospital laboratories; there was a significant difference ($p<0.05$) among the bacterial and fungal isolates from all the sites and MAK Mercy sinks (33.10%) and cabinets (11.87%) had the highest occurrence, followed by MAK Mercy cabinet fungi (31.84%) while no bacteria and fungi was observed and reported for Olugbon, world health and Oluyole cabinets (0.00%). The variation in the level of contamination of the different laboratories examined could be due to high rate of movement and communication of people who brought samples into the laboratory from outside and within the hospitals and according to Pradeep et al. (2020), living biological contaminants can be transmitted by infected people, animals and indoor air, and they can also travel through the air to get inside the buildings. High occurrence microbes in one laboratory than the other could also be due to the level of population in the room as reported by Moldoveanu (2014) that the presence of bacteria in a room indicates the presence of people and their levels may get high when the building is heavily populated.

Points of observation for microflora		
Clinical laboratories	Percentage Occurrence of bacteria isolates (%)	
	Sink	Cabinet
Mak	33.10b	11.87a
Olu	20.14c	00.00
W	22.70d	3.96e
O	3.96e	4.31f

Table 1: Occurrence of bacteria at chosen sites in Igboora

Key; Mak- Mak Mercy lab, Olu-Olugbon lab, W-World health lab, O- Oluyole lab

Table 2: Occurrence of fungi at chosen sites in Igboora

Points of observation for microflora		
Clinical laboratories	Percentage Occurrence of fungi isolates (%)	
	Sink	Cabinet
Mak	00.00	31.84g
Olu	13.41h	16.76i
W	24.02j	00.00
O	13.97k	00.00

The identity of the bacterial and fungal isolates from the different hospital laboratories in Igboora is shown in table 3. The isolates were Staphylococcus aureus, Baciilus cereus, Pseudomonas aeruginosa, Escherichia coli, Salmonella Typhi, and Salmonella serovar Typhimurium. The frequent occurrence of B. cereus and Salmonella from the cabinet and sink sites of the laboratories in this study disagrees with the finding of Poppert, et al. (2010) where microorganisms isolated and identified from different laboratory locations including walls, tables and floor were predominantly Corynebacterium sp. and Pseudomonas sp.

Table 4 showed the rate of occurrence of persistent bacteria in the four selected laboratories after disinfection with Sodium Hypochlorite (JIK) where 20.83% of Staphylococcus aureus were persistent in MAK Mercy cabinet, Bacillus cereus (16.67%, 15.63%) were persistent in Olugbon sink and carbinet. Mac Salmonella serovar typhimurium, Bacillus cereus, Salmonella typhi, Pseudomonas aeruginosa, Escherichia coli, but P. aeruginosa, S. aureus and B. cereus were found to be high after disinfectant with Sodium hypochlorite (Jik). This is similar with the research of Salgaado et al. (2015) and Isenberge (2011) where they reported that Shigella spp., Pseudomonas aeruginosa, Corynebacteria spp., Bacillus spp. and Staphylococci spp. were major resistant bacteria contaminants in biosafety laboratories in a University teaching hospital. Presence of large number of selected persistent bacteria in this study showed that the laboratory staffs may have not critically adhered to safety rules.

Fungal contaminants found associated with the cabinet site of the laboratories were Aspergillus niger, Fusarium oxyporum, Aspergillus ochraceus and Alternaria alternate which was in an agreement with findings of Salgado et al. (2015) who reported Cladosporium, Penicillium, Aspergillus and Alternaria as the most common fungi in biosafety cabinets. Regularly used furniture has been a major source of fungal spores and shade around the house has also increased indoor fungi population in fivefold (Saglani et al., 2015) since fungi grow anywhere indoor, where there is moisture and a food source in which many building materials consist of cellulolytic materials that are particularly suitable for fungi growth when they are wet, other materials that also support fungi growth include dust and paints.

KEY: Olu(s)-Olugbon sink. Olu(c)-Olugbon cabinet, O(s)-Oluyole sink, Olu(c)-Oluyole cabinet, Mak(s)-Mak Mercy sink, Mak(s)-Mak Mercy cabinet, W(s)-World health sink, W(c)- World health cabinet

Table 4: Occurrence of persistent bacteria at chosen site in Igboora

Isolates codes	Percentage Occurrence of persistent bacteria isolates (%)	Probable Bacteria
Mak(c)	20.83l	Staphylococcus aureus
Mak(s)	9.38m	Salmonella serovar Typhimurium
Olu(s)	16.67n	Bacillus cereus

Olu(c)	15.63n	Bacillus cereus
W(s)	7.29p	Escherichia coli
W(c)	14.58q	Salmonella typhi
O(s)	15.62o	Pseudomonas aeruginosa
`	7.29p	Escherichia coli

Values with different letters are highly significantly different ($P<0.05$)

CONCLUSION

All tested sites had microflora contaminants. The contaminated areas were in sink environment, and biosafety cabinets. Each site contained more than one microflora contaminants. The isolated bacteria and fungi contaminants were similar based on morphological and biochemical characteristics among the laboratories. Pseudomonas sp., Staphylococcus aureus and B. cereus were highest persistent bacteria isolates after disinfection with sodium hypochlorite (Jik)
