AGRICULTURAL SOCIETY OF NIGERIA
NATIONAL EXECUTIVE MEMBERS

S/N	Names	Positions
1.	Dr. M.N. Ishaq	President
2.	Prof. Jude A. Mbanasor	1st Vice President
3.	Dr. Solomon A. Afuape	2nd Vice President
4.	Dr. Adewumi G. Adesoji	General Seretary
5.	Dr. (Mrs.) C. Aniedu	1st Assistant General Secretary
6.	Dr. J. E. Ezwuziem	2nd Assistant General Secretary
7.	Dr. Ahmed A. Njidda	Treasurer
8.	Dr. (Mrs.) Helen N. Anyaegbunam	Assistant Treasurer
9.	Dr. A. I. Sharifai	Business Manager
10.	Dr. Adeyemi O. Olojede	Immediate Past President
11.	Prof. Chryss F. I. Onwuka	Council Member
12.	Prof. Nasiru D. Ibrahim	Council Member
13.	Prof. S. I. Omeje	Council Member
14.	Yarama D. Ndirpaya	Council Member
15.	Dr. B. C. Okoye	Editor in Chief

AGRICULTURAL SOCIETY OF NIGERIA
2022 ANNUAL CONFERENCE
PAST PRESIDENTS

Professor A. Oyenuga	(1962 – 1964)
Chief T.S.B. Aribisala	(1964 – 1967)
Chief B.S. Oloruntola	(1967 – 1969)
Professor L.K. Okpeke	(1969 – 1970)
Chief E.C. Ogor	(1970 – 1972)
Chief Ndaeyo	(1972 – 1973)
Chief C.O. Oranyeli	(1973 – 1977)
Dr. B.E. Onochie	(1977 – 1979)
Professor I.B. Olugbemi	(1979 – 1984)
Professor B.N. Okigbo	(1984 – 1988)
Dr. L.S.O. Ene	(1988 – 1993)
Sir Tunji Akiniyi	(1993 – 1998)
Dr. L.C. Igbokwe	(1998 – 2002)
Dr. E.D. Imolehin	(2002 – 2006)
Dr. C.O. Okonkwo	(2006 – 2010)
Professor I.U. Abubakar	(2010 – 2014)
Dr. Adeyemi O. Olojede	(2014 – 2018)

AGRICULTURAL SOCIETY OF NIGERIA

Biosafety issues in agriculture, Smart agriculture and climate changes, Agriculture engineering and mechanization strategies

PRESIDENTIAL ADDRESS OF THE AGRICULTURAL SOCIETY OF NIGERIA (ASN), BY DR. MOHAMMED NDAGI ISHAQ ON THE OCCASION OF THE OPENING CEREMONY OF THE 56th ANNUAL CONFERENCE OF THE SOCIETY AT THE CONFERENCE HALL OF LANDMARRK UNIVERSITY, OMUARAN.

His Excellency, The Executive Governor of Kwara State.
The Chancellor, Landmark University; Dr. David Oyedepo
The Vice Chancellor, Landmark University; Prof. Charity Aremu
Distinguished Keynote and Plenary Speakers
The Executive Director, National Cereals Research Institute, Badeggi
The Executive Director, National Root Crops Research Institute, Umudike
Presidents and Officers of Sister Societies in Agricultural Disciplines
Past Presidents and Fellows of Agricultural Society of Nigeria
Royal Fathers and other titled Men
Invited Guests
Members of the Press Corps
Ladies and Gentlemen

It gives me great Pleasure to honorably welcome you all to the 56th annual conference of our great society as I end my tenure as the President. It is my heart felt pleasure to welcome you to this annual event of the Society. I want to specifically welcome the Proprietor of this University, Dr. David Oyedepo who saw the light in Knowledge seeking and took a great stride to establish this beautiful fountain of knowledge. Landmark University is one of fastest growing University in Nigeria today. I am enormously delighted to welcome the Keynote Speaker, Mr. Leye Alayande, MD/CEO Hybrid Feed Ltd, the Lead Speaker Prof. Babalola, Research Director, North West University South Africa.
I extend a big welcome to our host, the Vice Chancellor, Professor Charity Aremu for the acceptance to host us and the much efforts she put in having a befitting conference despite numerous challenges. ASN is highly appreciative of the entire management staff and particularly the Local Organizing Committee who have been working tired less despite ASUU strike in other Universities.

AGRICULTURAL SOCIETY OF NIGERIA IN SYNOPSIS

The Agricultural Society of Nigeria (ASN) started as far back in 1962 at the Faculty of Agriculture, University of Ibadan. The society was started by a group of concerned Agricultural Professionals who graduated in various fields of Agriculture, Forestry and Veterinary Medicine, as well as those who had their Diploma Certificates in General Agriculture and Agricultural Engineering from Nigeria and abroad. The society was born out of patriotism to assist our nation, Nigeria, to regulate the practice of agriculture in all its fields, which includes plant breeding and genetics, soil science, animal husbandry, agronomy, forestry, plant protection, fishery, veterinary medicine, etc. The Society no doubt has come of age as it was formally registered with CAC and have made substantial progress in the bid to register Agriculture as a professional body in Nigeria.

THEME OF THE 56th ANNUAL CONFERENCE

The anchor theme of this year's Annual Conference is “Attaining sustainable food security and Agricultural Development Amidst Climate Change, COVID19 Pandemic and General Insecurity in Nigeria”. This caption, you would agree with has come in no better time than now that the Federal Government is making frantic efforts in sustaining food production despite the numerous challenges especially security issues. The keynote and plenary speakers are well experienced experts in the agrarian business both locally and internationally with requisite wealth of practical experiences to deal decisively on topics bothering on the theme and the sub-themes with the aim of addressing critical issues that has become the blight of agricultural development in Nigeria today. However, Careful implementation of suggested solutions no doubt will go a long way in making our country not only self-sufficient in food but will also, provide means of livelihood to the teeming unemployed youth population and provision of better security for farmers in particular and Nigeria as a whole.

THE NIGERIAN INSTITUTE OF AGRICULTURISTS(NIAg)

The engine of efforts has continued to steam and there is no going back towards registration of Agriculture as a professional body in Nigeria. Much success has been recorded and presently our bill is still waiting for Presidential accent. We are hopeful the Institute will soon be established. This is a joint effort by the Agricultural Society of Nigeria (ASN), Association of Deans of Faculties of Agriculture (ADAN) of Nigerian Universities to establish the Nigeria Institute of Agriculturists (NIAg) as a professional body. This is borne on the premise that registration of Agriculture as a profession in Nigeria will reposition Agriculture to play its leading role as a major driver of our economy. It is known that all disciplines in agriculture, which are interdependent cannot stand alone but MUST come under one multidisciplinary professional body and work in synergy for effective service delivery and for ease of governance. Our graduate agriculturist will also have a better consideration and placement on high grades like their counter parts in engineering, medicine. Surveyors etc. We there seek your support toward realization of this dream. NIAg will ultimately serve the same purpose just like COREN is to Engineers and NMA is to medical doctors with their affiliate bodies.

PROGRESS MADE BY THE SOCIETY

It is with deep sense of commitment that I wish to state some of the other progress the society has made these past few years. The Society owns and maintains a website: www.agriculturalsocietynigeria.com www.facebook.com/agricsocietynigeria10000 likes and followers. The society has a landed property within the premises of University of Abuja and we are poised to developing the property. The Institute building will definitely be sited there.

PUBLICATIONS OF AGRICULTURAL SOCIETY OF NIGERIA

The Society maintains and sustains regular Journal publication. The Journal of the Society contains information on new technologies and inventions in the field of Agriculture which is of high standard and highly subscribed by scientists all over the world. The 2022 edition of the Journal is available for purchase at moderate price. A copy of recent publication will also be included in your conference bag. Our journal is highly patronized worldwide as we had call, for purchase of past and present editions from outside the country. The Society also publishes book of Proceedings of the current conference which is a compilation of the papers to be presented during the conference. The current and old volumes are available when you visit our website. We also publish a quarterly Newsletter to give updates on the activities of the Society and state of agriculture in the country. Limited hard copies of this year's proceedings are available for sale on a first-come-first-served basis while the electronic copy is part of registration package.

MEMBERSHIP DRIVE AND CERTIFICATES

Membership of the society continues to grow. Presently we have over 3,000 members cutting across the various disciplines in agriculture. This was made possible through our redesigned website that facilitated online registration and payment. Membership certificates are dispatched in record time and this is renewable every year as soon as members pay their annual dues except for Life members.

FELLOWSHIP AWARDS

In the course of this conference 3 distinguished Nigerians will be inducted as Fellows and some others will be given award of excellence for their various contributions to the development of agriculture in Nigeria. The Chairman of the Award Committee will invite the recipients to the podium at the appropriate time.

CONCLUSION

I want to express my delight and gratitude e to the present executive council of ASN for supporting me throughout my tenure which ends tomorrow. In particular the elders among us, Prof Omeje, Prof. Onwuka and late sir Akinniyi (may we rise and observe a minute silent for him). He was among the founding fathers of the society and contributed immensely to the success of NIAg. The Proprietor of the University, Our Guests of Honor, Distinguished Guests, Ladies and Gentlemen, I wish to thank you and all for finding time to grace this occasion despite numerous challenges. Undiluted thanks go to our Host, The Vice chancellor of the University, for making this Conference a memorable one.
Please Remember to enjoy the ambience environment of Landmark University and Omu Aran town.

Thank you and God Bless You all.

Mohammed Ndagi Ishaq, PhD
President–ASN.

56th Annual Conference
Agricultural Society of Nigeria
24 - 28 Oct., 2022

ABSTRACT

Nigeria has been named one of the terrorist countries of the world. Many lives and properties have been lost and a large number of citizens rendered homeless due to the activities of Boko Haram insurgents, Fulani herdsmen and associated terrorists. While millions of farmers have been displaced from their ancestral farming communities, others are perpetually afraid for their lives and as such cannot optimally engage in farming activities. The direct implication is declining farm productivity with attendant food insecurity. Government had made frantic efforts to tackle these challenges posed by terrorism and insecurity in the country and put an end to it but the rate of insurgency and insecurity is still alarming. This paper is a review of existing literature on impact of rising general insecurity on agricultural business and food security in Nigeria. Findings have shown that the escalation of security situation in parts of the country has caused many farmers to abandon their farms. Thus, it is strongly recommended that Nigeria should seek adequate assistance from international communities in order to overcome terrorism in the country. Besides, government should support the call for ban on open grazing by the Southern state governors to curtail farmer-Fulani herdsmen conflict so as to foster the sustainability of a peaceful atmosphere where agricultural business, farm production and related socio-economic activities can thrive.
Key words: Agricultural Business, Terrorism, Insecurity, Food Security, Optimization

INTRODUCTION

Food security is a priority in every country, being a key driver for human survival and socio-economic development. Unfortunately, food insecurity is prevalent in Nigeria despite its favorable agro-ecological endowments. Food security has become a national priority for the country considering that a vast majority of its 198.1 million population is food insecure (FMARD, 2016). A household is considered food secure when its occupants do not live in hunger or fear of starvation (FAO, 2019). According to World Bank (2010), food security is of three folds, these are food availability, food accessibility and food affordability. Food availability for farming households means ensuring sufficient food for the households through production. A reduced production can lead to a decline in food availability which can cause a reduction in market access to buyers. Hence, food security connotes physical and economic access to adequate food for all household members, without undue risk of losing the access (Agaptus, John, & Modupe, 2019). Household food security issues cannot be seen in isolation from broader factors such as physical, policy and social environment. According to FAO (2019), between 2016 and 2018, the total number of undernourished Nigerians was 9.1 million but Nigeria's food and nutrition insecurity remains a worsening trend. Thus, this study underscores the impediment that rising general insecurity poses to the realization of sustainable agricultural business and food security in Nigeria.

METHODOLOGY

This is a review paper and its research methodology was based on review of existing literature

RESULTS AND DISCUSSION

Concept of Insecurity

Insecurity as a general term refers to a state of being subjected to fear, threat, danger, molestation, intimidation, harassment and its likes in all aspects. It is a situation of fear or anything that causes fear, harm, or has the capability to cause fear, harm, injury, destructions to an individual, group or nation. The concept of insecurity connotes different meanings such as: absence of safety; danger; hazard; uncertainty; lack of protection, and lack of safety. Beland (2015) defines insecurity as a state of fear or anxiety due to absence or lack of protection. Achumba, Ighomereho, and Akpor-Robaro (2013) also defined insecurity from two perspectives. Firstly, insecurity is the state of being open or subject to danger or threat of danger, where danger is the condition of being susceptible to harm or injury. Secondly insecurity is the state of being exposed to risk or anxiety, where anxiety is a vague unpleasant emotion that is experienced in anticipation of some misfortune. For the purpose of this study, insecurity is conceived as a situation where human and national security of a state is compromised by internal or external forces or interests exacerbated by the former's weak or poor economic, military and/or human resource development conditions.

Since the birth of Boko Haram in Nigeria in 2008, the country has witnessed an unprecedented level of insecurity. Banditry, kidnapping, farmers/herdsmen conflict, attacks by IPOB/ESN and other violent crimes have become the order of the day. No geopolitical zone has been spared by the vicious scourge of conflict though their prevalence and intensity have not been the same in occurrences across the length and breadth of the nation. The present situation is further intensified by elements of globalization, natural disasters, proliferation of weapons and light arms, corruption, executive lawlessness and leadership ineptitude (Chinwokwu, 2012).

The escalation of security situation in parts of the country has caused many farmers to abandon their farms. This is as a result of fear of attacks especially by marauding Boko Haram insurgents, clashes between herdsmen and the farmers, communal conflicts and other forms of conflicts. Northeast Nigeria has been struggling with the Islamist insurgency since 2008.

Violent conflict has severely weakened fragile livelihoods resulting in a deep humanitarian crisis. According to Eneja, Babagario, and Agri (2019), the states of Adamawa, Borno and Yobe recorded very high levels of food insecurity over the past decade. In addition to the deadly activities of the Boko Haram sect in the northeastern geopolitical zone of the country, another major threat to national security with serious implications for food security is the menace of Fulani herdsmen. The Fulani herders are mainly nomadic as they traverse the entire country in search of pastures for their herds. The transhumance tradition of the Fulani herders has often pitted them against sedentary farmers as a result of the destruction of the farms of the latter.

In the past, precisely before 1999, these conflicts were well managed by the herders and farmers that they never escalated to the level of recording fatalities. Most crop farmers and those dealing in livestock in the North are fleeing their land en masse and migrating to neighbouring countries because of the crisis. Food insecurity has become a chronic problem. Large-scale population displacement negatively impacted livelihood activities within displaced and host community households. With sustained violence in the northern part of the country and climate change, major cities like Enugu, Port Harcourt, Ibadan and Lagos are getting food price shocks as rising food prices bite into household budgets (MARD, 2016). The FAO (2019) has asserted that conflict-affected countries have on average higher rates of food insecure people than countries not affected by conflict. Violent conflicts can have short term effects on people's nutritional status. This in turn can have long-lasting impacts on their livelihoods.

General and Food Security

National security is all about achieving complete security for both the state and its citizens by engendering an environment of peace. This is paramount because it is only a peaceful environment that catalyzes the realization of people's wellbeing. A peaceful environment must reassure the citizens of their safety from every form of symbolic, physical and psychological threats. The reassurance must be anchored on the demonstrated capacity of the state to guarantee an environment where citizens would be safe to pursue their livelihood activities (Agaptus, et al, 2019). Human security primarily focuses on protecting the integral worth of people against insecurities by dealing with the circumstances that threaten the well-being and survival of the people. Thus, human security emphasizes the establishment of food and water security, economic and political security for the general population as critical mechanisms to achieve a more stable level of state security (Lanicci, Ramsay, & Murray, 2017).

Food security is presumed to exist when all people at all times have physical, social and economic access to food, which is safe and consumed in sufficient quantity and quality to meet their dietary needs and food preferences, and is supported by an environment of adequate sanitation, health services and care, allowing for a healthy and active life (FAO, 2019). This situation is practically unrealizable in Nigeria due to the existing national insecurity occasioned by protracted armed conflicts involving sundry groups, especially the Boko Haram group and Fulani herders. The activities of these groups in terms of invasion and sacking of farming communities have resulted in many civilian fatalities, thus creating acute insecurity. The state of insecurity in many of these farming communities has made it practically difficult for farmers to continue to engage in agricultural production optimally, thus affecting productivity and causing market disruptions with attendant food price shocks (Fadare, Akerele, Mavrotas, & Ogunniyi, 2019). The current situation is that Nigeria lacks both the capacity and capability to produce enough food to feed its population despite its favorable agro-ecological conditions.

The productivity challenge is a product of inefficiency arising from continued application of outdated input system and farming models (Esheya, 2019). While making efforts to modernize the agricultural sector, emphasis has also been placed on developing quality crops by revolutionizing seed varieties, fertilizer distribution system, irrigation system and general agronomy practices. At the apex of the checklist of actions necessary to create a conductive environment in which agriculture could thrive is improved security of farming communities to reduce the incidence of criminality (FMARD, 2016).The devastation, which the activities of Boko Haram has caused, is not only obvious but also far-reaching in its impact on agriculture. Besides the Boko Haram group, insecurity in Nigeria has been aggravated by the criminal activities of sundry groups. The group with the most devastating impact is the Fulani herders whose murderous campaigns have targeted farming communities, with no challenge from the state (Amnesty International, 2018). The displacement of farming communities as a result of attacks by armed groups, criminal violence and banditry is associated with the current alarming rise in food insecurity in Nigeria (OECD, 2020).

CONCLUSION AND RECOMMENDATIONS

Rising insecurity has caused serious disruptions in Nigeria's agricultural business activities as it undermines farming capacity and spawns the likelihood of galloping food prices; all of which exacerbate poverty and hunger and signpost a likely nationwide food crisis. The displacement of farmers from their ancestral farming communities by Boko Haram insurgents, Fulani herdsmen, bandits, kidnappers, militants, communal clashes and other associated terrorists has direct negative implication on food security. Many farmers have been forced to abandon their farmlands in search of security and safety, their farm produce destroyed while many of them have been killed. The way out under this circumstance is for government to strategically invest in the security sector by consistently equipping the security personnel with upgraded state of the art security gadgets and as well ensure adequate funding in order to defeat the Boko Haram insurgents and related criminalities; and support the call for ban on open grazing by the Southern state governors to curtail farmer-Fulani herdsmen conflict. This will foster the sustainability of a peaceful atmosphere where agricultural business, farm production and related socio-economic activities can thrive.

ABSTRACT

The Study was conducted to establish the demand analysis for beef among households in Oshimili South Local Government Are, Asaba, Delta State. 120 respondents were randomly selected for the study and primary data was collected through the use of questionnaire and analyzed by the use of descriptive and inferential statistics shows that: Most respondents were in the age range of 31-40 with a mean age of 45. There was more female respondent than male in the study area. Most respondents had 6-10 persons in their household. Most respondents were highly educated, that is there were more people with tertiary education. The bulk of respondents were into business. Result obtained indicates that most households in the study area demanded 1.1-2.0kg of meat per week. In the regression analysis, findings also showed that the 4 significant variables were income, price of beef, education and household size. All had positive effect on the demand for beef among households except for price which has a negative effect. Recommendations include that Government should subsidize the cost of inputs for cattle production, this will in turn cause a reduction in the price of beef.

Keywords: Analysis Demand, Beef, Household

INTRODUCTION

Agriculture is farming that includes raising of livestock such as ruminants like cattle, goats and sheep and non-ruminants like pigs and poultry. Agricultural economics on the other hand is an applied field of Economics concerned with the application of economic theories in the optimizing of production and distribution of food and fibre. Here, the theory of demand begins with the behavior of consumer, since the market demand is the summation of the individual consumers. Consumption decisions are made by individual or household groups. A consumer is assumed to be rational based on his income and the market prices of various goods and services the consumer plans spending income with the aim of attaining maximum possible utility or satisfaction (Subba *et al.*, 2004). Demand normally means the desire or willingness for a good but in economics, simple desire or willingness for a good alone may not represent demand. Apart from the desire or willingness, consumer should be able to buy the good. Demand is therefore an effective desire. Thus, desire and ability to buy are the key components of demand. It shows the amount of product or service the consumers are willing and able to purchase at each price in a set of possible prices during some specified time in a specified market. (Subba Reddy *et al.*, 2004). According to Eboh (2009) demand means "propensity of the consumers to buy different quantities of a particular good at different unit prices". It indicates how much the consumers would be buying when the price per unit of a commodity is changing (Subba *et al* 2004). The term consumer behavior was defined as the behavior that the consumer displays in searching for purchasing, using, evaluating and disposing of products, service and ideas which they expect would satisfy their needs (Schiffman and Kanuk, 1987). The field of consumer behavior also studies how individual's group and organization select, buy, use and dispose of goods, services, ideas or experience to satisfy their needs and desires (Kotler *et al* 2009). A consumer may feel dissatisfaction with the choice of a particular product or commodity either because he had to forego an equal alternative purchase in order to pay for it or because it has continuing service problem (Schiffman and Kanuk, 1987). Food products of animal origin have played a key role as supplies of human food calories and protein in virtually all parts of the world. Animals are an important source of food, particularly of high quality protein, minerals and vitamins and micro-nutrients. Animal protein contains essential amino acids that are different in cereals. Eating small amount of animal products will correct amino acid deficiencies in cereal based human diets, permitting more of the total protein to be utilized because animal proteins are more digestible and metabolized more efficiently than plant proteins. Furthermore, there is considerable value in diversity of diet for nutritional purposes as well as palatability. Around the world, animal protein is a major source of diversification of calories away from an over reliance on starchy staples (Delgado *et al.*, 1998).

Problem Statement

Animal protein is an essential part of human nutrition because of its biological significance. Tijani *et al* (2006) reaffirmed that animal proteins are more "biologically complete" than the vegetable proteins with regards to their amino acids composition. The dearth in the quantity and quality of protein is a challenge that is beyond dependence on plant protein alone (Tijani *et al 2006)*. It suffices therefore to explore quantity and quality of protein of animal origin of which beef is of prime importance. There is also need to find out the demand for beef by the household compared to the supply.

Objectives of the Study

The main objective of the study is to conduct a demand analysis for beef consumption among farm households in Oshimili South Local Government Are, Delta State, Nigeria. The specific objectives are to: Determine the socio-economic characteristics of household respondents; determine the quantity of beef demanded among households per week; analyze the socio-economic factor affecting the demand of beef and ascertain the factors that determine the demand of meat in the study area.

METHODOLOGY

The study area

The study area is Oshimili South Local Government Area. It covers an area of 268 square kilometres. The local government has tropical climate marked by two distinct seasons; the dry and wet seasons. Oshimili Local Government Area is bounded in the north by Oshimili North Local Government Area in the east by the River Niger, in the south by Ndokwa East Local Government Area. The major town is Asaba with communities such as Umuagu. Ugbomanta, Umuonaje, Umuezei, Umuaji, Anwai, Cable Point, West – End and Bonsac. The villages are Elenchele, Okwe, Powerline, Amakom. Oko – Obiokpu, Oko – Anala, Aniugo, Akpako, Oko – Ogbele and Odifulu. The common occupations in the study area include farming, trading, artisanships, private and public service among others.

Sampling and Sampling Techniques
Multi-stage random sampling technique was used to select sample for the study.The first stage was the selection of villages. 10 villages was randomly selected. Then 12 households were randomly selected from each of the selected villages giving a total of 120 household respondents used for the study.

Data Collection
Data was collected with the use of structured questionnaire administered on 120 respondents usually the head of household or any senior member of the household. There was 100% return rate of the questionnaire. In analyzing the demand of beef, information was collected on the following; the cost of beef in kilos (0.5, 1, ½, 2, etc.) and was gotten from various meat shops. This information is important because it was used in determining the amount consumers spend on these various meat commodities per week, monthly and those who normally demand for it on a rare occasion. Other data gathered include household size, income, sex of head of households and education.

Data Analysis
Data generated was analysed with descriptive statistics of frequencies, percentages and means. t-statistics and regression was also used for analysis.

Model Specification: the multiple regression models were specified and used to analyse the quantity of beef consumed (Y) as function of the selected variables. The explicit form of the mode, the form:

$Y_C – b_0 + b_i X_i + b_2 X_2 + b_3 X_3 + b_4 X_4 + b_5 X_5 + b_6 X_6 + N$

Where;

Yc = quantity demanded by the consumer (kg)

Xi = price of beef

X2 = income of the consumer (N)

X3 = taste (Dummy 1 = Yes, 0 = No)

X4 = Household size (number)

X5 = Age of household head (years)

X6 = price of chicken

b_0 = Constant

RESULTS

Socio-economic Characteristics

Age Distribution
Result in table 1 revealed that the age range of 11-20 there was 0.8%, 25.8% were in the age range of 21-30, 37.5% were in the age range of 31-40, 15.83% were in the range of 41-50, 11.6% were in the range of 51-60, 5.83% were in the range of 61-70 and 2.5% were in the range of 71-80. The mean age is 38.92

Table 1: Age Distribution

Age	Frequency	Percentage (%)	
		Mean	
11-20	1	0.8	38.92
21-30	31	25.8	
31-40	45	37.5	
41-50	19	15.83	
51-60	14	11.6	
61-70	7	5.83	
71-80	3	2.5	

TOTAL	120	100.00

Household Size

Result on household size in the study area indicated that 40.8% respondents had a household size of 0-5 persons, 55% had 6-10 persons in their household, and 4.2% had 11-15 persons in their household. The mean household size is 4.62. From the obtained result it is shown that household with more persons will have more demand for beef. FAO (2007) said the overall growth in demand for beef would be much accelerated by the surge in human population, rise in income and urbanization.

Table 2: Household Size

Household Size	Frequency	Percentage (%) Mean	
0-5	49	40.8	4.62
6-10	66	66.55	
11-15	5	5.42	
TOTAL	120	100.00	

Occupation

Table 3 showed that 15.8% respondent were farmers, 6.7% were bankers, 21.6% were civil servants, 3.33% were lecturers, 10% were teachers and 42.5% were business men/women. This implies that most people that demand beef and meat are people who are financially free, they do not depend on a fixed wage and also are self-employed.

Table 3: Occupational Distribution

Jobs	Frequency	Percentage (%)
Farmers	19	15.8
Banker	8	6.7
Civil Servant	26	21.6
Lecturer	4	3.33
Teacher	12	10
Business	51	42.5
TOTAL	120	100.00

Quantity of beef Demanded

Table 4 showed the quantity of beef demanded by household daily in the study area. Results indicated that 34% demanded 0-1.0kg, 43% respondents demanded 1.1-2.0kg, 20% demanded 2.1-3.0kg and 3% respondents demanded 3.1-4.0kg of beef in the study area per day. The result has revealed that a large percentage (38%) of people eat less than a kilogram (kg) of beef per day and thus reduced the nutritional benefit of beef needed by the body and this is in line with Osho and Asghar (2004) who stated that per capital consumption of meat has lagged especially in the less-developed countries of the world. This can be attributed to low income and also high price of beef. Olele (2010) reported that beef demand in most African countries is very low at a level of 2.5kg per day and the demand is even lower especially in the southern and eastern parts of Nigeria where production of animal protein has not been high enough to meet the demands of rapidly growing population.

Table 4: Quantity of Beef Demanded

Quantity of meat demanded (kg)	Frequency N=120	Percentages (%)

0-1.0	41	34
1.1-2.0	51	43
2.1-3.0	24	20
3.1-4.0	4	3
TOTAL	320*	100.00

*Multiple Response Recorded

Demand Analysis for beef in the Study Area

The different socio-economic and other factors could affect the demand of meat in the study area were determined through the use of Ordinary Least Square (OLS) regression analysis. This is in line with the traditional theory of demand. Hence the data generated were fitted into the regression model and tried in different functional forms including linear, semi-log and double log models. The linear model was adopted as the best fit as it has the highest R^2 value as well as highest number of significant variables. The R^2 value of 0.518 implies that about 52% of the changes in the demand for beef were actually caused by the changes in the variables that were entered into the model. It also implies about 48% of the changes in demand were caused by other factors which were not included in the model.

The detail of the variables coefficients standard errors, t-values and level of significance is as presented in the table.

Table 5: Demand Analysis for Beef

Variables	Coefficient	Std error	t-value	Significance
Constant	-535.272	170.408	-3.141	0.003
Sex	-418.062	551.661	-0.758	0.451
Age	489.341	3882.600	0.126	0.900
Marital status	808.095	520.843	1.552	0.077
Household size	421.753	131.367	3.210	0.001***
Education	386.922	197.602	1.958	0.005**
Price	-499.672	130.796	-3.438	0.000***
Income	982.082	155.111	6.332	0.000***

R^2 = 0.518

F-ratio = 7.39

***Significant at 1%, **significant at 5%, *significant at 10%

An F-ratio of 7.39 that the overall regression equation was significant at the 0.001 level of significance.

Table 5 showed that four variables were statistically significant on their effect on demand of meat in the study area. These are household size, level of education, price of the commodity and income.

Household Size: The size of the household with a coefficient of 421.75 and a standard error of 131.37 with a t-value of 32.1 is significant at 1% level. This showed that the more the household of the respondent the more the demand for meat.

Education: Level of education variable had a coefficient of 386.92 and a t-value of 1.96 which is statistically significant at the 0.005 level. This implied that the higher the level of education, the more the demand for beef.

Price of Meat: The price of the beef with a coefficient of -499.67 and t-value of -3.44 is statistically significant at the 0.01 level of significance. The coefficient is also negatively signed. The implication of this is that an increase in the price of beef will lead to a decrease in the demand of the products. This result is in line with the law of demand which states that the higher the price the lower the quantity demanded and the lower the price the higher the quantity demanded (ceteris paribus).

Income of Respondents: The level of income of respondents with coefficient of 982.08 and t-value of 6.33 is statistically significant at the 0.01 level. It is positively signed. This implies that the more the income of the consumer the more they demand meat products all things being equal. The result is also in line with respect to demand of normal goods.

Conclusion

The study showed that beef is an important part of household diet. Although household size is a factor that cannot be overlooked, income is an important determinant on the quantity the household will purchase. The study therefore made the following recommendations:
Government should subsidize the cost of inputs for cattle, this will in turn cause a reduction in the price of beef and poultry meat. Since cattle is not reared in Oshimili South Local Government, there is need for intervention in the area reduction in transport cost and provision of storage facilities. These will help to reduce prices of beef and increase the quantity available to households. Government should provide modern abattoirs for cattle slaughter to ensure quality beef are sold to the consumers. Also consumers of beef should join or form cooperative societies. This will help pool their resources together to purchase the product in bulk and reduce the price and increase the quantity of beef available than when the product is sold at retail prices.

ABSTRACT

The study analyzed the efficiency of sweet potato marketing in the study area. Data were collected with the aid of a well-structured questionnaire from 40 randomly selected sweet potato marketers from 2 purposively selected markets. Data were analyzed using descriptive statistics and stochastic profit function. Results showed that the mean age of the sweet potato marketers was 37 years and majority (57.5%) were female. All the parameter estimates such as cost price of sweet potato, transportation, market space (rent) etc have the expected sign and are statistically significant at 1% and 5% respectively showing that they are important determinants of total profit associated with sweet potato marketing in the study area. The maximum likelihood estimates for the stochastic profit function used in explaining the inefficiency parameters for the sweet potato marketers indicated that all the parameters such as sex, marital status etc except age had the *a priori* expected signs and are all statistically significant showing that an increase in any of them decreases inefficiency. The mean profit efficiency is 0.45 meaning that an average sweet potato marketer in the study area has a scope for increasing profit efficiency by 55%. It was concluded that sweet potato marketers are not profit efficient from their profit efficiency indices.

Key words; Marketing Efficiency, Sweet Potato, Covid-19, Stochastic Profit Frontier.

INTRODUCTION

Sweet potato, a neglected food crop in the past has found its place in the global market because of its ability to respond to the pressing need of boosting food security, wealth creation and nutrition amidst covid-19 pandemic. Sweet potato (*Ipomoea batatas)* is a herbaceous plant that belongs to the family of *Convolvulaceae* and genus of Ipomoea. Nigeria is the largest producer of sweet potato in West Africa (Udemezue, 2019). It is a source of food to humans, while the leaves and roots are used as animal feed. It is a great source of vitamin A (Hagenimana *et al.,* 2000). However, the Covid-19 pandemic according to International Labour Organization (2020) has disrupted the entire food system, preventing farmers from accessing markets and selling their produce, thus disrupting the food supply chain. Anudu (2021) reported that Nigeria's sweet potato production is estimated at 1.2 million MT (Metric Ton) while demand is 6 million MT leaving a supply gap of 4.8 million MT of untapped market potentials. This

could be linked to inefficient marketing system resulting from differentials in transportation cost, storage cost etc. Bridging this demand and supply gap of sweet potato in Nigeria amidst this pandemic through domestic production and efficient marketing offers a great investment potential to the Nigerian populace.
Marketing efficiency refers to the ability to make maximum marketing profit given the purchase and selling prices of the products and the level of fixed factors of the firm. Inefficiency is defined as loss of profit from not operating on the profit frontier (Rahman and Awerije, 2014). The stochastic profit frontier as used by Truong *et al.,* (2020) is defined as where π is the vector of profit defined as gross revenue minus variable cost divided by output price (Py).

$$\pi^* = \frac{\pi}{Py} = \mathrm{f}(Pi, Zi).\exp(Vi - Ui) \ldots. (1)$$

Where π* is the normalized profit computed for the ith firm, Pi is the vector of variable input prices, Py is the output price, Zi is the vector of fixed inputs, and i = 1…n is the number of firms in the sample. Vi is the independently distributed two sided random errors which represents random variations in profit attributed to factors outside the marketers control, Ui is the non-negative random variables associated with inefficiency. When u = 0, it means that the firm's profit is on the efficiency frontier and when u < 0 it means that the firm's profit is below the efficiency frontier. The marketing profit efficiency of an individual firm in this study using stochastic frontier profit function is defined as the ratio of the predicted or actual profit (πi) to the corresponding predicted maximum profit (πi*) for the frontier profit given the price of variable inputs and the level of fixed factors of production of that farmer. The formula is given as:

$$\mathrm{EE} = \frac{\pi i}{\pi i^*} = \frac{(Pi,Z)\ exp(Vi-Ui)}{(Pi,Z)\ exp(Vi)} \ldots.(2)$$

$$\mathrm{EE} = \exp\frac{(Vi-Ui)}{exp(Vi)} \ldots.. (3)$$

Where: EE is the profit of an individual marketer in the context of the stochastic frontier profit, πi is the predicted profit, πi* is the predicted maximum profit for the best marketer or frontier profit given the price of variable inputs (Pi) and the level of fixed factors (Z) used by the marketer. Vi and Ui are as stated above Many studies have been carried out on marketing efficiency of sweet potato and its determinants using parametric and non parametric efficiency measures such as efficiency index ratios, value addition and OLS multiple regression model as can be seen in Ejechi *et al.*, (2016), Girei, *et al.*, (2019), Sarma (2010), and Kyomugis *et al.*, (2018) etc but none of them used stochastic profit frontier. Based on the above, this study therefore examined the following: Socio economic characteristics of the marketers, Marketing efficiency and inefficiency of sweet potato marketers using stochastic profit frontier.

Hypothesis

H_0: Sweet potato marketers in the study area are not profit efficient.

MATERIALS AND METHODS

The study was conducted in Owerri Municipal Council of Imo State. The study area was selected due to the predominance of major markets in the area. Owerri Municipal has a population of about 127,213 according to 2006 population census. It is the head quarters of Imo State. Owerri Municipal area has two main seasons, the dry and wet season. The area has an annual rainfall of between 2250mm to 2500mm with average annual temperature of between 25-27^{0}c and annual relative humidity of 80% (Njoku and Igbokwe, 2021; Nwajei, *et al.*, 2017). Two markets were purposively selected which include the Relief and Owerri main market (Eke Ukwu Owerri). The purposive selection is because of the full business activities that go on in these markets on daily basis compared to those in the rural areas. Simple random sampling was used to select 20 potato marketers (retailers) from each of the 2 markets given a total of 40 marketers. Descriptive statistics was used in describing the socio economic characteristics of the marketers, while stochastic profit frontier was used to determine the profit efficiency and inefficiency of the marketers.

Stochastic Profit Frontier Function

Following Truong *et al*., (2020) the stochastic profit frontier was used to estimate the marketing profit efficiency of the marketers in the study area. The explicit Cobb-Douglas profit frontier for sweet potato marketers is specified as;

$$\mathrm{Ln}\pi^* = \beta_0 + \sum_{j=1}^{6} \beta_j \mathrm{Ln}X_{ij}^* + \beta_k \mathrm{Ln}X_k + \nu i - \mu i \quad \ldots\ldots (4)$$

Where, Ln = Natural Log, Lnπ^* = Natural Log of profit function, X_1^*= Cost price of Sweet Potato (₦/kg), X_2^* = Cost of loading and off loading (₦/kg),X_3^*= Cost of transportation (₦/kg), X_4^*= Cost of storage (₦), X_5^* = Rent (Market space) (₦), X_6^* = Association fee (₦), $\beta_1 - \beta_6$ = Parameters to be estimated, β_0 = Constant term, ν_i = Two sided random error, μ_i = One sided random error, e_i = ν_i- μ_i = Error Term. The inefficiency model (μ_i) is specified thus: μ_i = a_0 +$a_1 Z_1$ + $a_2 Z_2$ + $a_3 Z_3$ + $a_4 Z_4$ + $a_5 Z_5$ + $a_6 Z_6$ + $a_7 Z_7$……… (5) Where, Z_1 =Age (years), Z_2 = Sex (2, Male; 1, Female), Z_3 = Marital status (4, Married; 3, Single; 2, Widowed; 1, Divorced), Z_4 = Household size (Number of persons), Z_5 = Years of Education (Years), Z_6 = Marketing Experience (Years), Z_7 = Member of marketing Association (2, Yes; 1, No), a_0 - a_7 = Parameters to be estimated.

The socio-economic characteristics of the sweet potato marketers are presented in Table 1. The results show that the sweet potato marketers have a mean age of 37 years, 57.5% were female. This indicates that young women are more in sweet potato marketing which is in line with the findings of (Udemezue, *et al.*, 2018). The results also show that majority of the marketers (80%) belongs to marketing association with half of the respondents (50%) having household size of 5-8 persons. This is contrary to the findings of (Nkamigbo *et al.*, 2021). Majority (45%) are married with a mean marketing experience of 9 years and have spent some years in school showing that they are literates which is in line with (Ejechi *et al.*, 2016). The result of the maximum likelihood estimates of the stochastic profit frontier model is presented in Table 2. The elasticity values of the 6 parameter estimates were negative and have the expected signs and are statistically significant at 1% and 5% respectively. This shows that these factors (cost of sweet potato, loading and off- loading, transportation, storage, rent and association fee) are important determinants of total profit associated with sweet potato marketing in the study area. This result confirms the findings of (Odondo *et al.*, 2014). The maximum likelihood estimates for the stochastic profit function used in explaining the inefficiency parameters for the sweet potato marketers is also presented in Table 2. The coefficients of six (sex, marital status, household size, years of education, marketing experience and marketing association) out of the seven variables used had apriori expected signs and are significant at 1%, 5% and 10% respectively indicating that increase in them decreases inefficiency except for age which has positive relationship with marketing inefficiency (Konja *et al.*, 2019). The marketing profit efficiency scores is presented in table 3. The marketing efficiency of the sampled marketers ranged from 0.11 to 0.75. The mean profit efficiency is estimated to be 0.45, meaning that an average sweet potato marketer in the study area had a profit inefficiency gap of 0.55 leading to the acceptance of the null hypothesis.

CONCLUSION

The sweet potato marketers are not profit efficient because their marketing (profit) efficiency indices indicates that there are still inefficiency gaps to be filled in other to operate fully on the profit frontier.

PROCEEDINGS
56th Annual Conference
Agricultural Society of Nigeria
24 - 28 Oct., 2022

ABSTRACT
The study "Cost and return analysis on date palm (*phoenix dactylifera L.*) production among small-scale farmers in Jigawa state" a total of one hundred and thirteen (113) farmers from twelve (12) villages, were selected from two (2) Local government areas using multi-stage sampling procedure. Data were collected by the use of structured questionnaires; the data were analyzed using descriptive statistics and net farm income. The findings of this study revealed that the small-scale date palm farmers had a mean age of 51 years, the mean household size of 13 people and mean years of experience is 32 years, most 99% were married, 30% of the date palm producers had formal education, and about 11% were members of farmers' cooperative society. The total costs and return were estimated at ₦120,094.70 and ₦136,817.04 respectively, and a return on Naira investment of ₦1.14. Inadequate water source, inadequate government and private organisations intervention and inadequate awareness were the major constraints to small-scale date palm producers in Jigawa state. It was concluded that date palm production is a profitable enterprise, but most of the small-scale date palm farmers are realizing the best out of their investment.

INTRODUCTION
The new federal Agricultural Promotion Policy (APP) strategy focuses on solving the core issues at the heart of limited food production and delivery of quality standards (FMARD, 2016). As productivity improves domestically and standards are raised for all Nigerian food production, export markets will also benefit impacting positively on Nigeria's balance of payments. Crop sector plays a crucial role in rural economy and livelihood. This is one sector where the poor contributes to the economic growth directly instead of getting benefit from economic growth generated elsewhere. In Nigeria, the crop sector forms an important livelihood activity for most of the farmers, supporting agriculture in the form of critical inputs, contributing to the health and nutrition of the household, supplementing incomes, offering employment opportunities, and serving as a store of wealth in times of need. It acts as a supplementary and complementary enterprise.

Date palm fruit is important as a part of agriculture diversification and income enhancement. In 2020/2021 date fruit were the dried fruits most producing globally, and Saudi Arabia was leading producer of dates and account for about 21% of global production. (INC statistics, 2020-2021). Nigeria is not listed among the dates producers at the international scene, which may be attributed to dearth of information on the Nigeria date palm production sector. Chukwuemeka, (2013) urged Federal government to include date palm production in the Agricultural Transformation Agenda (ATA) Programme to ensure food security and combat desertification.

Nigeria is facing two key gaps in agriculture today: inability to meet domestic food requirements, and an inability to export at quality levels required for market success (FMARD, 2016). The former problem is a productivity challenge driven by an input system and farming model that is largely inefficient. As a result, an aging population of farmers do not have enough seeds, fertilizers, irrigation, crop protection and related support to be successful. The Nigerian date palm production is estimated at about 21,700 metric tonnes (AbdulQadir *et al.*, 2011), but due to the subsistence cultivation, the total area put into Date Palm production is not more than 1,446.8ha in Nigeria (Dada *et al.*, 2012), and the estimated consumption of date is put at 89,850 metric tonnes (Sani *et al.*, 2010), this shows that Nigeria can produce only 24% of its consumed date, the remaining 76% of date consumed in Nigeria are imported from the neighboring countries like Chad and Niger.

Despite the power vested on Nigerian Institute For Oil Palm Research (NIFOR) to provide new technologies and innovations on how to enhance and improve date palm production and productivity, it was discovered that the date palm production is trying to become history due to the urbanization of areas like Dutse Local Government Area (LGA) of Jigawa state, in which number of hectares under the possession of small scale date palm farmers were revoked by the government for other urban purposes, the trees were cut down without replacement. This brought about a large deficit in the date palm production in Jigawa State. The number of hectares and total date production in Nigeria was from a single source since 2010. There is no source that reported the cost and return analysis to ascertain the profitability of date palm production.

Datre palm has a comparative advantage in the area of study for having two growing seasons in a year. The cultivation of date is at subsistence level, with farmers having few trees stands on their farms and two or more stands in their homestead. However, no information is available on the production capacity as well as its costs and return structure in the country (Dada *et al.*, 2012). This study therefore sets to address the knowledge gap on the date's cost of production and profitability. The main objective of this research is to analyse the economics of date palm production in Jigawa state. The specific objectives are to;

i. describe the socio-economic characteristics of date palm farmers,
ii. determine the costs and return associated with date palm production,

Justification

The study focused on the economics of date palm production among small-scale producers in Jigawa State. This study is expected to provide valuable information on costs and return of date palm to enable farmers consider its production as a viable option. The findings of this study would help farmers and other agencies in identifying problems facing date palm producers for improvements, it will also be useful to both government in decision making and non-governmental organizations with a view to promote the date palm production. Similarly, the study would provide valuable information to the government of Jigawa State, as a basis for policy formulation for date palm production in the State, it is hoped that this work would be of assistance to researchers and add to the existing knowledge in date palm production among small-scale producers in Jigawa State.

Limitation

- ✓ There was a difficulty in measuring the farm size of the date palm farmers, this is due to the fact that majority of respondents interviewed for this study had their date palm trees in a scattered location, this gives room to exclude land size as a factor in the study.
- ✓ Current literature on date palm production exists, but there are less literatures and publications on the economics of producing date palm trees in Nigeria, and inadequate literatures on how to classify the date palm farmers into small scale, medium and large-scale producers. This give room to the study to categorise the producers scale based on farmers perspective, in which the small-scale farmers are categorised as those that own one (1) to twenty (20) trees, twenty-one (21) to fifty (50) trees as medium scale while fifty and above (>50) trees as a large-scale farmer.
- ✓ There was a dearth of information on the farmers' previous production record, and majority of the small-scale date palm producers owned date palm trees by inheritance, gift and purchase. This gives room to take the average purchase price of trees as the initial cost production and to use one seasonal data (i.e., 2016) to measure costs and return using Net Farm Income in date palm production in the study area.

MATERIALS AND METHODS (METHODOLOGY)

The study area: Jigawa State is situated in the north-western geopolitical part of the country between latitude 11.00^0 North to 13.00^0North and longitude 8.00^0East to 10.15^0East and a total landmass of 24,742 square kilometres (Jigawa 2009), a large proportion of this is certified to be arable land, with an estimated population of about 8,109,251 million (T.I.N. Magazine 2017), 85% of the population in the state lives in the rural areas (Jigawa, 2009). Jigawa State shares an international border with the Republic of Niger. This provides unique opportunities for international trade of date palm fruit produced in Niger and Nigeria. Annual rainfall is estimated to be between 600mm - 1,000mm with an average of about 650mm over the last few years. Rainfall in the state normally lasts an average of five months (May to September), the temperature ranges from 10^0C during the harmattan season to about 42^0C during the dry season and annual mean relative humidity of 30.8% (Jigawa, 2009).

Sampling Procedure: A multi-stage sampling technique was used in this study. two Local Government Areas were purposively selected from 'zone I' of Jigawa State Agricultural and Rural Development Authority Zones, namely; Dutse and Kiyawa due to the concentration and high intensity of date palm production in these areas, two wards from each local government were purposively selected, three villages were purposively selected from each ward. A simple census was conducted in each village and a total of 159 were identified and verified to be the small-scale date palm farmers. from each village 71% of the total population of each village was randomly selected, using random selection without replacement method, this gives a sample size of 113 small-scale farmers.

Data Collection: Primary data were used as a source of information in this study. The data was collected with the aid of a structured questionnaire administered to the date palm producers.

Data Analysis: Simple descriptive statistical tools such as mean, standard error, frequency and percentages were used for the socio-economic characteristics of the farmers, while, Net Farm Income was used to estimate the cost and returns in date palm production.

Model Specification for Net farm income: Net farm income (NFI) was employed for estimating the cost and returns in date palm production in order to see the profitability of date production in Jigawa State, it is expressed as:

NFI = TR – TC … (1)

TR = Total Output (kg) X Unit Price of the Output (₦/kg)

TC = TFC + TVC …(2)

Where;

NFI - Net Farm Income in Naira (₦)/Season
TR - Total Revenue in Naira (₦)
TC - Total Cost in Naira (₦)
TFC - Total Fixed Cost in Naira (₦) (Depreciation on hoe, knife, tube-well and watering can)
TVC - Total Variable Cost in Naira (₦) (organic fertilizer, pollen, net, jude sack, polyethene sack and rope).

GR = TC/GI …(3)

GM = GI - TVC …(4)

RI = GI/TC …(5)

Where;
GR - Gross Ratio
GI - Gross Income
OR – Operating Ratio
GM – Gross Margin
RI – Return on Naira Invested

RESULTS AND DISCUSSION

Socio-economic characteristics of small-scale date palm producers

Socio-economic characteristics used for this study were age, sex, household size, years of experience, marital status, and educational status of the small-scale date palm producers.

The result from Table 1 reveals that for Gender (sex) 100% are male, 34% are between the age range of 60-70years followed by the 38-48years. The mean age of 51 years and the category of farmers that has 34% indicates that majority of small-scale date palm farmers were above active age group. This may be due to the poor participation and practicing of date palm production by the middle age group, few among the middle age group are planting new set of date palm trees in the study areas. This does not conform to *a priori* expectation, as middle age farmers are expected to be the occupants of the production for its tedious nature. This finding did not conform with that of Gbolagade *et al.* (2013) who in the same location reported that 53% of the date palm farmers were in their active age group between 31 – 50 years.

Household Size: The result presented in Table 1 reveals the 46% of the household are between 4 – 10 person per household. This indicates that majority of the sampled farmers have household size that is larger than 5, it is expected that large number of household size could contribute a lot to the family labour and increases productivity which is in line with expectation among the small-scale date palm farmers.

Years of Experience: Table 1 reveals that the farmers had a mean age of 32 years. This shows that small-scale date palm farmers gained some level of expertise over the years, which further gave them a better understanding of the factors affecting their production. But still the years of experience doesn’t change the understanding of the date palm farmers in Jigawa state on the adoption of new technologies on date palm farming.

Marital Status of Small-Scale Date Palm Farmers: Result in table 1 reveals that majority of the respondents with 99.1% were married, this finding is similar to that of Gbolagade *et al.* (2013) who discovered in the same location that 99.1% of date palm farmers were married. This shows that majority of small-scale date palm farmers were responsible and good in decision making.

Educational Status: the result reveals that 70% had no formal education, this indicates that majority of the respondents don’t have formal education. This finding is in line with that of (Salman, 2011) who reported that 59.2% of the respondents had no formal education.

Membership of Farmer Groups/Cooperatives: Table 1 revealed that 89.4% are non-members of farmer groups, this is because most of the farmers believe that they will not have supports or access to any other important input on date palm production.

Table 1: Age, household size, years of experience of SSDPF

Items	Frequency	(%)	Mean	SD.
Age			51	12
27– 37	12	10.6		
38– 48	37	32.8		
49– 59	25	22.1		
60– 70	38	33.7		
71– 81	1	0.9		
Household size (No.)			13	6
4 – 10	52	46.0		
11 – 17	34	30.1		
18 – 24	21	18.6		
25 – 31	5	4.5		
32 – 38	1	0.9		
Experience (years)			32	13
06 – 17	14	12.4		
18– 29	24	21.3		
30– 41	51	45.2		
42– 53	19	16.8

Primary	24	21.2		
Secondary	4	3.5		
Tertiary	6	5.3		
Group membership				
Member	12	10.6		
Non-member	101	89.4		
Total	**113**	**100**		

Costs and return analysis

Table 2 depicts the various cost components involved in the date palm production in Jigawa state. Table 2 reveals the average number of date palm trees as 12 trees for a small-scale farmer with a minimum and maximum of 1 and 20 trees respectively. Net farm income for small scale date palm farmers is calculated as ₦11,057.17/stand/annum, this was computed based on the average of total operational costs and depreciated total fixed costs of ₦11,445.77 and ₦1,796.70 respectively, this give a total production cost of ₦13,242.47 on average small scale date palm farmer and gross income (return) of ₦24,299.64/stand per annum.

The result shows that cost of purchasing trees has the highest percentage accounting for about 51.25 percent of the total cost of production and 59.29 percent of the total variable cost, followed by labour cost accounting for about 14.35 percent of the total cost of production and 16.60 percent of the total variable cost, and this may be due to the tedious nature of the work (i.e. climbing trees for dethorning, pollination, covering and tie-down of bunches and cut down of fruit bunches).

Total variable cost accounted for about 86.43 percent while fixed cost accounted for 13.57 percent of the total cost of production. The net farm income calculated as ₦11,057.17

/tree/annum and a gross margin of ₦12,853.87 /tree/annum this implies that the date palm production among small scale producers is profitable. If necessary adjustments are made within the production such as increasing the number of tree stand, the return per naira invested of 1.83 can be increased (Olukosi and Erhabor 2008), and it can help the small-scale date palm farmers to increase their income and improve their livelihood.

Table 2: Costs and Return Associated with Small-Scale Date Palm Producers

Variable inputs	Quantity	Cost (₦/ha)	%TC	%TVC
Trees (Number)	1	6,786.77	51.25	59.29
Labour (Man-days)	2	1,900	14.35	16.60
Organic Fertilizer (kg)	40.05	387	2.92	3.38
Pollen (g)	7.45	157.85	1.19	1.37
Net (Number)	1	320	2.42	2.79
Jude Sack (Number)	3.5	290	2.19	2.53
Pesticides (Liters)	10cl	85	0.64	0.74
Polyethene Sack (Number)	2	120	0.91	1.05
Rope (Roll)	1	225	1.70	1.97
Transportation		1,174.15	8.87	10.26
Total Variable Cost		**11,445.77**	**86.43**	**100**
Fixed Inputs				**%TFC**
Hoe (Number)	1.14	130.52	0.99	7.26
Tube Well (Number)	1	1,436.96	10.85	79.98
Knife (Number)	1.27	86.55	0.65	4.82
Watering can (Number)	1	142.67	1.08	7.94
Total Fixed Cost		1,796.7	13.57	**100**
Total Cost		13,242.47	**100**	
Gross Income (Returns)		**24,299.64**		
Net Farm Income		**11,057.17**		
Gross Margin		**12,853.87**		
Gross Ratio		0.54		
Return on Capital Investment		**1.83**		

CONCLUSION

Based on the findings of this study on costs and return analysis it could be concluded that date palm production is a good enterprise for income generation, job creation and enhancement of livelihood among farmers in Jigawa State.

ABSTRACT
This study Assessed Post-harvest Management Training Needs for Tomatoes Farmers in Niger State, Nigeria**.** Sample size of one hundred and eighty (180) maize farmers were selected using multi-stage sampling method. Structured questionnaire complimented with interview scheduled were used for data collection. Data collected were analyzed using descriptive statistics such as (frequency, percentages and mean) The finding showed that processed of tomatoes to paste ($\bar{X}$ =2.41), sorting according to size and colour ($\bar{X}$ =2.33) and use of cold water bath ($\bar{X}$ =2.32) were the most important training needs for tomato farmers in the study area. The most constraints associated with post-harvest management in the study area were shortage of fund ($\bar{X}$ =3.76), inadequate credit facilities ($\bar{X}$ =3.68), and high cost of post-harvest materials ($\bar{X}$ =3.61). It is recommended that farmers should source for credit and fund from informal sources in order to address the problem faced in the study area. Also, the price of post-harvest material should be made flexible and avoidable for farmers in the study area.
KEYWORDS: Post-harvest; Training; Needs; Tomato Farmers.

INTRODUCTION
Tomato (Lycorpesicon esculentum) is vital at supplying human populace with vitamins and minerals required for growth and development. Tomatoes in Nigeria are mostly produced in Northern Nigeria as a result suitable agro-climatic condition that favoured mass production. Tomatoes are either used fresh or processed into paste. Unfortunately, they are not only seasonal but highly perishable and deteriorate due to lack of proper knowledge on post-harvest management and inadequate training needs by tomato farmers (Mohammed *et al.,* 2012). Tomatoes farmers post-harvest training needs in sorting, grading, processing, transportation, preservation and diseases control are expected to enhance longevity of tomatoes and reduce post-harvest losses that are accounted for more than 50% of the tomato produced in Nigeria (Muhammed *et al.,* 2015). A need-based training would bring a desirable alteration in the skills, knowledge and attitude of the farmers. Training enhances perfection and confidence in farmers. The objective of the study are to assess the post-harvest management training needs for tomato farmers and identify the constraints associated with post-harvest management in the study area.

MATERIALS AND METHODS

The researched was done in Niger State of Nigeria. the state can be found in the guinea savannah ecological zone of nigeria. The State is located within Longitude 3° 30' and 7° 20' east & Latitude 8° 20' and 11° 30' north, with a population of about 3,950,249 (npc, 2006) and with a growth rate of 3.2%, the state has estimated population of 5,586,000 in 2017 (Niger State Geographical Information System, 2015). Some of the tree crops are rice, beans, tomato, melon, guinea corn etc.

Multi-stage sampling technique was employed for this study. the first stage involved random selection of three (3) agricultural zones in the state. the second stage involved the selection of one (1) Local Government Areas (LGAs) from each of the zones making a total number of three (3) LGAs. the third stage involved random selection of four (4) communities each from the selected LGAs making a total of twelve (12) villages. the fourth stage involved the use of proportional sampling to select 10% of the farmers from the sampling frame which gave a total sample of one hundred and eighty (180) respondents.

Table 1: Showing sample distribution of the farmers in the study area

State	Agricultural Zones	LGAs	Communities	Sampling Frame	Sample Size (10%)

Primary data was used for this study. Data were collected by the researcher assisted by trained enumerators using structure questionnaire complimented with interview schedules. The objectives of this study were achieved using descriptive statistics such frequency distribution, percentage

Analytical Techniques

Post-harvest training needs of tomato farmers was measured using 3-points likert scale of Most important 3, Important 2, Not important 1. A mean score of 2.0 was obtained by adding 1+2+3=6 and dividing by 3. The decision rule was any mean ($\overline{X}$) scores > 2.0, indicates important, while scores < 3.0 is termed not important**.** The Constraints associated with post-harvest management of tomatoes were measured using 5-point Likert scale, and was allotted as follows: Very severe 5, Severe 4, Undecided 3, Less severe 2, Not severe 1. A mean score of 3.0 was obtained by adding 1+2+3+4+5=15 and dividing by 5. The decision rule was any mean ($\overline{X}$) scores > 3.0, indicates severe, while scores < 3.0 is termed not severe

RESULTS AND DISCUSSION

Post-harvest training needs of tomato farmers

Table 1 showed that the most important post-harvest training needs were processing of tomatoes into paste ($\bar{X}$ =2.41), size and colour sorting ($\bar{X}$ =2.33), use of cold water bath ($\bar{X}$ =2.32), use of open air dry ($\bar{X}$ =2.28), store in cool place ($\bar{X}$ =2.21) and fully and half ripe grading ($\bar{X}$ =2.21) ranked 1st, 2nd, 3rd, 4th and 5th respectively. The findings is in consonance with Muhammed *et al.* (2012) who reported tomatoes growers in Kano State, Nigeria were fully involved in sorting, grading and conversion of tomatoes to paste. Other important post-harvest management training needs in the study area include use of motorcycle for transporting tomatoes ($\bar{X}$ =2.19), use of crates for packing ($\bar{X}$ =2.18), keep tomatoes away from sunlight ($\bar{X}$ =2.15), use of traditional baskets, use of public transport ($\bar{X}$ =2.08) and sundried tomatoes into chips ($\bar{X}$ =2.07). This finding agreed with Azad *et al.* (2014) who stated that use of crate and traditional basket reduces deformities experience by tomato growers.

Table 1: Post-harvest training needs for tomato farmers

Training needs	Most important	Important	Not important	Sum	Mean	Rank	Decision
Sorting							
Size and colour sorting	77 (42.8)	86 (47.8)	17 (9.4)	420	2.33	2nd	Important
Grading							
Fully and half ripe	60 (33.3)	99 (55.0)	21 (11.7)	399	2.21	5th	Important
Packing materials							
Use of Nylon sacks	15 (8.3)	35 (19.4)	130 (72.2)	245	1.36	15th	Not important
Use of traditional baskets	45 (25.0)	110 (61.1)	25 (13.9)	380	2.11	10th	Important
Use of crates	58 (32.2)	96 (53.3)	26 (14.4)	392	2.18	8th	Important
Storage methods							
Store in cool place	65 (36.1)	88 (48.9)	27 (15.0)	398	2.21	5th	Important
Keep them away from sunlight	63 (35.0)	81 (45.0)	36 (20.0)	387	2.15	9th	Important
Transportation methods							
Use of public transport	46 (25.6)	102 (56.7)	32 (17.8)	374	2.08	11th	Important
Use of motorcycle	68 (37.8)	78 (43.3)	34 (18.9)	394	2.19	7th	Important
Use of fuel tanker	16 (8.9)	55 (30.6)	109 (60.6)	267	1.48	13th	Not important
Use of human labour	9 (5.0)	42 (23.2)	129 (71.7)	240	1.33	16th	Not important
Preservation methods							
Sundried into chips	52 (28.9)	89 (49.4)	39 (21.7)	373	2.07	12th	Important
Use of open air dry	99 (55.0)	34 (18.9)	47 (26.1)	412	2.28	4th	Important
Use of refrigerator	4 (2.2)	67 (37.2)	109 (60.6)	255	1.42	14th	Not important
Use of cold water bath	82 (45.6)	73 (40.6)	25 (13.9)	417	2.32	3rd	Important
Processing of tomatoes							
Processed to juice	1 (0.6)	73 (40.6)	106 (58.9)	255	1.42	17th	Not important
Processed tomatoes paste	86 (47.8)	82 (45.6)	12 (6.7)	434	2.41	1st	Important

Sources; Field survey, (2018)

Constraints associated with post-harvest management

Table 2 revealed that the most severe constraints associated with post-harvest management in the study area were shortage of fund ($\bar{X}$ =3.76), inadequate credit ($\bar{X}$ =3.68), high cost of post-harvest materials ($\bar{X}$ =3.61), inadequate training on post-harvest management ($\bar{X}$ =3.48). The findings agreed with Mohammed *et al.* (2018) who indicated that shortage of fund and inadequate access to credit were the major constraints affecting soya bean production in Northern Region of Ghana. Similar findings by Maxwell (2014) showed that inadequate access to credit was the most serious constraints affecting rice farmers in Sub-Sahara Africa. Other severe constraints in the study area were inadequate infrastructure ($\bar{X}$ =3.24), knowledge and skills limitation ($\bar{X}$ =3.33), lack of technical knowledge ($\bar{X}$ =3.27), limited knowledge on post-harvest management ($\bar{X}$ =3.27). These findings agreed with Elisha *et al.* (2016) who stated that inadequate infrastructure and knowledge and skills limitation were the major constraints faced by smallholder farmers in Ghana

Table 2: Distribution according to constraints associated with post-harvest management

Variables	Mean ($\bar{x}$)	Rank	Decision
Quick deterioration of crops	2.99	9th	Not severe
Inadequate credit	3.68	2nd	Severe
Inadequate market information	2.79	13th	Not severe
Inadequate trainings on post-harvest	3.48	4th	Severe
Shortage of fund	3.76	1st	Severe
High cost of post-harvest materials	3.61	3rd	Severe
Lack of farmers participation	2.98	10th	Not severe
Lack of technical knowledge	3.27	7th	Severe
Knowledge and skills limitation	3.33	6th	Severe
Insect attack	2.84	12th	Not severe
Limited knowledge on post-harvest management	3.27	7th	Severe
Disease Attack	2.88	11th	Not severe
Inadequate infrastructure	3.42	5th	Severe
Theft of produce	2.66	14th	Not severe
Reduction in taste qualities	2.48	16th	Not severe
Use of fake chemical	2.62	15th	Not severe

Sources; Field survey, (2018)

CONCLUSION AND RECOMMENDATIONS

Based on this finding it can be concluded processed tomatoes to paste, size and colour sorting, use of cold water bath and use of open air dry were the most post-harvest training needs for tomatoes farmers in the study area. The most severe constraints associated with post-harvest management in the study area were shortage of fund, inadequate credit and high cost of post-harvest materials. It is recommended that farmers should source for credit and fund from informal sources in order to address the problem faced in the study area. Also, the price of post-harvest material should be made flexible and avoidable for farmers in the study area.

24 - 28 Oct., 2022

ABSTRACT

This work was carried out to investigate packaging, handling and storage practises of farmers and onion marketers in Zaria, northern Nigeria. Needed information were obtained through interviews and physical observation on the current practices used in storage, handling and packaging of onions from farmers and marketers. It was observed that onions were packaged in jute gunny bags, baskets made from palm fonds or bamboo and polythene bags. 30% of the respondents who are farmers and 20% of the respondents who are marketers actually and properly cure onions prior to storage. 60% of the respondents who are farmers and 50% of the respondents who are marketers properly sort onions prior to storage, floor storage of onions in poorly ventilated rooms or stead was the common practise of onion storage amongst the farmers and marketers.

INTRODUCTION

Onion (Allium cepa L.) is a vegetable crop, which belongs to the family Alliaceous. It is an important vegetable crop in Nigeria based on nutritional and medicinal values. Oladeji (2018) reported that Nigeria ranks sixth amongst the top ten producers of green onion, and eleventh in terms of dry onion production in the world. The crop is grown for its bulbs, which are used daily in every home for seasoning and flavouring of foods. Onion is a valuable ingredient in the diet due to its sugar, vitamin and mineral contents (Ole et al., 2004).

There are different types of storage structures used in different parts of the country. Most of these structures lack proper ventilation resulting in higher storage losses. The poor aeration and air movement resulted in rise of storage temperature, which in turn adversely affects the product physiology and pathology (Olanipekun, 2018). Olanipekun (2018) reported that Nigeria loses as much as 50% of its onion harvest due to postharvest losses as a result of poor postharvest practices occurring throughout the onion value chain, especially during transit. Gaps in knowledge on how to grade bulbs for marketing, how to properly handle, package and how to manage stored produce accentuate losses. With only few and poor storage facilities available, farmers are forced to sell the products at low prices during glut periods, reducing their income.

This work seeks to investigate the packaging, handling and storage practices of onion by farmers and marketers, the problems associated with such practices and to seek remedy to such practices. This study would be advantageous to onion farmers, marketers and consumers.

METHODOLOGY

Study Area

The study area is located at Sabon Gari in Zaria, Kaduna State at approximately latitude 11.0855°N and longitude 7.720°E from the equator as shown in Figure 1. The market location can be considered to be strategic as it is located at the middle of Zaria metropolis

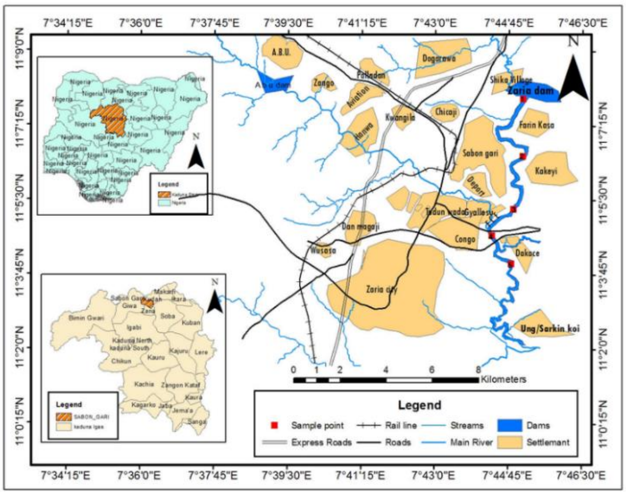

Figure 1: Study Area Map

Sampling Techniques

The sample of the study were the onion farmers and marketers selected through random sampling. In order words, it is the number of respondents which their responses were taken into consideration while taking the decision of the study. To be precise, random sampling technique was employed, this is a method by which selection of few individual member of the population is done in such a way that every other of the population has been represented.

Data Collection and Analysis

Needed information were obtained from a total of 20 farmers and marketers through oral interviews conducted by the researcher and physical observation on the current practices used in packaging, handling and storage of onions. Questions asked during the interview are presented in Appendix A-1. The Camry EK535 digital weighing balance was used to measure the weight of the onions in the packaged sack and a digital camera was used for photo capturing. The data collected were analysed by means of percentages and presented with statistical charts.

RESULTS AND DISCUSSION

Information was obtained from 5 farmers, 12 marketers and 3 respondents who doubled as farmers and marketers. Relevant questions were asked and on market physical observations were made. The farmers and marketers were able to answer the questions both individually and in groups. The results are presented in sections as follows.

Packaging Method

The results of the packaging methods employed by onion marketers and farmers as obtained from the respondents is shown in Table 1 and Figure 2

Table 1: Packaging Methods of onions

	Packaging Container	**Packaging Size**
Farmers	Jute Gunny Bags and Baskets	Large Sack (*solo*)

Wholesalers	Jute Gunny Bags	Large Sacks (*solo*) and ½ *solo*
Retailers	Jute Gunny Bags, Baskets from (palm fronds or bamboo) and Polythene bags	Variety of sizes based on Demand

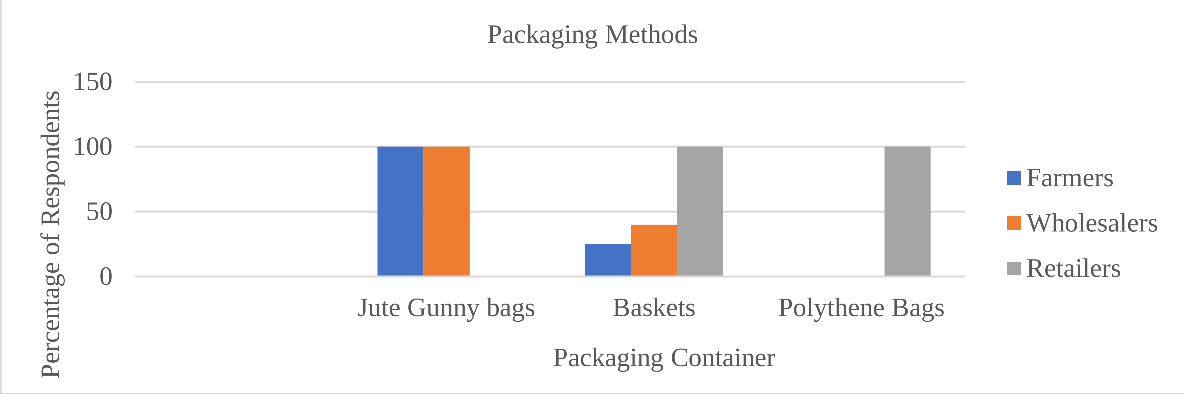

Figure 2: Packaging Methods amongst Farmers and Marketers

It was observed from Figure 2, that onions are mainly packaged in Jute gunny bags (sack), baskets and polythene bags. The largest packaging sack is locally known as '*solo*' weighing about 130kg. The jute bags or sacks are majorly utilized by farmers and wholesalers. Baskets made from palm fonds or bamboo are also used by farmers and marketers. Baskets come in different sizes depending on the quantity intended to be packaged. Large baskets are used by few farmers and wholesalers while the smaller baskets are utilized by retailers. Polythene bags are used solely by retailers.

The Polythene bags doesn't allow for sufficient aeration in the packaged onions, the baskets do not have a top cover, thereby, subjecting the packaged onions to influx of pests, diseases, dust and direct sunlight. The Jute gunny bags, allows for little aeration and protection from pests but when packaged weighing about 130kg, would not allow for ease of inspection especially when any of the bulb is injured or damaged.

<u>Handling Method</u>

The results of the handling methods employed by onion marketers and farmers as obtained from the respondents is shown in Table 2 and Figure 3

Table 2: Methods of handling and transportation of onions

	Handling and Transportation Method
Farmers and Wholesalers	Large trucks like *9 11*, lorries and large pickup vans
Large Scale Retailers	Small trucks like *J5* and cars
Small Scale Retailers	Motorcycle, cars and wheelbarrow.

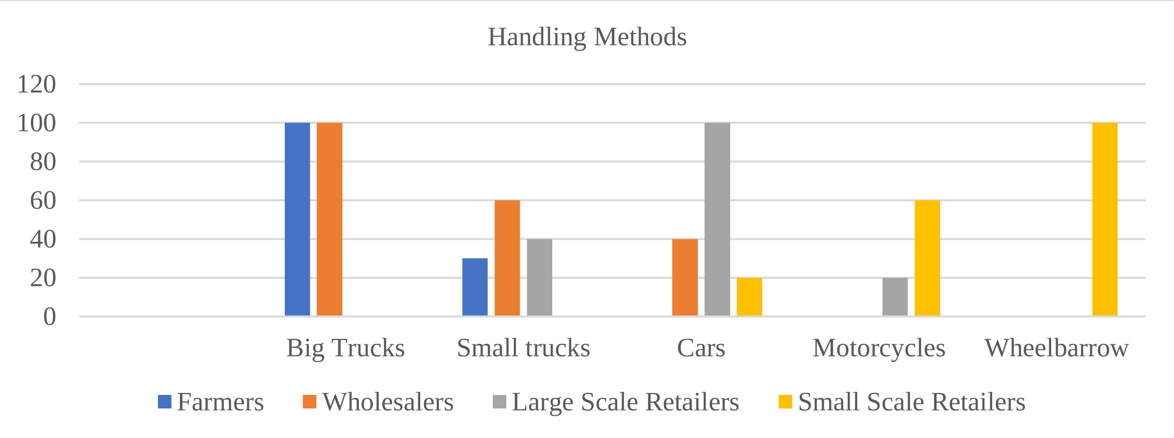

Figure 3: Handling and Transportation methods amongst Farmers and Marketers

It was observed as presented in figure 3 that, all respondents who were wholesalers and farmers utilize big trucks in handling and transporting onions, the middle men and retailers package onions in smaller gummy bags, baskets and uses wheel barrow, motorcycles, and cars as a mode of transport and handling and all small-scale retailers uses wheelbarrow for handling and transporting onions.

These methods of handling usually cause mechanical damage to the onions bulbs which in turn causes spoilage especially when used for long distance journey.

Storage method

The result for sorting and curing by onion farmers and marketers is presented in figure 4.

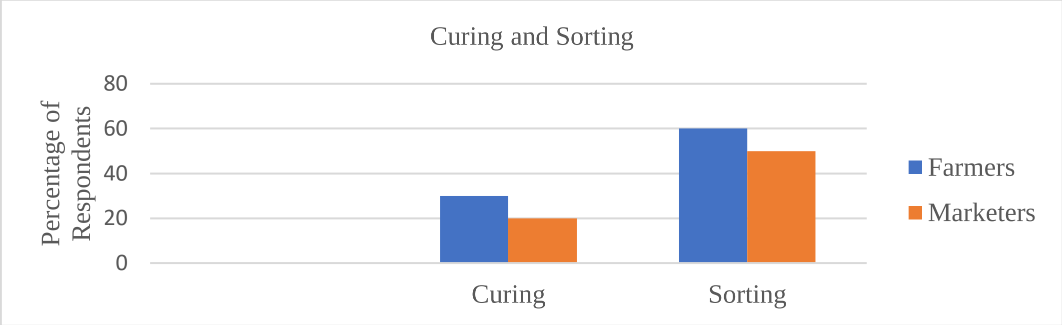

Figure 4: Curing and Sorting by onion farmers and marketers

It was observed as presented in Figure 4 that only 30% of the respondents who are famers, 20% who are marketers actually and properly cure onions prior to storage. 60% of the respondents who are farmers, 50% who are marketers properly sort onions prior to storage.

The farmers and marketers interviewed revealed that floor storage on dry soil majorly sandy soil in an open room is employed for onion storage in Zaria as shown in Plate 1

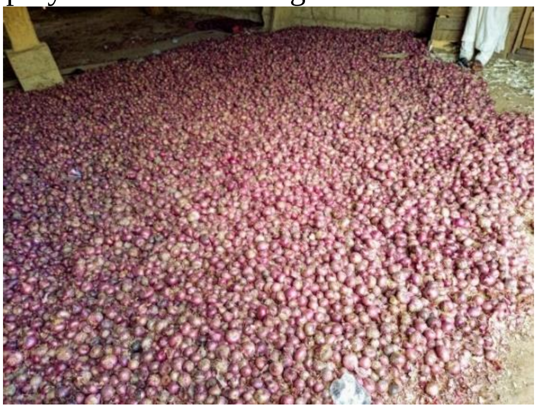

Plate 1: Floor Storage of Onions practised in Sabon Gari market, Zaria, Kaduna State.

Onions are loaded on the floor without proper grading and sorting. Basically, this storage method is accompanied with a lot of disadvantages such as less ventilation for relatively smaller sizes of onion bulbs, less bottom ventilation, pest infestation, and easy transfer of bulb diseases which bring about a lot of storage losses as reported by Deka *et. al.* (1995).

CONCLUSION

The following conclusion were arrived at after this research work:

i. Onions are packaged in jute gunny bags, polythene bags and baskets of different sizes by farmers and marketers
ii. Onions are handled and transported in big trucks, lorries, small trucks, cars, motorcycles and wheelbarrow
iii. Onions are not properly sorted and cured prior to storage
iv. Sandy soil floor storage in open rooms were predominantly used as the common storage practice in Zaria.

RECOMMENDATION
The following recommendations were proffered:

i. Better packaging material should be employed for onion packaging.
ii. Handling and transporting of onions should be done with care to prevent mechanical damage to the bulb.
iii. Proper sorting and curing of onions should be carried out prior to storage.
iv. Better storage methods should be researched upon.

ACKNOWLEDGEMENTS
The researchers would like to profoundly appreciate the guidance of **Prof. M. Isiaka, Prof A. M. I. El-Okene** and all staffs of the Department of Agricultural and Bio-Resource Engineering and Institute of Agricultural Research, Ahmadu Bello University, Zaria.

PROCEEDINGS
56th Annual Conference
Agricultural Society of Nigeria
24 - 28 Oct., 2022

ABSTRACT

The study analyzed economics of cocoyam production among rural households in Giwa Local Government Area of Kaduna State. Purposive sampling was used to select one hundred and twenty households and they were interviewed through the use of questionnaire. Data collected were analyzed using descriptive statistics, budgetary analysis and production function. The results in the budgetary analysis indicated that the average rate of (return per Naira invested) was 1.32. This indicates that for every ₦1 invested in cocoyam production in the study area a profit of 32kobo was made, for the production function education, household size and farming experience were significant at 1% level of probability and influenced cocoyam production among the rural households in the study area. That is 1.285,0.2874 and 2.583 unit increase in each of these that is education, household size and farming experience will bring about one unit increase respectively in the output, the business is worth investing in because it is profitable. The problem of lack of chemicals was the most severe constraint of the cocoyam farmers with 24.16% of the respondents attesting to this fact while about 18.39% of the respondents had the problem of lack fertilizer to improve their production. Therefore, it is recommended that agricultural inputs such as fertilizer should be subsidized and made available to farmers at the right time, for the farmers to improve their production and increase their yield in the study area. ii. Young farmers should be encouraged to remain in farming by providing different avenues to enlighten them on the benefits in farming cocoyam, iii. Inputs like chemicals should be provided for farmers or alternatives to be able to protect their crops from diseases and Government should educate the public on the high nutritional value in cocoyam, so as to encourage more farmers to be involved in its production.

Keywords: cocoyam, production, rural, households

INTRODUCTION

Root and tuber crops which are among the most important groups of staple foods in many tropical African countries Osagie, (1998) constitute the largest source of calories for the Nigeria population (Olaniyan *et al*, 2011). Cassava (Manihot esculenta) is the most important of these crops in terms of total production, followed by yam (Dioscorea spp), cocoyam (Colocasia spp and Xanthosoma spp) and sweet potato (Ipomoea batatas) (Olaniyan *et al*, 2011). The main root and tuber crops produced in Africa are: Cassava (Manihot esculenta) 53% of the world production, (Discorea spp) yam 96%, sweet potatoes (Ipomoea batatas L.) 70%, potatoes (Sotanum spp) 4% and other root crops Colocasia spp and Xanthosoma sagittifolium) 70%. Root and tubers are generally grown in countries located in the sub Saharan zones, notably in Nigeria, Ghana, Cote d' voire, Nigeria, Benin, Cameroun, Central African Republic, D.R.C, Tanzania, Mozambique, Angola, Uganda, Malawi, Madagascar and Rwanda. Nigeria is the largest producer of taro and cocoyam which makes up 35%, followed by Ghana 14%, Cameroon 5% and Cote d'voire 3%. The other countries in Africa produce 43% of the total 27,900.00 hectares of land out of the total available land under cocoyam production. Total production of root and tuber in sub-Saharan Africa was estimated as 254million tonnes per annum in 2012 (FAOSAT, 2013). Evidence abound that root and tuber crops are efficient sources of low-cost calories because of their adaptability to wide range of ecologies. Similarly, the rural poor in some African countries Aliyu, (2000), Nigeria inclusive obtain about 65-75% of their daily food energy from root and tuber crops. Scott *et al* (2000) and Chandara (2003), described root and tuber crops as crops that describe particular attention because many developing world's poorest and most food insecure households including Nigeria look at these crops as a contributory, if not the principal source of food nutrition and income. Cocoyam (Colocasia spp and Xathosomas spp) is grown in the tropical and subtropical regions of the world particularly in Africa for human consumption, animal feed and cash income for both farmers and traders (Onwueme and Charles, 1994). In Nigeria, it is regarded as a major crop especially in female headed household. The bulk of production of cocoyam is in the South East. Cocoyam leaves are used for making soup in various parts of the world. Cocoyam belongs to the family of Arcaceae. Cocoyam root and tuber crops are well known for their high nutritional content. It is an avoid because it is grown mainly for its edible germs, however their leaves can also be used for both medicinal and culinary purpose. It is mostly cultivated in countries like Nigeria, Asia, Pacific Island, Ghana and due to its high importance. Cocoyam (Colocasia esculenta and xanthosoma mafara. (L) are important carbohydrate staple food, particularly in the southern and middle belt areas of Nigeria (Asumugha *et al*, 2002). Nutritionally cocoyam is superior to cassava and yam in the possession of higher protein, mineral and vitamin contents in addition to having more digestible starch. Cocoyam which ranks third in importance and extent of production after yam and cassava is of major economic value in Nigeria (Udealor *et al*, 1996). It is highly recommended for diabetic patients; the aged, children with allergy and for other persons with intestinal disorders, boiled cocoyam peels, cut up, dried for some days and stored or milled into flour. The flour can be used for soup, biscuits, bread and pudding for beverages. The peels can also be utilized as feed for ruminants. The surplus of the product is supplied to the market in the rapidly growing urban centers. Ezenwa, (2010) observed that there has been a decline in the yield of cocoyam in the past few years. As population pressure on land continues to increase, the importance of cocoyam in land continues to increase, the importance of cocoyam in ensuring household food security should be given adequate recognition. Although presently yield is still below expectation which could be attributed to many factors such as climate variation, drought poor cultural practice among cocoyam grower, pest and disease infestations.

The Objectives of the Study Identify the inputs and output of cocoyam production in the study area, determine the profitability of cocoyam production in the study area, estimate the socio-economic factors influencing the profitability of cocoyam production in the study area and identify the constraints faced by the respondents in cocoyam production in the study area.

METHODOLOGY

Study Area

The study was carried out in Giwa Local government area of Kaduna State. The study area plays a significant role in agricultural production in Kaduna State. It is located on Latitude $11^0$12' North and Longitude $7^0$34' East. Giwa Local Government area of Kaduna State is bounded in the North by Funtua local Government area of Katsina State, in the west by Birni Gwari and Igabi Local Government area of Kaduna State also bounded in the west by Faskari Local government area of Kaduna State. In the east Giwa is bounded with Danja Local Government, and has a population of 300,200 persons mainly Hausa/Fulani with few other minor ethnic group like maguza was (NPC, 2006). There are eleven (11) districts in Giwa namely; Giwa, Gahara, Yakawada, Shika, Kaya, Patika, Tsibiri, Damawaye, Karakan, Kakangi, and Kidandan. The area is characterized by alternating dry and wet season with a mean annual rain fall of between 1000-1350mm. The duration in the area is about five months beginning from May and ends in October. The rainfall pattern in the area is therefore suitable for food crop production. The predominant occupation of the people in the Local Government Area is farming. In the Local Government Area crops grown include: Cocoyam, yam, Cassava, maize, Cowpea, sorghum, pepper, tomatoes, Groundnut, carrot, and potatoes while livestock such as cattle, sheep and chickens, guinea fowl are also fund in the area.

Sampling Techniques

Out of the eleven districts (11) of Giwa LGA, twelve (12) villages namely; Doka, Gangara, Patika, Tunburku, Tsibiri, Maguzawa, Yakawada, Kidandan, Kaya, Fatika, Galadimawa and Giginya, was randomly selected from the districts in study area. Ten (10) cocoyam farmers each from each of the villages were purposively selected to administer the questionnaires to them; this gave a total of one hundred and twenty (120) questionnaires respectively.

Data Collection

Primary data was used for the study. The primary data was collected by using well structured questionnaire and interview schedule.

Analytical Techniques

The following tools of analysis was used to achieve the stated objectives of the study. Descriptive statistics, budgetary Analysis and Production Function

Budgetary Analysis

This was used to analyse the cost and returns in cocoyam production as well as estimate the profit of the venture; as adopted by Akinpele and Ogbonna (2005)

Theoretically, the definitional equation is expressed as;

NFI = GFI -TC (TVC + TFC)

NFI = Net Farm Income, TVC = Total Variable Cost, TFC = Total Fixed Cost, TC = Total Cost

R/N = Return per naira.

Production Function

Production function was used to determine the physical relationship between the inputs and output of production to achieve objective (ii). It was expressed as:

$$Y = F(X1, X2, X3, X4, X5, X6 \ldots \ldots \ldots \ldots \ldots .. e)$$

Where,

Y= Output (N), X_1= Age (years), X_2= marital status (years), X_3= education(years)

X_4= Household size (number), X_5= farming experience, X_6= cooperative, b_1- b_6 = Regression Coefficients, b_0 = constant and e = error term

RESULTS AND DISCUSSION

Inputs in Cocoyam Production

Table 1 below show the highest value and lowest value of the inputs in cocoyam production in the study area fertilizer had the high value of ₦98,000 among the farmers who farm more than 5 hectare of land, why the lower price of ₦2000 are back yard farmers around the house gardens. Chemicals had ₦5,000 higher value and low value of ₦3000, seed have high value of ₦24,000 and low value of ₦600 and family labour highest value is ₦87,200 and low value of ₦1,200. The higher value of cocoyam production in the study area gives more outputs than the lowest value of those who farm for house consumption.

Table 1: Summary of Inputs used in Cocoyam Production in the study area.

	Fertilizer	Chemical	Seed	Family labour
Maximum	₦98,000	₦75,000	₦24,000	₦87,200
Minimum	₦2,000	₦3,000	₦600	₦1,200

Profitability of Cocoyam Production in the Study Area

The result in the Table 2 above revealed that the farmers used more cocoyam seed in the study area for the production of cocoyam. The quantity of seed used in was ₦17,234.71. The farmers in the study area mainly used unimproved seeds for their production. This was followed by the quantity of fertilizer which was ₦16973.13 which was used with the average market price of ₦7,500 per 50kg bag for the production of cocoyam. Also the labour costs consist of land preparation, planting, weeding, fertilizer application and harvesting. The family labour was computed on the basis of shortage of manpower. The wage rate varied according to farm operation to be performed. The average labour cost per hectare was ₦13,706.67 while the total cost of renting land and cost of depreciation of tools incurred on cocoyam production was ₦2500 and ₦1100 respectively and this constituted the total fixed cost. The result in the Table revealed that the total revenue (TR) was ₦77,208.34, while the total cost (TVC+TFC) was ₦58,593.03. the net farm income was therefore ₦18,615.31. The average rate of (return per Naira invested) was 1.32. This indicates that for every ₦1 invested in cocoyam production in the study area a profit of 32kobo was made. Thus, it could be concluded that cocoyam production in the study area though on a small scale, was economically viable. The finding is similar to that of Abdulrahman *et al* (2015) who observed that cocoyam production is profitable by reforming ₦1.69 to every ₦1.00 spent.

Table 2: Average Cost and return per hectare of Cocoyam Production

Variables	Values	% Contribution
Gross farm income	77,208.34	
Total cost (TVC + TFC)		
Inputs		
a. Seed	17,234.71	29.41
b. Fertilizer	16,973.13	28.97
c. Chemical	70,78.52	12.08
d. Labour	13,706.67	23.39
Total variable cost (a+b+c+d)	54,993.03	
a. Cost of renting land	2,500	4.27
b. Depreciation of tools hoe and cutlass	1,100	1.88
Total fixed cost = (a+b)	3,600	6.14
Total cost(TVC+TC)	58,593.03	
Net farm income = (NFI) = (GFI – TC)	18,615.31	
Return per Naira invested (GFI / TC)	1.32	

Multiple regression analysis of cocoyam production in the study area

The results of the analysis shows that the linear function had the best fit and was therefore chosen as the lead equation. This was due to the highest R^2 value of 0.521. This implies that 52% variability was explained by the independent variable while the remaining 48% was due to error term. The result further showed that the production of the cocoyam farmer was positively influenced by education, household size and farming experience. The result of this study has clearly shown that opportunities exist in cocoyam production. The result showed that there is a significant and negative relationship between years of experience production at 1% level of significance. That implies that cocoyam farmers with more years of experience exhibited significantly more production than farmers with less years of experience. This could probably be explained by the fact that farmers employ their years of experience over time as an opportunity to enhanced more production. This finding is consistent with the result in Table 3 also showed that there is a significant and positive relationship between education and production at 1% level of significance. This implies that cocoyam farmers with more education or who spent more years in school) exhibited significantly more production than farmers with less education, household size was also a very strong factor that influenced cocoyam production because the more the household, the more persons available in the form of family labour to help the farmers in his production.

Table 3: Multiple regression for respondents in the study area.

Variables	Parameters	Coefficients	St. error	T-Value
Constant		6.5642	0.839	0.403
Age	X^1	1.1018	1.491	0.139
Marital status	X^2	3.025	-0.174	0.862
Education	X^3	0.1999	1.285	0.000*
Household size	X^4	0.1548	0.2874	0.000*
Farm experience	X^5	0.9827	-2.583	0.000*
Cooperative	X^6	0.2289	-0.775	0.440
R=0.543				
R2=0.521				
Adjusted R^2 = 0.57				
Total observation = 120				

Constraints to Cocoyam production in the study area.

Tables 4 showed the problems faced by the cocoyam farmers in the study area. The problem of lack of chemicals was the most severe constraint of the cocoyam farmers with 24.16% of the respondents attesting to this fact. About 18.39% of the respondents had the problem of lack fertilizer to improve their production. According to the farmers fertilizer is made available when farmers are far into the production period. 15% of the respondents also reported lack of water and diseases respectively as the third major constraint they faced. About 10.84% of the respondents lacked capital to expand their production. Farmers also said that land size is not enough for them farming which caused shortage in their production and ranked as the fifth problem by 5.84%, lack of modern equipment was 4.16% which was revealed to boast their production was not available and making them to use crude tools such as hoe and cutlasses. Erosion problem in the study area made up 4.16% which washes the top soil making their production to be low. During the harvesting period lack of storage facilities made up 2.5% which makes the farmers to loose their products in cocoyam production. Although the last two constraints mentioned above were minor constraints faced by the farmers in the study area.

Table 4: Constraints of Cocoyam Farmers in the study area.

Constraint	Frequency	Percentage (%)
Lack of chemicals	29	24.16
Fertilizer	27	18.34
Diseases	18	15.00

Lack of water	18	15.00
Inadequate capital	13	10.84
Insufficient land	7	5.84
Lack of modern equipment	5	4.16
Erosion	5	4.16
Storage	3	2.5
Total	120	100

CONCLUSION

The findings of the study revealed that cocoyam production in the study area is profitable so that for every ₦l invested in cocoyam production in the study area a profit of 32 kobo was made. Also education, household size and farming experience were factors which influenced cocoyam production. The major constraints militating against cocoyam production identified were high cost of fertilizer, high cost of chemicals, lack of storage facilities and unavailability of land to increase their production.

RECOMMENDATIONS

i.Agricultural inputs such as fertilizer should be subsidized and made available to farmers at the right time, for the farmers to improve their production and increase their yield in the study area.ii. Young farmers should be encouraged to remain in farming by providing different avenues to enlighten them on the benefits in farming cocoyam, iii. Inputs like chemicals should be provided for farmers or alternatives to be able to protect their crops from diseases and Government should educate the public on the high nutritional value in cocoyam, so as to encourage more farmers to be involved in its production.

24 - 28 Oct., 2022

ABSTRACT

The study analyzed the economics of cassava production in Afikpo North LGA of Ebonyi State, Nigeria using 150 respondents selected through multistage and simple random sampling techniques. Data were collected with the aid of well structured questionnaire administered in form of interview schedule. Data collected were analyzed using descriptive statistics and budgetary techniques tools such as gross margin analysis, net farm income and Benefit-Cost Ratio. The result shows that majority of the respondents (65.33%) are females and 74.66% falls between the productive, active and energetic working age range of 31 – 60 years while 73.33% of the respondents are married. Furthermore, about 62.66% attended primary school and 84.65% have extensive household size of between 4 – 12. The result further reveals that farm size of cassava farmers in the area varied, 89.98% of the respondents fall between 0.6 – 2.0 hectares and a greater number of them (85%) practice multiple cropping system of cassava production while majority (93.66%) of the farmers have farming experience of above 6 years. The result of the constraints faced by cassava farmers in order of their severity include lack of storage facilities, low income, poor transportation system, land scarcity, high cost of agro-chemicals, inadequate capital, and lack of access to credit among others. The result of the cost and returns analysis using gross margin, net farm income and benefit-cost ratio reveals gross margin of N108, 050.00; net farm income of N96,050.00 per hectare obtained by cassava farmer and benefit-cost ratio of 1.67 indicating for every one naira invested in cassava farming, an additional N1.67kobo was realized. It was concluded that cassava production in the study area was profitable but with a lot of constraints. Therefore, the Government should assist in providing storage facilities and provide input incentives to encourage increased productivity and income to cassava farmers. Also, agricultural extension agents should be deployed to the area to facilitate the adoption of improved varieties and some other new technologies to boost cassava production in the locality.

KEY WORDS: Economic analysis, Cassava Production, Socio-economic variables, Gross margin, Constraints.

INTRODUCTION

Cassava (*manihot esculenta*), also called manioc or yuca, a tuberous edible plant of the spurge family (Euphorbiaceae) is said to have been introduced in central Africa from Brazil, South America in the sixteen century by the early Portuguese explorers. Cassava is among the main vitality agricultural produce for many African citizens. Empirical studies affirmed that in the 1980's, after rice, maize, and sugarcane, cassava was the fourth most important dietary source of calories produced within the tropics and probably still holds that position due to its great importance in the diet of Africans (Cock, 2011; Afedraru and Lominda, 2019) . Cassava flour, breads, tapioca, a laundry starch, and alcoholic beverages are derived from cassava (Esheye, 2019). The benefits of cassava to the Nigeria populace cannot be over emphasized. Apart from being a staple food in Nigeria, it is a source of energy, creates jobs, boost food security and national income (Ezedinma *et al* 2007 and IITA, 2017). In 2020, global production of cassava root was 303 million tonnes, with Nigeria as the world's largest producer, producing 20% of the world total; however, other major growers were Democratic Republic of the Congo and Thailand (FAOSTAT, 2019). Cassava was introduced in southern Nigeria by Portuguese explorers in the sixteenth century (Adeniji, et al, 2005). Cassava is a major economic crop in Nigeria, because of its tolerance of poor soils and low rainfall. Cassava acts as a famine reserve and offers flexibility to resource-poor farmers because it serves as either subsistence or a cash crop (Stone, 2002).

Although Nigeria is the largest producer of cassava in the world, the country is not an active participant in the international market on cassava when compared to Brazil, Indonesia and Thailand with lesser production output (Agom, et al, 2012) because 90% of the total cassava produced in Nigeria is for consumption, while only as low as 10% is for industrial use (Awoyinka, 2009). This study, therefore, intends to analyse the cost and returns of cassava production in Afikpo North Local Government Area of Ebonyi State, Nigeria as well as assess the current challenges of cassava production in the study area so as to proffer solutions to increase productivity and income. Specifically, the study described the socio-economic characteristics of cassava farmers; estimated the cost and returns of cassava production; and identified the challenges faced by cassava farmers in the study area.

METHODOLOGY

Study Area

The study area was Afikpo North Local Government Area (ANLGA), Ebonyi State, Nigeria. ANLGA is situated in the southern part of Ebonyi State. Afikpo is the second largest city in Ebonyi state. Its headquarters is in the town of Ehugbo and its important communities includes; Amata, Unwana, Itim, Ohaisu, Nkpoghoro, Ugwuegu/Amaizu, Ozziza, Amasiri and Ibii/Akpoha. It has an area of $240km^2$ in size with a population of 881,611 according Nigerian 2021 census. ANLGA has a tropical climate that is characterized by high temperature all year round. The area enjoys two distinct seasons, which are rainy season (April – October) and dry season (November – March). The climate supports the growing of the following crops, yam, cassava, oil palm, cashew, cocoa, vegetables, maize and rice

Sampling Procedure

The multi-stage and simple random sampling techniques were used in drawing samples from the study area. The first stage was a purposive selection of five (5) villages majorly known for its high production of cassava, namely; Ugwuegu, Amaizu, Nkpoghoro, Ohaisu and Ozziza, out of the nine villages in the Local Government Area. The second stage involved simple random selection of twenty (30) cassava farmers from each of the selected communities giving a sample size of 150 respondents for the study area. Structured questionnaire and oral interview schedule was used to collect data. Descriptive statistics such as percentages and frequencies as well as mean score likert scale were used to describe the socio-economic characteristic of the respondents and constraints faced by cassava farmers respectively in the study area. Budgetary techniques were used to estimate cost and returns on cassava production in the study area.

Data Analysis

Budgetary technique analysis such as gross margin, net farm income and benefit-cost ratio were used to estimate the costs and returns of cassava production in the study area. According to Okon and Okorji (2014), farm budgetary analysis enables the farmer estimate his total costs as well as the total revenue accrued to his enterprise within a farming season. Gross margin analysis (GMA) is a simple, reliable tool to assess the financial performance of an enterprise. Thus, gross margin (GM) is the difference between total revenue (TR) and the total variable cost (TVC) (Olukosi and Erhabor, 1998)

The gross margin is calculated as follows;

GM = TR –TVC

Where; GM = Gross Margin from cassava production (₦)

TR = Total Revenue from cassava production (₦)

TVC = Total variable cost from cassava production (₦)

While the net farm income (NFI) is calculated as follows:

NFI = TR – TC

The total cost of production (TC) is defined as TC = TVC + TFC

TFC = Total fixed cost (rent on land) (₦)

Also, benefit-cost ratio (BCR) is calculated as follows:

BCR = TR/TC

RESULTS AND DISCUSSION

Socio-economic Characteristics of the Respondents:

The socio-economic variables of cassava farmers may influence their decision regarding scale, enterprise diversification and production processes. The result of the socio-economic characteristics of the respondents is presented in table 1 below.

The result shows that majority of the respondents are females (65.33 %.) while the age range of active farmers is between 21-61 years which constitute 83.99% of the cassava farmers in the area with a mean of 45 years. The result further shows that 73.33% of the respondents are married. Furthermore, about 62.66% attended primary school and most of the respondents (84.65%) have extensive household size of between 4 – 12 with a mean family size of 9, indicating enough family labour and less been spent on hired labour. The result further reveals that farm size of cassava farmers in the area varied, 89.98% of the respondents fall between 0.6 – 2.0 hectares, the mean farm size being 1.23 hectares implying that farmers operate on a small farm holding of less than 1.5 hectares this is because they acquire their land predominantly through family land (Nandi, et al, 2011). Given the small farm size, 85% engage in multiple cropping system of cassava production in order to maximize the farm land. Majority (93.66%) of the farmers have farming experience of above 6 years implying that farming is their major occupation and means of livelihood.

Table 1: The distribution of socio-economic characteristics of respondents in the study area.

S/N	Variables	Frequency	Percentage	Mean
1.	**Gender:**			
	Female	98	65.33	
	Male	52	34.66

Major constraints faced by respondents in the area:

During the field work, the respondents were asked to indicate the extent to which some hypothesized constraints were binding to them. This was done using a four point likert scale namely, strongly agreed = 4, agreed =3, disagreed = 2 and strongly disagreed = 1 with a mean likert scale of 2.5. The table 2 below represents the result of constraints faced by farmers in order of their severity. The weighted mean of 2.5 was used as the critical value for comparing the order of severity. Result shows that all the listed constraints were considered as binding. At a mean of 3.6, lack of storage facilities is the most critical of all the constraints, followed by low income with a mean of 3.54, and poor transportation system with a mean of 3.47. Others are land scarcity (3.46), high cost of agro-chemical (3.36), inadequate capital (3.30), and lack of access to credit (3.28) among others. The result obtained in this study is consistent with that of Kuye (2015), who reported high cost of inputs as the constraints faced during cassava production in South South Nigeria. Also the result of this study agrees with findings of Itam, Ajah and Agbachom (2014) who conducted a similar study in Akpabuyo Local Government Area of Cross River State, Nigeria. However, constraints with less impact includes lack of processing facilities (2.80), low price of finished product (2.63), and cost of planting materials (2.58) while pests and diseases attack (2.1) was considered as not been a constraint. These constraints identified often lead to losses in terms of crop productivity, extra financial and material cost as well as have negative implications on the net returns of cassava eEnterprise. The findings of this study further confirm the report of Esheya (2019) in Ohaukwu local government area of Ebonyi State.

Table 2: Major Constraints Faced by Cassava Farmers in the Study Area (N = 150)

S/N	Constraints	Strongly Agreed	Agreed	Dis-agreed	Strongly Disagreed	Mean	Rank	Decision
1.	Land scarcity	95(380)	35(105)	15(30)	5(5)	3.46***	4rd	Accept
2.	Cost of planting material	6(240)	80(240)	59(118)	5(5)	2.58*	12th	Accept
3.	Lack of processing facilities	30(120)	77(231)	26(52)	17(17)	2.80*	10th	Accept
4.	Lack of improved cassava varieties	56(224)	54(162)	30(60)	10(10)	3.04**	9th	Accept
5.	Inadequate capital	78(312)	56(168)	16(32)	-	3.30***	6st	Accept

Cost and Returns of Cassava Production in Afikpo North LGA

The summary of costs and returns to cassava farmers in Afikpo LGA, Ebonyi State is presented in Table 3 below. The profitability of cassava production was determined using budgetary analysis such as gross margin, net farm income and benefit-cost ratio to estimate the cost and return. Gross margin is the difference between the Total Revenue and Total Variable Cost while Net Farm Income is the difference between the Total Revenue and the Total Cost accrued within a specific production period. Results show that at ₦131,900.00, the total variable cost (TVC) was higher than the total fixed cost (TFC) of ₦12,000.00 per hectare of cassava production in the study area. The result further showed that the total variable cost of ₦131,900.00 accounted for 92% of the total cost while the total fixed cost component of ₦12,000.00 accounted for 8% of the total cost. The total cost (TC) per hectare of **₦143,900.00** was incurred in cassava production with a total revenue of ₦239,950.00 showing a net farm income (NFI) of **₦96,050.00.** This result shows that cassava production in the study area was profitable which agreed with the findings of Esheya (2019) who reported a net farm income of ₦89,734.00 per hectare of cassava production in Ohaukwu Local Government Area which is also in Ebonyi State. The result also shows that for every one naira investment in cassava production in the study area 67 kobo is earned which shows a benefit-cost ratio of 1.67. This is also in support of Sanusi et.al (2020); Toluwase and Abdul-raheem (2013) who asserted that cassava production is a profitable venture and that an economic venture is considered viable if it has a positive gross margin and benefit-cost ratio greater than one. The results therefore suggest that cassava production in the study area is a profitable venture and a boost to food security and rural poverty alleviation.

Table 3: Average Cost and Returns of Cassava Production per hectare per Year in Afikpo North L.G.A

Variable Items	Unit	Quantity	Unit price (₦)	Cost (₦)	% of total cost (₦)
A. Variable cost					
Cassava cutting	Bundles	30	650	19,500.00	
Labour	Mandays			44,800.00	
Fertilizer	50Kg/bag	5 bags	8,000.00	40,000.00	
Herbicides	Litres	3	1,800	5,400.00	
Pesticides	Litres	3.5	1,800	6,300.00	
Other major expenses including transportation	-			15,900.00	
Total variable cost				**131,900.00**	91.66
B. Fixed cost					
Cultivated land rent	Hectare	1	12,000	12,000.00	8.33
Total cost				**143,900.00**	

C. Revenue				
Cassava stem	Bundles	115	250	28,750.00
Cassava tubers	Kg	11930	15	178,500.00
Quantity consumed	kg	2150	15	32,250.00
Total Revenue				**239,950.00**
Gross Margin/year				**108,050.00**
Net Farm Income				**96,050.00**
Cost- Benefit Ratio/ Return on Investment				**1.67**

Source: Field Survey Data, 2022.

CONCLUSION AND RECOMMENDATION

Based on the findings from the study, it can be concluded that cassava farming enterprise is a profitable business venture with an average gross margin of N108, 050.00 and Net Farm income of N96, 050.00 and Benefit-Cost Ratio of 1.67 per hectare, meaning that for every one naira invested in the production, there is a profit of N1.67 kobo obtained. This shows that cassava production in Afikpo North Local Government Area of Ebonyi State, Nigeria is economically viable and lucrative. Although cassava production in the study area was profitable but lack of storage facilities, low income, poor transportation system, land scarcity, high cost of agro-chemicals, inadequate capital, poor access to credit, scarcity of labour, lack of improved cassava varieties, lack of processing facilities, and low price of finished cassava products were the severe constraint faced by cassava farmers in the study area. It is therefore necessary that farmers should be encouraged to invest more on cassava production in the area by government assisting to alleviate most these constraints faced by cassava farmers in the area. Thus, government should assist in providing modern storage facilities and provide input incentives such as credit facilities, agro-chemicals and improved cassava varieties at a subsidized rate. Agricultural extension agents should be deployed to the area to facilitate the adoption of improved varieties and some other new technologies to boost cassava production in the locality. Generally, the Government should encourage the youths who are sources of labour and more active in cassava production by giving them financial grants and/credit. This will discourage rural-urban migration for white-collar jobs.

ABSTRACT

The study analyzed the COVID-19 policies effects on cassava production in Khana Local Government Area, Rivers State, Nigeria. The specific objectives were to describe the socio-economic characteristics of cassava farmers in the study area, determine COVID-19 policies effects on cassava production, and identify challenges to efficient cassava production in the study area. Data for the study were collected via the use of questionnaires from 120 respondents, and were analyzed using descriptive statistics. The result showed that most of the respondents were male 57.50% while 42.50% were female, 36.67% were married. about 35.00% of the respondents were within the age of 31-40 years. The study concluded that COVID-19 pandemic lockdown policies had devastating effects on cassava production. The study recommended that proactive government intervention policies to stimulate economic growth that will generate positive effects on the local players in cassava farming sub-sector of the economy be put in place during post COVID-19 pandemic era.

KEYWORDS: Covid-19, Pandemic, Lockdown, Effect, Cassava, Production.

INTRODUCTION:

Cassava (Manihot spp) a perennial woody shrub crop with an edible root, was first cultivated in South America and introduced to Nigeria in the Sixteenth century (Adenji et al., 2005).The majority of cassava farmers cultivate small farm areas which are not conducive or economical for mechanization yet, Abass et al. (2014) have argued that without mechanization, using improved inputs alone will not sufficiently boost cassava production in Nigeria, Cassava is one of the fastest expanding staple food crops in cassava consuming countries and has continued to gain prominence among farmers, while the industrial demand is also rising consistently (Food and Agricultural Organization FAO, 2018).

Covid-19 pandemic far more than a health crisis has affected societies and economics (IFAD, 2020). It has threatened people in every country through devastating lives and livelihoods. Lederer (2020) tagged it as the most challenging crises since world war 11, which could bring a recession. It has disrupted public health in an unprecedented manner and thus exposed the agricultural value chain to economic uncertainties (Lederer, 2020). The use of public measures like physical distancing, household isolation, massive lockdown, and border closures to slow the spread of the new virus is no doubt working, but not without delivering a significant fall in economic activity. The demand and supply of goods had been in shocks (FAO, 2020b).

It is, therefore, essential to examine the COVID-19 policies effects on cassava production in Khana Local Government Area of Rivers State, Nigeria. The specific objectives of this study were to: describe the socio-economic characteristics of cassava farmers in the study area; determine the effects of Covid-19 policies on cassava production; and identify challenges to efficient cassava production in the study area.

METHODOLOGY

Study Area: The research work on COVID-19 policies effects on cassava production was conducted in Khana Local Government Area of Rivers State. Its administrative seat (headquarter) is in Bori. It has a land area of 560km^2 and an average temperature of 25^{0}c. The postal code is 504 with a coordinates of 4.6476^{0}N and 7.3949^{0}E. Their major occupations are: farming, fishing, and trading. Their estimated population was about 294,217 in 2006 census (NPC, 2006)**Sampling Procedure and Sample Size**

Multi-stage sampling procedure was adopted to select ten farming communities that are preponderance cassava producers. They are kereken Bo-ue, Sogho, Bianu, Zaakpon, Kaa, Kaani, Kor, Gwara, Nwiiyaakara and Lueku. The next stage was the random selection of twelve cassava farmers from each of the communities already selected, giving a total of one hundred and twenty respondents that were used for the study.

Data Collection; Primary source of data was used via the instrument of structured questionnaire.

Data Analysis; Data collected were analyzed using descriptive statistics such as mean and percentages.

RESULTS AND DISCUSSION

Socio-Economic Characteristics of the Respondents

Table 1 indicates the Socio-Economic Characteristics of the Respondents.

Characteristics	Category	Frequency	Percentage	Mean
Age (years)	21-30	13	10.83	
	31-40	42	35.00	
	41-50	30	25.00	45.5
	51-60	27	22.50	
	Above 60	8	6.67	
Gender	Male	69	57.50	
	Female	51	42.50	
Marital Status	Single	36	30.00	
	Married	44	36.67	
	Divorced	17	14.17	
	Widow	23	19.16	
Household Size	1-5	68	56.67	6
	6-10	52	43.33	
Educational Qualification	None	12	10.00	
	Primary	28	23.33	
	Secondary	33	27.50	
	NCE	16	13.33	

	Vocational	8	6.67	
	Adult Education	5	4.17	
	HND/Degree	18	15.00	
Farming Experience (yrs)	1-5	26	26.67	15.6
	6-10	30	25.00	
	11-15	35	29.17	
	16-20	18	15.00	
	Above 20	11	9.16	

Source: Field Survey, 2022.

Age of the Respondents

The respondents' age ranged from 21-69 years. The highest age range of the respondents was found to be within 31-40 years of age, representing 35.00%, closely followed by the age range of 41-50years representing 25.00%, while 22.50% is within 51-59 years. The respondents within the age range of 21-30years accounted for 10.83%, while those above 60 years of age represent 6.67%, the average age mean of the respondents was 45.5years.

Sex of the Respondents

Furthermore, 57.50% of the respondents were male, while 42.50% were female. This shows the dominance of male in cassava production.

Marital Status of the Respondents

The results on marital status showed that 36.67% of the respondents were married 30.00% were single, 19.16% were widowed and 14.17% were divorced.

Household Size of the Respondents

The result on household size indicated that 56.67% of the respondents had up to 5 persons, while 43.33% had between 6-10 persons in their household. The average family size was six persons. This implies that the household size of the respondents were relatively large. Thus, this may positively influence farming activities. This agreed with the earlier findings of Omoare et al.(2014) that large family size is an indicator of labour availability for various farming activities.

Educational Qualification of the Respondents

The respondents attained various forms of education. Although 10.00% had no formal education, 23.33% had a primary school, 27.50% had secondary education, 13.33% had NCE qualification, 6.67% had no vocational training, 4.17% had adult education, while 15.00% had higher diploma or degree. It was observed that 90.00% had formal education. The high level of education among the respondents, according to Oyediran et al. (2015), may encourage acceptance of innovation.

Farming Experience of the Respondents

The result on farming experience indicates that 26.67% of the respondents had up to 5 years of farming experience, 25.00% had between 6-10years of experience, while 29.17% of the respondents had between 11-15years of experience. The rest 15.00% and 9.16% of the respondents had between 16-20 years and above 20 years of farming experience.

4.2 Perceived Effect of Covid-19 Lockdown policies on Cassava Production

Statements	SA	A	D	SD
COVID-19 will improve	13	17	30	60

Cassava production	(10.8)	(14.2)	(25.0)	(50.0)
COVID-19 will affect the availability of labour for land preparation	55 (45.8)	43 (35.8)	14 (11.7)	8 (6.7)
COVID-19 may affect cost of cassava production	40 (33.3)	36 (30.0)	10 (8.3)	12 (10.0)
COVID-19 may cause Cassava losses	49 (40.8)	43 (35.8)	17 (14.7)	11 (9.2)
COVID-19 will affect the Quality of produce for sale and thus impact human health	36 (30.0)	38 (31.7)	20 (16.7)	26 (21.7)
COVID-19 will affect Cassava farming activities Negatively.	57 (47.5)	44 (36.7)	10 (8.3)	9 (7.5)
Low rate of production will affect commodity prices	50 (41.7)	41 (34.2)	18 (15.0)	11 (9.2)
COVID-19 will affect sales of farm inputs, chemicals and fertilizer.	63 (52.5)	35 (29.2)	16 (13.3)	6 (5.0)

NOTE: The figures in parenthesis are in percentage
Source: Field Survey, 2022

The result presented in Table2 shows the perceived effect of COVID-19 lockdown policies on cassava production. The resultsshows that majority of the respondents (50.0%) strongly disagreed that COVID-19 lockdown will improve cassava production. The perishability or spoilage nature of crops was experienced by (40.8%) of the respondents as a result of COVID-19 lockdown policies, it affected sales of farm inputs, chemicals, and fertilizer during cropping season (52.5%). The restriction on movement and global agricultural activities affected the commodity price of farming inputs, and the low rate of production of cassava also affected the related commodity prices (41.7%). The respondents (47.5%) strongly agreed that pandemic affected cassava farming activities negatively as it alters the farming cultural practices because of the lockdown. It affect the quality of produce for sale further and thus impacted human health (31.7%), and thus affected the availability of labour for land preparation (45.8%). Finally, (33.3%) of the respondents strongly agreed that COVID-19 may affect cost of cassava production.

4.3 Constraints to Efficient Cassava Production

Table 3 shows a summary statistics of the challenges to efficient cassava production in the study area (n=120)

Challenges	Mean	Ranking	Result	Remark
Shortage of healthy and good-quality planting materials	3.93	1	>	Agreed
High incidence of pest and diseases	3.82	2	>	Agreed
Unavailability of agro-chemicals and other insecticides	3.78	4	>	Agreed
Soil erosion problem	3.61	5	>	Agreed
Soil fertility problem	3.80	3	>	Agreed
Damage by livestock	3.00	6	>	Agreed

Criterion Mean: >3.00
Source: Field Survey, 2022.

Table 3 shows that all the enlisted challenges of cassava production were experienced by the respondents in the study area. These include shortage of healthy and good-quality planting materials, high incidence of pest and diseases, unavailability of agro-chemicals and other insecticides, soil erosion problem, soil fertility problem and damage by livestock as they all had a mean value that is greater than the criterion mean (>3.00).

CONCLUSION AND RECOMMENDATION

The study examined COVID-19 policy effect on cassava production in Khana Local Government Area, Rivers State, Nigeria. The study revealed that COVID-19 pandemic and lockdown had a devastating impact on farmers and cassava production. Based on these findings, the following recommendations were made: proactive government policies to stimulate economic growth that will generate positive impact on the local players in the cassava farming sub-sector of the economy be put in place to cope with the post-pandemic effect of COVID-19.

ABSTRACT

Moringa oleifera-cowpea intercrop and its cost benefit analysis in Sabon-Gari Local Government Area of Kaduna state, Nigeria was examined in this study. 50 farmers participated in the adoption process with the aid of structured questionnaire. Result of the gross margin analysis indicated that Moringa/Cowpea intercropping is a profitable farming with a net profit of ₦65,180 which without Moringa stood at ₦27, 680 representing 57.5% rise in profit for the intercropping. The naira spent value of ₦2.20 implied that on every naira invested, the sum of ₦1.20k gain was made at 120% profit value thus Moringa/Cowpea intercrop is a highly veritable and profitable agro-business. It is quite evident that the farmers are not fully aware of the modern ways of propagation and multipurpose uses of Moringa oleifera. The need to harness the numerous uses of Moringa oleifera through research work, farmers' participation, training and retraining of both extension workers and farmers, involvement of all stakeholders is thus recommended by this study.

Keywords: Moringa, Cowpea, Intercropping, Propagation, *Moringa oleifera*

INTRODUCTION

Intercropping has been defined as the growing of two or more crops simultaneously or during parts of the component crop life cycle on the same piece of land (Alamu, 2002; Yusuf, *et al*., 2008). This farming practice is commonly used by subsistence farmers in the semi-arid areas of Africa. It provides the farmer with a variety of returns from land and labour, often increases the efficiency with which scarce resources are used, and reduces the risk of high dependency on a single crop that is susceptible to environmental and economic fluctuations. The reasons for practicing intercropping are rational; however, despite this logic, few research resources have been allocated in the past for investigating the complex interaction between crops growing on the same piece of land. This situation has existed as a consequence of the transfer of western concepts that are considered to be good farming practices and the technical problems involved in experimenting with intercropping. As a result, the biological effects of one crop on another and the economic costs and returns of intercropping have not been well understood. And yet, scientists now accept that intercropping is important to the subsistence farmer and many are convinced that research into the interactions between crops growing together must be undertaken to provide answers that will improve agricultural productivity for the subsistence farmer (Bruce, 1980). In Nigeria, income of farmers who harvest, and store cowpea fodder for sale at the peak of the dry season have been found to increase by 25% (Dugje, *et al*., 2009). Cowpea also plays an important role in providing soil nitrogen to cereal crops (such as maize, millet, and sorghum) when grown in rotation, especially in areas where poor soil fertility is a problem. It does not require a high rate of nitrogen fertilization; its roots have nodules in which soil bacteria called Rhizobia help to fix nitrogen from the air (Dugje, et al., 2009). Since Moringa does not fix nitrogen, it is expected that intercropping it with cowpea will bring about beneficial interaction. Moringa (*Moringa spp.*) is one of the world's most useful foods, medicinal and industrial plants. Fuglie, (1999); Foidl, *et al*., (2001) and Fahey, (2005) have all documented extensively the wonder plant called Moringa. It is a fast-growing tree and is grown throughout the tropics for human food, livestock forage, medicine, dye, and water purification. Moringa is grown traditionally as backyard trees or hedges for its leaves which are used domestically as culinary. The increased awareness of the multiple uses of Moringa leaves and seeds for both domestic and industrial purposes is leading to an increased demand for it, hence a view to evaluate farmers' response to cultivate *Moringa oleifera* as intercrop, determine the cost and returns of intercropping *Moringa oleifera* and cowpea and identify the problems facing cultivation and processing of Moringa- Cowpea intercropping in the area.

OBJECTIVES OF THE STUDY

- to evaluate farmers' response to cultivate *Moringa oleifera* as intercrop
- determine the cost and returns of intercropping *Moringa oleifera* and cowpea
- identify the problems facing cultivation and processing of Moringa- Cowpea intercropping in the area.

MATERIALS AND METHODS

This study was conducted in Sabon-Gari local Government area of Kaduna State, Nigeria. It is estimated to cover an area of about 600sqkm and has an estimated population of about 1.2 million people according to 1991 census. The population is projected to be about 1.8 million people in 2011. It is located on latitude $11^0 12^0$ north of the equator and longitude $07^0 37^0$ east of the prime meridian. It has average annual rainfall of 1500mm. Humidity is low in January between 15-35% and high in July between 65-85%. Annual temperature is between 24-28oC. The soil is generally described as sandy loam. Major occupation of the people is farming, trading, fishing and civil servants. A random sampling procedure was used in the study and questionnaires were administered to all the respondent at the study areas

Descriptive statistics and Gross Margin Analysis were used to achieve the objectives of this study. Descriptive statistics involved the use of frequency distributions, percentages and ranking using pie chart. The gross margin analysis was employed to determine the difference between the farmers' gross income and total variable cost. The selected farmer's costs and returns per hectare of land cultivated and average cost and average revenue per hectare of land cultivated was obtained from the gross margin analysis.

The mode for gross margin is expressed as: GM = GI – TVC

Where: GM = Gross Margin (N)

GI = Gross Income

TVC = Total Variable Cost

Gross Margin is a good approximation of Net Farm Income since small scale farmers usually have negligible fixed costs (Olukosi and Erhabor, 1988).

RESULTS AND DISCUSSION

The result of farmers' response to intercropping of Moringa with Cowpea is presented in Table 1. About 42% of the farmers responded positively and are ready to go into Moringa-cowpea intercropping, 40% said no while 18% were undecided. This explains reservation people have to new innovation.

Table 1: Farmers' response to intercrop Moringa with cowpea

Responses	Frequency	Percentage (%)
Yes	21	42
No	20	40
Undecided	9	18
Total	**50**	**100**

Sabon gari local government area 2014

The results in Table 2 present the Costs, Returns and Profitability of Moringa/Cowpea Production.

The result showed that 1ha plantation of Moringa oleifera gave a return of thirty seven thousand five hundred naira (₦37, 500) whereas cowpea on the same land gave returns of eighty two thousand, four hundred naira (₦82, 000). The gross margin of ₦65, 180 was realized from Moringa/cowpea intercrop. Sole cropping of cowpea generated gross margin of ₦27, 680 representing 45.5% of the profit. It is also noteworthy that Moringa and Cowpea cost of production is complemented and not distinctive thus saving cost of planting them separately. The naira spent value of ₦2.20 implies on every naira invested, the sum of ₦1.20k gain is made thus Moringa/Cowpea intercrop is a veritable business and profit oriented.

Table 2: The Result of Gross Margin Analysis

Items of Costs and Returns (₦)	Total	% contribution
Income:		
Moringa seed Revenue	37,500	31.4
Cowpea Revenue	82,000	68.6
Gross Income	119,500	
Variable Costs:		
Land preparation	8,000	14.7

Moringa seeds	5,100	9.4
Cowpea seeds	6,720	12.4
Pesticides	4,000	7.4
Planting	2,800	5.1
weeding	13,200	24.3
harvesting	4,000	7.4
Transport	4,000	7.4
Logistics	6,500	11.9
Total Variable Costs	54,320	
Gross Margin (intercrop)	65,180	57.5
Gross Margin (cowpea)	27,680	42.5
Return per N spent	440,500	**120**

Sabon gari local government area 2014

In Figure 1, 60% of the population agreed that Moringa products are accessible, 36% did not agree and 4% undecided. This is implicative that there is future for Moringa marketing.

Figure 2 revealed that 72% of the population agreed that Moringa has market acceptability if processed while the remaining 28% did not agree. This result however strengthens the conviction that marketability of Moringa products is on the positive side.

Figure 3 revealed Farmers' response to reality of problems in Moringa intercrops. It was observed that 64% of the population agreed that there are challenges facing Moringa intercropping while remaining 36% do not see any challenge. This majority subscription is a factor negating farmers' readiness to involve in mass production. Figure 4 showed the ratio of farmers attempt to manage challenges facing Moringa intercropping. 32 farmers that agreed there are challenges facing Moringa cultivation, 75% had made attempt to resolve the challenges while remaining 25% did nothing. Figure 5 showed Farmers' success in resolving the challenges that only 29% were successful, 23% partially successful and majority represented by 48% were not successful.

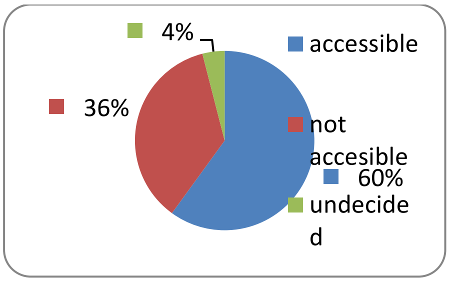

Fig 1: Farmers' response to moringa marketability

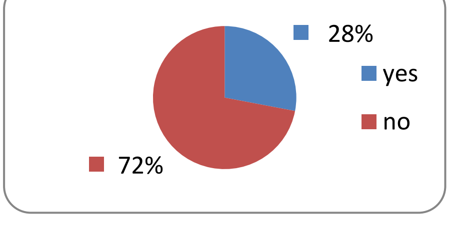

Fig 2: Farmers' response to market acceptability

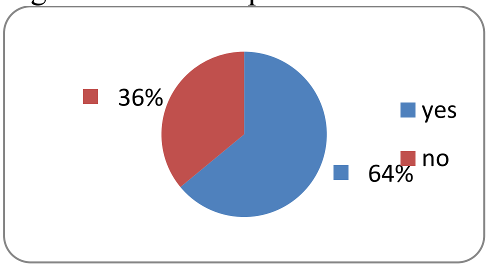

Fig 3: Farmers percentage facing challenges in Moringa management

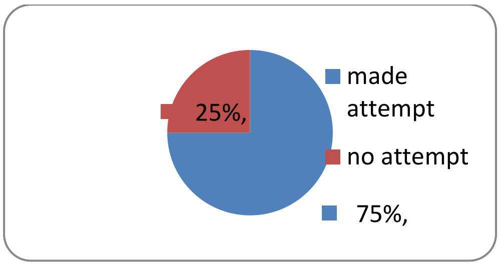

Fig 4: Farmers' percentage attempted to solve the challenges

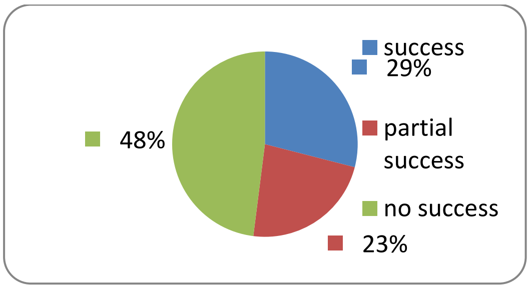

Fig 5: Farmers percentage of success in solving the challenges

CONCLUSION AND RECOMMENDATIONS

It is evident from this study that Moringa oleifera cultivation either as sole or intercrop is still a novel idea among Nigerian farmers despite its acclaimed economic values and importance. Many farmers are not aware of the multi various uses of the plant but a lot of them are willing to plant it if introduced to them. The need to place action on popularizing the plant among the Nigerian farmers is becoming evident. The result of this study has demonstrated beyond doubt that many farmers are aware of the existence of *Moringa oleifera* and are quite familiar with its traditional usage. Their understanding of its modern use is still at the mediocre level and thus the need to expose them further to its various processing becomes more relevant. Their readiness to adopt and utilize various technique learnt during the study is real and commendable but such enabling atmosphere of available land, storage facilities, equipment for processing, accessibility to all marketing chains are very evident. This study therefore recommends that there is a need for more training and awareness campaign for both farmers and extension agent in harnessing all the potentials of Moringa.

ABSTRACT

Profitability of cocoyam production in South East, Nigeria was studied using 400 sampled farmers. Structured questionnaire was used to collect primary data. Percentage responses and Net farm income were used to address the objectives of the study. The result of data showed that cocoyam production was profitable in the study area with Net Farm Income of 660,800 and Benefit cost ratio of 0.33. Also, the major constraints to cocoyam farming were; poor access to credit and high cost of labour. The need to enhance farmers' access to credit and labour saving devices were recommended.

Keyword Profitability, Cocoyam, Production, South East, Nigeria**.**

INTRODUCTION

The importance of cocoyam in enhancing economic growth is well acknowledged. Its prominence lies on ensuring food security, income generation and nutritional enhancement (FAO, 2020). Cocoyam compare to other roots and tubers have some intrinsic features that endeared it's production, included not having vines to stake as in yam (*discorea sp*), no strong obstructing stem as in cassava (*Manihot spp*) and no entangling vines like in sweet potato (*Ipomea batata*) which may obstruct its production (Okoye, *et al;* 2009),as yielding 30 – 60 metric tons/ha more than any root and corms, very low in starch gains, prone to mechanization using machinery, equipment and selection of clones, to reduce labour costs of production from 49% to 25% (NRCRI, 2021).

Nigeria is the largest producer of cocoyam in the world in terms of volume of production with the annual output of 5,068,000 metric tons/annum in 2019, (which represents 37% of the world output of cocoyam) as against the potential of 160 million metric tons/annum (FAO, 2020). The inability of the crop to meet its potentials could be correlated to storage problems, increasing input costs, labour scarcity, land scarcity, inadequate technical know-how among cocoyam growing farmers, lack of extension services, poor road network, perishability of planting material, unavailability and ignorance in the use of agrochemicals (fertilizer, pesticides etc) (NRCRI, 2021). The effect of the aforesaid problems is low productivity, leading to low yield. Therefore, there is need to assess the farmers' socioeconomic characteristics as it affects their performances in farming and their productivity in terms of profit accruing from their cocoyam production in the study area. This could aid in formulation and implementation of policies that will propel the farmers to improve on their productivity and among others. The main objective of the study is to determine the profitability and constraints to cocoyam production in the study area.

MATERIALS AND METHODS

The study was conducted in South east of Nigeria. The zone lies between 5 9'and 7 75'N of equator and longitude 6 85' and 8 46' East of Greenwich meridian time. .It has a total land area of 10952400 hectare. It comprises of five states; Imo, Anambra, Ebonyi, Abia and Enugu. Four states (Enugu, Ebonyi, Imo and Anambra) were purposively chosen because of intensity of cocoyam in these areas. Multi stage sampling technique was employed in selecting 100 cocoyam farmers from each state. A total of 400 respondents were interviewed with questionnaire and oral interview schedule for the study. Percentage responses and net farm income were used to capture the farmers' socio-economic characteristics, cocoyam profitability and constraints to the crop production in the study area.

Model Specification

Gross margin analysis. Gross margin = G.M. = TR – TVC ....(1)

i.e. G.m = $\sum_{1-1}^{n} P_1 Q_1 - \sum_{j-1}^{m} r_1\, x_i$ ....(2)

...The Net farm income can be calculated by gross margin less fixed input. The net farm income can be expressed as thus:

NFI = $\sum_{1-1}^{n} P_1 Q_1 - \left[\left(\sum_{j-i}^{m} r_i x_i\right) + k\right]$
....(3)

Where:
Gm =gross margin (₦), NFI = net farm income (₦), p1 = market (unit) price of output (₦), q = quantity of output (kg). Ri = unit price of the variable input (kg), xi = quantity of the variable input (kg), k = annual fixed cost (depreciation) (₦)

RESULTS AND DISCUSSION

Results and Discussion

Table 1 showed that 78% of cocoyam farmers were females, while 22%, males. Cocoyam cultivation according literatures is stereotyped female crop in many cocoyam producing areas (Ezedinma, 2006). As well, 64% of the respondents (17-41) were youths who can withstand strains and rigors associated with farming (Ume, *et al;* 2013). On farmers' farming experience, 40% of the farmers had farming experience of 10-14 years, while the least (10%), 1-4 years. Years of farming experience helps farmers to set realistic targets (FAO, 2020). Furthermore, the level of farming experience one acquired in a particular occupation, as reported by Eze and Okorji, (2004) could contribute significantly to his/her level of managerial ability and decisions in farm operations. These consequently results in high level of competence in utilization of resources for optimal productivity. Most (70%) of the respondents operated between farm size of 0.1-2.0 ha, which implies that the farmers are small scaled farmers. This is in line with apriori knowledge that farmers in most developing countries are small scaled in their operations and with their farms scattered (Okoye, *et al;*2009). Furthermore, 80% of the farmers had formal education, while 20% did not. The high educational attainment is a desirable condition for agricultural development, since it augured well for extension services in transferring research result for sustainable food production (NRCRI, 2020). In related study in cocoyam production across gender in Enugu North agricultural zone of Enugu State of Nigeria. Okoye *et al;*(2009) reported that educational accomplishment enhances managerial skills, resource management, decision making and adaptability of an individual. for higher productivity to be attained.

Among the variable costs used in cocoyam production as in Table 2, the cost of labour, 50.815 was the highest, while cost of the physical input (cocoyam sett, fertilizer, and miscellaneous), 39.41%. The cost of labour as reported in farming among peasant farmers could be related to near zero of farming crops like roots, tubers and corms. As well, the urban drift of able-bodied youths for white "collar job", hence leaving those labourers (youths) to charge higher to keep afloat with those in urban area(Ume, *et al;*2016). Also, the Table 2 revealed that the total revenue was ₦940,000, gross margin of ₦688800; Net farm income; ₦660, 800 with Benefit cost ratio of 0.33. Table 3 shows the constraints to cocoyam production of which 91 % of the total respondents complained of poor access to credit and ranked first. Credit facilitates adoption of innovations in farming, encourage capital formulation and marketing efficiency (Ume, *et al;* 2013). The poor access to credit could because of delay in loan approval and late release of fund to farmers during planting season and short repayment period (Okoye, *et al;*2009). Addition, 87.5% of the sampled farmers encountered the problem of high labour cost and ranked second. Urban drift of youths and feminization of agriculture may have contributed in labour being inelastic and expensive, consequently low returns results (Ume, *et al;*2016). As well, the least, (36%) was Fulani herders problem. The recent ban of herders in the region could be attested for the low percentage contribution to the constraints.

Table 1: Distribution of Respondents According to Socioeconomic Characteristics

Factors	Frequency (n=120)	Percentage
Gender (dummy)		
Male	312	78

Conclusion and Recommendations

The constraints to cocoyam production in the study area were poor access to credit and high labour cost. There is need to increase farmers access to credit through microfinance bank and other financial institutions. As well, the need to develop labour saving devices such as hand driven ploughs through research and disseminate to the farmers.

ABSTRACT
Using data from 120 small-scale sugarcane farmers in Niger State of Nigeria, this study examined the farmers' livelihood diversification and its determinants using logit regression. The results show that a majority of the farmers were male (87.5 percent), married (75.8 percent), having family size of 6-10 persons (30.8 percent), above 40 years of age with farming experience of above 10 years. Majority (93.3%) of the farmers diversify to generate more income, while 57% diversify to disengage from farming, 14% do not diversify due to availability of government grant. Access to market and weather condition significantly affect the farmers 'choice of livelihood diversification. The study recommends the promotion of non-farm employment as a good strategy for supplementing the income of farmers, as well as sustaining equitable rural growth.

Keywords: determinants, diversification, livelihood, Logit regression, sugarcane

INTRODUCTION
For many years, agriculture has been the primary source of income for rural residents. However, in recent years, as a result of low agricultural productivity, rural livelihoods have expanded to include not only agriculture but also business, services, remittance, and non-farm work (Jayne et al., 2014). Over time, household land holdings have decreased, and the agricultural sector's breadth has likewise shrunk (Djurfeldt, 2015). Agriculture is a risky investment due to the volatility in price and vagaries of weather. The risk and seasonality in agriculture has triggered the diversification of rural farmers from farming activities to other less risky and non-farm activities (Adepoju & Obayelu, 2013).

Livelihood comprises the capabilities, assets and activities required for a means of living (Oyinbo & Olaleye, 2016). A livelihood is sustainable when it can cope with and recover from the stresses and shocks and maintain or enhance its capabilities and assets both now and in the future without undermining the natural resource base (Roscher et al., 2022). Livelihood diversification is a process whereby households add new activities, maintain existing ones or drop others, thereby maintaining diverse and changing livelihood portfolios in order to survive and to improve their standard of living (Babatunde, et al., 2015).
Diversification is not only considered a risk management strategy, but also a means to increase overall income.
In Nigeria, where farm size average is small, poverty and food insecurity remain high among small landholders, the concept of sustainable agriculture through livelihood diversification should be viewed in the context of the need to improve farmers' economic conditions. All of this necessitates a thorough examination. Nevertheless, studies that have addressed this are rare in Nigeria to the best of researchers' knowledge. Hence this study to examine the livelihood diversification strategies employed by the sugarcane farmers, identify factors that determines the status of livelihood diversification strategies. Knowledge of livelihood diversification strategies and their determinants could be of great value for policy makers in designing effective diversification activities to improve small-scale farmers' livelihood.

MATERIALS AND METHODS

Study Area

The study was conducted in Niger State of Nigeria. Niger State is situated in the north-central geopolitical zone of Nigeria. The state lies between latitude 3.20° East and longitude 11.30° North, with a land mass of 86,000km^2 the state shares a country border with the Republic of Benin (West) and state borders within Nigeria. These include the Federal Capital Territory (FCT) on the South-East, Zamfara (North), Kebbi (North-West), Kwara (South-West) and Kaduna (North-East). Due to soil fertility and ample supply of water, the major crops cultivated in the state include sugarcane, rice, maize, and wheat.

Data Sources

A two-stage sampling technique was used to select the sample for the study. The first stage involved the purposive selection of two Local Government Areas (LGAs) in the state: Mokwa and Paikoro, due to the high prevalence of sugarcane production in the area. The second stage involved the random selection of 120 small-scale sugarcane farmers from the list of Sugarcane Farmers Association in the selected LGAs. Data for the study were collected using interview guide with structured questionnaire and were analysed with descriptive statistics and logit regression. Descriptive statistics was used to analyse respondents' socio-economic characteristics, livelihood strategies employed and constraints. The determinants of diversification status of farmers were analysed with logit regression.

Model specification ***(****Logit Regression****)***

The dependent variable (Zi) is dichotomous and takes the value 1 for the diversified farmers and 0 for the non-diversified farmer (Awotide, 2011). The model is given as:

$$Z_i = b_0 + b_1 X_1 + b_2 X_2 + b_3 X_3 \dots + b_8 X_8 + U$$

Where: Zi =Livelihood diversification status of the household (1=diversified, 0=otherwise)
X_1 = Access to Market (sold directly =1, through 3rd party, agents/others = 0)
X_2 = Level of Education

X_3 = Weather uncertainty (Dummy)
X_4 = Amount of Credit Accessed (Naira)
X_5 = Risk and Uncertainty (Dummy)
X_6 = Sugarcane Income (Naira)
X_7 = Farm location (Km)
X_8 = Subsistence Farming (Dummy)
U = Error term

RESULTS AND DISCUSSION

Socioeconomic Characteristics of the farmers

The result of the socio economic characteristics of the farmers shows that most of the farmers (88%) are male, and has most of their ages above 40 years. The arduous tasks associate with sugarcane production may explain the limited female participation. Majority of the farmers been in their middle age could result in positive effect on the efficiency of their farming.

Majority of the respondents (76%) with a mean household size of 8. Most of the farmers, 27%, have no formal education. This can negatively affect their adoption of new technologies.

Determinants of livelihood diversification among sugarcane farmers
Access to market and Weather (climate) has significant effect on the livelihood diversification of the farmers with a significance level at 0.1 and 0.05 respectively as shown in table 2.
Access to market significantly affect the farmers' choice of livelihood diversification, with a positive coefficient of 3.9. This implies that; increase in access to market will cause the farmers to diversify their source of livelihood from sugarcane farming into other line of production or agribusiness. This might be because of the several opportunities market brings and the likelihood of making profit from activities which require lesser labor in comparison to farming.
Also, weather is significant with a positive coefficient of 4.2. This implies that increase in the uncertainties of weather condition affects the farmer's choice of diversifying from sugarcane production into other line of agribusiness or completely leave production for marketing or distribution of agricultural product.

CONCLUSIONS

The study confirmed that sugarcane farmers in the study area are predominantly middle- aged male and they earn their income majorly through on-farm income and seldom through off-farm and non-farm income.

- The study recommends the promotion of non-farm employment as a good strategy for supplementing the income of farmers as well as sustaining equitable rural growth.
- Training on Climate Smart Agriculture for the farmers by the extension agents is also recommended.
- Also, Government should provide basic standard infrastructures such as good accessible roads that connects farm to market for easier transportation.
- Additionally, Government or Non-Governmental associations should make loans, grants and even skill acquisition experience available to farmers who are willing to diversify their livelihood.

ABSTRACT

Agriculture is dependent on climate for optimum production. Climate variability alter the level of expected output because climate has shifted from its normal or usual course. It has been variously documented that climate variability had impacted crop production negatively through crop damage leading to persistent low yield and thereby affecting farmers' socio-economic status. The study assessed the opinionated effects of climate variability on socio-economic status of arable crop farmers in Ogun state, Nigeria. Multi-stage sampling procedure was used to select 230 respondents. Majority (68.8% and 59.4%) of the respondents claimed that radio and extension agents, respectively, were the major sources of information on climate variability in the study area. Farmers who felt in their opinion that they eat what is available due to the effect of climate variability on their socio-economic status were ranked 1st. The result of Spearman Rho at p=0.01 revealed that there was a strong positive relationship between opinionated effects of climate variability and socio-economic status. It was therefore recommended from the findings that farmers must be proactive in taking actions on farming activities to mitigate the effects of climate variability.

INTRODUCTION

Arable crop and its production had gained prominence in ameliorating the challenges against food availability and food security especially in developing and underdeveloped countries of the world (Osabohien, Osabuohien and Urhie, 2018). Arable crops remain staple food in Nigeria as there is evidence that every household consume arable crops in different forms on daily basis (Sadiq, Oyelere and Olagoke, 2014). In the current food production and commerce scenarios, arable crops are playing roles of meeting food consumption and revenue generation, and consequently improvement in the socio-economic status of the farmers. Socio-economic status is used in determining the social ranking of an individual in relation to wealth, education, income, power as well as work status in the society. Therefore, the socio-economic status of the farmers will always be affected by the level of their farming productivity or output. Arable farmers' output is determined by total yields of the entire crop planted. In this situation, it is worth mentioning that what affects crop yields will affect farmers' socio-economic status. Climate variability will alter the level of expected output because climate has shifted from its normal or usual course. It has been variously documented that climate variability had impacted crops and that crop production was negatively badly affected through crop damage leading to persistent low yields thereby affecting farmers' socio-economic status (Sawe, *et. al.,* 2018; Islam, *et. al.,* 20016). A priori expectation is that when there is climate variability (a shift from normal climate situation) may not be so favourable to crop production (Oyelere, *et. al.,* 2019) which affect yields hence, socio-economic status.

To know what farmers think about the effects of climate variability on their crops is very germane to the determination of their crop yields. However, crop yield is a relevant indicator of knowing the level of farmers' wellbeing in the continuum of social ranking or socio-economic status. In order to know farmers' stance about the effects of climate variability on their socio-economic status, it is necessary to gather relevant information about their opinions. According to Kramer and Wadud (undated) gathering information on opinions is the process of finding out where people (in this case, arable crop farmers) stand on a particular subject matter in this situation which is the opinions about the effects of climate variability on socio-economic status of arable crop farmers. Hence, the study assessed the opinionated effects of climate variability on socio-economic status of arable crop farmers in Ogun State, Nigeria. The specific objectives were to identify the various sources of information on climate variability available to the respondents, determine yields and revenues of the respondents and determine the opinionated effects of climate variability on socio-economic status of the respondents in the study area. The only hypothesis was stated in null form that there is no significant relationship between opinionated effects of climate variability and socio-economic status of arable crop farmers in the study area.

METHODOLOGY

Structured interview schedule was employed to elicit the needed information from the respondents. Multi-stage sampling procedure was used to select 230 respondents for the study. Abeokuta and Ilaro zones of Ogun State Agricultural Development Programme (OGADEP), were purposely chosen to avoid sampling the same vegetation zone. Twenty percent (20%) of the blocks in each zone were randomly selected for the study; making 7 blocks in Abeokuta zone and 5 blocks in Ilaro zone. Ten percent (10%) of the registered arable crops farmers from the selected blocks were randomly chosen to give one hundred and twenty (120) and one hundred and ten (110) arable crop farmers from Abeokuta zone and Ilaro zone, respectively to give two hundred and thirty respondents (230) for the study during 2017-2019 cropping seasons.

RESULTS AND DISCUSSION

Mean yields and revenues of selected arable crops in three planting seasons

Table 1 shows the trend of yields and revenues of selected arable crops in three consecutive planting seasons in the study area. The apparent trend of maize yields and revenues between 2017-2019 cropping seasons revealed a downward trend. Also, when compared farmers' yields with expected yields, it resulted in reduced yields and this translated into sustained colossal losses. Data in the Table further revealed that in year 2017, percentage revenue loss for maize was 77.1%, in the year 2018, it was 78.1% while in the year 2019, the percentage loss was 80.3%. This huge loss, all things being equal, could be traced largely to climate variability. Yield trends of ysam production during 2017-2019 cropping seasons showed a sustained yield loss and supposedly, reduced revenue leading to high percentage loss in expected revenue. The trend of percentage revenue loss for yam in 2017, 2018 and 2019 were 76.1% 76.8% and 79.7%, respectively. Equally, trends of cassava yields in 2017-2019 showed a reduced trend. By extrapolation, the percentage of expected revenue loss kept increasing; such as 40.47%, 49.25% and 89.5%, respectively. A cursory look at the data suggested that the trends of yields and expected revenues of the three crops under review had been reducing. Maize was the most hit by the effect of climate variability when juxtaposing the data of the three crops. This indicated that maize was easily vulnerable to the shocks arising from vagaries of weather. Although maize has high production potentials, Olaniyan (2015) asserted that repeated drought, erratic rainfall, and stoppage of rainfall during cultivation period hinder optimum production of maize. However, yam and cassava were not so much affected or devastated like maize. Probably, this was due to fibrous root of maize that could not hold water while yam and cassava are tuberous crops whose tubers are prone to holding water. Data further revealed that cassava was least affected by vagaries of weather as it was not phenomenally affected. This was an indication that cassava was a tough crop that has the capacity to withstand the effect of climate variability than maize and yam.

Table 1: Average yields and revenues of selected arable crops in three planting seasons

Planting seasons	Farmers' mean yields(ton)	Average price per ton (N)	Average revenue(N)	Expected yield / ha	Recommended expected revenue(N)	% Loss
Maize						
2017	2.38	44,500	105,910	10.4	462,800	77.1
2018	2.28	52,000	118,560	10.4	540,800	78.1
2019	2.05	68,000	139,400	10.4	707,200	80.3
Yam						
2017	2.39	28,000	66,920	10.00	280,000	76.1
2018	2.32	35,000	81,200	10.00	350,000	76.8
2019	2.03	42,000	85,260	10.00	420,000	79.7
Cassava						
2017	6.31	10,000	63,100	10.6	106,000	40.47
2018	5.38	16,000	86,080	10.6	169,600	49.25
2019	3.39	22,000	24.580	10.6	233,200	89.5

Opinionated effects of climate variability on socio-economic status of respondents

Results from Table 2 have shown the opinionated effects of climate variability on socio-economic status of arable crop farmers in Ogun State, Nigeria. Results from Table 3 reveal that farmers, who felt in their own opinion that they eat whatever is available ranked 1st while those who opined that they cannot feed their children as a result of the effects of climate variability ranked 2nd. Table 3, also reveals that all the parameters investigated were crucial to the standard of living of the respondents, and in the opinions of the respondents had negatively impacted as a reason of climate variability. Hence, their socio-economic status was badly affected because Akinbile (2007) had described socio-economic status as the relative position which an individual occupies in a society concerning the amount of cultural possession, effective income, material possession, prestige and social participation. This then implies that the respondents' socio-economic status had been negatively affected by the effects of climate variability because education, income and health which are socio-economic status indicators had been badly affected as revealed in the table.

Table 2: Opinionated effects of climate variability on socioeconomic status

Opinionated effects of climate variability	WMS	RANK
We eat what is available	3.00	1st
I cannot feed my children	2.98	2nd
My children go to school in turns	2.91	3rd
Borrowing money from people	2.91	3rd
Cannot service membership in social organisations	2.91	3rd
Annual income has reduced	2.89	6th
Enterprise reduce to subsistence level	2.89	6th
Evasion of commodity tax	2.88	8th
Cannot build house	2.78	9th
Health deteriorating daily	2.78	9th
Many children cannot go beyond primary education	2.77	11th
I have withdrawn many children from school	2.72	13th
No possession of additional valuable materials	2.77	11th
Support towards community declined	2.70	14th
Swapping property for money	2.66	15th
I buy fairly used clothes	2.66	15th

WMS= Weighted Mean Score
Source: Field survey, 2020

Test of hypothesis

There is no significant relationship between opinionated effects of Climate variability and socio-economic status of arable crop farmers. Spearman Rho revealed the relationship between the opinionated effects of climate change and level of socio-economic status and was presented in Table 4. The r_s value of 0.985 and p value of 0.000 showed that there was a strong positive significant relationship at 0.01 level. It implies that the variability in climate has really affected the yields of arable crops; which translated into reduced income and socio-economic status that depends on farmers' income. Therefore, the biting/harsh effect of climate variability could have been the cause of low Socio-economic status of the arable crop farmers in the study area.

Table 3: Summary of Spearman's rho analysis showing relationship between opinionated effects of climate variability and socio-economic status

			Index SES	Index climate variability
Spearman's rho	Index SES	Correlation Coefficient	1.000	.985**
		Sig. (2-tailed)	.	.000
		N	320	320
	Index climate change	Correlation Coefficient	.985**	1.000
		Sig. (2-tailed)	.000	.
		N	320	320
**. Correlation is significant at the 0.01 level (2-tailed).

CONCLUSION AND RECOMMENDATIONS

The rurality of the respondents made them utilize the cheapest means of communication for getting information on climate variability. The yields and revenues accrued to the farmers in the study area had followed a reducing trend. Reduction in yields led to reduction in revenues to the farmers. In the opinions of the arable crop farmers in the study area, their socio-economic status was negatively affected. It was hereby recommended that farmers must be proactive in taking actions on farming activities to mitigate the effects of climate variability.

ABSTRACT

The study analyzed the composition of male and female headed cassava farm households. Total incomes from different sources in Umuahia Agricultural Zone Abia State and was guided by the following specific objectives; describe the socio-economic characteristics of male and female headed cassava based farm household in the study area; analysed composition of households was used in selecting 144 cassava-based farm households (consisting of 72 male-headed and 72 female-headed cassava-based farm households). The socio-economic profiles of male and female-headed cassava based farm households showed that the mean ages of male and female heads of cassava-based farm household's were54.09 and 46.42 years with mean 5.00 and 4.00 persons respectively and mean years of cassava farming experience 19.35 and 12.56 years respectively. The result on composition of annual total incomes indicated that all males and females-headed cassava farm households derive income from farming (48.07% and 56.69%) of annual total income in male and female-headed cassava farm households respectively. The study recommended that improved cassava varieties with short gestation periods should be extended to the farmers in the rural areas.

INTRODUCTION

Cassava makes a significant contribution to the rural economy's revenue and food security because of its ability to generate a respectable yield in a variety of soil types and its tolerance of drought (Osondu *et al*., 2014). Cassava production alone cannot provide sufficient livelihood opportunities for farmers hence there is a need for male and female headed households to embark in multiple income generating activities as a coping strategy to improve household livelihood and reduce poverty (Onwusiribe 2018). Both male- and female-headed agricultural families in Nigeria cultivate cassava more frequently than other crops.

Poor subsistence farmers are the principal growers of this crop, and women are mostly in charge of its processing into various products. The majority of Nigerian households who grow cassava rely on farming for the most of their revenue and survival, but occasionally they also participate in non-farming activities to augue their agricultural income (Odoemenem, 2013).

The headship of a household is usually identified with the person who has a greater authority in the household. Power and authority may be vested in the member who has control over the general affairs of the family unit, including decision making concerning economic, social and political interactions. Vander Toom (2015) asserts that while females are recognized potential household heads, in reality men are most often ascribed the headship position, a practice that still subscribes to the patriarchal view that men provide for the family while females nurture it. Thus, headship may be assigned without due regard to the actual economic contributions of the female members.

Multiple income generating activities refer to those incomes earned by the farmer from nonfarm income generating activities at different times of the year (Barrett *et al.*, 2001 and Carletto *et al*., 2007). Multiple motives prompt male and female headed cassava based households to diversify assets, incomes, and activities. According to the World Bank (2003), Lanjouw and Lanjouw (2001) male and female headed cassava based households world-wide embark in a variety of multiple activities to generate income. The engagement in multiple income generating activities is peculiar to rural farming communities in Africa. The major multiple income generating activities which the female headed cassava based households engaged in included food processing, trading, mat weaving and pottery, basket weaving, food vendoring, hair plaiting, petty trading, tailoring and collection of forest products (Oladeji, 2007). Also, male headed cassava based households embarked on multiple income generating activities such as black smiting, clothes weaving, carpentry, palm-tapping, welding, barbing, teaching, motorcycle (Okada) riding, brick layering, traditional medicine and transportation(Oladeji, 2007).

This research was guided by the following specific objectives to:

i. describe the socio-economic characteristics of male and female headed cassava based farm households in the study area;
ii. analyze composition of household's incomes from different sources in the study area;

RESEARCH METHODOLOGY

The study was conducted in Umuahia Agricultural Zone of Abia State, Nigeria. The sampling technique involved the use of multistage random sampling technique. In the first stage, three (3) Local Government Areas LGAs were randomly selected from the five LGAs that make up the agricultural zone. The selected LGAs were Ikwuano, Isiala Ngwa South and Umuahia North. In the second stage, two autonomous communities were selected randomly from each of the three selected LGAs, making a total of six (6) autonomous communities. The selected communities were Ibere, Ariam, Ama-AsaaNsulu, Ovungwu, Ibeku and Afaraukwu. This was followed by a random selection of two villages from each of the selected communities, making a total of 12 villages. From each of the chosen villages, a random selection of six (6) male-headed cassava-based farm households and six (6) female-headed cassava-based farm households was done using a list formulated with the help of natives. This gave a total of 144 cassava- based farm households (consisting of 72 male-headed and 72 female-headed cassava-based farm households). Primary data were elicited by use of a pre-tested and structured questionnaire for the study. However, 140 respondents' questionnaire were found usable for analysis.

Descriptive statistics such as frequencies, tables, means and percentages were used to analyze objectives (i) and (ii)

RESULTS AND DISCUSSION

Socio Economic Characteristics of Respondents

The Socio-economic profiles of male and female-headed cassava-based farm households in Umuahia Agriculture Zone is presented in Table 1. The Table shows that the mean ages of male and female heads of cassava-based farm households were 54.09 and 46.42 years. This implied that both male and female heads of cassava-based farm households were within the national active productive workforce age of 18 to 65 years and have the ability to withstand the rigours, strain and stress involved in cassava production (Onyenucheya and Ukoha, 2007).

Also, table 1 shows that the mean household sizes of male and female heads of cassava-based farm households were 5 and 4 persons respectively. This is a manageable household size. Higher household size can lead to high level of malnutrition, mortality, illiteracy, unemployment especially in the rural economy because income generated from different sources by the household may not be enough to take care of the needs of the family members which led to a change in family emphasis as reported (Ezeh, 2007).

Table 1 further shows that the mean years of cassava farming experience of male and female-heads of cassava households were 19.35 and 12.56 years respectively. This implies that headship of both groups of respondents were established and knowledgeable in cassava production. The number of years spent in farming give an indication of the practical knowledge acquired on how to overcome certain inherent problems in such a farm enterprise (Okolo, 2007).

Table 1: Distribution of Male-heads and Female-heads of Cassava-based Farm households by Socio-economic characteristics in Umuahia Agricultural Zone of Abia State, Nigeria

Variables	Male-Headed		Female-headed	
	Frequency (N=70)	Percentage	Frequency (N=70)	Percent age

Composition of Annual Income Generation Sources in Male-Headed and Female- Headed Cassava Farm Households

Table 2 shows the composition of annual total income and contributions of different income sources to total income of male and female- headed cassava farm households in the study area. The table shows that all male and female- headed cassava farm households derive income from farming, which however, accounted for 48.07% and 56.69% of annual total income in male and female- headed cassava farm households respectively. Crop farming (primarily cassava), which mainly was subsistence in nature, was the most important single source of income for the respondents, providing about 26.36% and 32.70 % of total income in male and female-headed cassava farm households respectively. Despite the growing skepticism on the role of agriculture (cassava production) in reducing poverty among rural households, this result shows that, it remains the major source of income for rural households (Van den Berg and Kumbi, 2001; Karugia *et al*., 2006).

A good proportion of the male and female- headed cassava farm households derive income from livestock enterprises, but income from this source was only 8.9% and 13.35% of total incomes of male and female- headed cassava farm households respectively. This suggests that they keep small scale livestock extensively on free range. The other income (51.93% and 43.31% proportions for male-headed and female- headed cassava farm households respectively) were derived from different off-farm sources. Self-employed income was important in female-headed households as it accounted for 15.69% of total income. Self-employed income came mainly from handicrafts, food processing, shop-keeping and other local services, as well as trade in agricultural and non-agricultural goods. Similarly, a good number of male-headed farm households in the study area received income from off-farm sources with remittances being the most important. A good proportion of the income of male headed farm households is made up of remittances from local and international sources which contributed 19.07% of their total annual income. This was expected since many of the farmers are truly poor and could not have any of their household members residing far from home to remit money. This is a reflection of the vicious cycle of poverty. It would be risky for poor farmers to rely on this income source (Babatunde, 2008).

Table 2: Annual income from different sources in Male-headed and Female- headed farm households in Umuahia Agricultural Zone of Abia State, Nigeria

	Male Headed		**Female Headed**	
Income pattern	income per capita (₦)	Share of total income (%)	income per capita (₦)	Share of total income (%)
Total farm income	118,328.57	48.07	101,156.81	56.69
Crop income	64,888.57	26.36	58,341.43	32.70

Livestock income	22,011.43	8.94	23,815.38	13.35
Agric wage income	31,428.57	12.77	19,000.00	10.65
Total off farm income	127,807.14	51.93	77,269.9	43.31
Non-Agric wage income	13,671.43	5.55	12,244.9	6.86
Remittance	46,928.57	19.07	18,482.14	10.36
Self employed	29,285.71	11.90	28,000.00	15.69
Other incomes	37,921.43	15.41	18,542.86	10.39
Total household incomes	246,135.71	100.00	178,426.71	100.00

Source: Field survey, 2018

CONCLUSION AND RECOMMENDATION

The study established income diversification measures among the male and female headed cassava based households in the study area with income from crop being the dominant. It is recommended that improved cassava varieties with short gestation periods should as a matter of emphasis be extended to the farmers in the rural areas.

PROCEEDINGS
56th Annual Conference
Agricultural Society of Nigeria
24 - 28 Oct., 2022

ABSTRACT

This study was carried out to assess cashew industry in Nigeria. Trend analysis was carried out to observe cashew yield, quantity produced and area(s) where it is harvested in Nigeria from 1990 to 2020. The study observed a sharp decline in cashew production around 2011 and 2012. Although there had been improvement in the on-farm production of cashew in Nigeria in recent years, the fact remains that the country has not been able to match its production levels of the early 2000s. It is also recommended that government invest massively in cashew research as this will encourage collaboration among stakeholders and scientists to come up with ideas on how to tackle the challenges besetting the cashew sector both locally and globally. Cashew is not just a cash crop; it also serves as a source of food material for households. Hence, the role of cashew in food security in Nigeria could become very vital if production levels are improved. This will increase farmers' income thereby improving their ability to afford other food products and also increase the local consumption of cashew. Therefore, efforts geared towards improving cashew production could improve food security in Nigeria.
Keywords: Nigerian, Cashew, Production, Trend, Food Security.

INTRODUCTION

Cashew (*Anacardium Occidentale L.*) is a multipurpose tropical tree crop whose origin is usually traced to the amazon basin in Brazil (Salau *et al*., 2017). The crop was introduced to Africa and Nigeria by the Portuguese explorers who visited the continent around the 15th and 16th century (Asogwa *et al*., 2008). The value attached to the crop was initially based on its ability to help against erosion and farm flooding; however, the edible apple was later recognised for its benefits. The most economic part of the fruit which is the nut was only recognised much later for its superior economic value and usefulness (Tola and Mazengia, 2019).

According to Adeigbe *et al.*, (2015), cashew was first planted in Nigeria at Agege in Lagos State; thereafter, the crop spread to other parts of the country. The crop was first planted for commercial gains in Nigeria in the mid 1950's at Ogbe, Oji, Mbala and Uji in the Eastern region and at Iwo, Eruwa and Oke-Ogun in the old Western Region (Asogwa *et al*., 2009). There were initial challenges in the cultivation of cashew in the country, which is as expected, was due to the novel nature of the crop when it was first introduced into the country. Another problem that arose was the poor state and neglect of cashew plantations around the country. However, by the mid-1980s the fortune of the crop changed as a result of the activities of private entrepreneurs, affluent farmers, and government agencies which ensured that more nuts were brought into the country from other climes and this improved the genetic base of Nigerian cashew (Adeigbe *et al*., 2015).

In present day Nigeria, cashew is grown in more than 20 states with majority of the produce coming from Kogi, Anambra, Oyo, Enugu and Osun states (Aremu-Dele *et al*., 2021). The crop has become a crucially important agricultural product for many farming households. It is also the main source of revenue for many farmers and a major export sector of the country. According to Esan *et al*., (2018), cashew exports contribute about 8% to Nigeria's non-oil export earnings this fact is also backed by Ogunwolu *et al*., (2020) which stated that between the periods 2010 to 2014, the crop contributed \$25million to \$35million.

According to Monteiro *et al*., (2017), declining production levels of agricultural commodities have been identified by various authors as a prominent cause of food insecurity in Africa. However, while there is a general agreement on the role of food crops in food security there have been inconclusive reports regarding the role of cash crops such as cashew in food security (Jarzebski *et al*., 2020). Some authors such as Gamborg *et al*., (2012) opined that cash crop production competes with food crop production thereby having an adverse effect on food security; conversely, authors such as Kuma *et al*., (2019) are of the opinion that the cultivation of cash crops increases farmers' incomes thereby improving their ability to access food and satisfy their dietary needs. Cashew not only serves as a cash crop but also as a source of food material for households, cashew nut is widely consumed and is considered as a snack to many, cashew apple can be readily consumed from the point of harvesting, while extracts such as juice and jam are also food items for household consumption (Olife *et al*., 2013). Hence, cashew provides food for farmers and also serves as a source of income as well. This implies that cashew can play an important role in improving the food security status of the country if its production is improved. The contribution of cashew to the agricultural sector and the economy as a whole cannot be overemphasized; hence, the broad objective of the study is to examine the Nigerian cashew industry as it affects food security and agricultural development overtime. The specific objectives are to:

a. Assess the trend of cashew production overtime (1990-2020)
b. identify causes for the trend
c. Proffer solution based on the observed trends perceived challenges

CASHEW PRODUCTION IN NIGERIA

Figure 1 presents an outline of cashew production in Nigeria. The figure reveals that cashew production has been on the rise since the early 1990s: there was a rapid increase in the year 1999 when cashew production increased from 152,000 tonnes in 1998 to 417,000 tonnes – this increase continued until 2009. However, by the year 2011, a rapid drop in production was observed. The drop continued until 2014 when cashew production in Nigeria fell to less than 100,000 tonnes per year. However, cashew production remained relatively stable at 100,000 tonnes from 2016 to 2019 only to fall slightly to 98,800 tonnes in 2020. The fall in cashew production experienced in 2020 may be attributed to the COVID- 19 pandemic which affected agricultural production.

Figure 1: Cashew production in Nigeria (1990-2020)

Figure 2 presented cashew production, yield and area harvested in Nigeria (1990-2020)**.** The behaviours exhibited by cashew production in Nigeria over the years are affected by cashew yield and area harvested. This implies that cashew production is directly proportional to the area harvested. Both cashew yield and area harvested were on an upward trajectory between the periods of 1990 to 1998. This may be due to the relative ease in cultivation and the rise in the value of cashew nut in the international market. Cashew yield showed even more promise in the year 1999 when the yield increased by over 60 percent; the growth in cashew yield was steady up till the year 2010. Similarly, area harvested showed a galloping upward trend from 1999 and got to its peak in 2010 after which there was downward trend. This probably may be as a result of renewed interest by farmers to expand their farm holdings or due to the application of good agricultural practices. Kolliesuah *et al.* (2020) attributed the rise in cashew production in the boom years of 1999 to 2009 to increase in harvested area. This conforms to the a priori expectation that an increase in the land used in the cultivation of the crop will normally increase the production levels of a crop all things being equal. According to Adeigbe *et al.* (2015) the decline in cashew production experienced in 2011 to 2014 may be attributed to poor pricing of Nigerian cashew in the international market which is as a result of the compromised cashew quality often affected by poor peel ability and storage. This serves as a form of discouragement for cashew farmers in Nigeria. Uwagboe *et al.* (2010) cited the lack of adequate infrastructure and modern breeding technology as one of the factors militating against cashew production in Nigeria. The relative stability in cashew production from 2014 to 2020 shows that despite the obvious issues confronting cashew production some farmers have refused to be crowded out; also this period coincides with the agitation for the diversification of the Nigerian economy, this may have prevented further decline in cashew production. Cashew yield in Nigeria has been relatively stable overtime showing that the behaviour of cashew production in Nigeria may not be attributed to increase or decrease in cashew yield but rather to changes in the harvested area.

Figure 2: The trend of cashew production, yield and area harvested in Nigeria (1990-2020)

CONCLUSION AND RECOMMENDATIONS

The study assessed the trends and challenges of cashew industry in Nigeria from 1976 to 2021. From the foregoing, it has been established that cashew production in Nigeria started declining around 2011 and 2012. Though the production showed slight improvement around 2018, the cashew production sub-sector remains a shadow of its old self as the country has found it difficult to replicate the high production levels witnessed in 2009 and 2010. Literature is not clear about the role of cash crops such as cashew on food security, however, cashew is not just a cash crop, it also serves as a source of food material for households. Hence, the role of cashew in food security in Nigeria could become very vital if production levels are improved upon. This will increase farmers' income thereby improving their ability to afford other food products and also increase the local consumption of cashew.

In order for the country to get back to its glory days as far as cashew production is concerned, it is recommended that cashew farmers, intending farmers and investors be encouraged by the government in the following ways:

- Protecting the value of Nigerian cashew nut in the global market by establishing a standard control agency that will ensure that only quality cashew nuts are exported in order to boost the value of the cashew nuts.
- Massive investment in cashew research as this will provide the scientists with the necessary tools required for the creation of better seedlings, better breeding technology and better pest control and disease prevention mechanisms as this will improve cashew yield.

24 - 28 Oct., 2022

ABSTRACT
There is need for this study to review the production and marketing of root and tuber crops as a remedy to the challenges facing agricultural development in Nigeria. Secondary data were used for the study. Root and tuber crops are staple food crops, being the source of daily carbohydrate intake for the large populace of the world and Nigeria in particular. Some selected root and tuber crops reviewed in this study are cassava, yam, potato, sweet potato and cocoyam. Production and marketing of root and tuber crops challenges include quality seed production, low level of financial base, high cost of labour, new variety adoption, seasonal variations, transportation and storage among others. Notwithstanding the challenges, root and tuber production has been found to be profitable. The study showed that production and marketing of root and tuber crops is important in agricultural development in Nigeria through provision of foods to man and animal feeds, raw materials for industries, income generation for farm families and creation of employment opportunities. It is recommended that farmers should be engaged in production and marketing of root and tuber crops for increased food availability, available raw materials for industries and sustainable income generation and creation of employment opportunities in Nigeria.

Key words: Production, Marketing, Root and Tuber crops, Nigeria.

INTRODUCTION
Agricultural production remains the main source of income for most rural communities (about 86 percent of rural people of about 2.5 billion depend on agriculture for their livelihood) (Nteranya and Adiel, 2015). Nigeria is an agricultural country that is endowed with enormous food and agricultural resources such as yam, cocoa, cassava, rice, sugar cane, maize, and millet (Nahanga and Vera, 2014).
Root and tuber crops comprises of crops covering several genera. They are staple food crops, being the source of daily carbohydrate intake for the large populace of the world. They provide substantial part of the world's food supply and also important source of animal feed and processed products for human consumption and industrial use (Chandrasekara and Kumar, 2016). They are crops grown in varied agro-ecologies and production systems ranging from highland densely populated regions to lowland drier areas prone to droughts or floods. These crops (cassava, yam, cocoyam, potato and sweet potato) account for about 95% of the total root

and tuber crops production in Africa and produce more than 240 million tons annually on 23 million hectares ((Nteranya and Adiel, 2015).
Importance of production and marketing of root and tuber crops in agricultural development of Nigeria cannot be over emphasized. The relative importance of these crops is evident through their annual global production which is approximately 836 million tons (FAO, 2013). Nutritionally, root and tuber crops have a great potential to provide economical source of dietary energy and about one-third of that of an equivalent weight of rice or wheat due to high moisture content (FAO, 1990). Therefore, there is need for this study to review the production and marketing of root and tuber crops as a remedy to the challenges facing agricultural development in Nigeria.

Root and Tuber Crops Production and its Relevance to Agricultural Development
Cassava
Cassava (*Manihot esculenta*) is an important and one of the widely grown staple in Nigeria (Okelola *et al*., 2014). It is very crucial in food economy of the nation, impacting on food and income security of the rural households (Mondo *et al*., 2019). Nigeria produces more than 45 million metric tons (MT) of cassava, thus, emerging as the world's largest producer. About one-third of the total national output comes from the Niger Delta region where many livelihoods depend on cassava as a main source of food and income (Igberi and Awoke, 2013). Global demand for the commodity has been growing significantly over time because of its appeal as a food security crop for growing populations in emerging markets, and the growing demand for industrially processed cassava products (Nteranya and Adiel, 2015). The Global Cassava Development Strategy study commissioned by IFAD and FAO and the Vision 2020 study of the CGIAR on root and tuber crops stressed the great potential of cassava to spur rural industrial development, raise rural incomes, and contribute to food security (Nteranya and Adiel, 2015). Cassava is used mainly for two main purposes in Nigeria: 90% as human food and only 5-10% as secondary industrial material (used mostly as animal feed). About 10% of Nigeria's industrial demand consists of HQCF used in biscuits and confectioneries, dextrin pre-gelled starch for adhesives, starch and hydrolysates for pharmaceuticals produces and as seasonings. Between 70-90% of cassava processed as human food is gari. Other common cassava products for human foods are lafun and fufu/Akpu. Processed products can be classified into primary and secondary products. The primary products are garri, fufu, starch, chips, pellets which are obtained directly from raw cassava roots, while the secondary products are obtained from the further processing of primary products for example, glucose syrup, dextrin, and adhesive are obtained from starch (Nteranya and Adiel, 2015).

Yam
Yam is one of the tuber crops produced in Nigeria and it has many species, of which six are economically important staple species. They are *Dioscorea rotundata* (white guinea yam), *Dioscorea alata* (yellow yam), *Dioscorea bulbifera* (aerial yam), *Dioscorea esculenta* (Chinese yam) and *Dioscorea dumetorum* (trifoliate yam). Out of these, *Dioscorea rotundata* (white yam) and *Dioscorea alata* (water yam) are the most common species found in Nigeria (Anozie *et al.*, 2014). Yams are grown in the coastal region in rain forest, woody savanna and southern savanna agro ecology. In many yam-producing area in Nigeria, it is said that "yam is food and food is yam" (Bolarinwa and Oladeji, 2009). Yam crop forms a staple food for most people of the tropics. Yam tubers are eaten in different forms including eating it boiled, fried, pounded or made into yam powder for fufu. As food crop, the place of yam in the diet of Nigerians cannot be overemphasized. It contributes more than 200 dietary calories daily, for more than 150 million people in West Africa as well as serving as an important source of income (Babaleye, 2003). It is also comparable to any starchy root crops in energy and the

fleshy tuber is one of the main sources of carbohydrates in the diet of most Nigerians (Okpara *et al.*, 2014). Yam also plays vital roles in traditional culture, rituals and religion as well as local commerce of African people (Izekor and Olumese, 2010).

Cocoyam

Cocoyam is an important staple food across many developing countries in Africa, Asia and Pacific (IITA, 2008). It is particularly important in sub-Saharan Africa where the two most commonly cultivated species *Colocasia esculenta* and *Xanthosoma sagittifolium* are grown extensively (Nwadili *et al.,* 2016). Cocoyam plays important roles in the livelihood of rural farmers. In some years back (2008-2012), Africa accounted for 86% of the global area harvested and 74% of total taro production. The west African sub-region alone accounted for 61% of global area harvested and 50% of global production (Okoye *et al.*, 2013). Although, the figures above indicated a decline in the contribution of the region in taro production, this may be attributed to infestation of Taro Leaf Blight (TLB) (Nwadili *et al*., 2016). It is of interest to note that cocoyam among other root and tuber crops such as cassava, sweetpotato and yam is not attacked by goat and sheep and it is edible crop, because the corms and cormels are eaten in various food forms while the leaves and flowers are commonly used as spice to garnish and flavor food (Chukwu, 2011). Cocoyam is adjudged to be nutritionally superior to major competitor roots and tubers in terms of digestibility, contents of crude protein and essential minerals such as Ca, Mg and P. The importance of cocoyam is not only attributed to its use as source of food for man; industrially, cocoyam is used for production of alcohol, medicines, flour, starch and feed for livestock.

Potato

Potato (*Solanum tuberosum* L.) is one of the major tuber crops in Nigeria. The crop is well known for its high nutritional quality; good source of carbohydrate; potassium, vitamin B and C. It is a source of both food and cash income and has been known as one of the major crops to alleviate hunger in the world (Crissman *et al*., 2017). Smallholder farmers in particular are discovering that the potato can help in food security because it is a high yielding cash crop with a short growing season. Highland potato farmers enjoy a comparative advantage in exploiting an ever-growing, high market demand for the crop, as potato production requires the cool temperatures typical of mid- to high altitudes. Furthermore, potato production is important in North Africa, where the crop offers a huge export market to Europe and under irrigation in Harmattan season in the Sahel Zones in West Africa. There are many compelling reasons for encouraging more wide-scale adoption of potato into the livelihoods of Africa smallholder farmers. The crop is short cropping cycle of three to four months is well-suited to the double cropping seasons in the African highlands, particularly in rain-fed systems. Harvestable tubers are available 60-100 days after the onset of the rainy season has a significant advantage over grains, which require six to nine months. This makes potato one of the first crops that can be harvested in any growing season, thus an important crop for the “hunger months” that is, a period of several months between harvests when people lack enough food to satisfy their hunger and meet their basic caloric and nutritional needs (Nteranya and Adiel, 2015). Potato is a cheap but nutritionally rich staple food for the fast growing cities of sub- Saharan Africa, contributing protein, vitamin C, zinc, and iron to the diet. There is a huge opportunity to exploit this largely untapped potential, creating entrepreneurial opportunities for all levels along the seed value chain, with a special focus on women and youth farmers (Nteranya and Adiel, 2015).

Sweet potato

Sweet potato (Ipomoea batata (L) Lam) is an important tropical root crop. It belongs to the morning-glory family known as convolulaceae and is originated from Latin America (Low *et* *al.,* 2009). It ranks second after cassava among the tropical root crops. The crop can be considered promoting nutritional security particularly in agriculturally backward areas. In recent times, the West Africa region has witnessed increase in crop output; sweet potato recorded a positive per capita annual rate of increase in production in sub-Saharan Africa (Ndaula *et al.,* 2020). Nigeria is the third largest producer of sweet potato in the world in terms of quantity, after China and Uganda. The crop can give a cash return in 3.5-4.5 months (Shanhbanden, 2018). Use of sweet potato in poultry and pig farming is very well established. Sweet potato offers a particularly significant potential for increasing food production and income in Nigeria. Sweet potatoes are cooked together with cowpea, lima beans, sesame, millet and/or other root and tuber crops to make a traditional porridge. Sweet potato dough is incorporated with other root and tuber crops to create two staple dishes in the country: fufu, a stiff, gelatinous dough prepared by pounding boiled tuber pieces in a mortar; and amala, a thick porridge that is often served with soup (Kathryn *et al.,* 2012). Most sweet potato farmers sell their sweet potatoes along the roadside or at their nearest semi-urban or urban market.

Marketing of Root and Tuber Crops

Marketing are those business activities associated with the flow of goods and services from production to consumption (Agunannah, Essien and Ewuziem, 2016). The marketing of root and tuber crops begins in the farm with the planning of production which is completed with sale of the crops to the consumers. In recent years, there has been increased exportation of root and tuber crops produce such as gari, yams and sweet potatoes to England and other overseas countries for sale to immigrant populations, as well as becoming a useful source of foreign exchange earnings, the growth of international trade in root and tuber crops increases effective demand for food produce (Nteranya and Adiel, 2015). Another market advantage of these crops is that they are largely traded locally and nationally. The market of root and tuber crops is important in the subsistence strategy of most rural households not only because most of the production resources comes from the market but mostly, it is the only way for producers to sell their product (Alleluyanatha, Asumugha and Mbanaso, 2016). The price of root and tuber crops such as yam and potato have gone up in some markets in Nigeria. For instance, a set of yam which consist of five tubers is sold for ₦6,000 and ₦8,000 depending on the size of the tubers. The same set of yam was sold in 2021 between ₦3,000 and ₦4,000. Also, 50kg bag of cassava root is ₦3,500 and it was sold in 2021 for ₦1,700 or less.

Constraints to Root and Tuber Crops Production and Marketing

Production of root and tuber crops challenges related to quality seed production, low financial base, high cost of labour, new variety adoption, losses due to insects and diseases, low productivity in poor soils, tolerance to stress associated with heat and drought, consumer preferences, and storage of harvested products among others. This is in agreement with the report of Oni (2013), who identified some of the constraints in the agricultural sector that inhibit performance and growth of the sector. Marketing of these crops is beset with a lot of problems, which constitute a bottleneck to the flow of goods and services. According to Alabi and Adebayo (2008), many problems affect agricultural commodity marketing which includes distance, cost of transportation, seasonal variation, storage, processing, grading and communication among others as hindrance to the flow of goods in the Agricultural sector. These problems notwithstanding, root and tuber production has been found to be profitable (Ogbonna, 2007).

CONCLUSION AND RECOMMENDATION

The study therefore, concluded that production and marketing of root and tuber crops is important in agricultural development in Nigeria through provision of foods for man and animal feeds, raw materials for industries and income generation for farm families. It is recommended that farmers should be more engaged in production and marketing of root and tuber crops such as cassava, yam, potato, sweet potato and cocoyam for increased food availability, available raw materials for industries, sustainable income generation and creation of employment opportunities in Nigeria.

ABSTRACT

The study estimated the Total Factor Productivity (TFP) and its determinants among arable crop farmers in Benue State, Nigeria with a view to examining the effect of soil fertility management on their productivity. Data were collected from 175 farmers using three stage sampling technique. Data analyses were carried out using descriptive statistics, Total Factor Productivity and least square regression analysis. Prevalent soil fertility management practices were; application of inorganic fertilizer (18.9%), crop rotation (15.4%), mulching (14.9%), application of organic manure (13.7%), alley cropping (13.0%), bush fallowing (12.6%) and cover cropping (11.5%). Result also indicates that 46.9% of the sampled household heads were productive, i.e. have their productivity value above average across all the soil fertility management categories. Determinants of TFP estimate reveals the following factors as having a significant contribution to productivity at different levels of significance in the study area; age (-1.469), education (0.417), farm size (0.046), alley cropping (.357), crop rotation (.380), application of inorganic fertilizer (.503), mulching (.560) and organic manure (.373). While age impacted negatively on productivity, all others impacted positively on productivity. The study concludes that soil fertility management practices are productivity enhancer. Promoting sustainable soil fertility management practices that are farm or farmer specific is recommended.
Keywords: Arable Crop Farmers, Determinants, Household Heads, Soil Fertility Management and Total Factor Productivity.

INTRODUCTION

Agriculture still remain the mainstay of Nigeria's economy as it accounts for 22.36 percent of National Gross Domestic Product (GDP) and providing livelihoods to approximately 70 percent of the country's active labour force (Bernard & Adenuga, 2017; National Bureau of Statistic [NBS], 2022). Agricultural sector grew at the rate of 4.1 percent in 2016 and it accounted for 75 percent of non-oil exports. To improve the sectorial performance, the Federal Ministry of Agriculture and Rural Development (FMARD) has approved Agriculture Promotion Policy (APP), building on the Agricultural Transformation Agenda (ATA) developed under the administration of President Goodluck Ebele Jonathan. The key themes of this policy are supporting productivity enhancements; crowding in private sector investment and FMARD's institutional realignment with a focus to improving the ease of transacting business in Nigeria's agricultural space (Oredipe, 2017).

Productivity is generally defined as the level of output in relation to levels of resources employed in a given period of time. It is the rates of flow of output when compared to rates of flow of resources such as land inputs used in production (Oyaide, 1994). Poor agricultural productivity and food insecurity are persistent features of many developing countries including Nigeria. Increases in food production in the recent past in Sub-Sahara Africa (SSA) are a result of more land being brought into production rather than higher output per unit area of land (World Fact Book, 2012). With the increasing population, cultivable land is becoming the limiting factor in meeting the growing food demand, implying that farm output growth needs to be achieved through higher productivity (World Bank, 2008).

Soil fertility is the intrinsic ability or capability of the soil to provide plant nutrients and water in adequate amount and when required, for good growth and development of the crops. Soil fertility decline (also described as soil productivity decline) is the deterioration of chemical, physical and biological soil properties and its subsequent reduction in providing the crops with adequate nutrients and water (Agboola, 2001). Good soil fertility management practice helps rejuvenates the soil after each cropping season and also keeps the soil in good shape to support another season, thus, the need for appropriate soil fertility management practices. Soil fertility management practices can be seen as management of the soil to increase the quality and durability of the soil to provide required plant nutrient and water in an attempt to maintain optimum crop productivity (Food and Agriculture Organisation, [FAO] 2001 & Oladipo, et al., 2017). With constant cultivation of the soil to meet the growing demand for food amidst changes in climate and decrease in the ability of the soil to provide the required nutrients for plant, it becomes imperative that appropriate soil management practices are explored to ensure sustainable agricultural production.

Based on this, the objectives of the present study are in three folds. First, to isolate the different soil fertility management practices prevalent among the arable crop farmers in the study area, second, to estimate the productivity of the farming household heads stemming from the different soil fertility management practice most frequently practiced and third, to isolate the determinants of total factor productivity in the study area.

METHODOLOGY

The Study Area

The study was carried out in Benue State, Nigeria. The state which is one of the states that constitute the north-central zone of the country is made up of twenty-three (23) local government areas and shares boundaries with Nassarawa to the north, Taraba to the east, Cross River to the south, Enugun, Ebonyi and Cameroon to the south east, Kogi to the west. The state occupies a land mass of 33,955 square kilometers with an estimated population of 4,253,641 (National Population Commission, [NPC] 2006). The state experiences two (2) distinct seasons; wet and dry with an annual rainfall of between 1250-1750mm while annual temperature ranges between 32-38^{0}c. Inhabitants of the state are predominantly farmers and they cultivate such food crops as yam, rice, cassava, soya beans, groundnut, sweet potatoes, millet and guinea corn while such tree/cash crops like mango, citrus/oranges, pawpaw and pineapple could also be found. Major ethnic groups and tribes in the state are are Tiv and Idoma: others are Igede, Etulo, Jukum, Hausa, Akweya and Nyifon.

Sampling Procedure

The study population was arable crop farmers living in the study area; the data used were collected from the 2020 production season. A three stage sampling technique was used in the study. The first stage was the random selection of four (4) local government areas from the state, the second stage was the random selection of fourteen (14) communities/ villages with probability proportion to the size of the local governments, while the last stage was the selection of farmers from the selected villages/communities based on sampling frame. A total of 200 copies of the questionnaire were administered with only 175 returned with useful information that was used for the analyses as shown in Table 1.

Table 1: Sampling Procedure for the Selection of Farmers.

State	LGAs	Communities	Number of questionnaire administered	Number of questionnaire retrieved
Benue	Buruku	Abwa, Biliji, Mbataase and Mbaya	68	57
	Oju	Obotu,, Oronu-Ainu, Okpoma Ainu, Oyinyi, Iyeche and Uchuo	64	59
	Otukpo	Otukpoicho and Okete	32	29
	Ushongo	Sati ikov and Bilaji Ikom	36	30
			200	175

Analytical Technique

This study employed a number of analytical tools based on the objectives of the study. The tools include descriptive statistics, total factor productivity and multiple regression. Descriptive Statistics was used to describe the soil fertility management practices using frequency and percentage. Total Factor Productivity Model as employed by Adepoju and Salman (2013) was used to estimate the productivity value of the farming household heads based on the soil fertility management practice most frequently used. Total Factor Productivity (TFP) is a method of calculating agricultural productivity by comparing an index of agricultural inputs to an index of outputs (Jean-Paul, 2009). Total factor productivity is therefore measured as the inverse of unit cost following Key and Mcbride (2003). This is the ratio of outputs in naira value to the total variable cost (TVC) of production. TFP measures that use physical quantities as output measures rather than revenue actually exhibit even more variation than do revenue-based measures as documented in Foster *et al*., (2008). Hsieh *et al*., (2009) also find greater productivity dispersion in the TFP measures that use quantity proxies to measure output.

$$TFP = \frac{Y}{TVC} \qquad \ldots 1$$

Where Y = Output in Naira value in line with Mwuese and Okorji, (2014).

TVC = Total Variable Cost

$$TFP = \frac{Y}{\sum P_i X_i} \quad i = 1, 2, \ldots\ldots n \ldots\ldots 2$$

Where Y = quantity of output in Naira and P_i = unit price of ith variable input and X_i = quantity of ith variable input

The inputs used in line with Fakayode *et al*., (2008) are: cost of labour, cost of planting materials, Cost of inorganic fertilizer, Cost of herbicide and Cost of pesticide. Following Akintayo and Rahji, (2011) to examine the effect of some socio-economic variables as well as soil fertility management practices on the Total Factor Productivity (TFP), the TFP estimate was subjected to ordinary least square regression to obtain the coefficient of multiple determinations (R^2), F- Statistics, standard error and their values. The ordinary least square regression model is a best linear unbiased estimator whose estimate possesses the desirable properties of unbiasedness, efficiency and consistency.

Model Specification

$$Q^* = f(X_1, X_2, X_3, X_4, X_5 \ldots\ldots X_{14}\ .\mu) \ldots\ldots 3$$

Where

Q* = TFP estimate

The Cobb-Douglas production function is specified as:

$$Q_i = A\ \pi_i\ Z_i^{\ bi};\ i = 1, 2, \ldots 14 \ldots\ldots 4$$

The expanded form is:

$$Q_i = A\ Z_1^{\ b1}\ Z_2^{\ b2}\ Z_3^{\ b3}\ Z_4^{\ b4}\ Z_5^{\ b5} \ldots\ldots Z_{14}^{\ b14} e^{ui} \ldots\ldots 5$$

Following Gujarati (2004), the empirical model to be used for this study can be cast in double-log form as follows:

$$\ln Q_i = \ln A + b_1 \ln x_1 + b_2 \ln x_2 + b_3 \ln x_3 + b_4 \ln x_4 + b_5 \ln x_5 \ldots\ldots b_{14} \ln x_{14} + u \ldots\ldots 6$$

Based on the view of Hussain and Perera, (2004) and as adopted by Akintayo and Rahji, (2011), Adepoju and Salman, (2013) the following factors were hypothesized as the determinants of TFP of arable crop farmers in the study area.

x_1 = Age of household heads (years), x_2 Number of years of formal education, x_3 = Household size (number), x_4 = Farming Experience (years) , x_5 = Access to credit(Dummy Variable; Yes = 1 otherwise = 0), x_6 = Farm Size (ha), x_7 = Extension contact (Dummy Variable; Yes = 1 otherwise = 0), Vector of index of soil fertility management practices (Dummy Variable; Yes = 1 otherwise = 0), x_8 = Alley cropping, x_9 = Bush fallowing, x_{10} = Cover cropping, x_{11} = Crop rotation, x_{12} = Application of inorganic fertilizer, x_{13} = Mulching, x_{14} = Application of organic manure

μ = error term which is assumed to be normally distributed and with mean zero and constant variance

RESULTS AND DISCUSSION

Households Soil Fertility Management Practices in the Study Area

Factors Affecting Total Factor Productivity (TFP)

As shown in Table 3, the coefficient of determination (R^2) for food crop farmers (0.758) indicates the presence of a high degree of association between productivity (dependent variable) and all independent variables. This implies that 75.8% of the variation in the farmers' productivity is explained by the variations in the independent variables. The F-statistics of the farmers (F-test= 581.71, P<0.001) was found to be highly significant, implying that the independent variables were collectively important in explaining the variation in the dependent one.

Of the fourteen explanatory variables specified, eight were statistically significant. These were age, education, farm size, alley cropping, crop rotation, inorganic fertilizer application, mulching and organic manure application. The negative coefficient ($p<0.01$) of age suggests that farmers were less productive as they age, older farmers are not physically able to produce as much as younger household heads because productivity is countered by declining physical strength and perhaps by negative attitudes toward innovation. The negative coefficient, which implies that a unit increase in farmers' age decrease productivity by 1.46, agrees with the findings of Ahmed and Elrasheed (2016).

Table 3: Factors Affecting Productivity of Food Crop Farming Household Heads in Benue State

Variables	Coefficients	Standard error	T	P> | t |

*** 1% significance level; ** 5% significance level; * 10% significance level
Source: Field Survey, 2021

The coefficient of years of education was positive and significant at 1% implying the significant contribution of the variable to productivity. This implies that a unit increase in years of education will tend to increase productivity by 0.417 unit. This is in conformity with the findings by Shittu et al. (2015) who stated that education increases farmers' productivity. The coefficient of farm size was positive and significant at 10% level and implies that a unit increase in farm size will tend to increase productivity by .034. This is likely to be so as farmers with large farms tend to enjoy economies of scale in the purchase of their inputs and sales of their output, thereby reducing the unit cost. The result conforms to the findings by Wawire at al. (2021).

Though not significant, the positive coefficient in respect of household size, farming experience, access to credit and access to extension contact implies that a unit increase in these variables tends to increase productivity by 0.006, 0.006, 0.003 and 0.0034, respectively. In addition, all the soil fertility management practices were positively related to TFP, implying that increased use of any of the management practices led to increased productivity. Although bush fallowing was not significant, alley cropping, crop rotation, inorganic fertilizer application, mulching and organic manure application were significant. The positive and significant value of organic manure is in line with Nuno and Baker (2021).

CONCLUSION AND RECOMMENDATIONS

The result of Total Factor Productivity estimate indicates that arable crop farmers practicing alley farming were the most productive while those practicing cover cropping were least productive. Practicing alley cropping, crop rotation, mulching and application of organic and inorganic fertilizer enhanced arable crop farmers' productivity in Benue State, Nigeria.

- Since age is negatively related to productivity, it is therefore recommended that youth empowerment program in the area should accord priority attention to agriculture so as to further encourage relatively young farmers into arable crop production.
- Education is productivity and soil fertility management enhancing variable since the level of formal education seemed to contribute to the total factor productivity of the farmers. This will not be unexpected as education has a way of helping farmers to reasonably commit their resources to any productive enterprise, resulting in increase in productivity. It is, therefore, recommended that basic education or adult literacy should be encouraged among farmers. There is need to constantly upgrade farmers' knowledge. Access to information on environmentally friendly and soil fertility management practices should be promoted through the provision of informal education for the farmers in the study area.
- Soil fertility management practices are productivity enhancer; the need to promote sustainable Soil fertility management practices that are farm or farmers specific is hereby recommended.

PROCEEDINGS
56th Annual Conference
Agricultural Society of Nigeria
24 - 28 Oct., 2022

ABSTRACT

The study examined the constraints to ginger production and consumption in Abia state, Nigeria. Using multistage random and purposive sampling techniques 120 respondents were selected from six (6) out of seventeen (17) Local Government Areas. Data were obtained using well-structured questionnaire and were analyzed using descriptive tools such as frequency, percentage, tables and 4- point likert type scale. Result showed that good proportion of the ginger farmers were at their productive age, married and educated. Result also indicated that ginger is consumed in different pattern and that is encouraging. In conclusion, lack of regulated markets, monopoly of the commission agents incidence, among others were they most important constraints to ginger production and consumption in the study area. Sequel to these finding, it is therefore recommended the need to evolve an integrated pest management programme besides strengthening the extension system in imparting knowledge about prevention and control of these diseases since all the farmers expressed incidence of diseases like root rot as one of major problem in ginger cultivation.

Keywords: Ginger, Production, Consumption, Constraints,

INTRODUCTION

Ginger (*Zingiber officinale*) is a rhizome, which consist of numerous short finger-like structures or branches born horizontally near the surface of the soil. Two commercial varieties are commonly cultivated in Nigeria. Ginger is produced in several parts of Nigeria particularly in the Guinea Savanna Zone (southern part of Kaduna State) and to a little extent in Keffi and Akwanga Local Government Areas of Nasarawa State (Dauda and Waziri, 2006). Although ginger has not been commercially recognized globally as functional food, especially from the regulatory/legislative point of view (ESFA, 2016), the many health benefits/ functions of ginger have been documented. Ginger has been used as medicine in Asian, Arabic and Indian herbal tradition since ancient times. Among its health benefits are: maintain normal blood circulation and fight common respiratory problems (Ali *et al.*, 2008), it prevents cold and flu, combats morning and motion sickness (Ryan *et al.*, 2012). It improves absorption and combats stomach discomfort (Ghayur *et al*., 2005), reduces inflammation and can relief menstrual pain

(Ozgoli *et al.,* 2009). Nigeria is one of the leading producers of ginger in the world; her production as in 2013 was estimated at 496 920 tonnes (representing approximately 21 % of the world production) (FAO, 2017).
Nigeria is one of the leading producers of ginger in the world; her production as in 2013 was estimated at 496 920 tonnes (representing approximately 21 % of the world production) (FAO, 2017). Of the total quantity of ginger produced in the country, 10 % is locally consumed as fresh ginger while 90 % is primarily for the export market (FAO, 2010). Nigeria is one of the leading producers of ginger in the world; her production as in 2013 was estimated at 496 920 tonnes (representing approximately 21 % of the world production) (FAO, 2017). Of the total quantity of ginger produced in the country, 10 % is locally consumed as fresh ginger while 90 % is primarily for the export market (FAO, 2010).This study therefore identified the constraints to ginger production and consumption in Abia State, Nigeria with specific objectives on socio-economics status of the respondents and their consumption pattern of ginger.

METHODOLOGY

The study was conducted in Abia state. The population of the study was made up of all ginger producers and consumers in Abia State, Nigeria. Multistage random and purposive sampling techniques were adopted in selecting 120 respondents for the study. In the first stage, two LGAs were randomly selected from each of the Political Zones of Abia State. This gave a total six (6) LGAs. In the second stage, two (2) autonomous communities were randomly selected from each of the 6 LGAs making a total of 12 autonomous communities. The third stage involved a random selection of 10 ginger consuming households in the selected autonomous communities. This made a total of 120 respondent which formed the sample size of the study. The questionnaire were used to elicit information while data realized were analyzed using descriptive tools such as frequency, percentage and tables for objectives 1, 3 and 4- point likert type scale for objectives 2, graded thus: always = 4, sometimes =3, rarely =2 and never =1. The values of the responses were added and further divided by 4 to obtain a mean score of 2.5, which was regarded as mean level of consumption pattern.

RESULT AND DISCUSSION

Some Selected Socio-Economic Characteristics of Respondents

The socio-economic result in Table 1 indicated that a fairly good proportion (37.5%) of the farmers were within the age range of 41 and 50 years while a high proportion (69.2%) of the respondents were married. This result concurs with findings of Ajah, (2013) that rural farmers in South- Eastern Nigeria were married. The result shows that a half (50.0%) of respondents had household size of between 6-10 persons with mean age of 6.0 persons. The implication of this finding is that more family labour would be readily available since relatively large household size is an obvious advantage in terms of farm labour supply, where wage rate is relatively costly. The result implied that moderate proportion (45.0%) of the rural farmers in the study area attended secondary school. It will likely make them more responsive to many agricultural extension programmes and policies. Abudu *et al*., (2014) reported that increase in education of farmers positively influenced adoption of improved agricultural practices. The result showed that a moderate proportion (48.3%) of the respondents had farm size of between 0.6 – 1.0 hectare with a mean farm size of 1.1 hectares. Large farm size increases agricultural productivity and improves farmer's technical, allocative and resource use efficiency as well as enhances access to credit and other farm inputs. The result reveals that majority (78.3%) of the respondents were not members to cooperatives while 21.7% belonged to different cooperative societies.

Table 1: Distribution of respondents according to selected socioeconomic characteristics

Variables	Frequency	Percentages	Mean

Consumption Pattern of Ginger

The result in Table 2 revealed that the consumption patterns of ginger were grinded ($\bar{x}$=3.68), fresh ($\bar{x}$=3.64), fried ($\bar{x}$=3.56), juice ($\bar{x}$=3.21), and dried ($\bar{x}$=2.88). This result implies the respondents consumed ginger in various forms for different reasons.

Table 2: Mean rating of Consumption pattern of ginger in the study area

Consumption pattern of ginger	Always	Sometimes	Rarely	Never	$\sum fx$	$\bar{x}$
Fried	67(268)	53(159)	0(0)	0(0)	427	3.56

Grinded	82(328)	38((114)	0(0)	0(0)	442	3.68
Dried	42(168)	44(132)	12(24)	22(22)	346	2.88

Constraints to Ginger Production and Consumption

The result revealed that lack of regulated markets (100.0%), monopoly of the commission agents (100.0%), incidence of disease (100.0%), absence of cooperatives (93.3%), lack of reliable source of information (99.2%), severe infestation of weeds (90.0%), and low price at the time of harvest and unnecessary deduction (86.67%), Seed unavailability (85.83%) among others. This result implies that the farmers faced several constraints in the production and consumption of ginger in the study area. Tripathi *et al*. (2006) identified that lack of approach road, monopoly of the commission agents, lack of regulated markets, low price at the time of harvest and unnecessary deduction, absence of cooperatives, limited government intervention in transportation and grading and lack of reliable source of information were the major constraints in the marketing of ginger. Policy options to improve the marketing efficiency and producer's share identified by them were formation of Self Help Groups (SHGs) to take up marketing activities, farmers' co-operatives, establishment of processing units, storage and transportation facilities, regulated markets etc. Efforts at providing cost effective storage facilities will reduce these constraints. Other important constraints are lack of access to credit and unavailability of farm inputs; this is in spite of the earlier finding that access to credit reduced the inefficiency of the farmers. But credit is needed to procure other farm inputs which they claimed was unavailable. Therefore credit plays a very pivotal role if the farmers are to improve their efficiency and operate on the frontier (Ezeagu, 2006).

Table 3: Distribution of respondents based on the constraints to ginger production and consumption

Constraints	Frequency	Percentages
Cost of production	92	76.67
Monolpoy of the commission agents	120	100.0
Lack of regulated markets	120	100.0
Low price at the time of harvest and unnecessary deduction	104	86.67
Absence of cooperatives	112	93.3
Lack of reliable source of information	119	99.2
Severe infestation of weeds,	108	90.00
Seed unavailability	103	85.83
Incidence of diseases	120	100.0

CONCLUSION

The study concluded that good proportion of the ginger farmers were at their productive age, married, educated and had moderate proportion of farm size of between 0.6 – 1.0 hectare with a mean farm size of 1.1 hectares. It was also concluded that a grand mean score of 3.41 which was above the decision mean count of 2.5 indicated that ginger is consumed in different pattern and that is encouraging. In conclusion, lack of regulated markets, monopoly of the commission agents, lack of reliable source of information, absence of cooperatives, lack of reliable source of information, Severe infestation of weeds, low price at the time of harvest and unnecessary deduction among others were they most important constraints to ginger production and consumption in the study area. Sequel to these finding, it is therefore recommended that farmers should form cooperatives to enable them pool their resources together, access markets and command better prices for their products. All the farmers expressed the incidence of diseases like root rot as a major problem in ginger cultivation. Hence, there is an urgent need to evolve an integrated pest management programme besides strengthening the extension system in imparting knowledge about prevention and control of these diseases.

ABSTRACT

This study analyzed the determinants of fish production output in Badagry Local Government area, Lagos State, Nigeria. A two-stage sampling technique was used to elicit information from 120 artisanal fish farmers through the use of a well-structured questionnaire. Data were analyzed using descriptive statistics and multiple regression analysis. Results revealed that majority (61.7%) were male, with a mean age of 44 years. Most (60%) of the respondents had secondary education and 62.5% had a fishing experience of between 6-10 years. Majority (75%) had contact with extension services twice per month and 60% are credit beneficiaries from cooperative society. The mean monthly revenue from fish farming was ₦23,343.17. The regression analysis result showed that artisanal fish production output was significantly influenced at different levels by sex, age, number of boats, fishing experience, credit beneficiary and frequency of extension contact. It was established from the study that artisanal fish farmers that are credit beneficiaries from the cooperative society and also employed more than one boat in fishing have higher fish output than others. The study recommended that credit facilities should be made more available to artisanal fish farmers by relevant stakeholders to enable them increase their production output in order to serve the teeming increasing population.

Keywords: Artisanal, Fish, Output, Production and Socioeconomic.

INTRODUCTION

In Nigeria, the fishery industry is made up of three key sectors which are the aquaculture (fish farms), artisanal (inland rivers, lakes, coastal and brackish water) and industrial fishing. Nigeria is a typical coastal country, with a coastline of around 800 kilometres, a continental shelf of about 256,000 kilometres, an exclusive economic zone of 210,900 kilometres and a marine area of 46,000 kilometres, which can be exploited for fishing. The country also has about 14 million hectares of reservoirs, lakes, ponds and major rivers, which can produce over 980,000 metric tonnes of fish annually (Oladimeji *et al.*, 2013). In Nigeria, artisanal inland fisheries are not only an essential alternative source of animal protein, but also important to the economy, accounting for around 5% of the country's GDP (FDF, 2013). Between 1991 and 2003, inland artisanal fisheries accounted for more than 85% of domestic fish production, with a total fish production of 615, 507metric tonnes in 2007 (Nwabeze and Erie, 2013). Artisanal fishing generates foreign cash for the country, as well as employment, income and raw materials for the livestock feed industry (FAO, 2010). Despite its immense potential, Nigerian fish production is still unable to bridge the gap between total production and total demand. According to statistical data on fish production in Nigeria, production has decreased from 1984 to the present to less than 400,000 metric tonnes, down from 508,000 metric tonnes in 1982. (FDF, 2008). In addition, with increased population and income, there is a very high demand for fish in Nigeria, but there is a substantial shortfall between demand and supply of roughly 0.44 million metric tonnes (FDF, 2008). Furthermore, according to Inoni and Oyaide (2007), the ability of the artisanal fisheries to maintain its function in food provision, employment creation and income generation in the Nigerian economy is centered on the adoption of relevant management techniques that will guaranty their sustainability in the face of intense fishing pressure. The artisanal fishery sector is plague with variety of challenges in spite of it being a vital source of income for the majority of coastal households. Despite various efforts to increase fish production, not much has been done to increase the productivity of artisanal fishing in Lagoon water (Okeowo *et al.*, 2015). Furthermore, there exist little literature on the socioeconomic determinants of artisanal fish production output in Badagry Local Government Area of Lagos State. Therefore, the study examined the socioeconomic determinants of artisanal fish production output in the study area.

METHODOLOGY

The study was conducted in Badagry Local Government Area (LGA) of Lagos State, Nigeria. The respondents were chosen using a two-stage sampling technique. Firstly, out of the 8 fishing sites in the study area, three fishing sites (Alakotomeji, Yevoyan and Aivoji) were purposefully selected due to high concentration of fishing activities in the area. Secondly, fisher folks were selected proportionately to size across the three fishing sites to give a total of 120 fisher folks which was the sampling population for this study.

Data on fisher folks' socio-economics, inputs use and cost, output realized from fish farming and prices were obtained with the aid of a structured questionnaire. Data collected were analyzed using descriptive statistics (frequency counts, percentages and mean) and Ordinary Least Square (OLS) regression analysis.

The model is explicitly stated thus:

$$Y_i = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_3 + \cdots \ldots \ldots \ldots \ldots \ldots \ldots \ldots . . + \beta_7 X_7 + \varepsilon_{it}$$

Where:

Y_i = Fish output (naira)

X_1 = Sex (male =1; 0 otherwise)
X_2 = Age (years)
X_3 = Educational level (number of years spent in school)
X_4 = Number of boats employed in fishing (number)

X_5= Fishing experience (years)
X_6 = Credit beneficiary (beneficiary = 1; 0 otherwise)
X_7 = Frequency of extension contact (number)
ε = Error term

RESULT AND DISCUSSION

Socioeconomic characteristics of artisanal fish farmers

The socioeconomic characteristics of the artisanal fish farmers sampled in the study area are presented in Table 1. Majority (61.7%) of the fisher folks were male while 38.3% were female. This means that artisanal fishing activity is male dominated. This conforms to the earlier documentation of Aminu *et al.*, (2017) on the same subject. More than one-third (37.5%) of the fisher folks were between 40-49 years of age. The average fisher man in the study area is about 44 years old. This implies that majority of the fisher folks are in their active and productive age and therefore best effort can be put in to guarantee optimum output. This further corroborates the findings of Olaoye *et al.*, (2012) and Aminu *et al.*, (2017).

The result further showed that majority (60%) of the fisher folks had secondary education while very few (10%) had non-formal education. In terms of fishing experience, majority (62.5%) of the fisher folks had between 6-10 years fishing experience, 20.8% had between 1-5 years while 16.7% had above 11 years. This suggests that a small proportion of the fisher folks were relatively new in the business. This is in tandem with the earlier report as opined by Olaoye *et al.*, (2012), who found that fishing experience is important in determining the output levels of artisanal fisher folks, the more the experience, the more fisher folks understand the fishing environment, conditions, patterns, styles, trends, terrains and prices. Some (38.3%) of the artisanal fisher folks had 3 boats for fishing, 25% had 2 boats while 36.7% had just one boat. Also, as shown in the table, 60% of the artisanal fisher folks were credit beneficiaries from the cooperative society while very few (40%) were non-beneficiaries. This could enhance and improve their output. Fish output in naira showed that a large number (66.7%) of the fisher folks realized between ₦10,000 and ₦ 50,000 on a monthly basis, 25.8% realized below ₦10,0000 while just very few (7.5%) realized above ₦ 50,000.

Table 1: Socioeconomic Characteristics of Artisanal Fish Farmers in the Study Area

Variables	Frequency	Percentage	Mean
Sex			
Male	74	61.7	
Female	46	38.3	
Age (years)			
30-39	39	32.5	
40-49	45	37.5	
50-59	29	24.2	
60 and above	7	5.8	44.4
Educational qualification			
Non-formal	12	10.0	
Primary	36	30.0	
Secondary	72	60.0	
Fishing experience (years)			
1-5	25	20.8	
6-10	75	62.5	
11 and above	20	16.7	8.1

Number of boats			
1	44	36.7	
2	30	25.0	
3	46	38.3	2.0

Ordinary Least Square Regression Analysis of the Socioeconomic Determinants of Artisanal Fish Production Output

The socioeconomic drivers of fish production output in the study area was investigated using Ordinary Least Square regression analysis. Table 2 showed that six explanatory variables (sex, age, number of boats, fishing experience, credit beneficiary and frequency of extension contact) are significant factors impacting fish production output at various probability levels. The diagnostic statistics revealed that the model is correctly fitted. The co-efficient of multiple determination, R^2 value of 0.641, revealed that the explanatory factors (sex, age, number of boats, fishing experience, credit beneficiary and frequency of extension contact) explained 64.1 percent of the variation in fish production output. The obtained coefficients are consistent with the *a priori* expectations. The F-ratio was 9.20 and statistically significant at 1%.

The coefficient of fisher folks' sex (X_1) is positive and significant at 5%. This means that fish output from male fisher folks were much higher than the female fisher folks. Age of the fisher folks (X_2) is positive and statistically significant at 10%. This implies that as their age increases, the output from fish catch also increases possibly due to perfection in fishing activities. Specifically, a unit increase in the age of the fisher folk will increase fish production output in the study area by 23.2%. This agrees with the earlier submission of Ifejika *et al.*, (2007); Onyenweaku *et al.*, (2010) and Oke *et al.*, (2021) who submitted that productivity increases with age possibly due to accumulated knowledge and experience gathered from years of observations and experimentations with various production technologies. Number of boats (X_4) is statistically significant at 1% but also has a positive relationship with fish output. This suggests that the higher the number of boats, the higher the fish output. Specifically, an additional boat usage in fishing will increase fish output by 81.5% in the study area. Fishing experience coefficient (X_5) is positive and significant at 10%. This suggests that the more experienced the fisher folks, the more the fish output. This may probably be due to the fact that perfection sets in with repetition of fishing activities over time. This results further agrees with the earlier submission of Oyinbo *et al.*, (2016) that experience positively influence farmers output. Credit beneficiary (X_6) was positive and statistically significant at 1%. The positive relationship observed also conforms to the *a priori* expectation. This implies that fisher folks who benefitted from credit facilities from the cooperative society had higher output levels than those who did not. Specifically, credit facilities will increase fish output level among the fisher folks in the study area by 53.3%. This corroborates the earlier findings of Chikezie *et al.*, (2012) and Onyekuru *et al.*, (2019) who submitted that credit play an important role in agribusiness activities and positively influence output level and its absence affect economic returns. Frequency of extension contact coefficient (X_7) was significant at 10% and had a positive relationship with fish output level in the study area.

Table 2: OLS Regression Analysis Result of the Determinants of Artisanal Fish Production Output in Badagry Local Government Area

Variables		Co-efficient	t-value
Sex	X_1	0.178	1.96**
Age	X_2	0.232	1.93*
Educational level	X_3	1.070	1.49
Number of boats	X_4	0.815	17.72***
Fishing experience	X_5	0.533	1.71*
Credit beneficiary	X_6	0.684	9.24***
Frequency of extension contact	X_7	0.200	1.90*
Constant		59327.79	2.38
Number of observation		120	
R^2		0.641	
Adjusted R^2		0.639	
F-ratio		9.20	

Source: Computed from Field Survey, 2021
***, ** and * denote significance at 1%, 5% and 10% probability levels respectively.

CONCLUSION

The study concluded that sex, age, number of boats, fishing experience, credit facilities, and frequency of extension contact had statistically significant influence on artisanal fish catch level in the study area. As a result, the study recommended that credit facilities be made more accessible to artisanal fish farmers by relevant stakeholders in order for them to increase their production output so as to serve the rapidly growing population.

ABSTRACT

Coronavirus pandemic is putting diets, food systems and agricultural production in jeopardy globally, with agricultural trade and value chains out of reach for masses. Therefore, this study analyzed the impact of coronavirus on food systems in Ikwerre LGA of Rivers State, Nigeria. Data were analyzed using descriptive statistics. The result of the socio-economic descriptions shows that majority (78.9%) of the farmers were married, and 71.9% indicated no interest in any farmers' association. Also, the result shows that majority (96.5%) of the farmers were aware of coronavirus pandemic, and 52.6% agreed that farmers were vulnerable to coronavirus. The study recommended that farming inputs should be subsidized and agricultural produce markets reorganized. Also, storage facilities should be made available in rural areas.

Keywords: *Coronavirus, food systems, distributions, vulnerability, sustainability*

INTRODUCTION

Food is indispensable and essential for human growth and well-being. Crop planting, hunting, fishing and other agricultural related activities have always been occupations that provide livelihood for majority of the rural populace. With job diversification and urbanization on the rise, agricultural activities have also become important sources of income, alongside food processing and marketing that have improved to feed cities (Dury, Bendjebbar, Hainzelin, Giordano & Bricas, 2019). Food systems means the chains of market and non-market operations and actors relating to food production, aggregation, transportation and storage, processing and catering, distribution, preparation and consumption, waste and resource management, agro-input suppliers (seeds, fertilizers, improved livestock) and the associated regulatory activities (Food and Agriculture Organization FAO, 2018). Abundant food alone does not guarantee food security as food availability are influenced by food supply and demand, food accessibility and affordability which are key drivers of food security. As a result, food systems are strategic in contributing to food security and social impacts (Dury *et al.*, 2019). FAO (2017), classified food systems into three focus areas which objectively address global food concerns in keeping with social implications. They are: food security and improved nutrition; inclusive development; creation of a sustainable environment and the fight against climate change.

Socio-economic trends are key drivers of the Nigerian food system. Nigeria is facing major challenges with high population growth, high number of people living in extreme poverty, rapid urbanization, and stagnating agricultural productivity. Public investments in the agricultural sector are low, resulting in underdeveloped (especially rural areas) infrastructure (roads, storage and processing facilities) as well as insufficient agricultural services such as advisory services, access to inputs and finance (Posthumus, Dengerink, Dhamankar, Plaisier & Baltissen, 2020). Due to the inadequate investment which resulted in low productivity, Nigeria is deficit in food production. The high urban demand is met through cheap food imports, which further lowers the incentives for investments in Nigerian agriculture. As such, the shortfalls in food supply at many levels seem to be enabling poverty by reinforcing increased demand for food. Environmental trends, such as soil degradation, climate change, water scarcity, deforestation and decreasing biodiversity pose further threats to the food system, as well as current pandemic of coronavirus. The novel coronavirus increasingly illuminates a serious underlying instability that goes beyond health. This instability stems from the fact that health, energy, finance, and food systems are all inextricably linked.

The spread of COVID-19 globally will compound pressures on food systems. Consumer access to food and producer access to markets could be impacted significantly. In Nigeria, especially Ikwerre Local Government Area of Rivers State Nigeria, the virus could take a significant toll on food production should it affect the aging agricultural workforce who are more vulnerable to it and/or prevent women and rural dwellers (who produce almost 70% of Nigeria's food) from farming. To this end this study examined the impacts of coronavirus on food systems in Ikwerre Local Government Area of Rivers State, Nigeria. The specific objectives of the study were to: describe the socio-economic characteristics of farmers in the study area; ascertain the influence of coronavirus on food production and distribution channels in the study area; determine the factors affecting food systems sustainability in the study area.

MATERIALS AND METHODS

The study was conducted in Ikwerre LGA in Rivers State, Nigeria. It is located between latitudes 4º58′10′′N and 5º14′30′′N, and longitudes 6º49′0′′E and 7º0′0′′E. It covers an area of about 655km^2 with projected population of 265,400 by 2021 (National Bureau of Statistics NBS, 2022). The Ikwerre LGA has ten (10) districts. namely Aluu, Elele, Igwurita, Isiokpor, Omogwa, Omadema, Omerelu, Ozuoba, Ubima, and Umuanwa.

Multistage sampling procedure was used to select the farmers for the study. Stage one was a random selection of four (4) districts. Stage two involves random selection of three (3) communities from each district, making twelve (12) communities. Lastly, nine (9) farmers were purposively selected from each community, this purposive selection was due to restriction on the movement during the period of data collection making a total of one hundred and eight (108) farmers of which eighty (80) were retrieved for the study. The data for the study were collected from primary source with the aid of questionnaire and interview schedule. Secondary sources include articles, journals, internet and review of books to provide the needed theoretical background for this study. Data were analyzed using descriptive statistics.

RESULTS AND DISCUSSION

Table 1: Socio-economic characteristics of the farmers

Variables	Mean	Minimum	Maximum
Age (Years)	41.61	17	65
Years spent in formal education	11.26	0	22

Household size	6	1	15
Farmers' household distance to the farm (km)	1.6	0	10
Farming experience	15.14	2	50
Crop farm size (ha)	0.85	0.1	3
Livestock size (number)	400	2	2500

Source: Field survey, 2020.

Table 1 shows that the farmers mean age (42 years) is within productive age. The farmers indicated sufficient number of years spent in formal education (11 years); which implies that they could read and write and are capable of keeping farm records. The farmers have adequate farming experience (15 years); crops and livestock were being produced at subsistence scale which could be made worse by the COVID-19 pandemic. Awareness of coronavirus by the farmers in the study area indicated that majority (96.3%) of the farmers were aware of coronavirus while about 60% attested to the vulnerability to coronavirus. This presupposes that the farmers could mitigate the effect of coronavirus in their production system.

Source: Field survey, 2020.

Table 2 shows the effects of coronavirus on food production and distribution channel. Insufficient access to capital due to restriction in banks and crowd, border closures due to inter-state transportation, perishability of most agricultural produce, increase in cost of farming inputs, trade restrictions imposed on exporters, reduction in incomes of the farmers and poor access to Medicare even after been infected were rated highest among the factors that affect food production and distribution. While threat to improved food nutrition, unsafe foods, reduced food security and supply chains restriction due to quarantines were ranked lowest among the factors that affect food production and distribution. This implies that coronavirus could compound the pressures on food systems, as all the actors along the food value chain could be affected in different ways. This finding agrees with FAO (2019) which stated that coronavirus pandemic is capable of disrupting the global food system.

Table 3: Control measures adopted in the community against coronavirus pandemic in the study area

Variables	Frequency	Percentage
Road blockage		
Adopted	48	60.0
Not adopted	32	40.0
Quarantine		
Adopted	53	66.3
Not adopted	27	33.7
Disruption and closure of market

Table 3 shows the control measures adopted during the pandemic of coronavirus. The strategies adopted for improving food system amidst coronavirus pandemic include; relocation of market (51.3%); mobile buying and selling (40%); use of mobile money transfer (40%); house-to-house selling (61.3%) and online platforms (social media) (47.5%) of the farmers.

CONCLUSION AND RECOMMENDATIONS

The impacts of coronavirus on food systems in Ikwerre LGA of Rivers State, Nigeria induced serious threats on food systems especially in the area of security, stability, accessibility, and distribution. Coronavirus with its hampering effects is capable of slipping Nigeria into deeper crisis of food insecurity and resource scarcity, thereby reducing the chances of being food sufficient as a nation. The study therefore recommended that: storage facilities should be made available even in rural areas where most of the foods are coming from to reduce the incidence of food spoilage; farming inputs should be subsidized for the farmers and agricultural produce markets for each commodity should be reorganized; there should be policies along the food supply chain which include: production, storage, processing, transportation, and purchasing activities to minimize food insecurity, malnutrition and famine; research should be developed and funded to undertake potential impacts on food system actors and their interconnecting risks; food processing machineries and equipment should be made available to counter the labour problems.

PROCEEDINGS
56th Annual Conference
Agricultural Society of Nigeria
24 - 28 Oct., 2022

ABSTRACT
The study assessed the utilization of Information and Communication Technology (ICT) in enhancing Cassava production in Oyo State Nigeria. Multi stage and simple random sampling techniques were used to select 120 respondents for the study. Interview schedule was used to retrieve data from the respondents. Descriptive analysis was used to describe socio-economic characteristics of the respondents. The inferential statistics (Chi-square) was used to test the hypothesis. The results showed that the majority (90.8%) of the respondents were married and with the Mean age of 39.1 years. All the respondents (100%) made use of at least one type of ICT to acquire information on cassava production activities. The type of ICT utilized mostly and regularly by the respondents in enhancing cassava production included; Mobile phone ($\bar{x}$ =3.85), Radio ($\bar{x}$ =3.39), Television ($\bar{x}$=3.15) while Poster/print media ($\bar{x}$ =3.11), Computer ($\bar{x}$ =2.82) and Internet ($\bar{x}$=2.56) were either occasionally or not utilized at all. Constraints to the use of ICT for cassava production were; network failure ($\bar{x}$=4.73), infrastructural problem ($\bar{x}$=4.09), interest of the farmers ($\bar{x}$=4.08), literacy level of the farmers ($\bar{x}$=4.06), availability of the resources ($\bar{x}$=3.79), awareness of ICT amongst cassava farmers ($\bar{x}$=3.71) and problem of technical skill ($\bar{x}$=3.69). It was recommended that agricultural extension agents should facilitate workshops where cassava farmers will be developed in ICT skills for their production.

INTRODUCTION
Apart from petroleum, agriculture plays prominent roles in Nigeria's economy. It Provides employment and alleviates poverty in youths and adults in most developed and developing countries. Still, it faces some serious challenges, such as poor communication, climate change and continued deficiencies in infrastructure in rural areas (Adebayo, 2015). However, adequate dissemination of detailed information is a necessary condition for improvement of all areas of agriculture (Fors and Merno, 2020). Thus, Information and Communication Technology (ICT) have been found to increase productivity and output, reduce cost of transportation among other benefits. Small scale farmers who dominate the landscape of developing countries need to

improve farming by acquiring adequate knowledge and information. ICT is an incorporated system which entails the use of computers, mobile communication gadgets, television, radios and satellite imagery equipment (Gelb and Parkers, 2006). ICT has proven to increase agricultural output by improving product quality, provision of full information for product pricing, enabling the collection of agricultural data more efficiently, improving soil testing techniques, improving marketing (e-commerce), easy sorting and record keeping, and so on. Ortmann (2002) opined that the use of ICT is becoming popular as more and more farmers are no longer interested in the traditional ways of keeping farm data and records because they are relatively simple to use and satisfy the recording and information requirement of many farmers. Farmers need different types of information during each stage of production, ranging from weather forecast, pest attack, input, improved cultivation practice, pest and disease management and prices (Jorge, 2002). Inaccessibility of most farmers to ICT had led to low productivity of output. The observed trend therefore necessitated the need for this research work. Hence, general objective of the study was to assess the use of Information and Communication Technology (ICT) in enhancing cassava production in Oyo State while specific objectives were to identify the socio-economic characteristics of the respondents, identify the type of ICT utilized by the cassava farmers in enhancing their production in the study area, examine perceived effect of Information and Communication Technology (ICT) utilization on cassava production and identify constraints to the use of ICT in cassava production in the study area.

METHODOLOGY

The study was carried out in Oyo State, Nigeria. Population of the study comprised of cassava farmers in Oyo State. Multi stage and simple random sampling techniques were used in selecting respondents in the study area. Data were collected from the respondents using interview schedule. The data collected were subjected to descriptive statistics such as frequency and percentage. The inferential statistics (Chi-square) was used to test the hypothesis. Oyo State Agricultural Development Programme (OYSADEP)'s zones such as Ibadan/Ibarapa, Ogbomoso, Oke ogun and Oyo were identified and selected (stage 1). Local governments in each of the agricultural zones were identified and listed (stage 2). 25% of the Local Government were randomly selected in each of the zones (stage 3) while simple random technique was used to select 120 respondents from the local governments selected in stage 3.

RESULTS AND DISCUSSION

Socio economic characteristics of the respondents

Table 1 shows that the mean age of the cassava farmers was 39.1 years. This shows that respondents who make use of ICT in cassava production were still active. This fell in line with the finding of Olise (2010) that young people participate more in ICT driven agriculture. Majority (90.8%) of the respondents are male while 9.2% are female. Majority of the respondents (91.7%) are married, 3.3% are single, 4.2% are widowed and 0.8% are divorced. This shows that matured and responsible respondents are engaged in the use of ICT for cassava production. The Mean household size was 7. This is a good source of cheap and affordable farm labour. Most of the respondents (74.2%) had between secondary and tertiary education. Education is a very vital tool in decision making which influences farm productivity as regards perception and adoption of innovation. This agrees with Ramli *et al.* (2013) findings that educational level enhances efficiency of farmers. The average annual income of the respondents was ₦862,851.44.

Table 1: Distribution of the respondents according to socio economic characteristics

Variable	Frequency (N=120)	Percentage %	Mean
Age			

20-30	31	25.8	
31-40	52	43.4	39.1

ICT utilized in enhancing cassava production;

Based on ranking, Table 2 reveals the ICT utilized by the respondents in enhancing cassava production in the study area. These include: Mobile phone ($\bar{x}$ =3.85), Radio ($\bar{x}$ =3.39), Television ($\bar{x}$=3.15), Poster/print media ($\bar{x}$ =3.11), Computer ($\bar{x}$ =2.82) and Internet ($\bar{x}$=2.56). This implies that majority of the respondents preferred mostly, the use of mobile phone to get agricultural information while the Internet is the least utilized by the respondents in the study area. According to the respondents, mobile phones have enhanced their ability to assess different agricultural information and group discussions. This was in agreement with Seyed and Seyed (2012) that most of the farmers made use of mobile phone, radio, television among others in agricultural activities.

Table 2: ICT utilized in enhancing cassava production in the study area.

Variable	SA	A	SD	D	U	Mean	Ranking
Mobile phone	106(88.4)	11(9.1)	_	3(2.5)	_	3.85	1st
Radio	24(20.0)	56(46.7)	2(1.7)	21(17.5)	17(14.1)	3.39	2nd
Television	21(17.5)	41(34.2)	10(8.3)	40(33.3)	8(6.7)	3.15	3rd

Perceived effect of ICT utilization on cassava production

Table 3 reveals the perceived effect of ICT utilization on cassava production. Most of the perceived effects according to the respondents were: easy access to various technology ($\bar{x} = 4.36$), easy contact between farmers and buyers ($\bar{x} = 4.25$), exchanging of information among the respondents ($\bar{x} = 4.19$), inter-personal relationship between the farmers and extension agent ($\bar{x} = 4.17$), enhancement of strong social cohesion between the farmers and the consumers ($\bar{x} = 4.14$), information obtained from ICT increased the source of income of the farmer ($\bar{x} = 3.99$), and it enable the farmers to get in touch with fellows farmers ($\bar{x} =3.88$). This implies that ICT played a great role in cassava production in the study area. This result is in consonant with Seyed and Seyed (2012), that the role of ICT in agricultural production can't be over emphasized.

Table 3: Perceived effect of ICT utilization on cassava production in the study area.

Variable	SA	A	SD	D	U	Mean	Rank
Access to various technolies.	41(34.2)	74(61.7)	_	3(2.5)	2(1.6)	4.36	1st
Easy contact between farmers and buyers.	56(46.7)	47(39.2)	5(4.2)	8(6.7)	4(3.2)	4.25	2nd
Exchange of information among farmers.	50(41.7)	58(48.3)	_	2(1.7)	10(8.3)	4.19	3rd
Promote interpersonal relationships between the farmers and extension agents.	54(45.0)	52(43.3)	_	3(2.5)	11(9.2)	4.17	4th

Constraints to the use of ICT for cassava production in the study area

Table 4 revealed the factors that hinder the use of ICT for cassava production in the study area. The factors as exposed by the Mean were: Bad net work ($\bar{x}$=4.73), infrastructural problem

($\bar{x}$=4.09), interest of the farmers ($\bar{x}$=4.08), literacy level of the farmers ($\bar{x}$=4.06), availability of the resources ($\bar{x}$=3.79), awareness of ICT among the farmers ($\bar{x}$=3.71) and technical skill problem ($\bar{x}$=3.69). The findings were in line with the work of Adebayo (2015) that various factors hinder the use of ICT in cassava production.

Table 4: Constraints to the use of ICT for cassava production in the study area

Variable	SA	A	SD	D	U	Mean	Ranking
Bad network	77(64.2)	42(35.0)	_	_	1(0.8)	4.73	1st
Infrastructural problem	36(30.0)	69(57.5)	_	7(5.8)	8(6.7)	4.09	2nd
Interest of the farmers.	45(37.5)	60(50.0)	_	4(3.3)	11(9.2)	4.08	3rd
Literacy level of the farmers.	43(35.8)	53(44.2)	2(1.7)	9(7.5)	13(10.8)	4.06	4th
Availability of the resources	25(20.8)	53(44.2)	_	7(5.8)	35(29.2)	3.79	5th
Awareness of ICT among the farmers	35(29.1)	43(35.8)	5(4.2)	14(11.7)	23(19.2)	3.71	6th
Technical skill problem	32(26.7)	38(31.7)	_	9(7.5)	41(34.1)	3.69	7th

Relationship between selected socio economics characteristics of the respondents and the use of ICT

Chi-square analysis results as indicated in the Table 5 shows that sex (x^2= 0.000), marital status(x^2 = 0.000) and educational level (x^2= 0.000) had a significant relationship with the use of ICT in the study area. This indicated that sex has relationship with the use of ICT. Education had a positive and significant impact on farmers adoption of new innovation. Marital status determines the social life of the respondents.

Table 5: Relationship between selected socio economics characteristics of the respondents and the use of ICT

Variable	X	Df	P-value	Remark
Sex	73.422	1	0.000	S
Marital	285.21	3	0.000	S
Educational Level	24.136	2	0.000	S

Source: Field survey, 2021 p-value = $\leq$ 0.005 S = significance NS = No significance

CONCLUSION

Based on the result of the study, it can be concluded that majority of the respondents used ICT to enhance cassava production and mobile phone, radio and television were the type of ICT mostly used. In view of the findings, the followings were recommended.

(i) The government should provide social amenities in the rural area such as electricity which will motivate the farmers to use ICT.
(ii) Agricultural extension agents should facilitate workshops where cassava farmers will be developed in ICT skills for their production.
(iii) The government should encourage software developers to reduce taxes paid by them so that suitable packages will be developed for agricultural productions.
(iv) The existing communication equipment should be upgraded by the Government and the concerned industries to ensure better cell phone and internet coverage.

24 - 28 Oct., 2022

ABSTRACT

Farmers especially yam producers are constrained by the availability of high-quality seed yam of improved genotypes. Temporary Immersion Bioreactor System (TIBS) is an advanced method of tissue culture used in raising virus- free clean yam plantlets. This production process will help make adequate clean planting materials available to seed companies. However, the economic status of this seed yam production enterprise is yet to be established. This study was aimed at assessing the economics of seed yam plantlets produced through TIBS for sustained seed yam production business in Nigeria. Through specifically estimating the production level, costs, benefit and profitability of yam plantlet produced from this enterprise. Data for the study was collected from National Root Crops Research Institute (NRCRI) tissue culture laboratory under the project of Yam Improvement for Income and Food Security in West Africa (YIIFSWA) sponsored by Bill and Melinda Gate Foundation. Data on fixed cost, variable cost and production volume was collected during 2020-2021 production period. The results showed that about 21,797 plantlets were produced within period under review. The sum of N4,395,629.46 (USD 10,579.132) was the total cost of production while the net profit of N3,887,230.54 (USD 9,355.548) was gotten. The production of yam plantlets in temporary immersion bioreactor should be considered a good business as it has shown evidence of good returns. This production process should be supported by both the public and private sector in other to promote availability of disease-free breeders' seed.

Key Words: Seed Yam, Agribusiness, Breeder, Plantlets.

INTRODUCTION

The productivity of yam in Nigeria is low when compared with the required optimal yield per hectare. (Balogun et al 2014). Seed yam producers are constrained with limited land area, poor soil fertility resulting from flooding and desertification, high labour cost, disease and pest infestation and unavailability of quality planting materials (Acheampong, et al 2020). The traditional approach has a slow propagation rate that occurs through vegetative propagation, thereby encouraging a build of so many diseases and pest infestation. Low quality seed yam containing pests and pathogens also result in a poor yield of ware yam tubers as well as yield loss of more than 80% (IITA, 2010). The expansion and increasing intensification of yam cultivation have raised the need for ensuring a sustainable availability of high-quality seed yam on a commercially viable basis in yam growing areas. However, high quality seed yam of improved genotypes is out of reach to most farmers. This has necessitated high demand for clean seed as up to 70% of production cost is spent on the purchase of seed yam (Ironkwe, 2005., Coyne, 2010 and Balogun et al 2014). Quality diseased free seed yam has been identified as one of the panaceas to enhanced yam productivity. To address these constraints, there is a need for developing an innovative yam propagation technique using other methods like the use of Temporary Immersion Bioreactor System (TIBS). TIBS is an advanced tissue culture (TC) technology, where plants are intermittently immersed in nutrient solution in contrast to conventional TC with continuous immersion. This novel technology was developed for high ratio propagation of high quality pre-basic and basic seed yam. The goal of increasing yam productivity for smallholder farmers in Nigeria can be achieved through innovative technologies among which is the use of Temporary Immersion Bioreactor System (TIBS). The use of new propagation systems for seed yam, which are quick, and result in clean planting material, thereby enhance the scaling up of formal seed yam production system. However, there is yet a report that put a cost on seed yam produced using this production process. The economic status of these seed yam production enterprise is yet to be established. This is necessary as it will encourage the incorporation of private sector into emerging formal seed system. This study is designed to empirically evaluate economics of seed yam plantlets produced from through TIBS for sustained seed yam production in Nigeria. This will be achieved through specifically to estimate the cost per plantlet from the production process, determine the profitability of yam plantlet produced from the enterprise and make recommendation to investors for better efficiency.

METHODOLOGY

The study used data collected from NRCRI tissue culture laboratory under the project of Yam Improvement for Income and Food Security in West Africa (YIIFSWA) sponsored by Bill and Melinda Gate Foundation. Data were collected on the cost factors for the production of yam plantlets and the selling price was established using 10% margin and the prevailing market price.

Analytical framework/model specification

Gross profit was used to determine the profitability of the enterprise. Thus
GP = TR-TVC -------------- (1)

Where:
GP = Gross Profit
TR = Total Revenue

TC = Total Cost of Production

Gross Margin (%) = GP/TR x 100-------- (2)

RESULT AND DISCUSSION

Capital Investment

The fixed cost was depreciated and calculated as was presented in Table 1. The items required to run a bioreactor include building which houses the production work space. The work space alone constituted about 33.95% to the annual fixed cost. Bioreactor vessel and screen house were also necessary as the constituted about 27.38% and 15.83% respectively of the total fixed cost. Other items include the shelves, Air conditioner and hardening tray altogether make up of about 10.29% of the annual fixed. The total annual fixed cost of N1,472,617 was incurred in running a bioreactor. Although is a capital-intensive venture but the cost could be spread along a time period.

Table 1: Depreciated cost of equipment associated with the production of seed yam plantlets in TIBS

Fixed Cost	Unit	Quantity	Unit Cost (N)	Total Cost (N)	Depreciated Cost
Production work space	Number	1	5,000,0000	5,000,000	500,000
shelves	Number	3	67600	202,800	40, 560
Electrical installation	Value		204,400	204,400	40,880
Bulbs	Number	3	1500	4500	2250
Air Conditioner	Number	1	138,000	138,000	46,000
Bioreactor Vessels	Number	8	252,000	2,016,000	403,200
Inverter	Number	1	750,000	750,000	75,000
Generator	Number	1	200,000	200,000	66,667
Screen house	Number	1	2,330,600	2,330,600	233,060
Hardening tray set	Number	5	39,000	195,000	65,000
TFC					1,472,617

Operational Cost

The results of the variable cost associated with the production of seed yam plantlets produced in temporary bioreactor system was presented in table 2. The items in the variable cost consist of consumables (reagents, Vivi packs, poly bag, labour and stock plantlets) The result shows that the total variable cost incurred in the production was N2, 523,409.78. The stock plantlets and the vivi pack were the highest contributors to the total variable cost amounting to 38.41% and 22.10% respectively. The total cost of production per annum was N3,996,026.78. The variable cost constituted about 63.15% and fixed cost 22. 79%.

Table 1: Variable Cost associated with the production of Breeders Seed yam in Temporary Immersion Bioreactor System (TIBS)

Revenue Estimation

Plantlets and micro tubers can be produced in Bioreactors. Plantlets could be due for harvesting between 8-10 weeks from the bioreactor vessel and further hardened in vivipack for at least two weeks. The result for the revenue estimate and gross margin analysis is presented in Table 3. The result shows that about 21,797 plantlets were produced within the period under review. An estimated price per plantlet was N262 (break-even price plus 30% mark-up). The gross profit for the period under review is N5,710,814 while the net profit is 1,315,184.54. the benefit cost ratio was reported to be 1.3, which implies positive returns to investment. The result shows that production of diseases free seed yam using Temporal immersion bioreactor is profitable.

Table 3: Gross margin Analysis

Table 4: Gross margin Analysis	
Revenue (1)	5,710,814
Variable cost (2)	2,523,409.78
Fixed cost (3)	1,472,617
Total cost (4)	4,395,629.46
Gross profit (1-2)	3,187,404.22
Gross margin	55.81%
Net profit (1-4)	1,315,184.54
Net margin	23.03%
Benefit Cost Ratio (1/4)	1.30:1

CONCLUSION

The study revealed that the production of yam plantlets in temporary immersion bioreactor should be considered a profitable business as it returns N1.30 in every N1 spent. This hope to increase in the long run as it is presently not running full capacity. It was therefore recommended that the scale of production should be increased in other to reduce cost of production.

Agricultural Society of Nigeria
24 - 28 Oct., 2022

ABSTRACT

This study assessed the profitability and marketing efficiency of yam production among yam farmers within the last three planting seasons in Ebonyi State, Nigeria. Rapid rural appraisal (RRA) involving multistage purposive and stratified sampling technique was adopted for farmers' selection based on sampling frame of contact farmers of the Agricultural Development Programme (ADP) in Ebonyi State, to select a total of 216 yam producers and marketers of the study area. The result of multiple regression on the effect of socio-economic characteristic of the farmers had a coefficient determination (R^2) of 78.9% and four variables out of ten had a positive coefficient and were significant at 1% and 5%. Good farming experience, good source of income, good prices of ware yam and marital status would encourage utilization of more land and production profitable as they increased revenue significantly. Budgetary and marketing efficiency determination and profitability in yam production revealed that the business is profitable with gross margin of ₦1,440,000, ₦1,512,000 and ₦1,764, 000 per tonne transacted and hectares cultivated and in three seasons, 2015, 2016 and 2017 respectively. The Benefit cost returns indicated that every 1 naira invested in each year returned ₦1.50, ₦2.53 and ₦2.59, respectively. Yam production was profitable in all the seasons but was constrained by high cost of planting material, high cost of labour, land fragmentation issue, lack of capital and dearth of storage facilities and machineries. Based on the findings, the policies recommended were proffered.

Key words: Assessment, profitability, marketing efficiency, production, three planting seasons

INTRODUCTION

Yam *Dioscorea species*) among other root and tuber crops is a tropical tuber crop that belongs to the genus *Dioscorea* and family *Dioscoreaceae* and it production is becoming a business venture globally as they are now the most widely cultivated both in Asia, America and have real economic significant in Africa (Norman *et al*., 2012). In West Africa, yam production has been extensively expanded cultivating four million hectare yearly with about 48 million tons amounting to 95% global food supply (IITA, 2013). Nigeria is the largest producer of valued edible yams, accounting for 70% to 76% of total world production, with 35.07 million meteric tones and largest consumers of yams (USDA, 2011; FAO, 2013).Yam production generally has increased but marketing efficiency is not yet actualize and in this, boosting production without boosting marketing system can lead to glut of yam in the market. This can depress prices and discourage smallholder farmers from investing in yam and other root and tuber crops such as cassava cultivation, cocoyam etc. (IFAD, 2013). In recent years, yam producers in general and especially smallholder farmers have faced considerable difficulties in cultivation and other agricultural practices. Among the challenges are high cost of seed yam (FDAE,2014), others include high cost of input materials, poor storage facilities, high cost of labour, high cost of mechanization, inadequate extension services/ technical advice, inadequate funds, inadequate supply of high yielding varieties, bad access farm roads, effects of weather and climate, production and price fluctuations, lack of price control, preservation and storage problems, value addition among others (FMANR, 2006; ICA,2010;Izekor and Olumese, 2010; IITA, 2013).

Yam is one of the most profitable crop but mostly lost in storage as the conventional barn storage system is the only available option. Similarly, FAO (2013) reported that on the volume of yam lost in metric tons in Nigeria, Ghana and Côte D'Ivoire between 1961 and 2009; Nigeria lost an annual average of 10% within the period under study. The country recorded the highest yam lost in 2006 with over 3.7 million metric tons.. However, its cultivation is very profitable despite high costs of production, yield lost and price fluctuations in the markets annually (Izekor and Olumese, 2010; IITA, 2013). An average profit per yam seed, per harvest and storage in Nigeria, was calculated at over US$13, 000 per hectare harvested (IITA, 2013). Households demand for yam consumption is very high in Sub-Saharan Africa. This made yam production and marketing a profitable business in economic terms as noted by Okeoghene *et al*., (2013) in Ika South LGA of Delta State, Nigeria.

The production sustainability as one of the most economically valued root crops in Ebonyi State, contributing to the dynamic value chains that generate income for local population while continuing to play a leading role of supporting food security and diversification as revealed by profitable cost analysis with improved agricultural programs done in Ebonyi State in 2016 to 2017, above all other factor is dependent on marketing activities (Aja and Igboji, 2017). The incessant rise in price of the planting material is attributable to high cost of production, high level of demand, use as food during scarcity period, yield losses as a result of recent flooding, dwindling farm size among others (Eyitayo *et al.*, 2010). It is imperative to address marketing issues as agricultural development has been constrained by marketing of commodities. It is on this note that needs arose to assess the profitability and market efficiency of yam production, as one of the major staple and cash crop of smallholder farmers in Ebonyi state and Nigeria in general. The broad objective of this study is to assess the profitability and marketing efficiency of yam production within the last three planting seasons in Ebonyi State. Specific objectives include identifying the socio-economic characteristics of yam producers of the study area, investigating marketing practices of the respondents, estimating the cost and returns associated with yam marketing at farm level per van of a hectare, estimating the marketing efficiency, as well as identify the constraints in yam production and marketing in the study area.

METHODOLOGY

The study was carried out in Ebonyi State, Nigeria. Ebonyi state comprises of three senatorial zones with 13 Local Government, namely, Ebonyi North (Ohaukwu, Ebonyi,Izzi and Abakaliki LGA), Ebonyi Central (Ezza South, Ezza North, Ishielu and Ikwo LGA) and Ebonyi South (Onicha,Ohaozara, Ivo, Afikpo south and Afikpo North LGA) senatorial zones. Population of the study area comprises all potential yam producers according to Agricultural Development Programme (ADP) in Ebonyi State, as identified as the major yam producing areas in the three senatorial zones of the State based on State Department of Agriculture annual production figures 2018-2019. In the first stage, 3 LGAs each were purposively selected from the 3 senatorial zones based on massive yam production in the area.

In the second stage, 2 autonomous communities were selected from each of the 3 LGAs, to give a total of 18 communities. The third stage involved cluster sampling of the yam farmers. From each community, 3 stratified villages were selected and 4 farmers stratified according to gender per village was randomly involved. In all, a total of 216 stratified and randomly selected respondents participated in the study. Data were collected using interview schedule to obtain relevant information from respondents and by using questionnaires structured in line with the specific objectives. These were administered in form of oral interview schedule in order to ensure that responses to the questions were correctly filled. Descriptive statistics such as frequency counts, tables and percentages were used to analyze socio-economic characteristics of the respondents, marketing practices and challenges facing respondents. Budgetary analysis was used to estimate cost and returns associated with the enterprise of the respondents. The marketing efficiency was calculated using its standard formula while multiple regression analysis was used to analyzed objective (i) and objective (iv) was analyzed using factor analysis.

RESULT AND DISCUSSION

The coefficients of age, educational level, cost of labour, and farm size were statistically significant and negative at 5% level of probability, while the coefficient of source of income, cost of ware yam at farm gate prices, marital status and farming experience were significant and positive at 5% and 1% levels of probability, respectively. This implied that the older the farmer, the lower the ability to make decision guiding farm business. In other words, old age doesn't transmit to high yam production rather it declines production. Years of schooling has negative coefficient of variation and was significant at 5%. This implies that the more years the respondent spent in the school the lower the revenue due to less attention to farming business. The higher the cost of labour, the lower the hectares under cultivation. This implies that an increase in the cost of labour hired will lessen the number of land to be cultivated and the total revenue generated. The source of income, cost of ware yam, marital status and farming experience were positively signed with revenue and so the aprior expectation was met. The higher the source of income, the higher the land under cultivation, and the larger the family, the higher the land under cultivation and consequent the farm net income. This is true because farming experience increases farmers' knowledge on how to handle production practices and business in making good profit in return. This result corroborated with findings of Okoye *et al*., (2009) but contradict the result of Eyitayo *et al.* (2010) who reported positive effects of higher educational level, farm size and amount of credit obtained by seed yam farmers on output.

Budgetary and marketing efficiency determination

Table II result revealed that total revenue per hectare differed in each year and variable cost comprised cost of buying seed yam, clearing, land preparation, planting and harvesting, fluctuation cost of ware yam (farm gate price) plus cost of marketing (transportation, labour i.e. loading and offloading yam tubers, e.t.c). The average marketing efficiency (M.E.) for the three years is 126.95% and the marketing efficiency ranges from 110.28% of 2015 to 114.34% and 159.22% for 2017 and 2018 respectively. M.E. > 100% implies that the respondent covered the cost of marketing and made a margin above the 100%, hence yam tuber production in 2019 performed associated functions efficiently in comparison to other years in the study area. However, there was yield decline in 2019 but increase in demand of ware tubers suppressed the high cost of planting materials. This result is in conformity with findings of Izekor and Olumese, (2010) and IITA (2013) both noted that yam cultivation is very profitable despite high costs of production and price fluctuations in the markets annually (Izekor and Olumese, 2010; IITA, 2013).

Benefit cost Ratio per year = total revenue divided by total cost 2017 = 2.1, 2018= 2.4, 2019 = 2.6. Appreciated BCR is 2.1:2.4:2.6. If the BCR< 1, the business is not profitable; If the BCR> 1, the business is profitable. The result indicates that the business is profitable. This is in agreement with the result of Okeoghene *et al*., (2013) who observed that yam is profitable business in economic terms in Ika South LGA of Delta State, Nigeria.

Profitability in yam production

The enterprise budgeting as well as cost and return shown in Table II was used in determining the profitability of yam production in the study area. The findings showed that the total revenue from yam production differed in each planting season. Costs and returns to yam production result indicated that the total revenue, gross margin, net farm income and profit realized per hectare of sold ware yam tubers by farmers within the three years were ₦1,440,000, ₦1,512,000 and ₦1,764, 000 representing production per hectare for 2017, 2018 and 2019 respectively. Return on investment (ROI) showed that the amount realized by farmer on every one naira spent on production fluctuated within the three years. This can depress farmers from production. This findings corroborated with IFAD (2013) who noted depress prices can discourage farmers from investing in yam cultivation. The ROI showed that every 1 naira invested in each year returned ₦1.50, ₦2.53 and ₦2.59 respectively. seed yam cost was the highest variable cost item estimated approximately to ₦880,000 and representing 46.9 percent of total production cost of ₦1,978,370. The yam producers within the three seasons realized gross margin, net farm income and net return on investment of ₦943,300; ₦870,880; ₦1,003, 500 and net farm income ₦863,300; ₦950,830 and ₦1,003,500 and approximately net return on investment 1.54 respectively. The net return on investment approximately estimated to value of 1.54, implied that the sum of ₦1.54 was returned as profit on every N1 invested in the enterprise, thus indicating that yam production in the area was profitable. These findings were consistent with IFAD (2013) who reported various levels of profitability and positive return on investment in seed yam production. The result also consonance with FDAE (2014) who noted seed yam cost is the highest variable cost in seed yam production.

Constraints to seed yam production

The production constraints faced by yam farmers range from high cost of seed yam to low yield caused by climate vagaries. As indicated in Table III, high cost of seed yam was the prime production constraint with mean value of 5.0 on a 5 point scale. Lack of modern farm machineries and technologies to produce planting materials in the agrarian rural communities was found to be the main reason for the high cost of planting material. This was closely followed by high cost of labour necessitated by shortage of labourers which was attributed to rural-urban drift of young and middle aged men in search of white collar jobs leaving yam production in the hand old farmers.

CONCLUSION AND RECOMMENDATIONS

The result indicated that yam production irrespective of the constraints militating against its smooth operation in Ebonyi State, proved a profitable enterprise given the positive values of gross margin, net production income and net return on investment. Yam production in the study area was gender biased in favour of males who were majorly of old age with age-long experience in farming business and with poor level of education. Socio-economic factors such as source of income, cost of ware yam, marital status and farming experience were found to be statistically significant and positively related to gross margin, net income return on investment and total revenue. Major factors found to be militating against increased and profitable production level were high cost of planting material (seed yam), high labour cost, pest and disease problem, land fragmentation, lack of capital and dearth of modern production and storage facilities. Marketing system was efficient in all production seasons despite the fluctuation in price of yam and its product.

It was recommended based on the findings that government policies should be focused on ways of assisting yam farmers with improved planting material, lease land freely to farmers as well as provide machineries for farm work, provide pesticides and insecticides to yam farmers, established board that would serve as middle men between farmers and government, access modern implements and technologies. The producers and marketers should also establish cooperative societies to help ease financial challenge of members and stabilize price of produce per season. This among others would help to ameliorate pressing challenges to yam production and marketing in the study area.

ABSTRACT

The study estimated the Total Factor Productivity (TFP) and its determinants among arable crop farmers in Benue State, Nigeria with a view to examining the effect of soil fertility management on their productivity. Data were collected from 175 farmers using three stage sampling technique. Data analyses were carried out using descriptive statistics, Total Factor Productivity and least square regression analysis. Prevalent soil fertility management practices were; application of inorganic fertilizer (18.9%), crop rotation (15.4%), mulching (14.9%), application of organic manure (13.7%), alley cropping (13.0%), bush fallowing (12.6%) and cover cropping (11.5%). Result indicates that 46.9% of the sampled household heads were productive, i.e. have their productivity value above average across all the soil fertility management categories. Determinants of TFP estimate reveals the following factors as having a significant contribution to productivity at different levels of significance in the study area; age (-1.469), education (0.417), farm size (0.046), alley cropping (.357), crop rotation (.380), application of inorganic fertilizer (.503), mulching (.560) and organic manure (.373). While age impacted negatively on productivity, all others impacted positively on productivity. The study concludes that soil fertility management practices are productivity enhancer. Promoting sustainable soil fertility management practices that are farm or farmer specific is recommended.
Keywords: Arable Crop Farmers, Determinants, Household Heads, Soil Fertility Management and Total Factor Productivity.

INTRODUCTION

Agriculture still remain the mainstay of Nigeria's economy as it accounts for 22.36 percent of National Gross Domestic Product (GDP) and providing livelihoods to approximately 70 percent of the country's active labour force (Bernard & Adenuga, 2017; National Bureau of Statistic [NBS], 2022). Agricultural sector grew at the rate of 4.1 percent in 2016 and it accounted for 75 percent of non-oil exports. To improve the sectorial performance, the Federal Ministry of Agriculture and Rural Development (FMARD) has approved Agriculture Promotion Policy (APP), building on the Agricultural Transformation Agenda (ATA) developed under the administration of President Goodluck Ebele Jonathan. The key themes of this policy are supporting productivity enhancements; crowding in private sector investment and FMARD's institutional realignment with a focus to improving the ease of transacting business in Nigeria's agricultural space (Oredipe, 2017).

Productivity is generally defined as the level of output in relation to levels of resources employed in a given period of time. It is the rates of flow of output when compared to rates of flow of resources such as land inputs used in production (Oyaide, 1994). Poor agricultural productivity and food insecurity are persistent features of many developing countries including Nigeria. Increases in food production in the recent past in Sub-Sahara Africa (SSA) are a result of more land being brought into production rather than higher output per unit area of land (World Fact Book, 2012). With the increasing population, cultivable land is becoming the limiting factor in meeting the growing food demand, implying that farm output growth needs to be achieved through higher productivity (World Bank, 2008).

Soil fertility is the intrinsic ability or capability of the soil to provide plant nutrients and water in adequate amount and when required, for good growth and development of the crops. Soil fertility decline (also described as soil productivity decline) is the deterioration of chemical, physical and biological soil properties and its subsequent reduction in providing the crops with adequate nutrients and water (Agboola, 2001). Good soil fertility management practice helps rejuvenates the soil after each cropping season and also keeps the soil in good shape to support another season, thus, the need for appropriate soil fertility management practices. Soil fertility management practices can be seen as management of the soil to increase the quality and durability of the soil to provide required plant nutrient and water in an attempt to maintain optimum crop productivity (Food and Agriculture Organisation, [FAO] 2001 & Oladipo, et al., 2017). With constant cultivation of the soil to meet the growing demand for food amidst changes in climate and decrease in the ability of the soil to provide the required nutrients for plant, it becomes imperative that appropriate soil management practices are explored to ensure sustainable agricultural production.

Based on this, the objectives of the present study are in three folds. First, to isolate the different soil fertility management practices prevalent among the arable crop farmers in the study area, second, to estimate the productivity of the farming household heads stemming from the different soil fertility management practice most frequently practiced and third, to isolate the determinants of total factor productivity in the study area.

METHODOLOGY

The Study Area

The study was carried out in Benue State, Nigeria. The state which is one of the states that constitute the north-central zone of the country is made up of twenty-three (23) local government areas and shares boundaries with Nassarawa to the north, Taraba to the east, Cross River to the south, Enugun, Ebonyi and Cameroon to the south east, Kogi to the west. The state occupies a land mass of 33,955 square kilometers with an estimated population of 4,253,641 (National Population Commission, [NPC] 2006). The state experiences two (2) distinct seasons; wet and dry with an annual rainfall of between 1250-1750mm while annual temperature ranges between 32-38^{0}C. Inhabitants of the state are predominantly farmers and they cultivate such food crops as yam, rice, cassava, soya beans, groundnut, sweet potatoes, millet and guinea corn while such tree/cash crops like mango, citrus/oranges, pawpaw and pineapple could also be found. Major ethnic groups and tribes in the state are are Tiv and Idoma: others are Igede, Etulo, Jukum, Hausa, Akweya and Nyifon.

Sampling Procedure

The study population was arable crop farmers living in the study area; the data used were collected from the 2020 production season. A three stage sampling technique was used in the study. The first stage was the random selection of four (4) local government areas from the state, the second stage was the random selection of fourteen (14) communities/ villages with probability proportion to the size of the local governments, while the last stage was the selection of farmers from the selected villages/communities based on sampling frame. A total of 200 copies of the questionnaire were administered with only 175 returned with useful information that was used for the analyses as shown in Table 1.

Table 1: Sampling Procedure for the Selection of Farmers.

State	LGAs	Communities	Number of questionnaire administered	Number of questionnaire retrieved
Benue	Buruku	Abwa, Biliji, Mbataase and Mbaya	68	57

Analytical Technique

This study employed a number of analytical tools based on the objectives of the study. The tools include descriptive statistics, total factor productivity and multiple regression. Descriptive Statistics was used to describe the soil fertility management practices using frequency and percentage. Total Factor Productivity Model as employed by Adepoju and Salman (2013) was used to estimate the productivity value of the farming household heads based on the soil fertility management practice most frequently used. Total Factor Productivity (TFP) is a method of calculating agricultural productivity by comparing an index of agricultural inputs to an index of outputs (Jean-Paul, 2009). Total factor productivity is therefore measured as the inverse of unit cost following Key and Mcbride (2003). This is the ratio of outputs in naira value to the total variable cost (TVC) of production. TFP measures that use physical quantities as output measures rather than revenue actually exhibit even more variation than do revenue-based measures as documented in Foster *et al*., (2008). Hsieh *et al*., (2009) also find greater productivity dispersion in the TFP measures that use quantity proxies to measure output.

$$TFP = \frac{Y}{TVC} \quad \ldots\ldots 1$$

Where Y = Output in Naira value in line with Mwuese and Okorji, (2014).

TVC = Total Variable Cost

TFP = $\frac{Y}{\sum P_i X_i}$ i= 1, 2, …………..n……………………………………………………………………2

Where Y = quantity of output in Naira and P_i = unit price of ith variable input and X_i = quantity of ith variable input

The inputs used in line with Fakayode *et al*., (2008) are: cost of labour, cost of planting materials, Cost of inorganic fertilizer, Cost of herbicide and Cost of pesticide. Following Akintayo and Rahji, (2011) to examine the effect of some socio-economic variables as well as soil fertility management practices on the Total Factor Productivity (TFP), the TFP estimate was subjected to ordinary least square regression to obtain the coefficient of multiple determinations (R^2), F- Statistics, standard error and their values. The ordinary least square regression model is a best linear unbiased estimator whose estimate possesses the desirable properties of unbiasedness, efficiency and consistency.

Model Specification

$Q^* = f(X_1, X_2, X_3, X_4, X_5 \ldots\ldots X_{14}, \mu)$ ……………………………………………………………………………3

Where

Q* = TFP estimate

The Cobb-Douglas production function is specified as:

$Q_i = A \ \pi_i \ Z_i^{bi}$; $i = 1, 2, \ldots 14$ 4

The expanded form is:

$Q_i = A\, Z_1^{b1} Z_2^{b2} Z_3^{b3} Z_4^{b4} Z_5^{b5} \ldots\ldots Z_{14}^{b14} e^{ui}$ 5

Following Gujarati (2004), the empirical model to be used for this study can be cast in double-log form as follows:

$\ln Q_i = \ln A + b_1 \ln x_1 + b_2 \ln x_2 + b_3 \ln x_3 + b_4 \ln x_4 + b_5 \ln x_5 \ldots\ldots\ldots b_{14} \ln x_{14} + u$ 6

Based on the view of Hussain and Perera, (2004) and as adopted by Akintayo and Rahji, (2011), Adepoju and Salman, (2013) the following factors were hypothesized as the determinants of TFP of arable crop farmers in the study area.

x_1 = Age of household heads (years), x_2 Number of years of formal education, x_3 = Household size (number), x_4 = Farming Experience (years) , x_5 = Access to credit(Dummy Variable; Yes = 1 otherwise = 0), x_6 = Farm Size (ha), x_7 = Extension contact (Dummy Variable; Yes = 1 otherwise = 0), Vector of index of soil fertility management practices (Dummy Variable; Yes = 1 otherwise = 0), x_8 = Alley cropping, x_9 = Bush fallowing, x_{10} = Cover cropping, x_{11} = Crop rotation, x_{12} = Application of inorganic fertilizer, x_{13} = Mulching, x_{14} = Application of organic manure

μ = error term which is assumed to be normally distributed and with mean zero and constant variance

RESULTS AND DISCUSSION

Households Soil Fertility Management Practices in the Study Area

Factors Affecting Total Factor Productivity (TFP)

As shown in Table 3, the coefficient of determination (R^2) for food crop farmers (0.758) indicates the presence of a high degree of association between productivity (dependent variable) and all independent variables. This implies that 75.8% of the variation in the farmers' productivity is explained by the variations in the independent variables. The F-statistics of the farmers (F-test= 581.71, P<0.001) was found to be highly significant, implying that the independent variables were collectively important in explaining the variation in the dependent one.

Of the fourteen explanatory variables specified, eight were statistically significant. These were age, education, farm size, alley cropping, crop rotation, inorganic fertilizer application, mulching and organic manure application. The negative coefficient (p<0.01) of age suggests that farmers were less productive as they age, older farmers are not physically able to produce as much as younger household heads because productivity is countered by declining physical strength and perhaps by negative attitudes toward innovation. The negative coefficient, which implies that a unit increase in farmers' age decrease productivity by 1.46, agrees with the findings of Ahmed and Elrasheed (2016).

Table 3: Factors Affecting Productivity of Food Crop Farming Household Heads in Benue State

Variables	Coefficients	Standard error	T	P>|t|
Age	-1.469	.200	-7.33 ***	0.000
Education	.417	.149	2.80***	0.006

N	161			

*** 1% significance level; ** 5% significance level; * 10% significance level
Source: Field Survey, 2021

The coefficient of years of education was positive and significant at 1% implying the significant contribution of the variable to productivity. This implies that a unit increase in years of education will tend to increase productivity by 0.417 unit. This is in conformity with the findings by Shittu et al. (2015) who stated that education increases farmers' productivity. The coefficient of farm size was positive and significant at 10% level and implies that a unit increase in farm size will tend to increase productivity by .034. This is likely to be so as farmers with large farms tend to enjoy economies of scale in the purchase of their inputs and sales of their output, thereby reducing the unit cost. The result conforms to the findings by Wawire at al. (2021).

Though not significant, the positive coefficient in respect of household size, farming experience, access to credit and access to extension contact implies that a unit increase in these variables tends to increase productivity by 0.006, 0.006, 0.003 and 0.0034, respectively. In addition, all the soil fertility management practices were positively related to TFP, implying that increased use of any of the management practices led to increased productivity. Although bush fallowing was not significant, alley cropping, crop rotation, inorganic fertilizer application, mulching and organic manure application were significant. The positive and significant value of organic manure is in line with Nuno and Baker (2021).

CONCLUSION AND RECOMMENDATIONS

The result of Total Factor Productivity estimate indicates that arable crop farmers practicing alley farming were the most productive while those practicing cover cropping were least productive. Practicing alley cropping, crop rotation, mulching and application of organic and inorganic fertilizer enhanced arable crop farmers' productivity in Benue State, Nigeria.

- Since age is negatively related to productivity, it is therefore recommended that youth empowerment program in the area should accord priority attention to agriculture so as to further encourage relatively young farmers into arable crop production.
- Education is productivity and soil fertility management enhancing variable since the level of formal education seemed to contribute to the total factor productivity of the farmers. This will not be unexpected as education has a way of helping farmers to reasonably commit their resources to any productive enterprise, resulting in increase in productivity. It is, therefore, recommended that basic education or adult literacy should be encouraged among farmers. There is need to constantly upgrade farmers' knowledge. Access to information on environmentally friendly and soil fertility management practices should be promoted through the provision of informal education for the farmers in the study area.
- Soil fertility management practices are productivity enhancer; the need to promote sustainable Soil fertility management practices that are farm or farmers specific is hereby recommended.

ABSTRACT

The study determined the perception of smallholder arable crop farmers towards climate change and its coping strategies in Ondo State. A multistage random sampling procedure was used to select 160 respondents from two agro-ecological zones. Data were obtained with a well-structured questionnaire and analyzed using descriptive and inferential statistics (Chi square). Findings show that 37.5% were above 50years, 75.0% were males, 96.8% were married, 38.8% completed secondary education, 81.3% had less than 1.5 hectares of land, 35.0% had 6-10 years farming experience. Radio was the major source of information on climate change The study concluded that climate change is having adverse effect on the productive engagement of smallholder arable crop farmers and this could affect their livelihood activities. The study therefore recommended that smallholder arable crop farmers should stick to ethno-engineering practices to prevent and mitigate the effect of climate change.

Keywords: Small holder farmers, Arable crop farmers, Climate change, Coping strategies.

INTRODUCTION

The issue of climate change has become more threatening not only to the sustainable development of socio-economic and agricultural activities of any nation but to the totality of human existence (ResearchClue, (2019)). As further explained by USEPA (2009), the effect of climate change implies that the local climate variability which people have previously experienced and adapted to is changing and this change is observed in a relatively great speed. The threat that climate changes pose to agricultural production does not only cover the area of crop husbandry but also inclulivestock and in fact the total agricultural sector.

Effects of climate change have also metamorphosed into some impacts such as the decline in agricultural production, drought, migration, health problems, crisis among farmers and herdsmen, flooding, erosion, hunger and poverty among others and other numerous problems yet to manifest.

According to Apata (2012), evidence has shown that climate change is already affecting crop yields in many countries (Agbola, P. and Fayiga, 2016). This is particularly true in low-income countries, where climate is the primary determinant of agricultural productivity and adaptive capacities are low (Agbola, and Fayiga, 2016).

Vulnerability to climate change is however more prominent among smallholder farmers irrespective of their gender. Smallholder farmers are at disadvantage in a lot of ways including but not limited to limited access to farmland, inadequate fund to commercialize farming, low opportunities for training, lack of technical know-how and limited access to farm input among others. There is a dearth of information on perception of climate change in previous studies, however, the largest variability, in responses comes from the individual coping and adaptation strategies. It could be inferred at this juncture, that small holder arable crop farmers' perception of climate change could go a long way to affect performance and overall productivity of arable crop farmers. There is a need to therefore assess small holder's farmer's perception of climate change and its adaptation strategies in Nigeria, hence the reason for this study.

Objectives of the Study: the main objective of the study was to determine smallholder arable farmers' perception toward climate change and its coping strategies in selected agro-ecological zones of Ondo state. The specific objectives are to:

i. ascertain the socio economic characteristics of smallholder arable crop farmers in Ondo State Agro-ecological zone in Ondo State:

ii. determine the perception of small-holder arable crop farmers of climate change and coping strategies in the study area:

iii. identify the climate change coping strategies adopted by small-holder arable crop farmers in the study area: .

METHODOLOGY

The study was carried out in the Ondo State which is located in the Southwest of Nigeria. According to Ondo State Agricultural Development Programme (ONDADEP) delineation, Ondo State was divided into two major zones (the Northern part and the Southern part), it was further divided into four sub-zones and eighteen blocks or Local governments containing 162 cells or circles. Zone I (Northern part) covers 8 local Government. Zone II (Southern part) covers 10 Local Government. Two zones were purposively chosen from the 4 sub-zones considering the degree of their rurality. Ten percent of cells from each of the two zones were randomly selected from Owo and Okitipupa. However, ten percent of the registered farmers were randomly selected to give 90 and 70 farmers respectively from Owo and Okitipupa, Structured interview schedule was used to elicit needed information from the respondents. Descriptive statistics such as frequency counts, percentages, mean were used to present the results of the findings

RESULTS AND DISCUSSION

Socioeconomic characteristics of respondents

Table 1 revealed that the mean age of respondents was 44 years which implies that the farmers were in their active ages and should be able to adopt both ethno-engineering adaptation techniques and series of micro- climate management practices aiming at reducing and or mitigating the destructive effects of climate change. Also, majority (80.6%) of the respondents were male, this implies that agricultural production in the study area is male dominated. Also, the Table further showed that most (97.5%) of the respondents were married. In the same vein, majority (86.2%) of the respondent had at least a secondary school education, implies that their level of education should have direct relationship in their ability to adopt varying adaptation and mitigation strategies against the manifestations of climate change in their farming activities. It also showed from the table that the mean household size was 7 people, it could be deduced that family labour will be available to assist in various adaptation and mitigation measures in response to the attendant effects of climate change (Odewumi,Awoyemi, Iwara and Ogundele, 2013). The Table depicted further that 80.0 percent of the farmers operated less than 1.5 hectare of land, while only few (2.5%) of the respondents had a farm size of above 2.91 hectares of land. With reference to the sources of information on climate change, the respondents got information from radio, co-farmers and agricultural extension agents (43.1%, 34.4% and 16.2%) respectively. This is in tandem with the submission of Oyelere, Sadiq, Olagoke and Adisa, (2020) that radio remains the major source of agricultural related information to farmers in Southwest Nigeria.

Perceived effect of climate change

Table 2 itemized the effects of climate change as perceived by the respondents on their farming activities in the study area. Majority (96.3%) of the respondents opined that climate change is responsible for flooding with its attendant effect on loss of farm produce, inability to go to their farms and possibly loss of lives when it persisted. The composite of flooding is soil degradation as submitted by 90.6 percent of the respondents. The removal of top soil is often caused by accelerated erosion and most spectacularly through flooding (Research Clue, 2019). From Table 2, most (90.6%) of the respondent affirmed that climate variability as an integument of climate change often necessitates adjusting planting dates to prevent colossal waste of resources in the Case of crop failure often precipitated by drought, pest and diseases. Also, 76.9 percent of the respondents traced the reduction in farm productivity to the debacle of climate change. This is in tandem with the opinion of Agbola and Fayiga, (2016) that extreme climate change manifestations such as fooling, extreme heat and drought often lead to soil degradation which results in low crop yield. Most (96.3%) of respondents perceived that excessive heat was a resultant effect of climate change.

Table 2: Distributions of Respondents According to the Perceived Effects of Climate Change (N=160)

Effects	Frequencies	Percentages
Flooding	102	63.7
Disruption of time of	145	90.6
planting	123	76.9
Reduction in farm yield	101	63.1
Changes in farming systems	145	90.6
Land degradation/ loss of		
soil nutrients	45	28.1
Deforestation	111	69.4
Fierce storms	154	96.3
High temperature		

Source: Field survey, 2021.

Coping and adaptation strategies

From Table 3, it showed that most (91.2%) of respondent often adjust crop production cycle in response to the probabilistic nature of the onset of rain, the length of drought and other variables associated with climate change that determine farm productivity. This is in line with the position of Nouri, et, al, (2017) that manipulating cropping calendar by changing sowing date is one of the ways to cope with the effect of climate change. Also, 65.6 percent of respondents affirmed that growing resistant varieties of crops to the vagaries of climate change effects, especially drought has proven to be an effective coping strategy. Further still, most (83.7%) of respondents opined that growing different crops has been one of the strategies they often adopt to mitigate the effects of climate change. This is in consonance with the assertion of Shuaibu, Akpoko and Umar, (2014) that one of the major strategies to adjust to the aftermath of induce shock occasioned by climate change is growing different crops. Reforestation and afforestation, better water management, adoption of soil moisture management such as mulching and application of organic manure, and application of integrated pest management, 13.7%,16.3%,27.5%3.8% respectively, were not considered despite their potency at ensuring environmental sustainability against climate change.

Table 4: Distribution of Respondents According to Coping and Adaptation Strategies (n=160)

Coping strategies	Frequencies	Percentages
Better water management	26	16.3
Adoption of soil moisture management strategies such as Mulching/organic matter incorporation.	44	27.5
	146	91.2
Changes to crop production cycles to align with seasonal fluctuation	62	38.7
Improved cultivation techniques and livestock management	22	13.7
Reforestation and afforestation	105	65.6
Investigating, identifying and growing drought tolerant crops	134	83.7
Growing different crops as a means of insurance	06	3.8
Application of integrated pest management practices

CONCLUSION AND RECOMMENDATION

The study revealed that climate change had negatively impacted on farm productivity and livelihood activities of arable crop growers in the study area. It was obvious that it had also aggravated environmental degradation due to flooding, deforestation and fierce storms. However, arable crop growers in the study area were adopting some ethno-engineering practices to cope and adjust to the debacle of climate change, such as; growing varieties of crops, adjusting planting dates against the debacle of climate change. Based on the findings of the study, the study affirmed that arable crop growers in the study area were aware of the effects of climate change and as such adjusting to the effect of it. The study therefore recommended that smallholder arable crop farmers should stick to ethno-engineering practices to prevent and mitigate the effect of climate change. Agricultural information on climate change should be well packaged in a very simple language of the people on Radio to mitigate the effect of climate change. In order to migrate from small farm holding, it is further recommended that cooperative farming should be encouraged among farmers in the study area to guarantee food security and reduce the effect of climate change.

24 - 28 Oct., 2022

ABSTRACT

The study examined the food security status of farm households amidst farmer-herder conflict in Southern Nigeria. Specifically, it described the socioeconomic characteristics; examined the severity of the farmer-herder conflict and determined the household food security status. The study used primary data collected from the 3 geopolitical zones in southern Nigeria, with the use of structured questionnaire. The stratified sampling technique was used to select the respondents and data collected were analysed using descriptive statistics, binary logistic regression and Food Consumption Scores and results for conflict and non-conflict areas were compared using t-test. The result showed that the non-conflict area was 39.19% food secure while the conflict area was 8.23%. The t-test shows significant difference in the food security status of the two strata. The statistically significant difference in household food security status existing between conflict-affected and non-conflict respondents confirmed that production and situational variables are highly significant factors determining the severity of the conflict as well as the food security status. Since the result shows significant difference, all efforts should be made to resolve the conflict.

KEYWORDS: Household Food Security, Farmer-herder Conflict, Food Consumption Score

INTRODUCTION

Food, the most basic of all human survival needs, is one of the most important outputs of any agricultural system. Food is life, central to the discussion of human rights and social development and hence an instrument of national power (Jenkins and Scanlan, 2001; Ojo and Adebayo, 2012). Ensuring food security for all citizens in all societies is of immense importance that the 2030 United Nations adopted Zero Hunger as the second Sustainable Development Goal (SDG), articulated to end hunger, achieve food security, improved nutrition and promote sustainable agriculture. SDG 2 requires the attainment of the objectives through the households because the households are the basic units of every society. Food security is said to exist when all people, at all times, have physical, social and economic access to sufficient, safe, and nutritious food to meet their dietary needs and food preferences for an active and healthy life (FAO 1996). FAO (2003) defined household food security as the application of the concept of food security at the family level, with individuals within households as the focus of concern.

Conflict occurs when two or more actors oppose each other in social interaction, reciprocally exerting social powers to attain scarce or incompatible goals and prevent the opponent from attaining them (Egbuta, 2018). A major violent conflict plaguing Nigeria in recent times is the farmer-herder conflict. It has been identified as one of the significant conflicts that causes food insecurity in the country as it involves two major actors in the food sector of the nation; the smallholder farmers and the herders. Apart from their contributions to the national GDP, the smallholder farmers are the engine room of food production in Nigeria, while the herders are the 80% custodians of cattle production in Nigeria, which is the main available source of animal protein in Nigeria (Ajala, 2006). Though this conflict is not a new occurrence, especially in the northern parts of the country, what is relatively new now is the increasing spread and magnitude of the conflict, particularly in the southern parts of the country.

Researchers have focused attention mainly on Northern Nigeria (Kazzah, 2018) and North Central Nigeria particularly Kogi and Benue States (Adisa & Adekunle, 2010). In Southern Nigeria, similar research has been conducted in Enugu state (Akerjiir, 2018), Cross River and Delta States (Ofem & Inyang, 2014) and in Oyo and Ogun States (Ayinde et al., 2020). However, there is a paucity of research on the conflict in other states in the southern part of Nigeria, its severity and its impact on household food security status in southern Nigeria as a whole.

The main objective of this study was therefore, to determine the farm household food security status amidst farmer-herder conflict in southern Nigeria. Specifically, the study described the socioeconomic characteristics of the respondents; identified the determinants of the severity of the farmer-herder conflicts and determined the household food security status of respondents in the conflict and non-conflict strata of the study area.

METHODOLOGY

Study area

The study area was southern Nigeria, which comprises of three geopolitical zones namely; South-East, South-West and South-South. Southern Nigeria is a conglomerate of 17 states. The area lies between the latitudes 4°32'N and 9°33'N of the equator and longitudes 3°25'E and 10°25'E of the Greenwich meridian (Ojemade et al., 2015). Southern Nigeria is a typical tropical climate, with the climatic zones running parallel to the coast, widening or narrowing as geographical features alter the steepness of the climatic gradient. The climatic zones are increasingly drier further inland from the coastal areas. The distribution of vegetation in southern Nigeria is dependent on the climate, therefore the area has varying vegetation zones comprising the rainforest zone in the south of River Niger, the mangrove forest of the coastal areas of Lagos, Calabar and Oron, and the guinea savannah of Oyo, Ondo, Enugu and the Anambra States. These vegetations offer an ample variety of fodders for grazing livestock, and as such attractive for pastoralists and equally supports the cultivation of variety of crops. The mean annual rainfall is from 2,000 to 2,500 millimetres (mm) (Ozor et al., 2010).

Sampling Technique

A multi-stage sampling procedure involving stratified and simple random sampling techniques, was adopted to select respondents from a state in each of the three geopolitical zones. Stage 1 was the purposive selection of a state that had witnessed the farmer-herder conflict. The selected states were Ebonyi State for the South-East, Edo State for South-South and Oyo State for the South-West. The second stage involved the purposive selection of 2 communities that have witnessed the conflict and two communities that have not witnessed the conflict from each of agricultural zones in the states. Stage 3 involved the determination of the sample frame from a reconnaissance study, from which the sample size was calculated using the Yamane formula, which gave the sample size of 627 respondents for the conflict stratum and 314 respondents for the non-conflict stratum, which were selected using the simple random sampling technique.

Analytical Techniques

The socioeconomic characteristics of the respondents were analysed using descriptive statistics. The determinants of the severity of the farmer-herder conflicts in the study area were identified using binary logistics model stated thus: $Y_i = \beta_0 + B_1 X_1 + B_2X_2 + B_3X_3 + B_4X_4 + B_5X_5 + B_6X_6 + B_7X_7 + \varepsilon_I$

Where Y_i = severity of the conflict measured in categorical variable (0 = not severe; 1 = severe) How was this categorized?

β_0 = intercept

X_1= socioeconomic factor expressed as mean of socioeconomic variables (obtained from a five-point Likert scale)

X_2 = situational factor expressed as mean of situational variables (obtained from a five-point Likert scale) What do you meam by situation variables?

X_3 = production factor expressed as mean of production variables (obtained from a five-point Likert scale)

X_4 = number of incidences of the farmer-herder conflict expressed as a continuous variable Number of incidence for what period? Wont this be the same for all the households in the same area?

X_5 = duration of the last incidence of farmer-herder conflict in days expressed as a continuous variable What is the unit of measurement? Duration (days? Hours? Week? Years?. Wont the duration be the same for all the households in the same area?

X_6= number of deaths per household resulting from the last incidence of farmer-herder conflict expressed as a continuous variable

X_7 = number of injured persons per household resulting from the last incidence of farmer-herder conflict expressed as a continuous variable

$\beta_1, \ldots, \beta_7$ = coefficient of the parameters $X_1 \ldots\ldots X_7$

εi = error term

The Food Consumption Score (FCS) was used to assess the household food security status of the respondents. The common local food eaten by households to ensure a nutritious diet, categorized into 8 food groups, were assigned different weights based on their nutrient contents in line with World Food Programme (2008).

RESULTS AND DISCUSSIONS

Socioeconomic characteristics of respondents

Table 1 showed the socioeconomic characteristics of the respondents. For the conflict stratum 86.9% were males, the mean age was 47.77 years and about 90% were married with a mean household size of 7 persons. The mean years of formal education was 8.89 years with 39.6% attaining between 7 to 12 years of formal education. The mean farm size was 3.48 hectares and an estimated annual income from their agricultural production was ₦ 688,305.71 while their estimated mean monthly food consumption was ₦ 44,280.99. In the non-conflict stratum, 83.4% of the respondents were with a mean age of 46.31 years with as many as 71.0% of the respondents aged from 40 to 59 years. About 88.9% of the respondents were married with a mean household size of 3 people. The average length of formal education is 9.74 years, the mean farm size was 2.32 hectares while their average estimated annual income was ₦ 388,865.1 and average monthly food expenditure was ₦ 46,350.88.

Determinants of the severity of the conflict

Table 2 showed the perception of the respondents in the conflict stratum on the severity of the conflict. About 70.3% of the respondents perceived the conflict as severe, which indicated that the conflict was severe in the study.

Table 2: Perception of the respondents on the severity of the conflict

Severity of conflict	Frequency	Percent
Not severe	186	29.7
Severe	441	70.3
Total	627	100.0

Source: Field Data (2022)

The output of the binary logistic regression presented in Table 3, showed that the Percentage Accuracy in Classification (PAC) of the model was 95.3%, showing that the model is relatively accurate. The output of the model further showed that the socioeconomic factors, situational factors, production factors, duration of the last incidence and death had significant effects on the severity of the conflict in the stratum. The variables that their odd ratios were greater than 1 were situational factors, production factors, number of incidences and injury, showing that the probability of the conflict being severe due to these factors is greater. The odd ratio of the model shows for any unit change in the situational factor, the log of odds of the conflict being severe increases 224 times; for any unit change in the production factor the log of odds of the conflict being severe increases 67 times; for any unit change in the number of incidences the log of odds of the conflict being severe increase 2 times, and for any unit change in the injury the log of odds of the conflict being severe increase 1.8 times. However, the number of incidents and injuries were not significant factors that determines the severity of the conflict.

Table 3: Determinants of the severity of the conflict

	B	S.E.	Sig.	Exp(B)

Household food security status

The result of the household food security of the respondents displayed in Table 4, showed that 39.60% of the respondents in the conflict stratum and 27.67% in the non-conflict stratum had poor scores in food security according to their level of consumption described on the Table 4. The scarcity of animal protein may be due to the driving away of the herders from the conflict communities making it impossible for the respondents to access animal protein. About 52.17% of the respondents in the conflict stratum and 33.14% in the non-conflict stratum were at the borderline of food security following their consumption level as shown in the Table 4. More of the respondents in the non-conflict stratum (39.19%), had an acceptable level of household food security as compared to 8.23% in the conflict stratum. This conforms to the opinion of Azad & Kaila (2018) that a major effect of the conflict included reduced agricultural production or price increases due to malfunctioning markets. This confirms that production and situational factors in Table 3 were very significant determinants of severity of the conflict which has affected their food consumption scores. The t-test shows a high statistical significance level at 5% as against the report of the research conducted by Azad & Kaila (2018) in the North East, North Central, and South-South zones; which reported that in North Central Nigeria, that showed that despites high food insecurity in the zones, there was no statistically significant level to conclude the differences observed. This may be because the severity of the conflict has heightened more than in 2018 when Azad & Kaila (2018) conducted their study.

Table 4: Household food security status using Food Consumption Score (FCS)

Household food security status		Farmer-herder conflict stratum (percent)	Non-conflict stratum (percent)	Description
Food insecure	Poor (≤ 28)	39.60	27.67	Consumption of staples 7 days, vegetables 5-6 days, sugar 3-4 days, oil/fat 1 day a week, while animal protein was totally absent
	Borderline (28.1 – 42)	52.17	33.14	Consumption of staples 7 days, vegetables 6-7 days, sugar 3- 4days, oil/fat 3 days, meat/fish/eggs/pulses1-2 days a week, while dairy products were totally absent
Food secure	Acceptable (42.1 - 105)	8.23	39.19	Had a greater number of days a week eating meat, fish, eggs, oil and complemented by other foods such as pulses, fruits and milk

Source: Field Survey Data, 2022

CONCLUSION AND RECOMMENDATIONS

This study concludes that the farmer-herder conflict has negatively affected the food security status of respondents. The study therefore recommends that:

1. there is a need for more concerted and deliberate efforts by stake holders and the government to find realistic and practical solutions to farmer-herder conflict because of the effect on production, socioeconomic and the number of lives lost from such incidences. Efforts by who?
2. The arable farmers should be encouraged to engage in backyard livestock production to augment their animal protein requirement.

ABSTRACT
Food losses and waste often translate into economic losses for farmers and others stakeholders within the food value chain, and higher prices for consumers, both of which affect food insecurity by making food less accessible for vulnerable groups. Food losses in low-income countries occur throughout food value chains, owing to managerial and technical limitations in harvesting, storage, transportation, processing, packaging and marketing. Food waste in middle and high-income countries is caused mainly by consumer behaviour and by policies and regulations that address other sectoral priorities. This review is focused on reduction of global food loses and waste and Making food systems more efficient, inclusive and resilient Reducing food losses and waste would increase the supply of available food and strengthen global food security.

INTRODUCTION
Food loses and waste comprises interconnected activities from the time of harvest through crop processing, marketing and food preparation, to the final decision by the consumer to eat or discard the food. Post-harvest food loss occurs within the farm-to-market period during harvesting, handling, storage, and distribution of food. These losses contribute to global hunger by decreasing both the supply of locally produced foods and purchasing power by reducing financial gains from crops.

Global food losses and waste
Globally, around one-third of all food produced is lost or wasted along the food chain, from production to consumption (HLPE, 2014). In a world where hundreds of millions of people go hungry, that is a stark indication of the inefficiency of current food systems. Food losses and waste often translate into economic losses for farmers and others stakeholders within the food value chain, and higher prices for consumers, both of which affect food insecurity by making food less accessible for vulnerable groups. Reducing food losses and waste would increase the supply of available food and strengthen global food security. Food losses and waste also hold back the transition to environmentally sustainable food systems (Alston, 2010). They represent

a considerable waste of land, water, energy and agricultural inputs, and cause the emission of millions of tonnes of greenhouse gases. Future efforts to address climate change will need to find ways to reduce food losses and waste. Because food production is responsible for a large share of GHG emissions, reducing food losses and waste contributes to climate change mitigation. At the same time, because climate change threatens food production in many food insecure areas, reducing food losses and waste can be an important part of climate change adaptation strategies (Bellú, 2016).
It has been observed that measuring food losses and waste is difficult, in part because food supply chains are long and involve many actors, including small farmers, transporters, processors, retailers and households. FAO (2012) defines food losses and waste as a 'decrease in quantity or quality of food', i.e. a reduction in the availability of food, a decline in its nutritional and/or economic value, and/ or deterioration in food safety. Food waste results from the 'discarding or alternative (non-food) use of safe and nutritious food for human consumption all along food supply chains'. Although the difference between food loss and food waste is not cut and dry, food loss is seen as accidentally occurring for reasons not under the direct control of the agents concerned, such as inadequate technology, lack of knowledge and skills, poor logistics and malfunctioning markets, while food waste is characterized by an element of intended or unintended behaviour, i.e. the removal of food fit for consumption by choice or negligence. Although food waste is often associated with final consumption, the deliberate discarding of food may occur at all stages of the supply chain. The distinction between food loss and food waste is important, because it underscores their different underlying causes. Policies and strategies need to take these into account when seeking solutions to the problem.

The causes of food losses and waste vary greatly by region

Accurate and time-wise estimates of losses and waste in the food system are unavailable. However, evidence to date indicates that, every year, about 670 million tonnes of food is lost or wasted in high-income countries, and 630 million tonnes in low- and middle-income countries – a total of 1.3 billion tonnes, or one-third of the edible part of food originally intended for human consumption (Alexandratos, and Bruinsma, 2012) Food losses and waste are caused by different factors at different levels:
• Micro-level causes resulting from the actions of agents at the same stage of the food supply chain (e.g. poor harvest scheduling and timing, poor harvest practices, careless handling of produce, lack of appropriate storage space, lack of transportation facilities, consumer behaviour).

• Meso-level causes related to a whole food supply chain, i.e. decisions or lack of decisions of agents in that particular chain (e.g. poor coordination, too long chains, failure to meet product standards, pesticide-contaminated processed products).

• Macro-level causes arising from the overall socio-economic environment, such as lack of infrastructure, inadequate legislative frameworks and price incentives and subsidies that promote excess production (HLPE, 2014).

In low-income countries, significant levels of food losses occur upstream, at harvest and during post-harvest handling, owing to poor infrastructure, low levels of technology, a limited knowledge base and lack of investment in production. Food losses also tend to be caused by managerial and technical constraints in harvesting, storage, transportation, processing, packaging and marketing. The greatest losses occur in small- and medium-scale agricultural and fisheries production and processing sectors. Uncertainty about weather and market conditions, and weak institutional frameworks, also contribute to losses. Each year in Africa, around 13 million tonnes of cereals, or more than 15 percent of total cereal production, are lost during post-harvest operations.5 In all regions, except South and Southeast Asia, food losses and waste account for more than 30 percent of food originally intended for human consumption. However, the extent of losses and waste along the food supply chain differs across regions (HLPE, 2014). In North America, Europe, Japan and China, around 15 percent of food is lost or wasted in the distribution and consumption stages. This percentage is lower in North Africa and Central Asia (11 percent) and much lower in Latin America, South and Southeast Asia and sub-Saharan Africa (5.9 to 7.8 percent). In contrast, North America, Europe, Japan and China lose or waste only around 15 percent of food in the harvest and post-harvest stages. In sub-Saharan Africa, where food losses and waste are particularly high at 36 percent, some 5.9 percent occurs in the retail and consumption stages, while more than 30 percent occurs in the harvest, post-harvest and processing stages.

Reducing food waste requires changing people's behaviour

In dealing with the problem of food waste, technological fixes do not offer lasting solutions. Responses must address the attitudes and actions of a range of stakeholders throughout the food supply chain. In high-income countries, food waste is caused mainly by consumer behaviour and economic decisions, and by policies and regulations related to other sectors. For example, agricultural subsidies may encourage the production of surplus food crops. This excess production helps contain prices but also causes less attention to be paid to food waste, both by value chain stakeholders and by consumers. Food waste is most often caused by retailers and consumers over-purchasing and then simply throwing away perfectly edible foodstuffs. In addition, food safety and quality standards may remove from the supply chain food that is still safe to eat. At the consumer level, inadequate planning of purchases and failure to use food before its expiry date also contribute to food waste. In addressing the behavioural causes of food waste, policy makers must recognize that food waste may be rational from an individual's perspective, resulting from the 'optimizing behaviour' of producers, processors, traders, and consumers. However, there are economic costs and negative externalities that individual economic agents may not consider, owing to imperfect markets and a lack of information.

From the point of view of society as a whole, food waste is considered undesirable because it generates net losses through its environmental impacts and associated socio-economic costs. Policies need to create conditions that enable the behaviour of different individual agents along the food supply chain to achieve a socially optimal level of food losses and waste. These policies include 'getting food prices right' by ensuring that the consumer assumes full responsibility for covering the environmental and social costs of producing – and eventually discarding – food. The recovery and redistribution of safe and nutritious food is another strategy option for reducing food waste.

Making food systems more efficient, inclusive and resilient

Food systems are characterized by the coexistence of modern and traditional supply channels. However, these systems are changing, as there is a growing reliance in many regions on global supply chains and large-scale distribution systems, such as supermarkets. Capital-intensive, vertically integrated supply chains both respond to the evolving demands for food and dietary preferences and shape the trajectory of their evolution. More efficient food systems also create new challenges and concerns: the high-calorie, but low-nutrient, content of many food items; the reduced access of small-scale producers and family farmers to viable markets; the high levels of food loss and waste; food safety problems; plant disease and animal health issues; and the higher energy intensity and heavier ecological footprint associated with the lengthening of

food chains. The implications of these challenges for future food security and nutrition will need to be viewed from the perspective of food systems at large, including the impacts on traditional food chains and the producers and consumers who rely on them.
Strengthened linkages between farms, markets and consumers can be an important source of income growth and job creation in both rural and urban areas.

CONCLUSION

Food losses in low-income countries occur throughout food value chains, owing to managerial and technical limitations in harvesting, storage, transportation, processing, packaging and marketing. Food waste in middle and high-income countries is caused mainly by consumer behaviour and by policies and regulations that address other sectoral priorities. For example, subsidies may encourage surplus food crop production, which reduces both prices and the attention that is paid to food losses and waste. Some food safety and quality standards may remove from the supply chain food that is still safe for human consumption. At the consumer level, inadequate planning of purchases and failure to use food before its expiry date also lead to waste. The challenge for many low- and middle-income countries will be to find dynamic pathways that connect local food systems to growing urban markets and to seize market opportunities. Cities account for the lion's share of demand for high-value foods, such as fruits, vegetables and dairy products. These are markets in which small-scale and family farmers can have an advantage because such products are labour-intensive. Food systems that link farmers to cities can have an enormous impact on rural poverty alleviation and agricultural development. Options include connecting small-scale producers and supermarket supply chains through contractual arrangements with mutually beneficial terms, and giving new impetus to the development of local food systems.

56th Annual Conference
Agricultural Society of Nigeria
24 - 28 Oct., 2022

ABSTRACT

Information is one of the most valuable resources for the development and progress of any enterprise. This study examined the sources of information and level of knowledge of sweet potato production by rural farmers in Ebonyi state. Primary data were collected from 400 small-scale sweet potato farmers using a multi-stage sampling procedure. The instrument used for data collection was interview schedule. Data collected were analysed using descriptive statistics. Findings reveal that fellow farmers with mean of (2.91) ranked 1st as the major source of information on sweet potato production in the study area while research institution with mean (1.87) ranked 6th as the least source of information on sweet potato production. For the knowledge level of the respondents on sweet potato production, some improved agronomic practices ranging from site selection, planting depth, sweet potato tillage practices, planting materials, fertilizer application, harvesting, storage and products forms were indicated by majority of the farmers that they have good knowledge of them as(55.5%) of the sweet potato farmers have high knowledge of sweet potato production. The result therefore call for policies aimed at enlightening farmers on the importance of formation of farmers groups since most trainings on new technologies, value addition, access to information on market opportunities and provision of loan packages can easily be disseminated through farmers group.

Keywords: Information sources, knowledge level, sweet potato,

INTRODUCTION

Sweet potato (Ipomoea batatas) is an important root crop that provides food to a large segment of the world population, especially in the tropics and subtropics where bulk of this crop is cultivated and consumed. Sweet potato is an important food crop in Nigeria that is valuable in the diet of rural poor in the tropics (Odebode, 2004). It is a low input crop and it is used as a vegetable, a desert, source of starch and eaten as a substitute for yam as a result of lower cost of production. The importance of the crop in national and household food security coupled with health and livelihoods of poor farming households in Nigeria cannot be over-emphasized.

In Nigeria, sweet potato production, marketing and utilization have expanded beyond the traditional areas of the central and river-rine zones to the humid and semi-arid regions in the last two and half decades (Tewe *et al*., 2003). Nigeria is one of the largest producer of sweet potato in sub-Saharan Africa with annual production estimated at4.03 million tons per year with farm size of about1.7mha and yield of 2.3t/ha (FAO, 2018). It can be grown three times a year, has a high yield potential, high nutritional value, resistance to production stress, environmentally friendly with diverse food forms among others (Ikwelle, Ezulike, & Eke-Okoro, 2001 and Kays,2004). The crop has moved up from the minor status to an enviable position of being the fourth most important root and tuber crops in Nigeria after cassava, yam and Cocoyam.

Sweet potato cultivation is still restricted to a few states and its production is mainly for local consumption (Ikerogu, 2003). The crop is often grown at a subsistence level, as a mono-crop or intercropped with other crops such as maize, yam, cassava and vegetable (Akoroda, 2009). Sweet potato is a drought tolerant crop with the potential to enhance food and nutrition security, especially for subsistence and small-scale farmers in Nigeria. For sweet potato, drought stress accounts for 25% total annual yield loss compared to more than 50% yield loss or complete failure in staple crops such as maize.

Despite this advantage, its importance as a food security crop is still underestimated and fails to attract sufficient attention from agricultural researchers (Motsa *et al.*, 2015). Sweet potato sector has lots of potentials for increased productivity in the country as the nation are blessed with rich and abundant sweet potato growing environments and numerous programmes, policies and improved varieties (Chukwu, 2013). This work is therefore designed to identify the sources of information and knowledge level of sweet potato production in Ebonyi State.

METHODOLOGY

Structured interview schedule was used as instrument for data collection. The study area was Ebonyi State with all the three Agricultural Zones; Ebonyi South, Ebonyi North and Ebonyi Central which followed a multi-stage sampling procedure. In the second stage, two local government areas (LGA) in each zones were purposively selected based on cropping intensity. Afikpo-South and Onicha LGAs were selected in Ebonyi South, Ohaukwu and Abakaliki LGAs for Ebonyi North and Ikwo and Ishielu LGAs for Ebonyi Central. In the third stage, two Council Wards were also purposively selected from each LGA, giving twelve Council Wards. Simple random sampling technique was used to select respondents who are sweet potato farmers in the study area. Consequently, thirty four (34) respondents each was systematically selected in four council wards giving a total of one hundred and thirty six respondents in Ebonyi central zone, because of its higher population. Thirty three (33) respondents were selected in eight council wards in Ebonyi-North and Ebonyi-South zones each, giving a total of two hundred and sixty four respondents in the zones. Thus, bringing total respondents administered with interview schedule to Four hundred. In analysing data generated for the study, descriptive statistics like percentages were used to describe the state of knowledge of sweet potato while three point likert rating was used to identify and rate the sources of information on sweet potato production in the study area.

RESULTS AND DISCUSSION

Table 1 revealed that fellow farmers with a mean of (2.91) ranked 1st as the major source of information on sweet potato production in the study area. This indicated that farmers in the study area have cordial relationship with one another; hence information regarding sweet potato production is well circulated among fellow farmers. Friends and neighbours had a mean of (2.80) and ranked as 2nd major source of information on sweet potato production. This is in line with the findings of (Omoare, 2014) who reported that majority 86.0% of the respondents always source their information on sweet potato production from their friends and neighbours. It also agrees with the findings of Mmasa *et al*. (2013) that sweet potato farmer's source information through their friends and fellow farmers. Similarly, respondents identified extension agents as 3rd source of information on sweet potato production. This implies that extension services have been an effective means for sweet potato farmers to source information from. This is quite beneficial for sweet potato production in the study area. Cooperative / farmers group with a mean of (2.15) ranked as 4th source of information on sweet potato production. Farmers group played a significant role in sourcing information on sweet potato production among its members. Information on improved sweet potato varieties and the recommended agronomic practices for optimum yield such as time of planting and harvesting, fertilizer and herbicide use, marketing and value addition of sweet potato are disseminated to their members. Radio/television with mean of (2.07) ranked as 5th source of information on sweet potato production but they are not the major source of information for sweet potato farmers in the study area because some of the farmers do not have television or radio to access information. Research institution with mean (1.87) ranked 6th is a source of information on sweet potato production but a minor one. Farmers do not usually access research institution for information on their farm practices.

The results in Table 2 indicated that majority (77.2%) of the respondents agreed that suitable site for sweet potato production should not be in waterlogged soil. About(82.5%) of the respondents indicated that soil depth of 20cm is satisfactory for sweet potato production while (91.6%) of the respondents indicated that sweet potato planted on ridges produce higher yields. This result is in conformity with the findings of (Omoare, 2014) which indicated that planting sweet potato on ridges gives room for easy farm operations and produces higher yields. Farmers' knowledge on sweet potato production was ascertained based on vines as the best planting material. About (98.1%) of the respondents are knowledgeable with vines as the best planting materials. Majority of sweet potato farmers agreed that some good agronomic/management practices of sweet potato production such as use of soil rich in organic matters for sweet potato production (85.8%), crop rotation to control sweet potato weevils(73.8%), application of fertilizer four weeks after planting (74.8%) and herbicide application as the best method of weed control in sweet potato farm(51.3%) enhances yield of sweet potato. Also, (89%) of the respondents agreed that sweet potato tubers matures when leaves stem/vines developed yellow colour and dies off.

In the same vein,(83.2%) of sweet potato farmers ascertained that bruising during harvesting and transportation should be avoided as this predisposes the tubers to pathogenic organism which will lower the shelf live and reduce the economic value of sweet potato.

Majority (64.6%) of the respondents indicated that they do not practice storage of sweet potato tubers after harvesting in pits with ashes, straw or grasses or did not have knowledge of this storage method for sweet potato. However,(81.6%) of the respondents indicated that piece meal harvesting of sweet potato is an indigenous practice on sweet potato farms that enable them to have food for longer period of time and to harvest and use as source of income in time of need. Furthermore, adding value to sweet potato through processing into diverse food forms and washing of tubers after harvesting enhances the marketability and acceptability of sweet potato to consumers as revealed by (85.6%) and (88.2%) of the respondents respectively. Result in table 2b revealed that (55.5%) of the sweet potato farmers have high knowledge of sweet potato production. This implies that farmers are not new in sweet potato production in the study area. Also (27.8%) and (16.7%) of the respondents had moderate and low knowledge of sweet potato production respectively.

Table 1: Farmers' sources of information on sweet potato production

Source of Information	Mean	Rank
Fellow farmers	2.91	1st
Friends and neighbours	2.80	2nd

Extension agents	2.47	3rd
Cooperative/ Farmers group	2.15	4th
Radio/Television	2.07	5th
Research Institution	1.87	6th

Source: Field Survey, 2019

Table 2: Distribution of respondents by their Knowledge level on sweet potato production practices.

S/N	Items	True	False
i	Suitable site for sweet potato cultivation should not be in a waterlogged soil	295(77.2)	87(22.8)
ii	Soil depth of 20cm is satisfactory for sweet potato	315(82.5)	67(17.5)
iii	Sweet potato requires minimum tillage practices to ensure adequate yield and better tuber formation	200(52.3)	182(47.6)
iv	Sweet potato planted on ridges produce higher yields	350(91.6)	32(8.37)
v	Sweet potato is a suitable intercrop and it obstructs erosion	335(87.7)	47(12.3)
vi	Yield in sweet potato declines drastically once intercrops suppress the sweet potato crops	290(76)	92(24)
vii	Vines are the best planting materials for sweet potato	375(98.1)	7(1.83)
viii	Soil for planting sweet potato should be rich in organic matter	328(85.8)	54(14.1)
ix	Crop rotation controls the spread of sweet potato weevil.	282(73.8)	100(26.1)
x	Fertilizer application should be done 4 weeks after sweet potato establishment on the field	286(74.8)	96(25.1)
xi	Spraying herbicide is the best weed control method for sweet potato	196(51.3)	186(48.7)
xii	Tubers are mature when leaves/stems/vines develop yellow colour or dries off	340(89)	42(10.9)
xiii	Bruising during harvesting and transportation should be avoided as this predisposes the tubers to pathogenic organisms	318(83.2)	64(16.7)
xiv	Storage of sweet potato tubers can be in pits with ashes, straw or dry grasses spread on them.	135(35.3)	247(64.6)
xv	Piece meal harvesting is an indigenous practices which may reduce weevil attack on sweet potato farms	312(81.6)	70(18.3)
xvi	Harvested tubers can keep long by processing it into diverse products forms such as sweet potato flour, sweet potato chips	327(85.6)	55(14.4)
xvii	Prior to marketing of sweet potato, the tubers must adequately be washed to look attractive to the consumers.	337(88.2)	45(11.7)
xviii	Decline in sweet potato production can be attributed to low knowledge of the farmers on sweet potato value addition	268(70.1)	114(29.8)

Knowledge level	Scores	Frequency	Percentages
High Knowledge	30-36	212	55.5
Moderate Knowledge	23-29	106	27.8
Low Knowledge	18-22	64	16.7

Source: Field Survey, 2019

CONCLUSION

Farmers' sources of information had influence on the decision to accept or reject a technology or innovation. Knowledge level of sweet potato farmers in the study area were also determined using 18 items. It was discovered that fellow farmers ranked first on farmers sources of information on sweet potato production in the study area while research institution ranked 6th and last position on the farmers' sources of information on sweet potato production. For knowledge level of sweet potato, majority of the farmers reported having knowledge of good agronomic practices of sweet potato production ranging from site selection, planting depth, sweet potato tillage practices, planting materials, fertilizer application, harvesting, storage and product forms.

It is recommended that rural sweet potato farmers should join farmers group where information and trainings on new technologies and management practices, value addition, access to information on market opportunities are disseminated among members. Also, increase in extension outreach, provision of loan packages to help farmers expand/establish their sweet potato farm which serves as a means of their livelihood in the study area.

24 - 28 Oct., 2022

ABSTRACT

The study assessed the utilization of odourless cassava fufu processing technology among households in Abia and Iimo States, Nigeria. A purposive and multistage random sampling procedure was used to select a sample of 180 respondents across the two states. Data were collected through well-structured questionnaire. Descriptive and inferential statistics were used to realized and test data. Respondents in the two states use similar methods in processing odourless cassava fufu and high level of utilization of odourless cassava fufu was recorded in the two states. The tobit result shows that households' socio-economic characteristics have a lot of bearing on their ability to partake and utilize the technology. The study recommended the use of more channels of communication in technology dissemination in other to get the target goal desired by the developers of the technology and there is need to revive the extension services programme for appropriate and effective technology dissemination and follow up.

Keywords: Assessing, Utilization, Odourless Cassava, Fufu

INTRODUCTION

Cassava Fufu is the second major product next to gari in importance and consumed by households in South-eastern Nigeria (Saleh *et al*., 2016). It is a fermented wet paste made from cassava roots. Traditionally, it is produced in the wet form with moisture content of 40 -50 percent and with characteristic offensive odour (NRCRI, 2012). In order to increase its shelf life, quality and quantities supplied, odourless cassava fufu processing technology was developed by the National Root Crops Research Institute, Umudike some decades ago. Odourless cassava fufu is a fermented carbohydrate food produced from cassava root, unlike the traditional fufu which is normally in wet form, and highly perishable. The fufu is presented in dried form, is odourless, inelastic and slightly sour having a low particle size and zero cyanide content (Ekweanya, 2020). Odourless Cassava fufu processing involves a combination of activities which are performed in stages. The National Root Crops Research Institute

(NRCRI), Umudike having promoted value addition and processing technology for odourless cassava fufu years back, it is expected that these technologies would have been in use in different locations for consumption, income generation and creation of employment (Nwakor *et al*., 2014). This study, therefore, sought to provide information on the level of utilization of odourless cassava fufu processing technology among households in Abia and Imo states, Nigeria, and to specifically identify the different type of methods of processing odourless cassava fufu; examine the level of utilization of odourless cassava fufu based on preferred improved cassava varieties; and identify challenging factors to utilization of odourless cassava fufu in Abia and Imo states

METHODOLOGY

The study was carried out in Abia and Imo States located in south-east Nigeria. A multi-stage sampling technique was used to elicit data for the study. In the first stage, two LGAs were purposively selected from each the state (Abia State- Umuahia North and Ukwa west; Imo State-Owerri west and Nkwerre) making it four LGAs. The reason for purposive selection is because value-added innovations of cassava have been massively introduced in those states through suitable training. In the second and third stages, three communities and three villages were randomly selected from each of the LGAs and communities, making it twelve communities and thirty-two villages. In the fourth and last stage five respondents were purposively selected from each village to give a total of one hundred and eighty respondents, ninety respondents from each state. Well-structured questionnaire was used to interview the respondents, in all 180 respondents made up the sample size for the survey. Data collected were analysed by means of descriptive statistics, mean count and tobit regression model.

RESULTS AND DISCUSSION

The result in Table 1 revealed that the respondents were utilizing almost all the methods involved in the processing of odourless cassava fufu technology, 100%of the respondents agreed on peeling, washing, fermentation, grating the cassava mash and dewatering in Abia and Imo states. Also, majority of them utilized other methods accordingly. This implies that the respondents in the two states use similar methods in processing odourless cassava fufu. This findings is in accordance with the report of Ekweanya (2018).

Table 1: Different types of Processing Methods Utilized in Processing Odourless Cassava Fufu by the Respondents

Odourless Cassava Fufu processing methods	Abia Freq	%	Imo Freq	%	Pooled
Peeling cassava roots	90	100	90	100	100
Washing cassava peeled roots	90	100	90	100	100
Soak in water for two days fermentation	90	100	90	100	100
Remove from water and grate into cassava mash	90	100	90	100	100
Put the grated mash into a container, cover and leave for 24 hours	71	78.9	84	93.3	86.1
Dewater the mash by pressing inside a clean bag	90	100	90	100	100
Break the pressed caked mash into granules	69	76.7	73	81.1	78.9

Spread thinly to dry on a clean surface preferably on a raised platform	55	61.1	68	75.6	68.4
When dry, mill into fine powder and sift	60	66.7	80	88.9	77.8
Package in an air tight container or food-grade polythene bag	42	46.7	69	76.7	61.7

Source: field survey, 2021 multiple responses recorded

Level of Utilization of Odourless Cassava Fufu based on Improved Cassava Preferred

The level of utilization of odourless cassava fufu with improved cassava varieties were examined (Table 2) and it shows that the mean utilization score of TME 419, TMS 89/0505, TMS 89/0851, other varieties which are higher than the decision mean cut off of 2.5 is an indication that users prefer using the mentioned varieties to process odourless cassava fufu in the study area. Furthermore, the grand mean score for Abia (2.8) and Imo (2.9) is an indication that the level of utilization of odourless cassava fufu is higher among households in Imo than their counterparts in Abia. Low utilization of NR 8082, pro vitamin A cassava and TMS 89/0851 calls for serious attention and upgrading.

Table 2: Level of Utilization of Odourless Cassava Fufu based on Improved Cassava Varieties Preferred

Challenging Factors to Utilization of odourless cassava fufu in Abia and Imo states

The majority posited that poor extension contact (73.9%) high cost of technology, (57.8%), undesirable traits (57.2%), unavailability of improved cassava stems for planting (53.4%), some of the improved cassava used for the cassava odourless fufu not being palatable (53.4%) greatly affected utilization of odourless cassava fufu technology in the study area.

Table 3: Challenging Factors to Utilization of odourless cassava fufu in Abia and Imo states

Determinants of utilization of odourless cassava fufu in Abia and Imo states

The relationship between households' utilization of odourless cassava fufu and socio-economic characteristics in the study area was analyzed using tobit regression model. The R^2 value (0.457) for Abia state which implies that about 46% of the variation and R^2 value (0.665) for Imo state which implies that about 67% of the variation in the utilization of odourless cassava fufu was explained by independent variables and Chi^2 was highly significant at 1% level of probability respectively indicating goodness of fit. For Abia state, the results in table 4 depict that sex was negative and significant at 5% level of probability, implying that more women utilize odourless cassava than men. Household size, level of education, experience and sources of information were positive and significant at 10% and 1% level of probability respectively. This implied that increased number of households, possession of formal education, advanced in experience of processing odourless cassava and sources of information increase the utilization of odourless cassava fufu. Similarly, the result shows that for Imo state, sex was negative and significant at 10% level of probability, education, experience, sources of information and cassava output were positive and significant at 10%, 1%, and 5% level of probability respectively. This implied that farmers' socio-economic characteristics have a lot of bearing on their ability to partake and utilize the technology. Education has always been known to play positive role in adoption and utilization of innovations among farmers. Sale *et al* (2016) suggested that as farmers education level improves, they are likely to utilize a technology. Source of information (1%) was highly significant and positively related to utilization, showing that majority of the respondents received information about the technology from multiple sources, such as media, fellow farmers and processors, NRCRI, ADP-Extension agents, cooperative societies among others. This also confirms that farmer's information sources were significantly related to their awareness of odourless cassava fufu processing technology in the study area (Adeleye *et al*, 2016). This concurs with the submission of Bamidele *et al*., (2015) that experience influenced the adoption of new cassava cultivates and value addition technologies.

Table 4: Tobit Regression estimates of the determinants of utilization of odourless cassava fufu in Abia and Imo states

CONCLUSION

The study revealed that households in Abia and Imo states use almost same methods in processing odourless cassava fufu. TME 419 was revealed to be the massively used and preferred variety for processing odourless cassava fufu in the two states. However, poor extension visit, high cost of the technology and undesirable traits some of the improved varieties possession are the very serious constraint to utilization of odourless cassava fufu in the two states. The respondents' socio-economic characteristics have a lot of bearing on their ability to partake and utilize the technology. Therefore, the study recommended the use of more channels of communication in technology dissemination in other to get the target goal desired by the developers of the technology and there is need to revive the extension services programme for appropriate and effective technology dissemination and follow up.

ABSTRACT
The study analyzed the performance of the cassava producers in Abia State, Nigeria. A multi-stage random sampling procedures was used to select 120 cassava producers with the use of a structured questionnaire, to collect primary data. Data collected were analysed with cost and returns model and ordinary least square (OlS) regression model. The cost and returns result shows that variable costs accounted for a very large proportion (96%) of the total cost of cassava production. The OLS regression result showed that farming experience, distance to the nearest market, quantity supplied of cassava, cooperative membership, household size and farm size influenced the profit level of the cassava producers at 10%, 5% and 1% levels of significance respectively. The study recommends cassava producers to form more cooperatives in order to enjoy credit facilities, increase their performance in cassava production and high profit in the cassava business.

Keywords: Cassava producers and Performance Analysis

INTRODUCTION

Farmers participating in the food market are a byproduct of progress poverty (Olwande and Mathenge, 2011). Farmers must have access to production technology, as well as appropriate private and public goods, as well as upgraded technologies. Ensuring widespread low-cost access to a competitive, well-functioning market necessitates large governmental investments funded by taxes or assistance flows, as well as proper institutional, endowment, and pricing. Primary producers cannot add value to their products due to socioeconomic, economic, environmental, and technological constraints. As a result, low manufacturing efficiency and product diversification has been limited. Furthermore, farmers' insufficient capital development may have hampered farm and household revenues. Cassava production and marketing are difficult for smallholder farmers. This could help smallholder farmers overcome obstacles along the cassava value chain. According to Achem *et al*. (2013), cassava root processing and value addition are required to extend shelf life (rots within 3-4 days of harvest), improve nutritional content (low in other nutrients, particularly proteins), and convert cassava root into other goods. Even in years of normal rainfall, some farmers are net purchasers of food, while others are neither buyers nor sellers. There is a price disparity between rural and urban consumers and producers. This implied that although cassava processing needs huge capital investment in the processing equipment at the initiation of the enterprise, however, once established, processors normally operate at optimum level hence enjoying the economies of scale. Despite farmers' difficulties in reaching markets, few studies on analyzing the performance of cassava producers in Nigeria and Abia state have been conducted. The specific objectives of the study were to determine the performance of the producers regarding their cost and returns and examine factors influencing the profit level of the cassava producers

METHODOLOGY

This research was carried out in Abia State. This study's population included all cassava farmers who produced tubers and processed tubers for market. The respondents for the study were chosen using a multi-stage sampling technique. First, one local government area from each of the three agricultural zones was chosen. Four autonomous communities were chosen from each of these local government areas, for a total of twelve communities. Two villages were chosen from each community, for a total of 24 villages. Ten cassava farmers producing for market were chosen from these villages, resulting in a total of 240 producers. As a result, a total of 240 respondents were used in the study. The primary data were collected directly from the field survey using well-structured questionnaires. In the data analyses, cost and returns model was used to analyzed objective three (3) which is to estimate the cost and returns associated with cassava production. The cost and returns model is given as:

NR= TR – TC

Where:

NR = Net Returns (₦)

TR = Total Revenue (returns) from the cassava enterprise

TC= Total Costs (₦)

N/B: TC = TVC + TFC

TVC = Total Variable Cost; TFC = Total Fixed Cost

N/B: Equation 3.3 was analyzed for both cassava producer

Objective five (5) which is to examine the factors influencing cassava producers and processors' level of performance was realized using the multiple regression analysis. The four functional forms (Linear, Semi-log, Cobb-Douglas and Exponential) of the model were tried and the best fit selected. The model is specified implicitly below:

Implicit Form:

$Y = F(X_1, X_2, X_3, X_4, X_5, X_6, X_7,)$ .... (3.9)

Where:

Y = Net return in Naira

X_1 = Age of respondent in years

X_2 = Level of education in years

X_3 = Farming experience in years

X_4 = Purchase price in Naira

X_5 = Depreciation in Naira

X_6 = Selling price in Naira

X_7 = Quantity of product sold/month

ei = Error term

b_o = Slope

b = Co-efficient

RESULTS AND DISCUSSION

Performance analysis of the cassava producers

The result shows that cuttings accounted for about 42.4% of the total cost of production of cassava in the study area, followed by fertilizer (34.3%) while labour (8.4%) was the least. It is well known that cassava production is labour intensive. However, the lower cost incurred from labour may be related to the utilization of household members in farm activities, while hired labour was for augmenting the family labour. In general, variable costs accounted for a very large proportion (96%) of the total cost of cassava production. Fertilizer utilization in the area of study is generally high, either because of the importance of fertilizer in increasing yield or due to the poor nature of the soils as a result of continuous use. Agrochemical use is moderate, probably because of the disease resistant nature of the varieties planted.

Table 1: Performance analysis of the cassava producers

Cost items	Amount (₦)	%
Variable costs		
Stem (₦)	61381.67	42.4
Fertilizer (₦)	49716.67	34.3
Agrochemicals (₦)	15350.27	11
Labour (₦)	12206.46	8.4
Total variable cost (TVC)	**138655.28**	**96**
Depreciation (₦) **(TFC)**	6164.58	4
Total cost, TC = TVC+TFC	**144,819.86**	
Quantity sold (kg) (Q)	8155	
Average price/kg (₦)	80	
Total Revenue, TR = (Q*P)	652,400	
Profit (TR – TC)	**507,580.14**

Factors Influencing the Profit level of the Cassava Producers

The Ordinary Least Square (OLS) was used to estimate the performance (profit) determinants of cassava producers (Table 1). The four functions of the multiple regression model were tried, and the lead equation (semi-log) was selected based on the statistical and econometric criteria. The model coefficient of multiple determination (R^2) of 0.817 implies that about 82% variation in the profit level of the cassava producers was explained by the independent variables included in the model. The F-ratio was significant at 1%, indicating the model's goodness-of-fit. The result showed that farming experience, distance to the nearest market, quantity supplied of cassava, and cooperative membership were positively related to the profit level of the cassava producers (all at 1% level of significance). In comparison, the household size and farm size were negative at 5 and 1% levels of significance respectively. The positive coefficient of farming experience suggests that farmers who are more experienced in farming are more profitable than less experienced. This follows that experience is a core requirement to farmers' profitability as it informs good decision making relating to the purchase of production inputs, resource utilization, market conditions, and general farm decisions. According to Lagat and Maina, (2017), experience helps processors better appreciate the benefits and increase their profits In addition, processors with more years of experience acquire the knowledge and skills necessary for choosing appropriate processing technologies. The result showed that distance to the nearest market unexpectedly had a positive coefficient on the profit level of the cassava farmers. This implies that farmers situated in locations far from the market stand better chances of making higher farm profits than those located around the markets. Furthermore, Sebatta *et al.*, (2014) found out that being nearer to the market made it easier to access buyers who offered better payments hence more market participation**.** Quantity supplied was positively related to the profit level of the cassava producers, indicating that the larger the quantity supplied for sales, the higher the profits, all things being equal. Given that demand remains unchanged, additional product units will imply more sales and, consequently, higher profits. This is more so when farmers create artificial scarcity of the product. According to Mussema and Daniel (2012), when farmers produce more, they are motivated to sell more, attracting higher profits. The coefficient of cooperative membership was positively signed, indicating that farmers who belong to cooperative societies earn higher farm profits than those who do not belong to farmers' associations. Cooperatives play decent roles in the development of agriculture, especially among rural and poor-resource-based farmers (Onyemauwa, 2012). Contrarily, the household size coefficient was negatively related to the profit level of the producers. This result implies that farmers with large households are less likely to make profits than those with limited household members. This confirms Abu et al.'s (2014) results, who argued that most of what the family produced is consumed with large family size. Farm size also showed an unexpected negative coefficient, implying that farmers with larger sizes make lower profits when compared to farmers with smaller farm areas for cultivation. It is generally accepted that the larger the farm area, the larger the output and consequently profits. Allocating more land for production increased the extent of market participation and the sales volume. However, farm size could pose a challenge to farm incomes when the farmers cultivate large land areas and fail to manage them properly by enforcing good cultural practices, despite heavy farm investments. Sabasi and Shumway (2014) argue that it could be attributed to managerial ineffectiveness as farms get large.

Source: Field survey, 2020. *,** and * = 1, 5 and 10% levels of significance**

CONCLUSION

The study concluded that a profit of 507,580.14 was made under cost and the variable costs accounted for a very large proportion (96%) of the total cost of cassava production. The OLS regression result also showed that farming experience, distance to the nearest market, quantity supplied of cassava, cooperative membership, household size and farm size influenced the profit level of the cassava producers at 10%, 5% and 1% levels of significance respectively. The study recommends cassava producers to form more cooperatives in order to enjoy credit facilities, increase their performance in cassava production and high profit in the cassava business.

24 - 28 Oct., 2022

ABSTRACT

The study was designed to examine factors that determine the adoption of selected loss reducing technology among rice producers in north-central Nigeria. Three hundred and seventy two (372) rice farmers were randomly selected through a multistage sampling procedure. Data collected through the use of structured questionnaires were analysed using Multivariate Probit. Various factors that promote the adoption of loss reducing technologies in North-central Nigeria include: off farm income, the amount of credit accessed by the farmers, being married, years spent in school, contact with extension agent and being from the derived savanna agro-climatic zone of Nigeria. Being a native of the study area, the presence of economically active members in the household and the proximity of the farm from the major road are other factors which promote adoption off loss reducing technologies. Based on the findings, the study recommends that the government as a matter of priority invest in and/or improve on institutional infrastructures – schools, roads, extension services, banks and other credit facilities to enhance farmers output. There is also the need to encourage farmers to attain some level of education as well as supplement their income by engaging in other income generating activities to improve in their farming activities and consequently on their food security.

INTRODUCTION

The food situation in Sub-Saharan Africa (SSA) over the past few decades has been an issue of major concern to both national governments and international development agencies. The incidence of hunger, poverty and undernourishment in the region are on the increase thus putting the region at risk of food insecurity. Issues relating to agricultural production and production incentives, policies, climate change, postharvest technologies and other economic factors are some of the major factors affecting food supply in the region (De Graaf *et al*., 2011; Sasson, 2012; Mahamat 2020).). The situation is further complicated by rapid increase in population (Mahamat 2020) and losses in the food value chain (Danbaba *et al.*2020)

With an estimate population of 200 million people Nigeria rely on import to compensate for shortfalls in domestic food supply particularly in rice a major staple food which is consumed across all the geopolitical zones and socioeconomic classes. This has become imperative as a result of supply demand gap, population growth among other factors identified to have aggravated rice self-sufficiency in Nigeria. Sanusi (2019) reported that Nigeria spend the sum of N7.92 trillion on importation of agricultural goods annually and rice alone account for N0.59 trillion. Shahandeh (2021) reported that about 1.8 Million Metric Tonnes (MMT) of rice was imported into Nigeria in 2020/2021 which is a decrease from the preceding years (2018 and 2019) where an average of 2.3 MMT of rice was imported annually (PWC 2021). To ensure self-sustenance and attain food security, local production must necessarily and significantly increase to meet the demand. Equally important is the adoption of relevant technologies by value chain actors; the absence of which has contributed to huge food losses over the years.

Statistics shows that losses in rice are increasing in spite of governments' interventions and policies. Kok and Snel (2019) reported that in Nigeria, about 35% of rice is lost from harvest to end of processing - the two points of losses are at harvest (12%) and threshing (11%). This is not surprising as post-harvest infrastructures are lacking /and or inadequate (Atibioke *et al*., 2012; Ndukwe *et al*., 2015, Danbaba *et al*/. 2020). Losses will remain a problem even in the presence of abundant technology when the technologies are not adopted by individuals who are the end users. Therefore, to improve production and consequently the farmers welfare in the rice subsector, it is imperative to examine rice production in Nigeria with emphasis on the adoption of loss reducing technologies in rice production.

The objective of this study is therefore to determine factors that promote the adoption of loss reducing technologies by rice producers.Given the large figures on importation, a reduction of food losses will reduce importation, encourage local production, lower prices for consumers and at the same time, increase farmer's income (IRRI, 2012; Berdu and Motunrayo, 2020). This will have far reaching beneficial implications for self-sufficiency in rice for the country, food security, income enhancement and poverty reduction for rice farmers and their households.

MATERIALS AND METHODS

This study was conducted in the derived and southern guinea savannah agro-ecological zones of Nigeria(North-central zone), three states of Benue, Nasarawa and Niger where chosen as they are ranked among the main rice producing States in Nigeria (NCRI, 2019). The respondents were drawn in a multi-stage sampling process, 232 farmers were selected and interviewed. Primary data obtained from farmers, through the use of structured questionnaires were analysed using the multivariate Probit.

The specific form of Multivariate Probit model is given as:

$$Y_{ik}^* = W_i' \beta_k + \varepsilon_i \qquad (k = CH, CV, IG, AWD, WH, RI, IPM) \qquad (1)$$

Where:

Y_{ik}^* = The net benefit that the farmer derives from the adoption of kth loss reducing technologies – combined harvester (CH), improved crop variety (CV), irrigation (IG), alternate wet and dry (AWD), water harvesting (WH), residue incorporation (RI), and integrated pest management (IPM)

W_i = observed household and socio-economic characteristics

ε_i = error term

β_k = unknown parameters to be estimated

Using the indicator function, the unobserved preferences in equation (1) translate into the observed binary outcome equation for each choice as follows:

$$Y_{ik} = \begin{cases} 1 \; if \; Y_{ik}^* > 0 \\ 0 \; otherwise \end{cases} \qquad (2)$$

Equation (1) is a system of k equations as shown in equation 3 below;

$$Y_{1k}^* = \beta_1' W_{1i} + \varepsilon_{1i} \quad Y_{1k} = 1 \; if \; Y_{1k}^* > 0, Y_{1k} = 0 \; otherwise$$

$$Y_{2k}^{*} = \beta_2' W_{2i} + \varepsilon_{2i} \; Y_{2k} = 1 \; if \; Y_{2k}^{*} > 0, Y_{2k} = 0 \; otherwise$$
$$\vdots$$
$$Y_{Nk}^{*} = \beta_k' W_{ki} + \varepsilon_{ki} \;\; Y_{Nk} = 1 \; if \; Y_{Nk}^{*} > 0, Y_{Nk} = 0 \; otherwise$$

Variables that were hypothesized to affect Farmers' adoption decisions

- Dependent variables;

Y_1 = adoption of combined harvester (1 if adopted, 0 otherwise),
Y_2 = adoption of improved crop variety (1 if adopted, 0 otherwise),
Y_3 = adoption of irrigation (1 if adopted, 0 otherwise),
Y_4 = adoption of alternative wetting and drying (1 if adopted, 0 otherwise),
Y_5 = adoption of water harvesting (1 if adopted, 0 otherwise),
Y_6 = adoption of Residue incorporation as manure (1 if adopted, 0 otherwise),
Y_7 = adoption of (IPM) Integrated Pest Management (1 if adopted, 0 otherwise).
Independent variables hypothesized to affect Farmers' adoption of postharvest technologies
W_1 = age (years),
W_2 = age squared,
W_3 = gender (0 if male, 1 if female),
W_4 = marital status (1 if married, 0 otherwise),
W_5 = farm size (hectare),
W_6 = dependency ratio (measured as proportion of household members that were not working to members who were working),
W_7 = off-farm income (Naira),
W_8 = nativity (1 if a native, 0 otherwise),
W_9 = extension contact (1 if respondent had contact, 0 otherwise),
W_{10} = amount of money borrowed (Naira).
W_{11} = membership of cooperative society (1 if a member, 0 otherwise),
W_{12} = economically active members of the household (number).

RESULTS AND DISCUSSIONS

Determinants of loss reducing Technology Adoption in Rice Production

As shown on Table 1 the likelihood ratio test (l = 182.75, $p<0.05$) suggests that the MVP suitably fits the study data. Consequently and as evident by the determinants of correlation (ρ), the null assumption of zero correlation between the covariance of the error terms across the adoption equations is rejected. The correlation coefficients show non-zero correlations throughout the model estimations; further justifying the choice of MVP for this objective. This implies that rice technology adoption decisions among rice farmers in the study area are jointly explained by certain socio-economic variables. A positive coefficient of correlation shows that these joint decisions are complementarity in technology adoption decision. This suggests that unobservable factors that increase the probability of adoption of a given technology also increase the adoption of another as found in Ashfaw *et al*. (2016), Kassie *et al*. (2015), Kahman (2015), Mulwa *et al*. (2017). Conversely, an inverse relationship indicates substitutability of rice technologies.

i Determinants of the Use of Improved Variety in Rice Production.

Farmers who were married had a higher probability of adopting improved rice varieties than their counterparts who have never been married. Farmers who had contact with extension agents had higher probability of adopting improved rice variety than farmers without contact. Furthermore, rice farmers in the derived savannah ecological zone are more likely to adopt improved rice varieties than farmers in other rice production ecological zones in North-central Nigeria

ii **Determinants of the Use of Combined Harvester in Rice Production**

Educated rice farmers were highly probable to adopt combined harvester (for harvesting) in rice production operations. Moreover, the positive effect of education on improved rice variety adoption will likely bring about higher yields which might inform the decision to use better technologies to adequately manage a bumper harvest. However, native farmers (indigenes of farming communities) were found to be probably more apt to adopt combined harvester technology. This may be connected to the fact that the use of these machines require proper and specific field preparation to allow access to the farm for harvest and being that the cost of implementing new practices usually yield long term profits rather than short term profits (Rodrique *et al*., 2013); this being the case, non-natives who had no claim of ownership to land would not want to invest heavily on such lands (in form of making such lands accessible to farm machinery to work on) since the short term benefit may not be cost effective.

iii Determinants of Retained Residue Practice in Rice Production

The number of economically active members in a household increased the probability of adopting the technological practice of retaining and incorporating residue into the soil rather than burning. While this practice is in itself a relatively cheap method of soil nutrient management (in terms of cost), households with more economically active members tend to have the means to pay the additional cost of labour associated with the use of the technology. Native farmers had a relatively higher probability of using retained residue than non-native farmers. This may be that native farmers have more claims to /ownership of land than non-natives, and being that nutrients from refuse are slow releasing therefore the benefits are long term.

Non-natives therefore did not have the motivation of using this technique in enriching the soil particularly if the land is leased on short term basis. Natives would therefore not hesitate to adopt technologie s that may require long term returns on investment. This result is in line with the findings of Teklewold *et al*. (2013), Asfaw *et al*. (2014). The shorter the distance of rice farm from motor-able road, the higher the probability of rice farmers adopting the practice of retained residue. This result is in line the result of the work of Asfaw *et al*. (2016) and Bizimana *et al*. (2002) who reported access to road as being a positive determinant in the adoption of technologies as cost associated with moving inputs and equipment over long distance is high.

Determinants of Practice of irrigation in Rice Production

Results further show that formal education increased the probability of rice farmers adopting irrigation on their farmlands. The likelihood of educated rice farmers adopting this technology is based on their exposure to useful information on the importance of water conservation practices and the associated advantages. This result is in line with the findings of Teklewold *et al*. (2013) and Asfaw *et al*. (2016) in the adoption of organic fertilizer and modern inputs. Nevertheless, irrigation is labour intensive and likely to increase total variable cost of production of a given rice farm; hence, rice farming families with higher dependency ratio are significantly not inclined to adopt the technology.

V **Determinants of Alternating Wetting and Drying (AWD) Practice in Rice Production**

Results in Table 1 show that married rice farmers tend to have a higher probability of adopting AWD relative to single farmers. Being married may suggest availability of household labour which could help in farm operation particularly where it involves the opening and closing of bonds around the plots when water is needed and not needed respectively. The chances of adopting AWD also increased significantly with farmers-extension agents/services contact.

v. Determinants of Practice of Water Harvesting in Rice Production

Income from participation in off-farm activities is observed to drive water harvesting technology adoption decision among rice farmers. As off-farm income rises, on the average, farmers' adoption tendencies increased; this is contrary to the findings of Mulwa (2017), who reported a negative relationship between off-farm income and adoption of technologies. This result justifies the assertions that household income diversification improve farmers' credit constrained conditions regarding agricultural technology adoption and farm production expansion. Similarly, effective borrowing for farm production engagement supports technology adoption; thus, the probability of adopting water harvesting technology increased with increase in the Naira amount a rice farmer was able to borrow from formal and informal sources. This is expected as credit is reported to enhance adoption (Mariano *et al*., 2012; Uaiene *et al*., 2009). Contrary to expectation, however, rice farmers who were members of a cooperative society had lower probability of adopting water harvesting technology than non-cooperator farmers. Perhaps cooperatives members have access to better irrigation facilities therefore are not drawn to the idea of make shift facilities like harvesting water in ponds for cropping.

Determinants of Integrated Pest Management (IPM) Practice in Rice Production

Household dependency ratio of farmers was found to lower the adoption of IPM in rice production significantly. Rice farmers from households with relatively large number of dependents scarcely adopt IPM in rice pest control. While IPMs in themselves are not particularly cost ineffective, the need to combine different approaches, each of which involves individual cost implications, may be a reason farmers who have higher economic pressure on their disposable income were unable to explore the benefits of IPM.

CONCLUSION

Various factors promoted the adoption of loss reducing technologies in rice production in the study area: being married, Years spent in school, contact with extension agent', being from the derived savanna agro-climatic zones, being a native of the study area, the presence of economically active members in the household, the proximity of the farm from the major road. Other factors which enhanced the adoption include, off farm income and the amount of credit accessed by the farmers. From the forgone results being that factor such as education, contact with extension agents, credit, other sources of income, access roads are determinants to the adoption of loss reducing technologies the study recommends that the government as a matter of priority invest in and/or improve on institutional infrastructures – schools, roads, extension services, banks and other credit facilities to enhance farmers output. There is also the need to encourage farmers to attain some level of education as well as supplement their income by engaging in other income generating activities to improve in their farming activities and consequently on their food security,

ABSTRACT:
This study focused on the constraints to the use of climate variability/ change adaptation strategies in Kogi State, Nigeria. Multistage random technique was employed to select the location and the respondents. Descriptive statistics and Factor analysis were the analytical tools used in this study. Uncovering the constraints to the use of climate variability/ change adaptation strategies among crop framers is important to give a realistic direction in the development of farmer-inclusive climate policies in Nigeria. The factor analysis result showed that the major constraints that the farmers faced in climate change adaptation were public, institutional and labour constraint, irrigation technology constraints, inadequate credit and farm inputs constraints, cost of land constraints and facility constraints information constraint; access to climate information, off-farm job and credit constraint; and poor agricultural programmes and service delivery constraint. These findings pointed out the need for both the government and nongovernment organizations to intensify efforts on institutional, technological and financial support to enable them get access to farming inputs, friendly land tenure and information systems as effective measures to guide climate change.
Keywords: Climate change; Adaptation; Constraints; Factor Analysis; Kogi State Nigeria

INTRODUCTION:
The climate has changed, is changing, and will continue to change regardless of all human investments (Falaki., *et al* 2013). The impacts of climate change are expected to be more pronounced in the developing countries particularly in Sub-Saharan Africa because their livelihood is dependent on agriculture which is highly sensitive to climate change. Nigeria is already experiencing climate changes ranging from more frequent erratic rainfall, and unpredictable onset of rain and increasing air temperature thus threatening ecosystems, infrastructure food production and livelihoodsand adaptation efforts seems not to be providing adequate responsive solution to the problem due to adaptation constraints (Guodaar and Asante 2018).

Eboh (2009) argued that no matter the sustained efforts to reduce GHG emissions in the atmosphere, the potential adverse effects of the changing climate cannot be avoided therefore; the mitigating efforts to enhancing the sinks of GHGs will take time and can only happen to a limited extent. It is in regard of this that adaptation has become a basic condition in climate variability discourses. Adaptation can be viewed as reducing the severity of many impacts if adverse conditions prevail. Simon (2011) also viewed adaptation as actions targeting changes to lifestyles, livelihoods and lived environments in order to be better able to cope with environmental changes. Consequently, it focuses on the implementation of policies and changes in management activities, institutional settings and infrastructure that enable effective responses to climate change. .Adaptations are adjustments or interventions, which take place in order to manage the losses or take advantage of the opportunities presented by a changing climate. Thus, the goal of an adaptation measure is to increase the capacity of a system to survive external shocks or changes. Thus, IPCC (2007) sees adaptation as an adjustment in natural or human systems in response to actual or expected climatic stimuli or their effects, which moderates harm or exploits beneficial opportunities.

Ifeanyi-Obi*et al.* (2012) opined that, agriculture is practiced across a broad range of climates and environmental conditions which makes it necessary for any country to develop an array of adaptation options that will meet the different conditions of the different ecological locations of the nation.Consequently, knowledge of the adaptation methods on the side of smallholder farmers may make it better to tackle the challenge of climate change.

However, a lot of adaptations options have been tried by farmers, these adaptation strategies are in most cases not used in seclusion. Farmers can combine many options where necessary in order to achieve the desired result. Therefore, building up adaptation strategies to cope with the changing climate becomes the most realistic alternative for farmers to employ in fighting climate change menace (Ifeanyi-Obi *et al*., 2012).

How much one can hold climate responsible for changes in agricultural productivity in Nigeria, will for long remain a subject of research as long as other factors are at interplay. Thus, understanding farmers responses to climate variations and climate change are crucial in designing appropriate adaptation strategies.

However, to cushion themselves against potential welfare losses, small holder farmers need to recognize the changes already taking place in their climate and undertake appropriate investment in climate adaptation.

Owing to increasing climatic change and frequency of extreme events in Nigeria, it is exceedingly imperative to understand the human-environment interactions in a local context by exploring the effects of climate change on rural livelihoods and associated adaptation efforts. Also, many existing studies in Nigeria show the need for adaptation research but actual field-based studies on farm level adaptation are not common. Therefore, it becomes pertinent to examine the constraints to the use of climate change adaptation strategies among rice farmers using factor analysis as the central focus of this study.

METHODOLOGY

This study was carried out in Kogi States, Nigeria. Kogi State is located in the north central Nigeria. In order to select a representative sample of the respondents for this study, multistage and stratified sampling techniques were adopted. Kogi State is made up of four agricultural zones A, B, C and D respectively. The first stage involves selection of two local government area each from all the agricultural zones where rice is grown. Secondly, two (2) villages were randomly selected

based on the enumeration areas making a total of sixteen (16) villages. The communities include Aiyetoro and Iya (Ijumu), Iluke and Odoekpe (Kaba/Bunu)from zone A, Kpanche and Ikande (Bassa), Echa/Abejukolo and Bagana (Omalla) from zone B, Kakand and Eggan (Lokoja), Girinya and Kotonkarfi (Kogi) from zone C, Ejule and Aya (Ibaji), Igalamela and Owolikpa (Idah) from zone D. Sampling frame of households was generated using the 2006 population census enumeration area list. However, Taro Yamane's (1967) formula was used to generate the sampled size at 9% from each of the agricultural zones. Lastly, a total of one hundred and twenty three (123) rice farmers' were selected.
The primary data were obtained using questionnaire and interview schedules. Data collected were on socioeconomic characteristics, adoption strategies and constraints faced by rice farmers. Data were analyzed using descriptive statistics and factor analysis.

Model Specification
Factor Analysis Model
Factor analysis provides a geometric representation that allows for a visual description of behavioral relationships. Factor analysis model is thus specified as:
The FA theoretical model applied in this study is expressed in the matrix:
$X = \Lambda f + e$
Where
x = the vector of n observable variables,
f = is the vector of m unobservable factors,
Λ = is the loading matrix of the order nfm and
e = representing the error vector of nxl
The KMO index and the Bartletts test at 0.00 significant levels were used as the basis for selecting the underlying factors that explained the data. For this study, only variables with factor loadings of ±0.4 and above were considered and used in naming the factors. The number of factors to be retained was on the basis of Latent root criterion (eigenvalue criterion) and the screen plot. The communalities represent the relationship between the variables and all other variables. However, the communalities above 0.3 were used to further confirm that each item shared some common variance with other items and thus ensures the adequacy of the data for the application of the factor analysis.

Table 1: Sample distribution of respondents by zones in Kogi State

Zones	LGAs	EAs	Sample Frame	Sample size
A	Ijumu	Aiyetoro	11857	7
		Iya	8302	5

Source; 2006 National Population Census Figures

Table 2 revealed the adaptation strategies adopted by rice farmers. A number of adaptation options used by famers have been explored. Accordingly, the following adaptation strategies have been identified as a prominent adaptation strategies used in the study area. These are identified by considering the number of frequencies of these adaptation strategies among farmers as compared to all other options analyzed. It is found that farmers are using change of crop variety (57.69%), adjustment of time of operation (52%), crop diversification (25%), diversification to off-farm enterprise (22%), soil and water management (43.9%) andchange in cultural practices(41.56%) which accounts the response of sample households respectively to reduce the negative impact of climate change. Majority (57.69%) of the farmer decided to change crop variety is to enable cultivate three times within a year while the decision to change the time of farm operations is because of flood which usually comes at the peak of operation.

Table 2: Adaptation strategies used by smallholder farmers to deal with climate variability stresses in Kogi State

Adaptation strategies	Number of respondents(n=123)	Percent (%)*
Change in timing of operation	86	69.91
Change in crop variety	80	65.04
Crop diversification	55	44.71
Diversification to off-farm enterprise	30	24.39
Change in cultural practices	62	50.40
Water and soil conservation	43	43.95

Source: Field survey 2018

* Percentages cannot be added to 100 since a farmer can employ more than one adaptation strategy at a time

RESULTS AND DISCUSSION

Table2 revealedclimateadaptation constraints of rice farmers' in Kogi State, Nigeria. The data showed that five (5) factors were responsible for the challenges rice farmers confronted with in adapting to the changing climate. These factors include (Factor 1) shortage of labour, poor technical know-how and widespread nomadism constraints. Factor 2; high cost of inputs and low education constraint. Factor 3; extensive rain-fed agriculture and low migration constraints. Factor 4; poor access to extension service delivery and limited land availability constraints while Factor 5; inadequate information on climate change and poor access to inputs supplies constraints.

However, after the rotation factor 1 accounted for 14.9% of the variance, factor 2 accounted for 13.2%, factor 3 accounted for 11.7%, factor 4 accounted for 11.4% and factor 5 accounted for

10.9%. Therefore, the true factors that were retained explained 62.1% of the variance in the 15 constraining variables.

Table 2: PCA constraints of rice farmers to climate adaptation strategies in Kogi State, Nigeria

	Constraints	Components					Communality
		Factor 1	Factor 2	Factor 3	Factor 4	Factor 5	
1	Shortage and high cost of labour	0.737					0.626
2	Poor technical know-how of the farmer	0.685					0.729
3	Widespread nomadism	0.524					0.495

Source: Field survey 2018

Under factor 1 (labour constaints), the specific issues that loaded high were shortage of labour to assistance rice farmers in adapting to climate adaptation strategies (0.737), poor technical know-how of farmers (0.685) and wide spread nomadism (0.524). Labour is one of the factors that drive agricultural growth and development in Nigeria and in the entered Africa countries and as such labour shortage has policy implications on agricultural productivity in rice producing communities in Nigeria. Labour shortage could be as a result of migration to urban areas and shift from farming by younger community members into other activities. Labour cost was also a daunting challenge to the farmers. The ability of rice farmers to hire labour on a farm during the entered production stages has potential challenge on productivity. Thus, smallholder farmers' cannot adapt to climate change adaptation strategies in the area. Ozor *et al*., (2010) affirmed to this assertion in the study; barriers to climate change adoption among farming households of Southern Nigeria.

Personal constraints: The variables that loaded high under factor 2(personal constraints) include high cost of farm inputs (0.788) and low education among rice farmers (0.783). The high cost of farm inputs like the agro-chemicals (herbicides, pesticides, fungicides) fertilizers, tractors could eventually lead to a high cost of food production, hence affecting food security. All these variables suggest scarcity of resource inputs, which raise their prices beyond the reach of the farmers. This could pose threats to the coping strategies of the farmers as noted by Ozor *et al*., (2010), climate change might constitute significant addition to the stresses already borne by farmers, thus, adapting to it might be beyond their resource capabilities. This agrees with the findings of Antwi-Agyei *et al*., (2013) who identified lack of climate risk information and early warning systems due to poor meteorological facilities and equipment as having adverse effects on farming activities in Ghana.

The variables thatloaded high under factor 4 (poor extension service delivery directed to meet climate change adaptation strategies (0.753) and limited land availability (0.637). /Inadequate extension officers coupled with poor extension service delivery hinders proper extension services. Information dissemination on climate variability and application of right extension technologies are very vital in providing early warning signals and reorienting the mindset of farmers towards sound adaptive capacities. This corroborates with the findings of Otitoju et al., (2016) that lack of/or inadequate extension programme is a constraint to the use of climate change adaptation strategies among food crop in South-West Nigeria. Guodaar & Asante (2018) also affirmed that farmers' access to extension service is a major determinant of swiftness of adoption procedures to climate change.

Regarding factor, 5 the variable that loaded high include inadequate information on climate change (0.743) and poor access to input supplies (0.678). Otitoju and Enete (2016) affirmed that information problem could pose serious challenges to farmers' adaptation strategies as they may not be aware of current developments concerning climate change and the necessary readjustments required. Furthermore, the poor anticipation by government agency on how climate will affect farmers' live now and in future, leading to inability to make provisions for uncertainty, is a result of poor funding of the agricultural sector.

CONCLUSION AND RECOMMENDATIONS

This study revealed that the climate change adaptation strategies used in rice production were change of crop variety, adjustment of time of operation, crop diversification, diversification to off-farm enterprise, soil and water management andchange in cultural practices. The study also revealed that some farmers sometimes failed to employ any adaptive strategy in the event of climate variability risks.

The major factors that hinder rice farmers' adaptive practices were personal barriers, institutional and labour constraints, irrigation technology constraints, inadequate credit and farm inputs constraints, cost of land constraints and facility constraints information constraint; access to climate information, off-farm job and credit constraint; and poor agricultural programmes and service delivery constraint

There is complete need to take out and address these constraints encountered by trice farmers in adapting to the effects of climate change as this will have far-reaching implications on policy implementation that is geared towards food production and consumption. There is therefore the need for public and private financial institutions to provide farmers with some financial support to enable them get access to farming inputs, friendly land tenure and information systems as effective measures to guide climate change.

ABSTRACT

The study was carried out to assess the effect of sweet potato vine (seed) production technologies' adoption on the welfare of rural farmers in Abia State. Data were collected from a sample of 60 farmers with the use of structured questionnaire. Frequencies, percentages and means were used for data analysis. The results showed that the majority (58.3%) of respondents were female, about 65% of the respondents fell within the age range of 31-50 years, 50% of the respondents had farming experience of between 11-30 years. It was also discovered that adoption of sweet potato vine (seed) technologies had positive effect on the welfare of the farmers particularly increased farm income of the respondents, which translated to improvement in their standard of living, expansion of their farms and it also impacted on their children's education and nutrition status of the farmers.

Key words: **Sweet potato, Vine (Seeds), Adoption, Welfare, Farmers**

INTRODUCTION

Sweet potato (Ipomoea batatas (L) Lam) is an herbaceous warm weather creeping plant belonging to the family Convolvulaceae and genus ipomoea (International Potato Centre (CIP) 2010). Sweet potato originated from South America. Sweet potato is a food and nutrition security crop grown in almost all Asian countries with China taking the lead, then Africa and Latin America (CIP,2009).Nigeria is one of the largest producers of sweet potato in Sub-Saharan African (SSA) with annual production estimated at 4.03 million tons per year with farm size of about 1.7mhaand yield of .3t/ha (FAO, 2018).Sweet potato is an important staple crop grown in all parts of Nigeria by small-scale farmers. The crop has moved up from the minor status to an enviable position of being the fourth most important root and tuber crop in Nigeria after cassava, yam and cocoyam. Sweetpotato vine (seeds) or planting materials refers to cuttings from sweet potato plant vines, they can be planted and are genetically identical to the mother plant. Plant breeders can also produce 'true seed' by fertilising a sweetpotato flower with pollen from another sweetpotato plant. Sweetpotato vines are used vegetative to propagate another sweetpotato plant. Some improved production technologies have been developed and disseminated by National Root Crops Research Institute for adoption and continuous use to increase sweet potato production in Abia state and by extension increase the income and well-being of the farmers. National Root Crops Research Institutes (NRCRI), Umudike embarked on rigorous and active research into the genetic improvement, production, processing, storage, utilization and marketing of root and tuber crops of economic importance in Nigeria NRCRI (2009). These research efforts have led to the introduction of improved varieties of sweet potato such as TIS 87/0087, TIS 2532, OP.1.13, TIS 8441, TIS 8164, Umuspo 1 and Umuspo 3 which are high yielding and resistant to disease and pest attack, also tolerant to prevalent pests, notably sweet potato weevil, Cylas spp and with wide adaptation across Nigeria (NRCRI, 2009).The components of the sweet potato production seed technologies are:20x10 spacing of rapid multiplication of sweet potato, Harvesting of vines at 8WAP first, then every 4weeks, planting on beds not on ridges or mounds using slanting method, Weeding at 4weeks after planting then rouging, Use of herbicide and pesticide and application of fertilizer at 4WAP. Adoption of improved sweet potato Vine (seed) technologies to achieve higher yield can directly affect income and welfare of farmers, food and nutritional security through changes in production patterns. Welfare of farmers relates to their standard of living, farmers' ability to afford the basic needs of life such as quality health care, housing, clothing, education and nutritious food. This study assesses the effect of sweet potato Vine (seed) production technology adoption on welfare of rural farmers in Abia state The objectives were to describe the socio-economic characteristics of farmers in the study area and to assess the effect of the technologies on welfare of rural farmers in Abia state

METHODOLOGY

The study was conducted in Abia State. The State has three Agricultural zones with 38 extension blocks and 27 circles (ADC,2019). These zones are Aba, Ohafia and Umuahia. . Multi stage and purposive sampling techniques were used to elicit information for the study. Three Agricultural zones of the state were involved in the selection of the respondents for the study. One block in each zone was purposively selected because of their involvements in sweet potato farming and the technologies have been disseminated to the area, giving a total number of three blocks. Two circles from each block were purposively selected for the same reason. Ten (10) farmers were randomly selected giving a total of 60 sweet potato farmers (vine multipliers). Primary data were used for the study and data were collected using structured questionnaires. Data were analyzed using descriptive statistics such as frequencies, percentages and five point likert scale strongly agreed (5), Agreed (4) Undecided (3), Disagreed(2) and Strongly disagreed(1).

RESULTS AND DISCUSSION

Socio-economic characteristics

The result in table 1 showed that Majority (65%) of the farmers fell within the age range of 31-50 years. This implied that young people of active age dominated the activities of sweet potato production technologies in the study area but younger female farmers were the most dominants of the practice. Majority (58.3%) of the farmers were female which implied that women were more involved in the production of sweet potato than men. The result also shows that majority (63.3%) of the farmers had household size of between 5-7 persons. This means that the farmers had relatively large-sized households since they believe that getting married and having children is an alternative source of labour to the usage of hired farmlands. The result also shows that most Farmers (70%) earn annual income of between sixty thousand ₦60,000 to two hundred and fifty nine thousand ₦259,000. A few of the farmers about 10% earned up to four hundred and sixty thousand naira (460,000) and above.

Effect of sweet potato seed technologies on the welfare of rural farmers

The result from table 2 revealed that increased income with mean (4.6) ranked first as the major effect of sweet potato seed technology adoption on farmers' welfare in the study area. Adoption of improved sweet potato seed technology is expected to lead to increased production and productivity and consequently improving farm incomes and hence household welfare. With increase in income, there will be positive change in socio-economic status of the farmers leading to improved standard of living in the study area. This is followed by improved standard of living which had mean (4.1) and ranked second as major and positive effect of sweet potato vine technology adoption on farmers' welfare. Obviously, farmers agreed that the moment their income increased, there will be commensurable improvement on their living standard and that of their households members which will manifest in every areas of their lives such as housing, clothing, health care services and education. Similarly, respondents identified expansion of farms with mean (4.0) as third major and positive effect of sweet potato vine technology adoption on farmers' welfare. In line with a prior expectation that when farmers expand their land or increase their farm size under sweet potato cultivation, it is expected that there will be increased yield which by extension increase the income of farmers and raising their living standard thereby impacting positively on the welfare of farmers. This finding was consistent with the finding of Diagne *et al*. (2009) and Mendola (2006) who found a significant positive difference in farm size between the technology adopters and non-adopters with the adopters cultivating larger farm size. However, the higher land area cultivated by the adopters, translated to increase in annual household income. Other major and positive effect to sweet potato seed technology adoption on farmers' welfare was training of children and wards with a mean of (3.9) ranked fourth, sweet potato vine technologies are able to send their children/wards to school and access quality health care. This result agrees with Anaglo *et al*. (2017) who discovered that majority of farmers with high levels of adoption (95.62%) demonstrated an improvement in the ability to pay children school fees compared with the majority of those with low levels of adoption. Another important of sweet potato vine technology adoption on farmers' welfare as reported by the farmers was acquisition of new properties with mean of (3.3). Finally is improved food and nutrition with mean (2.0) according to the respondents, this does not have major effect on farmers welfare. This is from the reasoning that sweet potato vine technology adoption will always translate to high yield which makes food available at all times in the farmers households but often times there are gluts when the sweet potato is in season making its price to be low in the market.

Table 1: Socio-economics characteristics of the respondents

Variables	Frequency(60)	Percentage(100)	Mean
Age

SA (Strongly Agreed) A (Agreed) U (Undecided) D (Disagreed) SD (Strongly Disagreed) Field Survey, 2019.

CONCLUSION

The study investigated the effect of sweet potato vine (seed) technologies adoption on the welfare of rural farmers in Abia state. The result revealed that women were more involved in the activities of sweet potato vine production. Majority of sweet potato farmers were still in their middle active productive age with varying levels of education. . It was also discovered that adoption of sweet potato vine technologies had great effect on the welfare of the farmers particularly on increased farm income, which translated to improvement in their standard of living, expansion of their farms and it also impacted on their children education and nutrition status of the farmers.

ABSTRACT

The study examined the livelihood diversification strategies among Fadama and Non Fadama users in Imo State. Nigeria. Data used for the study were collected with the aid of structured questionnaire administered to 150 randomly selected Fadama users and 150 non-Fadama user making it a total of 300 questionnaires. Data were analyzed using descriptive statistics and net farm income model. Result of the analysis showed that farming activities is the major source of income generation among Fadama and non Fadama users in the study area, contributing 63.6% and 51.9% of Fadama and non Fadama users' total household income. Non-farm activities contributed 36.4% of the Fadama users' total household income. In the same vain, non-farm activities among non Fadama users contributed 48.1% of their total household income. Despite growing concern that farming alone may not provide sufficient income for sustainable livelihood, it still dominates income generating activities among Fadama and non Fadama users. It is therefore recommended that Government policies aimed at leveraging from donor assisted projects for agricultural purposes and income generation should eliminate factors that could create barrier for some farmers or community members from accessing such donor assisted projects.

Keywords: Farm, Off Farm, Income, Fadama, Non Fadama.

1.0 INTRODUCTION

The vast majority of poor households living in the developing areas rely on agriculture for their food, income, and livelihood (Dethier and Effenberger 2012; Larsen and Lilleør 2014). In Nigeria, agricultural sectors still constitute the source of employment and livelihood for about three quarters of the population and it is also the dominant activity in terms of linkages with the rest of the economy, plays important role in the livelihood and social- cultural system of the country. According to the Labor Force Survey for 2019, the agricultural sector employs 67million persons. 41.6% of the total labor force (Ashiru, 2019). Agriculture share GDP of 55% in 2019 (Adewale, 2020). According to (World-Bank, 2010), majority of the farm household populace either depend entirely on farming for survival and generation of income, or depend on farming to supplement their main sources of income. Agriculture is still the major sector upon which the majority of Nigeria's rural poor depend on for their livelihood, (Oladimeji, *et al*. 2014),

In recognition of the importance of the agricultural sector in Nigeria, the government has initiated and endorsed many national and international projects, programs and policies aimed at increasing farmers' income, supporting livelihood activities and thereby reducing poverty. Laudable among these programs is the National Fadama development programme. Fadama is a Hausa name for irrigatable land which is flood plains and low lying areas underlined by shallow aquifers and found along Nigeria's river systems. Fadama areas are typically waterlogged in the rainy season but retain moisture during the dry seasons. These areas are considered to have high potentials for economic development (NFDP II, 2014)

Imo State is among the states that benefited in both Fadama I, Fadama II, Fadama III and Fadama III Additional Financing whose development objective was to increase the incomes of users of land and water resources on a sustainable basis. It also seeks to reduce conflict among users and aims to address some factors that militate against the full realization of the potential benefits of agricultural production activities- poor development of infrastructure, storage, processing and marketing facilities (FADAMA III AF 2017).

Despite this laudable project, it has been established that Farming as a primary source of income has failed to guarantee sufficient livelihood for most farming households in developing countries (Babatunde, 2015, hence rural farming households have been found to diversify their income sources thus, allowing them to spread risk and enhance income generation, Maniriho and Nilsson (2018). More than 80% of the rural households in Nigeria relate their poverty status to problems in the agricultural sector and specifically to lack of inputs and not being able to afford inputs such as fertilizer and seeds. To overcome this problem, farm households often diversify their livelihood from farm into off-farm activities to earn income to finance farm investment in the absence of a functioning credit market (Nawoji et al., 2018). According to (Bola et al.2019). Non-agricultural income constitutes 40 - 45 per cent of farming household income across the developing world. Farming households in developing nations receive quite reasonable proportion of their incomes from off and on-agricultural employment and off and on-farm income, is income earned from non-agricultural sources either in wage-employment or self-employment (Mohammed et al., 2019).

Non-farm income generating activities include all economic activities in rural areas except agriculture, livestock, fishing and hunting. It includes all off-farming activities, processing, marketing, manufacturing, wage and causal local employment in the rural villages (Igwe, 2013). It encompasses all economic activities except the conventional crop production and livestock rearing (Agbarevo and Nmeregini, 2019).

Rural people have diversified their livelihood means and income earning portfolio across farm, non-farm and off-farm activities, (Agbarevo and Nmeregini, 2019). According to Musa and Kumilachew (2018), findings consistently show that incomes generated from off-farm activities ease the burden on agriculture as it enables households to have better incomes. Hence, they enhance food security as they manage food consumption fluctuations better than a household without such an activity (Hoang et al. 2014; Mishra et al. 2015). The push factors that may drive off-farm income generation includes the need to increase family income when farm income alone cannot provide sufficient livelihood (Nawoji et al., 2018).

Furthermore, the perceived advantage of off farm income generation is increasingly becoming important in the light of reiterated environmental, economic, farmers herder crisis, banditry and kidnapping affecting the rural areas of our countries. Thus, a thorough understanding of farm and off farm incoming generation among fadama and non fadama households is indispensable. This would help development institutions to review their strategies, so as to address the needs and problems of farming households.

This study, therefore, attempted to analyze the farm and off farm income generation among fadama and non- fadama users and their income share in the study area.

2.0 MATERIALS AND METHOD.

This study was conducted in Imo state, Nigeria which is among the states in Nigeria that benefited from the National Fadama Development project. Imo State lies between Latitude $5^0 10'$ and $6^0 35'$ North of the equator and between Longitude $6^0 35'$ and $7^0 31'$ East of the Greenwich meridian. The State has a population of about 3,934 million people disaggregated into 2,032 males and 1,903 million females (NPC, 2006). It is bounded on the East by Abia state, on the North by Anambra and Abia State, and on the West by Rivers State. The State is divided into 27 administrative units called Local Government Areas which are grouped into 3 agricultural zones viz Owerri, Okigwe and Orlu. Fadama II was implemented in 11 local government areas of the state, while Fadama III was implemented in 20 local government areas of the state. The population for our study encompassed the beneficiaries of Fadama II, Fadama III and Fadama III Additional financing and their non-beneficiaries. Multistage random sampling technique was used in the selection of the sample. In stage one, two Local Government Areas (LGAs) that participated in both Fadama II Fadama III and Fadama III additional financing were purposively selected from each agricultural zone. In the second stage, 5 Fadama community Associations (FCAs) were chosen randomly from each of the selected local government areas, thus giving a total of 30 Fadama Communities Associations. The third stage involved random selection of 5 Fadama user groups (FUGs) from each of the 30 Fadama communities Associations making a total of 150 FUGs. In the 4^{th} stage, a member of the Fadama user group (FUG) was chosen randomly from each of the selected Fadama User Groups, thus giving a sample size of 150 Fadama respondents. In order to study uniform number of parallel respondents, 150 non Fadama users were drawn randomly from the same thirty (30) communities where the Fadama community associations and fadama user groups were chosen (5 non Fadama users from each community), bringing the cumulative sample size of 300. Data were sourced both through primary and secondary methods. Primary data were obtained with the aid of structured questionnaire. Secondary data were obtained from relevant current literature. Data were analysed using Aggregate Net Household income (Y) = Net Cash Value + Net Imputed Value, to determine the income of the respondents and simple descriptive statistical tools to determine the income share of the respondents.

3.0 RESULT AND DISCUSSION

3.1 FADAMA, Farm and Non-Farm Activities

The distribution of Fadama by Farm and Non-Farm activities with income share is presented in Table 3.1.

Table 3.1: Farm and Non-farm activities engaged by Fadama users with their income share

Farm Activities	Aggregate income (₦)	No of participants	Income share	% income share
Crop	198257.7	142(95)*	0.354	35.4
Livestock	103049.2	71(47)*	0.184	18.4
Forestry	20161.8	9(6)*	0.036	3.6
Fishery	34723.1	20(13)*	0.062	6.2
Self-employment	98008.75	70(47)*	0.175	17.5
Non-farm Wage employment	102489.15	31(21)*	0.183	18.3
Farm wage employment	3360.3	5(3)*	0.006	0.6

Source: Survey data, 2021. Figures in parentheses are percentages * multiple responses.

The table showed that 95% of the Fadama users engaged in crop activities, contributes 35.4% of the aggregate household income of Fadama users in the study area. Livestock is another important farm income generating activity among the Fadama users. Hence analysis of the result suggests that 47% of Fadama users participated in livestock activities and generated 18.4% of the household income. The result also showed that 6% of Fadama users participated in forestry activities and generated 3.6% aggregate household income. Finally, 13% of Fadama users are involved in fishery activities and contributed 6.2% of aggregate household income. the table also showed that 47% of Fadama users participated in self employment with 17.5% income share, non farm wage employment among Fadama users' accounted for 18.3% of aggregate Fadama users household income with 21% of the households participating. Farm wage employment as a non farm income generating activity accounted for 0.6% of aggregate Fadama users' household income.

3.2 NON- FADAMA, Farm and Non-farm Activities

Table 3.2: depicts farm and non farm activities engaged by non-Fadama users with income shares.

Table 3.2: Farm and Non-Farm Activities Engaged by Non Fadama Users with their Income Shares.

Farm Activities	Aggregate income (₦)	No of participants	Income share	% income share
Crop	193029.31	146(97)*	0.413	41.3
Livestock	31782.07	28(18.7)*	0.068	6.8
Forestry	13554.12	12(8)*	0.029	2.9
Fishery	4206.45	5(3)*	0.009	0.9
Self-employment	107498.17	70(38)*	0.230	23
Non farmWage employment	84596.38	31(16)*	0.181	18.1
Farm wage employment	32716.83	5(14)*	0.070	7.0

Source: survey data 2021. Figures in parentheses are percentages * Multiple responses.

The analysis in Table 4.9 showed that 97% of non Fadama users engaged in crop activities and generates 41.3% of aggregate household income. The result also showed that 18.7% engaged in livestock activities and contributed 6.8% of aggregate household income. Forestry and fishery accounted for 2.9% and 0.9% income share with 8% and 3% participation respectively. The further showed that 38% of non Fadama users that engaged in self employment activities generated 23% of the aggregate houseold income. The data also showed that non farm wage employment among non Fadama users' accounted for 18.1% of the aggragate non Fadama usrs household income with 16% of households participating. Comparatively the results of analysis in Tables 3.1 and 3.2 seem to suggest that Fadama users participated more in wage employment activities than non Fadama users. This goes to show that those who benefited from Fadama project are not only poor resource farmers but also salary eaners. Non farm activities acounted for 36.4% of the total Fadama users' income and 48.1% of the total non Fadama users' income. This finding is similar to the work of Amanze et al. (2015) whose study showed that about 35% of rural incomes in Nnewi South stem from non-agricultural activities. The result of the analysis also showed that both Fadama and non Fadama users do not attach so much importance to fishery and forestry activities. This is evidenced from the number of participants in each of the activities. The finding showed that the major income generating activities for both Fadama and non Fadama users are crop and livestock activities. However, despite the degree of diversification among Fadama and non Fadama users, farm activities remain the main source of income generation. The difference in percentage of income generated from farm activites among Fadama and non Fadama users could be attributed to the grant for asset acquisition, capacity building, advisory services and input support given to Fadama users by the Fadama project. The findings of this study are in line with the work of Tijani et al (2014) whose report showed that Fadama users and non Fadama users participated and generated more income from crop activities than any other activity in a similar study in Kogi and Kwara States.

CONCLUSION AND RECOMMENDATION

Fadama and non Fadama users are involved in multiple sources of income generating activities simultaneously as a means of income generation. Fadama as community development project, boosted farming activities among her users, hence Fadama beneficiaries participated and generated more income from farming activities than Non- farm activities in the study area. Members of the community should actively participate in community development projects designed and sponsored by government and donor agencies that will enhance their income generation. Government and donor agencies during project design should eliminate factors that could create barrier for some farmers or community members from accessing such donor assisted projects.

ABSTRACT
Cassava value addition is an important activity that has the ability to improve the financial earning capacity of farm households. Yet, little is known about the determinants of participation in cassava value adding activities by farm households. Thus, this study analyzed the determinants of farmers' participation in cassava value addition in Benue State. The primary data used was collected with the aid of questionnaire from the respondents selected using multi-stage sampling techniques. The data were analyzed using descriptive statistics and probit regression. The results of probit regression show that membership of cooperative society, access to extension agents, years of farming experience and number of working household members had direct significant influence on participation, while marital status indirectly influenced it. Policies that will encourage farmers to join cooperative societies and increase farmers' access to extension services are suggested.
Keywords: cassava value chain; farm households, determinants, probit regression

INTRODUCTION
Cassava is a nutty-flavored, woody shrub mainly cultivated for its starchy root vegetable or tuber. Native to South America, it is a major source of calories particularly for people in developing countries. The cassava tuber is drought resistant, can be grown on land where other crops do not do well, and requires little inputs. For these reasons, African small and poor farmers grow it widely as a subsistence crop. It is not known when Cassava was actually introduced into Nigeria but the diffusion of cassava can be described as a self-spreading innovation that at some point found its way into the country. Its ability to grow well in poor soils and withstand drought make it an ideal crop to cultivate in places where other crops struggle, and the crop thrives in Nigeria's soils. The Food and Agriculture Organization (FAO) estimated global production of cassava in 2014 at about 268 million tons out of which Africa produced about 54%. Nigeria alone produced about 55 million tons, which, also at an estimate, is about 21% of total global production.

Most of the cassava produced in Nigeria (88%) is used for human food, with over 50% used in the form of processed products. Other uses are in the form of animal feed and industrial raw material purposes (starch, ethanol). Cassava, especially in its value added forms, has the potential to increase farm incomes, reduce rural and urban poverty and help close the food security gap. Yet, it has been observed that the involvement levels of farmers in value adding processes especially cassava value chain activities is startlingly low (Ogunyinka et al., 2018). This could be attributed to a lack of standardized products and, low competitiveness within the commodity market, due to inadequate infrastructure and technology. This has led to the continued low production capacity and income. To this end, this study focused on the determinants of farmer households' participation in cassava value addition

MATERIALS AND METHODS

The study was conducted in Benue State, Nigeria. A three-stage sampling techniques was used to select respondents. The first stage was a purposive selection of two local government areas (LGAs) which are known for their high cassava production. The second stage was a random selection of 10 villages from each of the LGAs to give a total of 20 villages. The enumerators with the help of village heads helped in compiling the list of households in the selected villages. At the third stage, there was the random selection of respondents proportionate to the size of cassava-based households in each of the villages. Data was collected from them with the use of questionnaire. The data were analysed with descriptive statistics and Probit regression. While descriptive statistics was used to analyse respondents' socio-economic characteristics, their participation status in value adding activities was analysed with Probit regression.

RESULTS AND DISCUSSION

Socioeconomic characteristics of respondents

The results of the socio-economic characteristics of respondents are presented in Table 1. The average age of respondents was 46 years (Isitor et al., 2017). The mean household size and annual income stood at 10 persons and ₦1,025,687 respectively. The mean year of farming experience stood at 19.68 (Isitor et al., 2017). The average distance between farmers' residence and the nearest market was 3.63 Km. About 89% of the respondents were married with more than three-quarter of them being males. About 16% had no formal education (Adewuyi et al., 2013). Less than halve of the respondents owned the cassava land they cultivated. Only about 72% of the farm households were able to access credit in the year preceding the survey. This is contrary to the submission of (Adeyonu et al., 2017). More than three-quarter of them were members of cooperative society (Osuji, 2019). While about 59% of them had access to extension services, the remaining 41% could not access extension services. About 65% had access to electricity for a minimum of five hours daily, while the remaining were denied access.

Determinants of farmers participation in cassava value addition

The probit regression returned a coefficient of determination of 0.69 implying that 69% of the variation in the dependent variables was explained the variation in independent variables. Five of the variables significantly explained the decision to participate in value adding activities. The coefficient of marital status is significant and negative, indicating that the likelihood of participating in cassava value adding activities is higher among non-married farmers compared to their married counterparts. More experienced farmers were also more likely to participate in cassava value chain (Ao et al., 2019; Apata, 2019). Membership of cooperative society was also found to significantly increase the probability of participating in cassava value chain by the smallholders (Adeyemo, et al., 2019). Also, access to extension services significantly increased the likelihood of participation (Onakuse, et al., 2018). Finally, the number of members of household earning income is significant and positive, implying that the larger the more the number of working household members, the higher the probability of the household participating in cassava value chain.

CONCLUSION

This study analysed the determinants of the participation of cassava farmers in value addition in Benue State, Nigeria. The factors with positive influence on participation are membership of cooperatives, access to extension services, planting experience and having a large number of income earners in the household, and the only variable with a negative effect is marital status. Policies that will encourage farmers to join cooperative societies and increase farmers' access to extension services are suggested.

ABSTRACT

Farm house are those structures sited within the farm area to facilitate storage and ease of movement of farm produce on the farm. It supports maximum productivity of plants and animals, enhance the preservation of farm tools and promote favorable environment for farm resources. As such their economic importance cannot be overemphasized. This paper aim to look into the various forms of farm structures set up on the farm such as maize crib, silos, yam barn, processing sites, screen house, tractors or farm machinery house, poultry house, pig house, fish pond, sheep and goat house. The method it applies embraces the cogent roles displayed by agricultural economics and extension service provider in facilitating the establishment of these structures on the farm. It further highlights the challenges encountered in the course of maintaining these structures and proffers appropriate solution. The result comes in the form of providing concrete solutions that will increase the life span of these structures through the various measures outlined, with the synergetic effort of farmers, agricultural economics and extension providers. In conclusion, value of farm produce in rural and urban areas can be effectively enhanced and sustained over-time, pest infestation and wastage can be successfully reduced to the minimal. Also, plant and animal growth can be technically managed by farmers through the assistance of extension personnel with credited expertise for increased farm productivity and farmers' profitability.

Keywords: Farm house, Economic importance, Agricultural Economics, Extension, Service providers.

INTRODUCTION

Definition of farm house

Farm house vividly describes the siting of buildings on the farm in order to be able to carry out specific farm operations and activities without any stress. They often come with specific purpose attached to their establishment on the farm. This often relate to the various farm enterprises that farmers often engaged in within the farm premises, which subsequently necessitates the establishment of these structures on the farm. This often facilitates optimum plant growth, plant and livestock management, excellent storage system, processing, packaging and marketing of farm produce. Without the establishment of these structures on the farm, it could limit the rate at which each of the various activities carried out on the farm could be well managed, thereby leading to a lot of production deficiencies on the farmers' part. Several studies related to this study has either worked on single unit of farm structure on the farm stead, some on storage and feeding system and many others worked on intricate details in constructing these structures on the farm. This paper tends to bring in a new dimension by emphasizing the role played by agricultural economics and extension personnel in the establishment of these farm structures. Previous studies reviewed by Blakely, Aviagen, Simpson, Campbell and Macklin (2007) studied the economic importance of poultry house and ventilation management, also Mississippi State University Extension, (2018) also worked on feedstuff handling, storage and feeding system for livestock. Moreover, Ojedele, Ezejiofor, Ehiomogue and Orji (2018) investigated the necessity of farm structures in Nigeria. However, there is need to ascertain the economic importance of these farm structures in relation to the perspective of agricultural economics and extension service providers, in order to minimize loss, wastage of farm produce, improve plant and livestock management, maximize profit in agricultural production as well as promoting value additions to these produce on the farm.

Economic Importance of these structures to the farmers

Establishment of farm buildings or structures comes with great economic value to the farmers in diverse forms. Starting with the construction of the maize cribs, it helps the farmers to prevent unnecessary wastage and spoilage of their unsold or leftover maize at the farm gate. The left over maize are preserved from rot and infection by storing them in the cribs. It also provides increment in the shelf life of the crop due to the efficient storage system along with the provision of adequate aeration of the maize crops within the crib (Manandhar, Milindi, and Shah, 2018). The use of silos poses an advantage in prolonging the shelf life of variety of grains stored inside them. The preservative environment within the structures is usually prepared by farm workers, which helps in warding off susceptible insects, weevils, rodents, as well as regulating the moisture content of these grains over a long period of time. Certain factors such as moisture content, relative humidity, temperature and oxygen are carefully controlled by these service providers (Manandhar, Milindi and Shah, 2018). Grain contaminations through microbial or fungi infestation during storage are also eliminated during this period. The quality of grains would have been enhanced and as such tend to attract a higher purchasing power from the consumers.

Moreover, when these grains are scarce in the market, the economic advantage is much more pronounced for higher sales as consumers demand rises to have these grains at all cost. This will inadvertently improve the standard of living of the farmers whenever the grains are needed for commercial purposes either on a large-sale or small-scale (Ojedele, Ejiofor, Ehiomogue and Orji, 2018). The economic advantage of using barns tend to be well pronounced during marketing, as reduction in transportation cost based on the number of tubers being transported to the market are minimized. This comes into play when excess tubers are carefully stored in the barns; these help farmers in preserving those tubers for the next cropping season as well as reduce the proportion of tubers that would have been damaged in the process of sorting, grading and packaging during marketing (Umogbai, 2013). Farm processing buildings helps in reducing the stress of conveying farm produce to processing centers outside the farming premises. Hence it promotes proper coordination of women processors who are able to mobilize themselves for optimum productivity of those farm products with better processing and packaging skills (Manandhar, Milindi and Shah, 2018).

Roles played by Agricultural Economics and Extension Service Providers in the use of these structures

- First and foremost before the establishment of any structure on the farm, there is need to engage in rigorous planning. This entails getting specific details of areas to be mapped out during construction, the size of the enterprise the farmer is involved in i.e. whether it's a crop or livestock, small or large scale; which could determine how small or big the farm structures will be in the long run. Agricultural economics provider has a major work to play by intimating the farmer on the pros and cons of siting the structures on distinct areas of the farm. For instance, considering the topography of the farm land, checking the master plan of the farmland, the type of soils present within proposed farm area and the distance where farm structures should be to the cultivation site will juxtapose the credibility of choosing such areas for farm use. The extension provider also guides the farmer to where he can purchase those tools or machineries at affordable prices as well as making sure they are of good quality to ensure durability of these tools (DLEC, 2019).
- Establishment of farm structures is very relevant to both agricultural economics providers as well as agricultural extension providers. Both practitioners influences the way these structures are functional and well managed on the farm on a consistent basis (FAO, 2020). They practically guide the farmers on making optimum use of these structures through thorough managerial procedures, regular check- up, daily maintenance before every farm operations and harvesting period. In relation to the Agricultural Economics providers, they equally help in supervisory roles with the assistance of farm managers.
- Farm managers and extension agents' offers practical advice to farmers by assisting farmers in taking sound decisions regarding current and up to date structures that will be very relevant to their various enterprises (FAO, 2016). This consequently have a way of improving the productivity of such farmers, especially those farmers that are embarking on going on a larger scale in their farming business.
- Farm managers and extension providers also engage in educative roles by educating and training the farmers on the benefits derived in having adequate and functional structures on the farm. These structures could also have further sub-structures where different home products can be produced. For example, siting of oil-palm processing center on the farm can further lead to production of soaps, detergents, palm oil, shea butter, body creams, etc. This could contribute to the farmers' entrepreneurial capacity by diversifying into other farm preservative skills (DLEC, 2017). One good thing this creates for the farmers is the provision of other reliable coping strategies that they can easily fall on during off-season or non-farm activity periods.

Challenges encountered in the course of establishing and maintaining these structures

- Part of deficiencies that could be experienced during production if these farm structures are not in place include: physical loss such as glut of farm produce like eggs, spoilage of grains, wastage of fruits, theft, loss of energy, fatigue and experiencing unnecessary financial stress in the transportation of these produce. All of these challenges poses a great threat to the health of the farmers (FAO, 2016).
- Also the challenge of inadequate land allocation or land space in constructing a durable structure also poses a threat to the farmers. Farmers that are struggling to buy more land

in expanding their farming business might find it very difficult in ensuring standard structures for each of the various enterprises they are engaged with on the farm due to poor access to funds (FMARD, 2020).

- There is also the issue of post- harvest losses which originates from poor construction of farm structures which could affect the crops that are stored in the storage facilities or houses. This has the tendency of facilitating deterioration easily, if adequate care and proper farm building recommendations are not taken into consideration when siting these structures. The crops might be at the risk of microbial infestation such as fungus, microbes, mold etc. This usually comes up as a result of not fumigating the grains, crops or farm structures very well before storage. It could also be as a result of dampness or high moisture content in the storage houses. Most post-harvest losses encountered by farmers are usually caused by inadequate post-harvest management practices (FAO, 2020).
- Another issue that could be encountered on the farm is rodents and pest attack during storage. These include grain borer, moths, beetles, weevils, etc. All of these are facilitated through other physical conditions that are not well managed. These include openings or cracks along the farm structures like the roof, walls or floors. Other factors that could influence these also are unstable room temperature; moisture level of the materials used in constructing these farm structures such as wood, asbestos, used aluminium foils as well as crop grains stored within the storage facilities. All of these can trigger the multiplication of these pests and insects within a short period of time thereby causing irreparable damage to the grains and farm structures (FMARD, 2020).
- Another factor that can affect building of farm structures is inability to contract farm building experts who are competent in establishing these structures for small-holder farmers. For instance, a farmer who barely has a two acre of land for his arable crops would be the last person to consider establishing standard farm structures on his farm based on low farm space and poor financial capacity in setting up these structures on his farm (Ruwaichi and Werema, 2018).

SOLUTIONS TO ENSURING ELONGATION OF LIFE SPAN OF FARM STRUCTURES

a. Farmers can receive mutual support from other farmers by soliciting for help from others in siting farm structures on their farms and also making sure the same help is rendered back to farmers' that gives them a helping hand. This way unnecessary spending can be reduced by getting extra hands to assist in farm labor in the siting of farm structures. This emphasizes cooperative support among farmer groups by forming viable farmer cooperatives based on the various enterprise engaged by the farmers in rendering both physical and financial aid.

b. Economics and extension providers should ensure that farmers have access to good farming materials by advising and encouraging them on the benefits of using durable materials for the farm structures to be sited on their farms. This will help them to have minimal loss and rodent attack as regard the produce stored in these structures (FAO, 2020).

c. Economics and extension providers should also link the farmers with viable credit institutions where they can have access to credits, loans in order to equip their farms with current and relevant farm structures. Institutions like micro finance banks, agro-allied banks and non-governmental organizations will be relevant in accessing adequate funds for the farmers' need of standard structures on the farm. This is mainly due to the fact that these specific aforementioned financial institutions specially have genuine interest in developing grass-root farmers, so that their standard of living and productivity on the farm can be enhanced (Ruwaichi and Werema, 2018).

d. Economics and extension providers can also ensure that environmental conditions are well monitored and properly controlled. For instance, in the case of siting of screen house, one will have to ensure that optimum flow of air, sunlight, water and humidity is carefully monitored and maintained all through the growing period of the crops (Kittas, Katsoulas, Rigakis, Bartzanas and Kitta, 2012). This will increase the quality of the crops produced under this stable environment. The same applies to other structures like silos, livestock structures and machinery structures on the farm. It will prevent spread of diseases, erosion of farm implements as well as pollution of farm produce (DLEC, 2019).

CONCLUSION AND RECOMMENDATION

The establishment of farm structures on the farm is very vital for the farmers' economic virility and feasibility as regard agricultural production all through the farming season and beyond. It helps in building cohesive units for marketing, storage and processing of the farm produce harvested. The role of agricultural economics and extension service providers over the siting of these structures vary from giving practical advice, educating farmers, planning on how to establish these structures, monitoring and supervising how they can utilize these structures effectively for the development of their farming business. These service providers are also capable of giving hands on learning on how to operate and maintain the structures over a long period of time by using durable materials. They can also help in the provision of necessary farm supplies or services such as source of labor from other farmers within the farming settlements. Challenges encountered while using these structures can be effectively monitored and curbed by the relevant and current information received on the sustainability of these structures through the advice and training given by these service providers. It is therefore recommended that government should work hand in hand with these agricultural service providers in order for the latter to have a sustainable impact by ensuring the establishment of viable structures on farmers' farm. They can also help in linking farmers up to agricultural financially based institution so that they can have access to credits. They can also do well in advising the farmers on how to procure durable farm materials and structures that can boost the farmers' standard of living and farming conditions.

ABSTRACT

The study investigated the effect of climate change on catfish households' welfare in Ogun state. Data were collected with the aid of structured questionnaire to elicit information from 80 catfish farmers in the riverine communities of Odogbolu LGAs that were selected through a multistage random sampling technique. Data were analyzed using descriptive statistics and inferential statistics. The average age, education and fishing experience of the respondents were 43.5 years, 13.8 years and 12.6 years respectively. Perception of climate change attributes showed that 65%, 97.5%, 87.5% and 76.5% of the catfish farmers have observed increased temperature, rainfall, changes in timing of rains and stronger winds. Similarly, 85% of the fishers have experienced flooding in their farms. Ordinary Least Square result showed that education, experience, extension contacts, household size, experienced losses due to flooding and proportion of income loss due to flooding were the relevant and significantly determined catfish households' welfare. Policies attention should be provision of early warning signal through extension agents, improving adult literacy programme among the fishing communities to help mitigate the adverse effect of climate change.

Keyword: Climate change, Catfish farmer, Flooding, Households' welfare

INTRODUCTION

Climate change as defined by United Nation Framework Convention on Climate Change (UNFCC) refers to a change of climate that is attributed directly or indirectly to human activity that alters the composition of the global atmosphere and which is in addition to natural climate variability observed over comparable time periods. The growing evidence from the Intergovernmental Panel on Climate Change (IPCC, 2007; Mikhaylov et al. 2020) that climate will change as greenhouse gases accumulate has added urgency to the need to understand the consequences of global warming. Initial studies of climate change, using a variety of methods, identified Africa as one of the most vulnerable locations on the planet to climate change because it is already hot and dry, a large fraction of the economy is tied to agriculture, and the farming methods are relatively primitive (Mendelsohn and Williams 2004). Climate change creates uncertainty in the rainfall pattern (timing and amount) and affects agricultural activities. Over 60% of the Nigerian populace depends so much on agriculturally related activities for sustenance. Agba *et al*. (2017) opined that climatic fluctuation is putting Nigeria's agriculture system under serious threat and stress. This implies that rural sustenance and food security in Nigeria is under serious threat. Current environmental problems in the coastal area of the country are flooding which comes from the high rainfall, run off from rivers and urban chains and tidal movement and wind (Echendu, 2020). There is glaring evidence that climate change is not only happening but it is changing our lives.

As a result of flooding, some species of fishes have migrated to another location while some others died. This leads to low productivity and consequently reduced fish catch and low standard of living. The consequences of flood due to climate change such as loss of fish, change in fish species, erosion of human habitat, and land will have greater impact on the welfare and the livelihood of fishers most especially in terms of income realized from fishing activities.

MATERIALS AND METHODS

The study area was carried out in Ogun state, Nigeria. The state has a natural vegetation that is broadly of two types: the forest and the savannah vegetation which are almost evenly distributed throughout the zone. The climate in the state is characterized by a generally high but uniform temperature, a high relative humidity and a marked rainy season. The State is divided into four Agricultural Development Programme zones (namely the Egba, Ijebu, Remo and Yewa zones) by the Ogun State Agricultural Development Programme (OGADEP) Authorities. The state has 20 local government areas. A multistage sampling techniques was employed for the study. Ijebu Ode zone was purposively selected from the four zones of the Ogun State Agricultural Development Programme (OGADEP) this is because of large concentration of catfish farmers along the riverine communities of this zone. In stage two, Odogbolu local government area was purposively selected based on the records of catfish farmers obtained from the village extension officer covering the areas. In third stage, three riverine communities where catfish rearing activities was prevalent (Eriwe farm, Iwata and Ikangba) were purposively selected from the local government area. Finally, eighty catfish producers along the river banks of these communities were randomly selected in a proportionate sampling method. The study was conducted between June-November, 2021 after the floods that ravaged these communities in that year.

Primary data were collected from catfish producers through the aid of well-structured questionnaire. The questionnaire covered the socio-economic characteristics of the catfish famers, climatic variables, flooding experience etc Descriptive statistics that was employed for analysis include: frequency, percentages, mean, and standard deviation were used to analyze the socio- economic variables of the respondents, climate variables (rainfall, temperature, wind), flooding experience and proportion of loss income due to flooding) Also, Inferential statistics were used to estimate the relationship between the household welfare using an ordinary least square (OLS) regression estimation. The dependent variable used to capture household welfare is per capita expenditure. Expenditure on food and non-food items were aggregated for each household and divided by household size to obtain the per capita expenditure for each household. Per capita expenditure is used as proxy for per capita income and employed as a measure of welfare.

Model specification

$$Y = f(X_1, X_2, X_3, X_4, X_5, X_6, \dots\dots\dots\dots\dots..X_{11}) \ldots\ldots\ldots\ldots(1)$$

Y = Log of per capita expenditure (Total household expenditure/ household size), X_1 = Gender (1 =male, 0 = otherwise), X_2 =Age of fishers in years, X_3 = Education in years, X_4 = Household size, X_5= Fishing experience (years), X_6 = Dependency ratio (Non-working households / working households), X_7 = Membership of Association (1= belong to an association, 0 = otherwise), X_8 = Access to credit (1 = have access, 0 = otherwise), X_9 = Extension contact (Number of visit),X_{10} = Experience loss due to flooding (1=Yes, 0 = otherwise), X_{11} = Proportion of loss due to flooding (% of loss of income from fishing activities due to flooding).

RESULTS AND DISCUSSIONS

Table 1 presents the socioeconomic characteristics of catfish farmers in the study area. The result shows that the mean age of the catfish farmer was 43.5 years, this indicates that catfish production in the study area were dominated by those in their adulthood age. Hence, they would be able to withstand and manage the risk associated with adverse weather effect in production. The average fishing experience was 12.6 years. This implies that with the level of experience of the sampled farmers they are expected to have more knowledge and information about climate change and agronomic practices that they can use in response to climate change. The mean household size was 8 persons. This implies that other members of the household can provide labour in catfish production thus limiting their dependence on hired labour and saved cost.

Table 2: Socioeconomic characteristics of smallholder maize farmers (n=80)

Variable	Mean	SD
Age (years)	43.5	9.15
Fishing experience (years)	13.6	8.82
Household size(number)	8	1.23

Source: Field survey, 2018

Table 2 shows the climatic change experienced by catfish farmers in the study area. Result shows that 65% of the catfish farmers experienced increased temperature while 16.5% of the respondents said they experienced decreased temperature Almost all the respondents (97.5%) claimed to have experienced increased rainfall which cause serious flooding along the river banks during the year under review. Contrarily, none of the catfish farmers experienced decreased rainfall during the year under study. However, about 87.5 % of the fishers claimed to have experienced changes in the timing of rains. This, according to the fishers caught them unawares thus cannot be able to predict the time of rains with certainty. Also, 76.3% of the catfish farmers have experienced stronger winds that led to heavy storm that destroyed most of the barricades built to fenced the ponds as a coping mechanism against floods hence resulted to loss of catfish during the flooding period. Catfish farmers' flooding experience revealed that 85% of them experienced flooding during the year under study while 15% of the sampled respondents claimed not to have experienced flooding during same period. Proportion of loss during flooding indicates that 32.4% of the fishers lost 75% of their income during the period, 58.8% of those that experienced flooding during the period claimed to have lost 50% of their income and 11.8% of the catfish producers lost 25% of their income as a result of the flooding during the year under study. This lost is attributed to significant quantity of fish that was wiped away by the flooding that occurred between June-November, 2021 which corresponds to the peak period of raining season.

Table 2. Experience of catfish producers with Climate change characteristics (June-November, 2021)

Climate change experience	Frequency	Percentage
Increased temperature	52	65
Decreased temperature	45	56.5
Increased rainfall	78	97.5
Decreased rainfall	-	-
Change in timing of rains	70	87.5
High winds	61	76.3
Flooding experience		
Experienced loss	68	85
No loss was experience	12	15
Proportion of loss Due to flooding		
75 percent	22	32.4
50 percent	40	58.8
25 percent	8	11.8

Source: Field survey, 2021 Note: Multiple response

Table 3 presents the result of Ordinary least square estimate of the determinants of catfish farmers' household welfare. The co-efficient of determination (R^2) was 0.658. This implies that 65.8% variations in household welfare are explained by the explanatory variables included in the model. The adjusted R^2 (0.589) suggested that the model was not over-fitted. The F-statistics (8.582, $p<0.01$) indicates that the overall model is significant at 1% and Durbin Watson of 1.576 shows the absence of autocorrelation. Result show that the coefficient of education, fishing experience, extension contacts have a positive and significant relationship with households' welfare while the coefficient of household size, experienced loss due to flooding and proportion of income loss due to flooding have a negative and significant relationship with household welfare in the study area. Increase in the year of education and years of fishing experience by 1% will increase household welfare by 16.1% and 19.1% respectively. This implies that an educated catfish farmer possessed the ability to adopt new and improved technologies to mitigate the adverse effect of climate change and ability to better optimize on fish farming practices. Similarly, the accumulated years of experience may enable them to evolve the fishing practices that are most suitable to their environment which may impact positively on the household welfare. Also, receiving extension services has the positive impact on fishers' household welfare. Result further revealed that household size, experience loss due to flooding and proportion of loss due to flooding has negative coefficients and significant at 1% probability level respectively. This implies that increase in these variables will reduce household welfare by 3.2%, 15.6% and 42.1% respectively. By implication, this study shows that flooding affects the welfare of catfish farmers negatively. This result corroborated the findings Ajibade et al., (2015) and Udemezue et al., (2019) who in their respective studies reported that flooding resulted in significant economic losses to farmers.

Regression result of factors determining Catfish farmer's households' welfare

Variables	Co-efficient	Standard error	T-value

CONCLUSION AND RECOMMENDATIONS

The study revealed that catfish farmers in the study area have experienced adverse effect of climate change attributes of which the most prevalent is the flooding that resulted from increased rainfall that ravaged the communities in the year under study. About 85% of the catfish farmers experienced a loss in income as a result of flooding. Ordinary Least Square result showed that education, experience, extension contacts, household size, experience loss due to flooding and proportion of income loss due to flooding were the relevant and significant variables that determined catfish households' welfare. Policies focus should be the need for early warnings signal by Nigerian meteorological agency through the extension agents to fishing communities to enable them make informed decisions and allow them to better prepare for adverse weather conditions, improvement of adult literacy programme as this will increase fishers' knowledge and help them appreciate the benefits of adapting to climate change.

ABSTRACT

The study examined the influence of cooperative credit use on arable crops production in Yewa Division of Ogun State, Nigeria. Primary data were collected through a multistage process from 79 (38 cooperative and 41 non-cooperative) arable crop farmers in the study area. Data were analysed using descriptive and Logit regression. The findings revealed that cooperative credit is considered as the basic ingredient for each and every economic activity including agriculture. Results of the analysis showed that the probability of accessibility to credit and farm productivity was highest for farm size (0.795) and least for farm input (-0.826) implying that increasing farm size to access credit was the most desirable. Also, in the same category is the co-efficient of variable regular payment of monthly dues (X_1) which is significant at 1% level. This has a direct bearing on policy formulation that farm size and regular payment of monthly cooperative dues are required as criteria for accessibility of cooperative credit. The study concludes that credit acquisition by the farmers is mainly determined by gender, farm income, farm inputs and experience. The study recommends policy formulation that improves allocation of more farmland for arable farming and encouragement of gender equality in arable crop production.

Key words: *Arable crop production, agricultural credit*

INTRODUCTION

Credit accessibility is a crucial factor in the development of the agricultural sector. Agricultural producers rely on credit facilities to raise the capital required to initiate and sustain production activities. The role of credit in agricultural production is crucial because inputs such as seeds and fertilisers are purchased at the beginning of the production season, but returns are realised only at the end of the season (Masuku, 2009). Credit availability to agriculture is particularly justified when farmers have very low savings capacity, poorly developed rural financial markets and availability of appropriate farm technologies whose adoption is constrained by shortage of funds. These conditions hold in Nigerian agriculture.

Muhammad, Munir, Kalbe (2003) opined that agricultural growth depends on increased use of agricultural inputs, technological change and technical efficiency. The optimal use of inputs requires funds at the disposal of farmers. In less developed countries like Nigeria where savings are negligible especially among the smallholder farmers, agricultural credit becomes an essential input along with modern technology for higher productivity.
In this realisation, Nigerian governments, supported by multi- lateral and bi-lateral aid agencies, have devoted considerable financial resources to supplying cheap credit facilities to the farmers and other rural entrepreneurs in a myriad of institutional settings (Nwaru, 2004). Unfortunately, these rural credit structures have not been able to achieve the desired aim of effectively and efficiently facilitating the inflow of financial services into the rural economy to enable rural entrepreneurs, including the farmers to employ efficient production techniques designed to raise their physical output and incomes (Nwaru, 2004).

PROBLEM STATEMENT

The population expansion together with a poor distribution of food is among the world's greatest problem today. In Nigeria, production of food has not increased at a rate that can meet the increasing population. In developed countries, growth of population in relation to farm output is rather stable but in a developing country like Nigeria, there is no compensation for population increase by the total farm output. The arable crop production is not playing the role of effectively supplementing the food content in the average consumer's diet in Nigeria. These problems centre on inadequate finance which leads to low production and many still use traditional method of crop production. Other problems include high cost of input, diseases and marketing problems. This situation has forced many small scale farmers to close down and those still managing to survive are producing at very low with serious inputs' limitations. Capital is needed to modernize agriculture because new technologies have to be purchased before they can be used on the farms. In spite of the serious need for capital, the amount of it available to most farmers is a quantum compared to the alternative uses for the capital. Inadequate capital stems from small – scale of operations of most farmers as a result of which they have little surplus to generate income. This study thus sets to examine the determinants of agricultural credit on arable crops production.

METHODOLOGY

The Study Area

The study was carried out in Yewa division of Ogun State, Nigeria. Yewa division has five Local Government Areas. The division is bounded to the West by the Republic of Benin with which it shares a long stretch of international boundary. It is bounded in the East by Oyo State, Abeokuta-North, Ifo Local Government Areas and in the South by Lagos State. The climatic condition and physical environment have been generally supportive to farming as reflected in the variety and quantity of cash and arable crops grown in the area.

Sampling Technique

The data for the study were essentially from primary source with the use of structured questionnaire in a multistage process. In the first stage, two (2) Local Government Areas were chosen randomly out of the five Local Government Areas in the Yewa Division. The second stage involved the selection of five (5) towns from the two Local Government Areas selected. The third stage involved the selection of five (5) cooperative and six (6) non-cooperative arable crop producers from each of the town selected in stage two, but data from 79 respondents (38 cooperative and 41 non-cooperative arable crop producers) were used for the study.

Methods of Data Analysis

The data collected were subjected to descriptive analysis and Logit.

Descriptive Statistics

The socioeconomic features of the arable crop farmers were statistically described using mean, frequency distribution, and percentage.

Logit Regression Model

For the logit model, it is assumed that an individual is faced with two alternatives, arable crop farmers acquire credit from the Cooperative Credit Societies or not. Therefore, logit model was employed to determine the characteristics that influence the probability that enables arable crop farmers to acquire credit. The logit regression model is characterized by binary dependent variables with mutually exclusive outcomes. The dependent variable is the credit status of the respondents which is one (1) if he/she obtain credit and zero (0) if otherwise. Since the dependent variable is ordinal in nature, a variant of the ordered probit, and an ordinal logit model (Zavoina and McElvey, 1975), was used to analyse the dichotomous access to credit.

For the ordinal logit model we let,

$$Y_i^* = \beta^! x_i + \varepsilon_i \qquad (1)$$

Where Y_i^* is the underlying latent variable that indexes the credit access that arable crop farmer experience, x_i is a vector of explanatory variables, β is a column vector of parameters to be estimated and ε_i is the stochastic error term. The probability for each observed ordinal response, which in this case are only of two categories (1,0) for credit access, no credit access is given as;

$$P(Y=1) = P(Y^* \leq 1) = P(\beta' x_i + \varepsilon_i \leq 1) = F(-\beta' x_i)$$

$$P(Y=0) = F(\delta_0 - \beta' x) - F(-\beta' x) \qquad (2)$$

$$Y_i = \alpha + \beta_{i1}X_1 \ldots\ldots\ldots\ldots\ldots\ldots + \beta_{i1}X_{18} + \varepsilon_i \qquad (3)$$

Where:

Y_i = (= 1 if the arable crop farmer is a credit beneficiary, 0 = non beneficiary)

The explanatory variables are:

X_{1i} = Regular payment of monthly dues (Yes = 1, No = 0)
X_{2i} = Age of the household heads (years.)
X_{3i} = Gender (Male =1, Female = 0)
X_{4i} = Credit experience (years)
X_{5i} = Loan default (%)
X_{6i} = Interest rate (%)
X_{7i} = Number of loan applicants received (number)
X_{8i} = Income (₦)
X_{9i} = Farming experience (years)
X_{10i} = Farm size (hectares)
X_{11i} = Household size (number)
X_{12i} = Educational attainment of the household head years spent in formal school
X_{13} = Labour cost (₦)
X_{14i} = Farm input (₦)

RESULTS AND DISCUSSION

Socio – Economic Characteristics of Arable Crop Farmers

The summary of the socio-economic characteristics of arable crop farmers is presented in Table 1. The variables discussed include age, farm size, farm experience among others. Majority (31.5%) of cooperative arable crop farmers had farming income within ₦300.001 – ₦400,000 compare to their non-cooperative counterpart that majority (58.6%) had farming income within ₦100.001 – ₦200,000. This implies that cooperative farmers had higher income due to credit availability to their farm production compare to their non-cooperative counterparts that had lower income. Majority (39.6%) of the cooperative farmers has farm experience within 31 – 40 years while majority (36.8%) of the non-cooperative farmers had farming experience of less than equal 20 years, it corroborated with the findings of (Olarinde *et al* 2004) who stated that farming, like any other business, also require experience and management skill, which are associated with age.

Table 1: Distribution of socioeconomic of Arable Crop Farmers

Variables	Cooperative Credit Beneficiaries		Non – Cooperative Credit Beneficiaries		Pooled Data	
Age Group (Years)	Frequency	Percentage	Frequency	Percentage	Frequency	Percentage

Determinant of Cooperative Credit Acquisition among Arable Crop Farmers

The Logit regression model was used to determine the factor enhance arable credit accessibility. The findings shows that six (6) variables among fourteen (14) regressed have significant influence on the arable crop farmers access to credit. The chi - square (σ^2) value was 73.760, with a p – value of less than 0.01 and log likelihood function – 98.038. Hence, sigma square was statistically significant, thus indicating that the model displays a good fit. The variables that had significant co-efficient are regular payment of monthly dues (X_1), gender (X_3), income (X_8), experience (X_9) and farm input (X_{14}). It should be noted that a positive sign on a parameter indicated that higher values of the variables tend to increase the likelihood of credit accessibility and impact on agricultural productivity. Similarly, a negative value of a co-efficient implied that higher values of the variables would reduce the probability of credit accessibility and impact on the farm productivity.

The probability of accessibility to credit and farm productivity was highest for farm size (0.795) and least for farm input (-0.826) implying that increasing farm size to access credit was the most desirable. Also, in the same category is the co-efficient of variable regular payment of monthly dues (X_1) which is significant at 1% level. This had a direct bearing on policy formulation that farm size and regular payment of monthly cooperative dues are required as criteria for accessibility of cooperative credit. Hence, payment of dues should attract topmost importance on the priority list of cooperative members.

Table 2: Logit Model Explaining the Determinants of Cooperative Credit Acquisition of Arable Crop Farmers

CONCLUSION AND RECOMMENDATION

The mean age of the respondents was about 45 years and 40 years respectively. This implies both farmers are in their active and productive age, this result also revealed that Cooperative credit beneficiaries farmers are in their active age and can perform better. The probability of accessibility to credit and farm productivity was highest for farm size (0.795) and least for farm input (-0.826) implying that increasing farm size to access credit was the most desirable. In addition the study indicated that the credit acquired by the respondents had significant effects on their output and income. The study concludes that credit acquisition by the farmers had a significant effect on the producitivity of arable crop. Recommend that the farmers should be adequately motivated with needed credit facilities so as to enhance their agricultural production.

ABSTRACT

This study investigated the impact of extension agents training programme on farmers productivity in Delta North and South agricultural zone, Delta State, Nigeria. It described the socio-economic characteristics of the farmers trained extension agents in Delta State, determined the level of productivity of the extension agents trained farmers, determined the level of satisfaction of training received by the farmers and ascertain the derived benefits obtained from the training received. A sample size of 111 was used for the study and it was obtained through multi-stage sampling technique. Descriptive statistics and inferential statistics was respectively used to analyze the objectives and hypothesis of the study. Results revealed that respondents mean age, household size, farm size, farm experience and farm income was 45.27 years, 6 persons, 2.75 ha. 10.26 years and ₦328,378.38 respectively. Majority (87.39%) of the respondents were satisfied with the extension agents training programme due to benefits obtained from the training programme. Based on results women should be encouraged to participate in training programmes since they are known as stake holders in where farming is concerned.

Keywords: *Training, farmers, extension agents, benefits, programme, satisfaction.*

INTRODUCTION

Farming activities carried out by farmers require so much of training especially if good and sustainable results on productivity on farmers level of output are expected Onuka (2012). Training helps to guide against accidents and wastage of farm resources. Buttressing further, Salihu (2011) stated that level of training is directly in line with level of productivity. Against this background, Salihu (2011) advocated the need for steady manpower training as it helps as an instrument for effective achievement of organizational objectives and goals that is likely to result to greater farm productivity and consequently income. Farmers training is carried out by the extension agents functioning in agricultural institutions (Erie, 2009). Erie (2009) opined that the basic reason why extension agents train farmers is to equip them with the skill and procedures that would help improve farming methods techniques and as well increase production efficiency, income and better standard of living. This study therefore examines the impact of training received by farmers on their farm productivity.

Specifically, the study describes the socio-economic characteristics of the farmers trained by the extension agents in Delta State, determine the level of productivity of the extension agents trained farmers in the area, determine level of satisfaction of training received by the farmers and ascertain the derived benefits obtained from the training received by the farmers in the Delta State.

Hypothesis of the Study: There is no significant difference between the proportion of farmers satisfied and those not satisfied from the training received from the extension agents.

MATERIALS AND METHODS

The study was carried out in Delta State. Delta State is made up of three agricultural zone (Delta North, Delta South and Delta Central, with 25 local government areas (LGAs) and the capital is Asaba. It is made up of a population size of 5,475,139 (NPC, 2016). It is also known to have many towns like Asaba, Sapele, Agbor, Ughelli, and Warri which is known as the economic nerve centre of the state (NAEC, 2008). Delta State has a size of 17,698Km^2 and so ranks 23rd amongst other states in the country (Delta State, Wikipedia). The people engage in different occupation like farming, oil prospecting, and civil service among others.

The study was carried out in Delta State and it adopted a multi-stage sampling technique. Stage 1 started with a random selection of Delta North and Delta South agricultural zones. This is followed by the random selection of 2 LGAs per agricultural zone, thus making them 4 LGAs that were used for the study. Three (3) communities / towns were then randomly selected per LGA, thereby resulting the communities / towns to 12. The final stage involved a random selection of 10 farmers out of about 15 of them being trained by the extension agents per community / town, thus making the total number of farmers contacted for the study to 120. The researcher ensured that the selected farmers are those served by the extension agent of the area. They were served with the question instrument and from those returned, one hundred and eleven (111) (92.5%) which were suitable for analysis were selected and used for the study.

Descriptive statistics involved the use of frequency tables, percentages and means and they were used to analyze the objectives of the study. On the other hand, inferential statistics (Binomial test) was used to analyze the study's hypothesis. A four-point Likert scale was used to analyze the derived benefits from training by farmers The scale ranges from, Strongly Agree: (coded 4), Agree: (coded 3), Disagree: (coded 2) and Strongly Disagree: (coded 1). The weighted mean score of 2.50 (obtained as: 4 + 3 + 2 + 1) / 4 = 2.50) and above was agreed as derived benefits by the farmers from training received.

Binomial test was used to determine if there was any significant difference between the proportion of farmers that were satisfied and those not satisfied with the training received from the extension agents training programme. The formula for binomial distribution is given as follows:

$b(x;n,p) = nCx*px*(1-p)\ n-x$

Where b = binomial probability; x = total number of successes (satisfied or not satisfied); p = probability of success on an individual trial; n = number of trials

Decision rule: In making a decision, the possible values of the test statistics are divided into two ranges. The critical region of the sample distribution is the area or areas of the sampling distribution of a statistics that will lead to the rejection of the hypothesis tested when that hypothesis is true (Okwuokenye, 2020).

RESULTS AND DISCUSSION

Socio-economic characteristics of respondents

The socio-economic characteristics of the respondents is shown in Table 1. It revealed that most (64.86%) of the extension agents trained farmers were males while females constituted the minority (35.14%). The result suggest a poor response of females participation in public groups. This result is in line with that of Mgbada (2006) who reported low women participation in social groups. The mean age of the respondents was 45.27 years with most (36.94%) of them between the age bracket of 40 – 49 years, thus indicating that they are young and active. The average household size of the respondents was 6 persons with the modal (56.76%) having between 4 – 6 persons in their households. This indicates that they have people who depend on them for survival. Similarly, marital status showed that majority (73.87%) of the farmers were married, indicating that they are responsible. Similar results on low women participation in training groups, similar household size range (4 – 6 persons) and marital status was reported by Okwuokenye and Akintoye (2016).

The respondents educational level showed that most (66.67%) of them schooled up to secondary educational level. This implies that they are literate. The average farm income of the respondents was ₦328,378.38 and most (31.53%) of them earned between ₦300,001 – ₦400,000. The amount earned from farming is an indication that training has impacted positively on the farmers productivity and income. The results on farmers education and impact of training on productivity agree with findings of Okwuokenye and Urhibo (2019) which indicated that farmers who participate in groups are mostly literate and that such participation in training do well in helping to boost farmers output and income. Respondents average farm size was reported to be 2.75 ha. and most (61.26%) of their farm size was between the range of 2.1 – 4.0 ha. This indicates that they are small-scale farmers. Respondents farm experience revealed that the average was 10.06 years with most (40.54%) of them having between 10 – 14 years experience in farming, thus indicating that the respondents are experienced in farming operations. Results of Ovharhe (2014) revealed similar farm size and experience of farmers in Delta State.

Table 1: Socio-economic characteristics of respondents. n = 111

Characteristics	Categories	Frequency	Percentage	Mean
Sex	Male	72	64.86

Level of productivity of the farmers trained by the extension agents

Table 2 shows the respondents level of farm productivity. The result revealed that most (58.56%) of the respondents had high level of farm productivity, while very few (5.41%) of them had low level of farm productivity. On a larger consideration, about 94.59% of the farmers had productivity level that was of average and above in consideration. Okwuokenye and Urhibo (2019) share similar considerations in terms of impact of training on farmers productivity and income.

Table 2: Level of productivity of the farmers from extension agents training programmes (n = 111)

Level of Productivity	Frequency	Percentage
- Very High	16	14.41
- High	65	58.56
- Average	24	21.62
- Low	6	5.41

Effect of training of farmers on improved farm technologies by Extension Agents

The effects of training of farmers on improved farm technologies revealed that the average mean income earned by the farmers before and after receiving training was ₦247,297.30 and ₦328,378.38 respectively. The difference was ₦81,081.08 and in favour of the farmers after receiving training from the extension agents (see Table 3). This implies that training of farmers have positive impact on their productivity and farm income of the farmers and this was corroborated by the findings of Okwuokenye and Urhibo (2019).

Table 3: Effect of training of farmers on improved farm technologies by Extension Agents

	Income of farmers before training			Income of farmers after training		
Farm income (₦)	**Freq.**	**%**	**Mean**	**Freq.**	**%**	**Mean**
< 100,000	15	13.51		-	-	
100,001 – 200,000	21	18.92		21	19.92	
200,001 – 300,000	39	35.14		27	24.32	

300,001 – 400,000	26	23.42		35	31.53	
400,001 – 500,000	8	7.21		15	13.51	
500,001 – 600,000	2	1.80		9	8.11	
> 600,000	-	-	247,297.30	4	3.60	328,378.38

Difference in income before and after training = ₦328,378.38 - ₦247,297.30 = ₦81,081.08
Source: Field survey, 2021

Level of satisfaction derived by farmers from extension agents training programmes

Farmers' level of satisfaction from participating in extension agents training programmes is shown in Table 4. It revealed that most (49.55%) of the farmers are just satisfied with extension agents training programmes. On a broader classification, a large fraction (88.29%) of the farmers had a reasonable level of satisfaction, while only a small fraction (11.71%) had a satisfaction level that was below average. The result generally implies that the level of farmers' satisfaction with extension agents training was high and encouraging. The result agrees with reports of Okwuokenye and Urhibo (2019) which stated that majority of extension agents operating in Delta State are performing above average.

Table 4: Level of satisfaction derived by farmers from extension agents training programmes (n = 111)

Level of Satisfaction	Frequency	Percentage
- Very High	19	17.12
- Just High	55	49.55
- Averagely High	24	21.62
- Fairly High	8	7.21
- Not High	5	4.50

Agricultural services carried out by Extension agents on farmers

Table 5 shows the various agricultural services rendered to the farmers by the extension agents and this was measured by a weighted mean index of 2.50. Transportation / distribution of farm products services, Marketing services and Crop production services were the first three agricultural services agreed by the farmers been rendered to them respectively had means of 3.60, 3.58 and 3.42. The fourth, fifth, sixth and seventh ranking services offered to the farmers by the extension agents were advisory services (mean = 3.14), farm management services (mean = 3.05), financial services (mean = 2.89) and land preparation (mean = 2.51). The aforementioned services are in line with the findings of Anyoha *et al*. (2018) that revealed services like transportation, marketing, crop production, advisory, farm management, financial and land preparation as major services carried out by the extension agents in where farming is concerned.

Table 5: Agricultural services rendered to farmers by extension agents. n = 111

Agricultural services	Mean	Standard Dev.	Ranking
- **Financial services**	2.89	0.73	6th
- **Advisory services**	3.14	0.67	4th
- **Land preparation services**	2.51	0.89	7th
- **Crop production services**	3.42	0.57	3rd
- **Farm management services**	3.05	0.63	5th
- **Marketing services**	3.58	0.55	2nd
- **Transportation / distribution of farm products services**	3.60	0.50	1st

**Regular (mean ≥ 2.5), Source: Field survey, 2021*

Derived benefits by farmers from participating in extension agents training programmes

The benefits derived by farmers from participating in extension agents training programmes are shown in Table 6. Training of farmers on input use (mean = 3.68), advisory role of extension agents (mean = 3.43) and demonstrating on input use (mean = 3.16) respectively ranked 1st, 5th and 10th benefits derived by farmers from participating in extension agents training programmes. These findings are in line with the results of Okwuokenye and Urhibo (2019) which identified these aforementioned functions as regular roles of extension agents in groups. Information on crop protection (mean = 3.52) and access to financial services (mean = 3.36) respectively ranked 4th and 6th benefits derived by the farmers. Anyoha *et al.* (2018) confirmed these functions amongst others as those impacted on farmers by extension agents through the use of Information Communication Technologies (ICTs). In addition, access to farm input (mean = 3.60) ranked 3rd and production of services that can improve produce (mean = 3.27) ranked 8th of the derived benefits from their participation in extension training programme. Other perceived benefits were increased yield of produce (mean = 3.65), ability to control pest and diseases (mean = 3.36), increased farm income therefore enhanced farmers welfare (mean = 3.21) and improvement of quality of produce (mean = 3.08). These later factors ranked 2nd, 6th, 9th and 11th most derived benefits respondents get from training received from extension agents training programmes. These results are in consonance with findings of Madukwe (2005) who opined that training of farmers helps to improve on their farm production and income.

Table 6: Perceived benefits derived by farmers from participating in extension agents training programmes

Perceived benefits derived from extension agents training	Mean	Standard Dev.	Ranking
- Training of farmers on farming activities	3.68*	0.73	1st
- Increase in yield of produce	3.65*	0.75	2nd
- Provision / access to farm inputs	3.60*	0.78	3rd
- Information on crop protection	3.52*	0.81	4th
- Advisory role of extension agents to farmers	3.43*	0.81	5th
- Access to financial services	3.36*	0.85	6th
- Ability to control pest and diseases	3.36*	0.83	6th
- Production of services that can improve produce	3.27*	0.76	8th
- Demonstrating on input use	3.16*	0.79	10th
- Improvement in quality of produce	3.08*	0.86	11th
- Help farmers avoid harvest losses	2.41	0.88	12th

Test of difference of farmers that are satisfied and those not satisfied with extension agents training programme

The test of significant relationship between farmers that are satisfied and those that are not satisfied with extension agents training programmes was carried out with the use of Binomial test and this is shown in Table 7. The result revealed that a larger proportion (87.39%) of the farmers was noted to be satisfied with the extension agents training programmes. On a statistical consideration, the result was significant at the 1% level of probability and for this reason, the alternative hypothesis was accepted and it states that: there is a significant difference between farmers that are satisfied and those that are not satisfied with the extension agents training programme. It therefore implies that the extension agents have performed creditably and such is evident in their level of productivity. This result is in conformity with that of Okwuokenye and Okoedo-Okojie (2014) which indicated that the extension agents serving in the Delta State are meeting up with their assigned task and thus helping to boost farmers output and income.

Table 7: Test of difference in CBO farmers satisfaction with extension agents farming programme

Satisfaction Status	Frequency	Percentage	Prob. Level
Satisfied	97	0.8739	0.001
Less satisfied	14	0.1261	
Total	111	1.0000	

Source: Field survey, 2021

CONCLUSION

From findings, it was concluded that most of the farmers who participate in extension agents training are males who are married, strong and active. They are also small-scale farmers who are literate and experienced in farming. Most of the farmers were satisfied with the extension agents training programmes carried out on them and this is evident in the benefits derived from their participation in the training programmes.

RECOMMENDATIONS

Based on findings, the study recommends that: women should be encouraged to participate in training programmes since these women are known as stake holders in where farming is concerned. This has become necessary since they were observed to have low participation in extension agents training programmes.

ABSTRACT

The study focused on the socio-economic determinants of adoption of agricultural extension strategies by farmers in Umuahia South LGA of Abia State. The specific objectives were to describe the socio-economic characteristics of the respondents, identify agricultural extension strategies extended and determine the effect of socio-economic characteristics of the farmers on adoption of Agricultural extension strategies. Multistage random sampling technique was employed. Data were collected from 120 respondents using a structured questionnaire. Data obtained were analyzed using descriptive and inferential statistics. The result shows that the likelihood ratio test has a significant value of -37.26 implying that the estimated model is statistically significant. Hence the model is considered to be good fit. R^2 implies that about 65% of the adoption by the respondents were due to the variables included in the model. This implied that the model consists of most of the determinants for Farmers Adoption of Agricultural Extension Strategies for Poverty Alleviation in the study area. The study recommends that emphasis should be made on education so as to equip the people with the necessary information they need to move out of poverty, farmers should be encouraged to form association so as to enable them easily obtain loans and credit facilities, as well as pool resources together, participatory extension service should be practiced which enable farmers to determine and accept change, when farmers determine changes, they agree to it and actively partake in it. The changes should be such geared towards improving their livelihood, and income.

Keywords: Socio-economic, extension strategies, determinants, adoption, Farmers.

INTRODUCTION

Agriculture is an important sector in the economic development and poverty alleviation drive of many countries. The importance of this sector is more pronounced in developing countries including Nigeria, where it is the main thrust of national survival, employment, food and foreign exchange (Adebayo and Okuneye, 2020). With the globalization of agriculture, major emphasis is laid on increasing productivity. Major emphasis has been given on production-led extension in the past (FAO,2010). Farmers have received most of the production technologies from the extension system. The extension system needs to be oriented with the knowledge and skills related to the market. This revamping of extension system will certainly play a catalytic role for ushering in farmer-led and market–led extension (Nwaneri, 2018) which can alleviate poverty. Birner (2006) highlighted the importance of institutional reconstructing and renewal, and decentralized extension structure. Recently, many developing countries have reaffirmed the essential role that agricultural extension can play in agricultural development as pointed out by Birner (2006) and Anderson (2007). In Nigeria, the incidence of poverty has been high and upward swinging since 1980. The rising profile of poverty in Nigeria is assuming a worrisome dimension as empirical studies have shown. Nigeria, a sub-Saharan African country, has at least half of its population living in abject poverty (Onoh and Peter-Onoh, 2012). Similarly, the publication of the Federal Office of Statistics (FOS, 1996) reveals that poverty has become massive, pervasive and engulfs a large portion of the Nigerian society. Nwaneri et al., (2021) states that the scourge of poverty in Nigeria is an incontrovertible fact, which results in hunger, ignorance, malnutrition, disease, unemployment, poor access to credit facilities and low life expectancy as well as a general level of human hopelessness. He asserts that Nigeria presents a paradox. The country is rich, but the people are poor. Onoh and Peter-Onoh (2012) perspicaciously remarked that Nigeria has witnessed a monumental increase in the level of poverty. According to them, the poverty level stood at 74.2% in the year 2000. It is indeed sad that twenty years after, poverty has been on the increase among its populace.

MATERIALS AND METHODS

Study Area Description

The study was conducted in Umuahia South Local Government Area of Abia State, Nigeria. The headquarters is at Apumiri-Ubakala. It has an area of 140km^2 and a population of 138, 570 people (NPC, 2006). Umuahia South L.G.A lies within Latitudes 5^0 31' and 9^0 68'' North of the Equator and Longitudes 7^0 29' and 10^0 60'' East of the Greenwich meridian (Wikipedia, 2017) and elevation of 55 meters above sea level. The climate is tropical and humid all year round. Annual rainfall ranges from 2000mm to 2500mm while the temperature ranges from 22^0C and 31^0C. It has 23 autonomous communities and 36 villages. The major occupation of the people is farming. Multistage random sampling technique was employed in the selection of respondents for the study. Firstly:3 communities were randomly selected from the 23 Autonomous Communities in the L.G.A. Secondly:4 villages were randomly selected from each of the selected communities, making a total of 12 villages. Stage three: 10 farmers were randomly selected from each of the selected villages giving a total of 120 respondents as sample size. A semi-structured questionnaire was used in soliciting information from the respondents. Objectives i and ii were analyzed using descriptive statistics such as percentages and frequency counts presented in tabular forms while objective iii was achieved using logit regression analysis. The explicit form of the model is represented thus;

$Y = {}_{g0} + {}_{g1}X_1 + {}_{g2}X_2 + {}_{g3}X_3 + {}_{g4}X_4 + {}_{g5}X_5 + {}_{g6}X_6 + {}_{g7}X_7 + ut$

Where;

Y = Adoption of the technologies (Adopted = 1, not adopted = 0)

X_1 = Age of respondent (years as supplied by the respondents)

X_2 = Gender of Respondent (dummy; male 1, female 0)

X_3 = Income level of respondents (# measured in Naira)

X_4 = Household size of respondents (number of people living together in a house)

X_5 = Farm size of respondents (Ha)

X_6 = Educational qualification of respondents (years measured in years of formal schooling)

X_7 = Marital status (dummy, variable; married 1, otherwise 0)

g_1–g_7 = Estimated parameters

g_0 = autonomous level of production known as the constant.

RESULTS AND DISCUSSION

Table 1 shows the socio-economic characteristics of Respondents. The result indicates that majority (67.50%) of the farmers were males. The dominance of male farmers is probably because the males own most of the farm assets including farm lands and therefore had an edge over the females. This is in line with Nwaneri (2018), who opined that training services should primarily be directed towards men because they are more likely to adopt technologies faster than the females. The table further shows that farmers within the age bracket ranged between 20-39 years were in majority (42.5%). This implies that most of the respondents were married. Age is vital in Agricultural production especially labour which is intensive and could be better accomplished by able bodied and energetic individuals, (Nwaneri et al.,2021). Majority (96.66%) of the respondents were educated attaining various levels of education. This implies that the respondents had one qualification or the other ranging from WAEC to BSC. The level of education attained by a farmer not only increases his farm activity, but also enhances his ability to understand and evaluate new production technologies (Nwaneri, 2018). The table further revealed that majority (40.83%) of the farmers had household sizes between 4-6. The implication of this revelation is that large household sizes is an advantage to farmers in terms of labour supply. Large household size has shown to provide cheap labour, especially where labour wages are costly. It is therefore expected that the family embarks on technologies that will increase their farm output. A fair proportion (47.50%) of respondents were married with farm sizes between 2-3 hectares, this is a clear indication that the farmers are small scale farmers (Nwaneri,2018).

Table 1: Characteristics of Respondents in Umuahia South L.G.A, Abia State (N= 120)

Characteristics	**Frequency**	**Percentage**
Gender		
Males	81	67.50
Females	39	32.50
Age (years)		
20 – 39	51	42.50
40 - 59	42	35.00
60 – Above	27	22.50
Marital Status		
Single	45	37.50
Married	57	47.50
Widow	11	9.17
Widower	7	5.83
Level of Education		
No formal education	4	3.33
Primary school	31	25.83
Secondary school	36	30.00
Tertiary school	49	40.83
Household size		
1 – 3	47	39.17
4 – 6	49	40.83

7 - 9	22	18.33
10 – Above	2	1.67
Farm size (Ha)		
0.1-1	40	33.33
2-3	56	46.67
4-5	15	12.50
6 - Above	9	7.50
Total	**120**	**100**

Source: *Field Survey data,2021*

The distribution of respondents according to Agricultural extension strategies extended to them is shown in Table 2. The table revealed an overwhelming (100%) indication of the extension strategies like; agricultural capacity building, participatory extension, focus on high value enterprises, formation of farmers' association, formation of self-help groups, farmer to farmer extension and community empowerment were the strategies extended to respondents in the study area. While T & V based extension strategy and workshop and seminars had fairly good proportion (77.50% and 81.67% respectively) indication as being available in the area. It is one thing for an innovation to be available and a different thing for the technology to be utilized (Nwaneri., *et al* 2019; Nwachukwu and Onuegbu, 2005).

Table 2:Distribution of Respondents According to Agricultural Extension Strategies Extended in Umuahia South LGA.

Packages Extended	*Frequency	Percentage
Agricultural Extension Capacity Building	120	100.0
T & V Based Extension Strategy	98	77.50
Workshop and Seminar	93	81.67
Participatory Extension Strategy	120	100.0
Focus on High Value Enterprises	120	100.0
Formation of Farmers Association	120	100.0
Formation of Self-help Groups	120	100.0
Farmer to Farmer Extension	120	100.0
Community empowerment	120	100.0

Source: *Field Survey Data,2021*
*Multiple responses recorded

The result on the table 3 shows that the likelihood ratio test has a significant value of -37.26 implying that the estimated model is statistically significant. Hence the model is considered to be good fit. R^2 implies that about 65% of the adoption by the respondents were due to the variables included in the model. This implied that the model consists of most of the determinants for Farmers Adoption of Agricultural Extension Strategies for Poverty Alleviation in the study area. Therefore, among the variables tested, coefficient of age of the farmers was negative and statistically significant at 1% level of probability, which implies that as the age of the farmers' increases, the rate at which they adopt the strategies decreases. This does not align with the researcher's *a priori* expectation since increase in age may decrease the farmers' agility, zeal or interest in farming and as well lead to decrease in adoption of extension technology packages. This does not submit to the findings of Nwaneri *et al* (2019) which reported that older farmers are risk averse and so may not adopt improved technologies. However, the coefficient of gender was positive and statistically significant at 5% level of probability. This implies that as more male farmers involve in the programme, the adoption of the strategies increase. This may be because the male farmers have more resources such as land to practice the newly introduced innovation than the females. This connotes that gender of farmers influences the adoption of extension technology packages among rural farmers in the area. This does not align with the *a priori* expectation given that both males and females have equal opportunities to adopt extension technology packages if they have the capacity to do so. This corroborates the report of Nwaneri (2018) who opined that both males and females have equal adoption to improved technologies. On the contrary, the coefficient of annual income was negative and statistically significant at 1% level of probability, this implies that as the income of the farmers' increases, the farmers' adoption of the strategies decreases. This could be because the more income a farmer has determine his or her tendency to engage in the other businesses than the agricultural activities.However, the coefficient of education was positive and statistically significant at 10% level of probability implying that the educated farmers had greater participation in agriculture in the study area. The innuendo is that any increase in quality of education acquired by the farmers will directly lead to increase in the farmers' adoption of extension technology packages and vice versa. This succumbs to the *a priori* expectation of the researcher who noted that access to quality education is an expository value which places farmers to quickly understand the usefulness of an extension technology and as such enhance adoption. This sees eye to eye with the finding of Nwachukwu and Onuegbu (2005) who argued that increase in access to quality education increases farmers' adoption of improved technologies in the area. Similarly, the coefficient of the marital status was positive and statistically significant at 1% level of probability. This implies that as the farmer gets married, so adoption of strategies to alleviate poverty increases. This is in agreement with the findings of Onoh and Peter-Onoh (2012) who disclosed that married people have higher family responsibilities to meet and so are under much pressure to adopt improved technologies to improve yield for better family enhancement.

Determinants of Farmers Adoption of Agricultural Extension Strategies for Poverty Alleviation in Umuahia South LGA of Abia State, Nigeria.

CONCLUSION AND RECOMMENDATION

The study analyzed the socio-economic determinants of adoption of agricultural extension strategies by farmers in Umuahia South LGA of Abia State, Nigeria. The result on socio-economic characteristics indicates that majority (67.50%) of the farmers were males while their age bracket ranged between 20-39 years. This implies that most of the respondents were married. Majority (96.66%) of the respondents were educated attaining various levels of education. This implies that the respondents had one qualification or the other ranging from WAEC to BSC. The result further revealed that majority (40.83%) of the farmers had household sizes between 4-6. The implication of this revelation is that large household sizes is an advantage to farmers in terms of labour supply. A fair proportion (47.50%) of respondents were married with farm sizes between 2-3 hectares, this is a clear indication that the farmers are small scale farmers (Nwaneri,2018). It was observed that socio-economic characteristics of the farmers actually influenced their adoption of Agricultural extension strategies. There is a greater chance that people, will participate in extension activities and high income ventures if they are empowered. Based on the findings of this study the following recommendations were made: Emphasis should be made on education so as to equip the people with the necessary information they need to move out of poverty, farmers should be encouraged to form association so as to enable them easily obtain loans and credit facilities, as well as pool resources together, participatory extension service should be practiced which enable farmers to determine and accept change, when farmers determine changes, they agree to it and actively partake in it. The changes should be such geared towards improving their livelihood, and income.

ABSTRACT

The study evaluated selected socio-economic factors affecting homestead garden egg production in Ezza North Local Government Area of Ebonyi State, Nigeria. The specific objectives were to describe the socio-economic characteristics of the respondents and evaluate the socio-economic factors affecting homestead garden egg production by the farmers in the study area. A structured questionnaire was administered to 90 respondents randomly selected from Ezza North LGA of Ebonyi State. Data obtained were analyzed using descriptive and inferential statistics. It was observed that socio-economic characteristics of the farmers actually affected Homestead Garden Egg Production in the area such as gender and marital status as shown on the regression result which indicated that R^2 of 0.5801 as observed in the model implies that about 58% of the variation in the quantity of garden egg harvested was as a result of the factors included in the model. The overall fitness is confirmed by the significant f-value. Based on the findings of this study the following recommendations were made: there is need for government to promote extension services by allocating sufficient funds to facilitate extension staff to reach farmers frequently to teach them the new ideas in garden egg production, farmers' financial problems may be solved through access to loans from commercial banks, microfinance banks and other lending agencies probably by forming or joining cooperative societies.

Keyword: Homestead, Garden egg, Production, Socioeconomic, Factors

INTRODUCTION

Generally, home gardening refers to the cultivation of a small portion of land which may be around the household or within walking distance from the family home (Abu *et al*.,2017). Homestead gardens are also called kitchen gardens, backyard gardens, compound gardens, rooftop gardens, is a type of agriculture that has been in practice since the beginning of the agricultural system. It is a garden not far from the home that is owned and maintained by the household and kept mainly for household food supply (Balogon, 2016). Among common vegetable crops seen in a typical Nigeria homestead garden include, fluted pumpkin, bitter leaves, water leaves, garden egg, beans, curry, scent leaves among others. A homestead vegetable crops which is to be given priority under this study is garden egg. Garden egg or scarlet eggplant (Solanum aethiopicum) is one of the most important vegetable crops in tropical Africa. Garden eggplants are fruit vegetables of some varieties which are white and shaped like chicken eggs, hence the name 'eggplants' (Ahmed, *et al*., 2016).

Among many crops which are important nutrient dietary that no much attention seem to have been given by research or neglected by governments and farmers in Nigeria in particular is garden egg, (Ahmed, *et al*., 2016; Amoako, J. (2017). The neglect could be attributed to among others; lowly contribution to the nation's foreign exchange, (Akpan, 2014), ignorance of the nutritive values and diversified food forms from garden egg, by greater percentage of the populace (Akpan, 2014), poor acceptance by high income countries for both consumption and other purposes and high labour intensive nature of its production entails almost has zero mechanization (Enete and Okon 2018).

MATERIALS AND METHODS

Study Area Description

The study was carried out in Ezza North Local Government Area of Ebonyi State, Nigeria. Ezza North shares boundaries with Ikwo in the East, North-East and Southeast with Ezza South and Abakaliki in the North and Onicha in the West and Southwest. The mean temperature is 28^0C- 42^0C, having an annual rainfall of 1800mm - 2000mm, relative humidity of 65%. It is located between Latitude 6^049^l and 6^032^l North of Equator and Longitude 8^03^l and 7^098^l East of the Greenwich meridian. The people are mostly farmers who take advantage of the rich and abundant farm land to cultivate yam, rice, garden egg, cassava, cereals and vegetables, among others. It has an area of 324km^{2}and population of 133,625(NPC, 2006). Multistage random sampling technique was employed in the selection of respondents for the study. Firstly, 2 communities; Umuezekaoha and Oshiegbe were randomly selected because of their massive involvement in the production of garden egg. Secondly, 3 villages (Okwuhieonu, Agbo and Izenyi) were selected from Umuezekaoha community while 3 villages (Azomele, Azuda and Odeligbo) were selected from Oshiegbe to give a total of 6 villages. Thirdly, 15 garden egg farmers were randomly selected to give 90 respondents. A structured questionnaire was used in soliciting information from the respondents. Objective i. was analyzed using descriptive statistics such as percentages and frequency counts presented in tabular forms while objective ii was achieved using regression analysis. The explicit form of the model is represented thus;

Linear form:

$Yd = f(X_1, X_2, X_3, X_4, X_5, X_6...... +e_i$ (explicit form)

$Yd=a+b_1x_1+b_2X_2+b_3X_3 +b_4X_4+b_5X_5+b_6X_6...... +e_i$ (implicit form)

Semi log form:

$Yd=a+b_1logX_1+b_{29}logX_2+b_3logX_3+b_4logX_4+b_5logX_5+b_6logX_6 ....+e_i$

Double log form:

$Log Yd=a+b_1logX_1+b_2logX_2 +b_3LogX_3 +b_4logX_4+b_5logX_5+b_6logX_6 ....e_i$

Exponential form:

$LnYd=a+b_1X_1+b_2X_2+b_3X_3+b_4X_4+b_5X_5+b_6X_6 ....+e_i$

Where

Y_d = Output of garden egg by rural household farmers (kg)
X_1 = Age of the farmers (years)
X_2 = Marital Status (single=1, married=2, widow=3, widower=4, divorced=5)
X_3 = Household size (number of persons)
X_4 = Gender (male = 1, Female = 0)
X_5 = Educational qualifications (years of formal schooling)
X_6 = Farming Status (in time duration)
X_7 = Farming Experience (in years)

X_8 = Access to credit facilities (yes=1, No=0)
X_9 = Agro-chemical (herbicides =1, pesticides=0)
X_{10} = Extension contact (yes=1, No=2)
e_i = Error term

RESULTS AND DISCUSSION

Table 1 shows the socio-economic characteristics of Respondents. The result showed that 61.11% of the respondents were at the age bracket of 31-50. This implies that the respondents were young and very active to go into garden egg production. The finding also conformed to those of Nwaneri et al., (2021) that most farmers in Nigeria are above 40 years. The result also showed that 65.56% were female. This implies that most of the garden egg farmers in the area were female. The result further showed that 44.44% of the respondents were married. This implies that most of the garden egg producers in the area were married which means that they have farming to care for. The involvement of married class in agriculture is in line with Nwaneri., et al (2021) whose report shows that married class are more involved in agriculture because of the need to supplement the families' means of livelihood. Majority (38.89%) of the respondents had household size of 4 to 6 persons while 75% of them were educated attaining various levels of education. The level of education attained by a farmer not only increases his farm activity, but also enhances his ability to understand and evaluate new production technologies (Nwaneri, et al., 2021). Also, 41.11% had farm size of 0.1-0.5 indicating that the respondents engaged in small scale production as their major source of labour is both family and hired labour, while a good proportion (87.78%) belonged to cooperative society or farmers' association. These implies high innovativeness among the respondents due to influence of good dynamic effects. The involvement of farmers in association or cooperatives enabled them share ideas and work as a unifying force (Nwaneri et al., 2019). The result further showed that majority of the respondents (91.00%) do not have access to extension visit while a large proportion (72.27%) of the respondents do not have access to credit facility which resulted to reduction in the production level of garden egg. This agrees with the findings of (Nwaneri et al., 2019) who posited that having access to credit facility is opening a way for increase in productivity.

Table 1: Characteristics of Respondents in Ezza North L.G.A, Ebonyi State (N= 90)

Characteristics	Frequency	Percentage
Gender		
Males	31	34.44
Females	59	65.56
Age (years)		
<30	10	11.11
31 - 50	55	61.11
61 – Above	25	27.78
Marital Status

Table 2 showed the multiple regression result of effect of Socio-economic Characteristics of homestead garden egg farmers on their Output. Among the models fitted, linear model was chosen as the lead equation because it satisfied the economic criteria of highest R^2 value (0.5801), the highest number of the significant variables (gender, marital status, membership of cooperative, extension contact, household size, access to credit and farm size) and the high f-value (15.06). The R^2 of 0.5801 implies that about 58% of the variation in the quantity of garden egg harvested was as the result of the factors included in the model. The overall fitness is confirmed by the significant f-value. The coefficients of gender, marital status, membership of cooperative and extension contact were negative and statistically significant at 1% level of probability. This implies that as the number of males involved in garden egg production increases, the quantity of garden egg harvested decreases. Also, as the number of married farmers increased, the quantity produced decreases. As the farmers belong to cooperatives, theirs contact to extension services increases and the introduction of innovations increases which deviates the farmers interest on the garden egg production, thus reduces the quantity of garden egg produced. However, the coefficients of household size, farm size and access to credit were positive and statistically significant at 1% level of probability. This implies that as the family size of a farmer increases, the farmer has more access to finance which enables him to acquire more lands; with which he practices other innovations and still increase the quantity of garden egg produced in the area.

Table 2 Regression Result on the Relationship between the Socio-economics Characteristics of the homestead garden egg farmers and their Output.

CONCLUSION AND RECOMMENDATION

The study evaluated Selected Socio-Economic Factors Affecting Homestead Garden Egg Production in Ezza North Local Government Area of Ebonyi State, Nigeria. The result showed that 61.11% of the respondents were at the age bracket of 31-50. This implies that the respondents were young and very active to go into garden egg production. The result also showed that 65.56% were female. This implies that most of the garden egg farmers in the area were female while 44.44% of the respondents were married. This implies that most of the garden egg producers in the area were married which means that they have farming to care for. Furthermore, 38.89%) of the respondents had household size of 4 to 6 persons while 75% of them were educated attaining various levels of education. Also, 41.11% had farm size of 0.1-0.5 indicating that the respondents engaged in small scale production as their major source of labour is both family and hired labour, while a good proportion (87.78%) belonged to cooperative society or farmers' association. These implies high innovativeness among the respondents due to influence of good dynamic effects. The result further showed that majority of the respondents (91.00%) do not have access to extension visit while a large proportion (72.27%) of the respondents do not have access to credit facility which resulted to reduction in the production level of garden egg. It was observed that socio-economic characteristics of the farmers actually affected Homestead Garden Egg Production in the area such as gender and marital status as shown on the regression result which indicated that R2 of 0.5801 as observed in the model implies that about 58% of the variation in the quantity of garden egg harvested was as a result of the factors included in the model. The overall fitness is confirmed by the significant f-value. Based on the findings of this study the following recommendations were made: there is need for government to promote extension services by allocating sufficient funds to facilitate extension staff to reach farmers frequently to teach them the new ideas in garden egg production, farmers' financial problems may be solved through access to loans from commercial banks, microfinance banks and other lending agencies probably by forming or joining cooperative societies.

ABSTRACT

This study investigated the level of gender participation in the formal and informal markets in Southeast Nigeria. The study was carried out in Southeastern Nigeria to determine the participation of cassava value chain actors in the formal and informal market by gender. Multi-stage sampling procedure was used to in the selection of 432 respondents used for the using a well-structured questionnaire. Data were analyzed using simple descriptive statistics and inferential statistical tools. The results revealed that in the formal market, male producers and processors had 0.88 and 0.83 Market participation index which was adjudged to be high, while the marketers had only 0.37 of participation. The female gender had 0. 63 market participation index for the producers and marketers in the same market which was considered to be moderate. The results also revealed that all the male cassava value chain actors in the informal market had high market participation index (0. 80 and above). While their female counterparts had at least 0.55 Market participation index in all the chains. The study therefore recommends that The female actors should be given more access to land, inputs, credits and loan to enable them to participate more in the formal market and to create more value that may help them to be more productive, increase value in business and market oriented

KEYWORDS: Participation index, Percentage sales, Gender, Markets, Cassava value chain.

INTRODUCTION

Cassava is produced by smallholder farmers and it's strategically valued for its role in food security and poverty alleviation. Markets play a vital role in ensuring better incomes and welfare for farmers through diverse channels. Formal market refers to reliable (contract arrangement) and lucrative (profitable) markets or the high value markets while informal market on the other hand is a market where there is no involvement of any formal arrangement (e.g. contract) for a sale of goods between a farmer and a buyer. Market participation refers to the extent by which households participate in the market as a seller, (Berhanu and Moti, 2012)

The participation of men and female cassava value chain actors in the formal and in the open markets enhances the potential that unfolds economic opportunities that improves the value added along the chain. The terms upon which the actors enter and participate in formal or informal markets are sometimes inequitable (Osmani and Hossain, 2015). Women in agricultural production chains are excluded from transportation of goods to the market or from marketing or sales roles of goods, even when women are the main producers of these goods (International Finance Corporation, 2016). Lack of access to market and poor market information prevalent in Southeast always result in production and processing activities not well organized in line with consumer demand for cassava roots and processed-products.

Thus, cassava has been the focus of many market-led development initiatives, such as the Pan-African Cassava Initiative (PACI) launched by NEPAD and IITA in 2004; the Cassava: Adding Value for Africa project; and the Regional Cassava Processing and Marketing Initiative (RCPMI) with IFAD in West Africa among others. All these initiatives have worked and is still working to promote and uphold cassava development in different ways, as well as other activities to support increase in production and processing ability, from improving the agricultural inputs such as improved cassava varieties to the growth and expansion of new products to enhance market demand, and strategy guidelines to support growth in cassava commercial opportunities and value chains (Forsythe, Posthumus and Martin, 2016). Despite these initiatives, the practices, policies and programmes in cassava value chain are gender blind in market participation and do not consider women's unique needs and knowledge; unequal rights and responsibilities between men and women or limited participation of women in decision-making processes (World Bank, 2009). Therefore there is a dearth of information on gender differentials generally, or with respect to formal and informal market participation among cassava value actors in southeast Nigeria. Against this background, it becomes pertinent to examine the level of gender participation in the formal and informal markets by cassava chain value chain actors in Southeast, Nigeria.

METHODOLOGY

The study was carried in South-east agro-ecological zone of Nigeria. Using the multi-stage sampling procedure, three States were randomly selected. These were Imo, Abia and Ebonyi States. Secondly, two agricultural zones, according to the State ADP's delineation were selected from each State and two Local Governments based on the intensity of cassava production were purposively selected, given a total of twelve Local Government Areas. Two (2) communities known for intensity of cassava production were purposively selected from each of the selected Local Governments.

To ensure representative sample selection, a pre-survey sampling frame was determined by compiling lists of cassava producers, processors and marketers in the selected twenty four communities collected from the selected LGAs, village heads and the related associations in cassava value chain in the area. From these lists, six (6) producers (3 males and 3 females), six processors, (3 males and 3females) six marketers, (3 males and 3 females) were randomly selected, making a total of one hundred and forty four (144) for each of the producers, processors and marketers giving a sample size of four hundred and thirty two (432) respondents that were used for the study.

The study utilized primary data collected using structured questionnaire, informant interviews and focus group discussion. Data were analyzed using descriptive and inferential statistics.

The ***Level of gender participation in the formal and informal markets along the chain was analyzed using Market Participation Index.***

*The Market participation index is measured by the level of involvement in sales of cassava value products in the formal and informal markets along the chains. F*ollowing Osmani and Hossain, (2015), the level of participation in the formal and informal markets was derived using the following model stated as:

$$Mp_i = \frac{Vs_{ik}}{Vpm_{ik}} \times 100 \qquad (1)$$

Where:
Mp_i = Sales in the ith market type (percent)
Vs_{ik} = value of sales in the ith market type at the k^{th} stage (naira)
Vpm_{ik} = Total value of products for ith actor at the k^{th} stage
In this case, the model was used to measure the percentage sales in the formal and informal markets.

RESULTS AND DISCUSSIONS

Table 1: The Levels of Gender Participation among Cassava Value chain Actors in the Formal Market

	Formal market					
	Male			Female		
.	Prod.	Proc.	Mkter.	Prod.	Proc.	Mkter.
Quantity harvested/ processed/ purchased (Kg)	15012.83	2491.92	3878.98	15809	2290.51	3525.59
Quantity sold (Kg)	13333.1	2076.11	1436.43	10098.9	1003.85	2228.3
MPI-Level of participation (Qty Sold/Qty Harvested)	0.8881	0.8331	0.3703	0.6388	0.4383	0.6320

Source: Survey data, 2019,
Prod= producers, Proc = processors, Mkter= Marketers, MPI= Market Participation Index

The result of the level of market participation among male and female cassava actors were measured in percentage sales. The analysis showed that the level of male participation in the study area was high (88 and 83 percents) for the producers and processors and low (37%) for the marketers. For the female gender, the percentage sale in the formal market was also moderate (63% for both actors) for the producers and marketers. However, the result revealed that the level of female gender participation- for the processors was low with percentage sale of43%. The result is in contrast with the finding of Riisgaard; Fibla, and Ponte, (2010), who reported that small scale cassava processing is the domain of women. However, men are becoming more involved in cassava processing probably because it is becoming more lucrative. Other researchers have corroborated this finding and noted the trend of men operating processing plants and becoming managers of such enterprises as processing became increasingly commercialized and mechanized (Adebayo, Lamboll and Westby, 2008). This indicated that male producers and processors participated more in the formal market than their female counterparts. This might be explained by the fact that male farmers with bigger cultivable land were found to participate more because of their ability to produce bigger volumes that ensures marketable surplus. Lerman, (2004) revealed that farmers with large cultivable land were found to participate more because of their ability to produce larger volumes that ensured market surpluses. However, the female marketers participated more in the formal market than their male counterparts with only 37% sales.

Furthermore, the results of the analysis also show that while the male actors harvested 15012.83kg of fresh cassava roots they were able to sell 13,333.1kg at the formal market and probably consumed or disposed 1,679.73kg of their harvest. For the female producers, they had

15809kg of cassava roots, sold 10098kg and disposed the remaining 4990.1kg of their harvest. This result was similar for all the actors in the formal market. This implies that while the female actors harvested/processed/purchased more quantity of cassava products, they sold only a smaller portion unlike the male who sold more and probably consumed less. These findings confirm the fact that the male actors were more formal market oriented than their female counterparts. This observation was similar along the chain for the male and female processors in the formal market. The large amount- harvested by the male producer may be as a result of area cultivated with cassava compared with large total area held for agricultural activities as shown in the socio economic variables statistics. The higher proportion of land a household allocated to the more marketable crops, the more the household produced for market following the findings of Berhanu and Moti, (2012) and Okoye, (2018).

In the marketing chain, the male marketers in the formal market were able to sell 2228.3kg out of 3525.59kg of gari purchased, while their male counterpart sold 1436.42kg from 3878.98kg purchased. This confirmed the result of David and Madu, (2014) who noted that sweet potato and cassava crops were traditionally marketed by women while an increasing number of men were into production and cultivation of sweet potato on their own plots because of its high level of profitability.

Level of gender participation by cassava actors in the informal market

The result in Table 2 shows the level of gender participation among cassava value chain in the informal market.

Table 2: Level of gender participation in the informal market along the chain

	Informal market					
	Male			**Female**		
Variables	**Prod.**	**Proc.**	**Mrkt.**	**Prod**	**Proc.**	**Mrkt.**
Quantity harvested/processed/purchased (Kg)	16435.4	1979.62	2855	14888.95	1920	2821
Quantity sold (Kg)	13835	1800	2288.2	10125	1058.5	2767.5
MPI (Qty Sold/Qty Harvested)	0.8418	0.9093	0.80147	0.68004	0.5513	0.9810
%age sales in the market	84.1781	90.9268	80.1471	68.0035	55.1302	98.1035

Source: Survey data, 2019.. MPI= Market participation Index

Prod= producers, Proc.= processors, Mkter= Marketers

The result of level of gender participation in the informal market is presented in the Table 2. The level of participation for all the male actors in production, processing and marketing was high at 84, 91 and 80 percents respectively. For the female gender, the percentage sales were 68,55and 98 percents for the producers, processors and marketers respectively. The high market participation index for the male actors indicated that the male actors participate more in the market than their female counterparts in exception with the female marketers. This is against a prior expectation probably because most of the actors are aged and had preference to informal market more than the formal market because of their age. Although Adjimoti, (2013) in his study on market participation noted that male cassava actors have preference for the informal market more than their female counterparts.

CONCLUSION AND RECOMMENDATIONS

The male and female cassava value chain actors such as the producers, marketers and processors participate in the formal and informal markets as sellers based on the quantity of produce harvested, processed or sold. The male producers and processors had more Market participation index in the formal and informal markets more than the marketers. The female producers and processors had higher percentage sales in the formal and informal markets more than the processors. Relatively, the male participated more in the formal and informal markets than their female counterparts. The study therefore recommends that In view of the fact that both male and female cassava value chain actors participate in the formal and informal markets and take part in all aspects of cassava enterprise development activities, research should be geared to develop gender sensitive technologies for dissemination to both gender to enhance production, productivity and quality of processed products .Also the female actors should be given more access to land, inputs, credits and loan to enable them to participate more in the formal market and add more value that may help them to be more productive, increase value in business and market oriented.

ABSTRACT

The objectives of this study was to assess how the United States Food Security Module can be used to measure the food security status of farming households during corona virus disease lockdown in the study area, to determine the coping-strategies adopted by farming households and to compare the food security status of farming households in the three agricultural zones of the State. This study conducted in Cross River State used primary data which was obtained between April and May 2020 using questionnaire. Two hundred and forty (240) farming households were randomly selected from a list of registered farmers and a six-item short form of the United State's Food Security Survey Module was applied for the assessment. The findings revealed that majority of the households (rural households) were food insecure (64.58%) while only (35.42%) of households were food secure confirmed by the number of affirmative responses to 5 out of 6 questions in the survey module. Also, households with high food insecurity status employed more of the coping strategies such as reducing the amount of food consumed (18.75%), borrowing from family and friends (25%), selling small assets (25%) as well as acquiring additional job (20.83%) to survive. COVID -19 lockdown disrupted the food supply chains and cause a sharp rise in commodity prices beyond the reach of households. The state could cushion the impacts by introducing measures such as massive investment in agricultural sector, social assistance benefits like conditional cash transfer to vulnerable farming households and provision of agricultural inputs and credit facilities to farmers.

INTRODUCTION

The corona virus disease (COVID-19) which was declared as pandemic by World Health Organization (WHO) on the 11th of March 2020 was actually first reported on the 31st of December, 2019 in China, precisely in Wuhan in the Province of Hubei. In Nigeria, the first case was reported on February 28, 2020 (Federal Ministry of Health (FMH) 2020). The disease usually starts with difficulty in breathing resulting to a Severe Acute Respiratory Syndrome virus (SARS-CoV-2) is the prime suspect (WHO, 2020). The virus disease like wild fire has spread worldwide with its resultant effect on lives and properties in addition to paralysis of economic and social activities across regions. However, interests have been growing on how poverty and food insecurity can be alleviated across the world particularly in this pandemic era. It is likely that African countries may be the worst hit by the corona virus disease in developing countries especially in the long-run (World Bank 2020). From experts advise, the aging population of several countries are the most at risks (Gardner *et al.*, 2020; Lima *et al.*, 2020), or poor infrastructural healthcare system (Tanne *et al.*, 2020; Mikhael *et al.*, 2020). Other emphasis has been place on the role of the environment naturally (Marco *et al.*, 2020) all of which are characteristics of African countries. Statistics globally with respect to Covid-19 as at October 22, 2020 indicates that total cases was 41, 570,428 resulting to 1, 137, 693 deaths and 30, 957,964 recoveries while similarly in Nigeria, the number of total infection as at October 22, 2020 was 61, 667 with 1,125 deaths and 56, 880 recoveries or discharged (www.worldometers.info/coronavirus). Covid-19 outbreak has heightened the threat to human lives and food security all brought about by the new wave of violence and conflict across the world. It therefore means that the capabilities of the states to protect her citizens are weaken and as such public goods and basic services may not be readily available. The livelihoods of several Cross Riverians and Nigerians have been lost due to the several lockdown orders for Covid-19 even though the State did not record any index case of Covid-19 within the period of this study thereby triggering an increase in conflicts, crime and violence.

In order to cope with the impact of Covid-19 pandemic, governments across the world provided measures to take care of their citizens and improve the economy as well as food security. Africa countries have responded with Nigeria rolling out the sum of N50 billion stimulus package for households and small and medium-scale enterprises (SMEs), "all CBN intervention facilities are hereby granted a further moratorium of one year on all principal repayments as well as interest rate reduction from 9 to 5 percent per annum for 1 year effective March 1, 2020" etc. (CBN, 2020, NCDC, 2020). In other words, Covid-19 has resulted in a give and take situation even though what it takes is greater than what it gives. Keeping aside the wanton loss of lives and livelihoods, almost every fabrics of the society are affected like the economy, transport, education, communication and commerce as well as trade.

In spite of the different realities created by the pandemic worldwide, one critical question still demand an answer and that is: what was the food security status of households during Covid-19 mitigation and restrictive measures in Nigeria and Cross River State in particular. More so, prices of food items and other consumables are reported to have sky-rocketed since the beginning of the Covid-19 pandemic, also, the likelihood of illness-related labor shortages in the food and agricultural sector, the break in transportation systems; isolation measures restricting market access as well as the disruption of the supply chain could lead to food loss and waste in addition to losses in the purchasing power thereby reducing the way and manner people eat thereby resulting to nutritional deficits (Rashul *et al.*, 2020. Hence, this study aimed at assessing how the United States Food Security Module could be used to measure household food insecurity during corona virus disease lockdown in Cross River State, to determine the coping-strategies adopted by households during the lockdown period and to compare the food security status of households in the three agricultural zones of the state.

MATERIALS AND METHODS

This study was conducted in Cross River State, one of the six states in South-South Nigeria. The study made use of primary data collected through the use of questionnaire from the three agricultural zones namely; Northern Agricultural zone, Central Agricultural zone and Southern Agricultural zone which took place between April and May 2020. From a list of registered farmers obtained from the Cross River Agricultural Development Programme (CRADP) headquarters, three hundred (300) farmers were randomly selected for the study, although only two hundred and forty (240) households filled and returned their questionnaire which was used as sample size. The six-item short form of the United State's Food Security Survey Module was applied to assess the food security status of farming households. Households' responses were scored from a total of 6 questions (each scored as '1' for affirmative response and '0' for negative response) and the total scores (range 0-6) were categorized into three (3) food security statuses: high or marginal food security (food secure) (0-1), low food security (2-4) and very low food security (5-6). In other words, streamlining the categorization into two gives: food secure from 0-1 and food insecure from 2-6.

RESULT AND DISCUSSIONS

Table1: Distribution of respondents by food security status in the zones and the state

Food security status	North **Percentage(80)**	Central **Percentage (80)**	South **Percentage (80)**	State **Percentage (240)**
Food secure	20 (25%)	25 (31.25%)	40 (50%)	85 (35.42%)
Low Food security	40 (50%)	45 (56.25%)	20 (25%)	105 (43.75%)
Very low food security	20 (25%)	10 (12.50%)	20 (25%)	50 (20.83%)
Total	**80 (100%)**	**80 (100%)**	**80 (100%)**	**240 (100%)**

Source: Field survey, 2020

The result of Table 1 shows that food secured households in the North was 25%, Central 31.25% and South 50% while food secured households in the entire state was 35.42%. On the other hands, low food security status was 50% in the North, 56.25% in the Central; 25% in the South and 43.75% in the state; whereas very low food security status was 25%, 12.50%; 25% and 20.83% across the Northern, Central and Southern agricultural zones and the state respectively. Therefore, in comparison, the Northern agricultural zone recorded the highest level of food insecure households of 75% which is higher than the entire state, followed by the Central zone with 68.75% and the Southern agricultural zone with 50%. The reason being that the Northern agricultural zone is the most rural of the entire zones and the least developed. The Central zone is more or less a border community with the Republic of Cameroun and as such boasts of some lively economic activities even though borders were shutdown while the Southern agricultural zone is an urban area and the administrative headquarters of the entire state, hence, several opportunities abound. In other words, only 35.42% of households were food secure during the coronavirus lockdown in the state while 64.58% of households were food insecure. This result is in agreement with the assertion by Rashul *et al.*, (2020) .

Table2: Distribution of respondents by coping strategies

Coping strategies	North **Freq/Percent**	Central **Freq/Percent**	South **Freq/Percent**	State **Freq/Percent**
Reducing amount of food consumed	30 (37.5%)	10 (12.5%)	5 (6.25%)	45 (18.75%)
Borrow money from family/friends	30 (37.5%)	20 (25.0%)	10 (12.5%)	60 (25.00%)
Acquire additional job	-	10 (12.5%)	40 (50.0%)	50 (20.83%)
Sold small assets	20 (25.0%)	30 (37.5%)	10 (12.5%)	60 (25.00%)
Migrated internally	-	10 (12.5%)	15(18.75%)	25 (10.42%)
Total	**80 (100%)**	**80 (100%)**	**80 (100%)**	**240 (100%)**

Source: Field survey, 2020

From Table 2 on coping strategies used by households during Covid-19 lockdown, it was clear that 37.5% in the North, 12.5% in the Central, 6.25% in the South and 18.75% in the state had to reduce the amount of food consumed by household members. This result may not be a surprise because the zone had the highest level of food insecure households and so to cope with the emergency situation; it became rational for households to reduce the amount of food consumed while the other zones thrives on minimal levels of food consumption confirming the studies of Rashul *et al.*, (2020). In a similar way, 37.5% in the North, 25% in the Central, 12.5% in the South and 25% in the State had to borrow money from family and friends in order to survive. Again, the higher level of food insecurity in the North warrants wanton borrowing from family and friends to make up for food shortages and less purchasing power while other zones borrowed moderately to survive. It was shown from Table 2 that no household in the North acquire additional job during the period, whereas 37.5% of households in the Central, 50% in the South and 29.17% in the State acquired additional jobs as coping strategies. Meanwhile, 25% of households in the North, 12.5% in the Central, 12.5% in the South and 16.67% in the State sold small assets to cope with the crisis. The Northern zone with high food insecurity sold much of her small assets especially land to carter for household member during the pandemic lockdown. On the other hands, 12.5% of households in the Central, 18.75% in the South and 10.42% in the State migrated internally during the lockdown period while no household from the North migrated. This result confirm results of earlier studies by (World Bank, (2020) Gardner *et al., (*2020); Lima *et al.*, (2020); Tanne *et al.*, (2020); & Mikhael *et al.*, (2020),

CONCLUSION AND RECOMMENDATION

Covid-19 pandemic has succeeded in disrupting the global food supply chain and the economy in 2020. The lockdown and restrictions has disrupted the value chains resulting in the abrupt falls in food supply and fiscal revenues and a sharp rise in commodity prices beyond the purchasing power of individual households. The state can cushion the impacts of corona virus disease by introducing measures such as massive investment in agricultural sector, social assistance benefits like conditional cash transfer to vulnerable farming households; tax relief for farmers; provision of agricultural inputs and employment retention/ unemployment benefits that will protect the vulnerable ones. Although, these measures might not contain the pandemic, the citizens should be encouraged to adhere strictly to the National Centre for Disease Control (NCDC) guidelines and protocols to reduce the spread of the virus and also assist in reducing food and nutrition insecurity as well as poverty.

ABSTRACT

This study assessed percieved effect of post-harvest management practices on rural farmers livelihood in Kogi State, Nigeria. Sample size of one hundred and sixty (160) rural farmers were selected with multi-stage sampling method. Structured questionnaire complimented with interview scheduled were used for data collection. Data collected were analyzed using descriptive statistics such as (frequency, percentages and mean) and inferential statistic (Kendall Coefficient of Concordance). The finding showed that 83.5% of farmers were males with mean age of 43 years. Improved income and livelihood of rural household ($\bar{X}$ =2.23) and make food available all through the years ($\bar{X}$ =2.14) were the major perceived effect of post-harvest management on farmer livelihood. The most constraints associated with post-harvest management in the study area were poor funding ($\bar{X}$ =7.74) and unfavorable price due to low income ($\bar{X}$ =8.05). It is recommended that credit and fund should be made available by governments and non-governmental organization so that farmers could easily purchase post-harvest tools and materials.

KEYWORDS: Post-harvest; Management-practices; Farmer; Livelihood

INTRODUCTION

Post-harvest can be defined as the stage of crop production immediately after harvesting. It involves stages such as drying, shelling, cleaning, sorting and packing (Vellema, 2008). Post-harvest management can be defined as methods or system applied to farmers' produce after harvesting purposely for preservation, conservation, quality control/enhancement, processing, packaging, storage, distribution, marketing, and utilization to meet the food and nutritional requirements of consumers and also to enhance their livelihood status. The roles of post-harvest management in agricultural production cannot be overemphasized, post-harvest management enhance agricultural production by reducing post-harvest losses to the bearest minimum, improves nutrition and livelihood status of farmers, adds value to agricultural products by opening new marketing opportunities, generating new jobs and enhance other related economic sectors for viable growth. Similarly, post-harvest management have ability to meet food requirement of the rural households by reducing avoidable losses. Post-harvest management also has the ability of transform rural areas economically thereby reducing the income disparities between urban and rural areas (Abeleira *et al.*, 2008). The objectives of the study are to describe the socioeconomic characteristic of farmers, examine perceived effects of post-harvest management practices on farmers livelihood and identify constraints associated with post-harvest management practices in the study area.

METHODOLOGY

Kogi State is located in the Guinea savannah ecological zone of Nigeria. The headquarters of the State is Lokoja, which is situated at the confluence of rivers Niger and Benue making the State to be popularly known as the confluence State. The State like any other State. The State is located between latitude 6^0 33' and 8^0 44'N and longitude 5^0 22' and 7^0 49'E. The major food crops grown in the State are yam, cassava, maize, sorghum, rice, millet, cowpea, pigeon pea, groundnut, bambaranut, cocoyam, sweet potato, beniseed, melon, banana, plantain and cotton. Fruits and leafy vegetables such as okra, pepper, fluted pumpkin and spinach are highly cultivated in the area. Tree crops grown in the State are: cashew, oil palm, citrus, cocoa, coffee and kolanut (Kogi State Ministry of Information Working Document, 2016). Multi-stage sampling technique was used for this study. The first stage involved random selection of three (3) Agricultural zones out of four (4) Agricultural zones in the State. The second stage involved the selection of one (1) Local Government Area (LGA) from each of the zones making a total number of three (3) LGAs. The third stage involved random selection of four (4) communities each from the selected LGAs making a total of twelve (12) villages. The fourth stage involved the random selection 10% of the farmers from the sampling frame.

Table1: Showing sample distribution of the farmers in the study area

State	Agricultural Zones	LGAs	Communities	Sampling Frame	Sample Size (10%)
Kogi State					
	Zone A	Yagba East	Alu	198	20
			Ponyan	172	17
			Ejuku	147	15
			Oranre	110	11
	Zone B	Dekina	Abocho	170	17

Source: Agricultural development project in Kogi (2016)

Primary data was used for this study. Data were collected by the researcher assisted by trained enumerators using well-structured questionnaires. The objectives 1 and 2 of this study were achieved using descriptive statistics such as frequency distribution, percentage and mean.

Analytical Techniques

Perceived effect of post-harvest management on farmers livelihood measured using 3-points likert scale of Significant effect 3, Less effect 2, No effect 1. A mean score of 2.0 was obtained by adding 1+2+3=6 and dividing by 3. The decision rule was any mean $(\bar{X})$ scores > 2.0, indicates significant effect, while scores < 2.0 is termed no effect.

Kendall's Coefficient of Concordance

To examine the constraints associated with post-harvest management practices objective (iv), the Kendall's coefficient of concordance (*W*) adopted from Mohammed *et al.* (2018) was used to rank the problems. A lower mean rank indicates the problem is severe and vice versa. The Kendall's *W* was computed as shown below.

$$W = \frac{12\sum R^{-2}i - 3N(N-1)^2}{N\,(N-1)}$$

Where:

W = Kendall's value, *N* = total sample size, *R* = mean of the rank. The Kendall's coefficient of concordance (*W*) is a measure of the extent of agreement or disagreement among farmers of the rankings obtained. The value of *W* is positive and ranges from zero to one where one denotes perfect agreement among farmers of the rankings and zero denotes maximum disagreement.

RESULT AND DISCUSSION

Socioeconomic Characteristics of Farmers

Results in Table 2 showed that the mean age of the farmers in Kogi State was 43 years. This result revealed that farmers in the study area were still in their active and productive age. This may influence their readiness to try innovation, acquire new skills and knowledge on every aspects of post-harvest management which are expected to have positive effect on their income and livelihood. This finding is in consonance with that of Jabil and Abdul (2012) who stressed that younger farmers are more willing to adopt new techniques and knowledge than older ones. Results in Table 2 revealed that majority of the farmers (83.5%) in the study area were males. Male dominance might be due to difficult tasks involved in post-harvest management ranges from sorting, grading, packing, shelling, cleaning, processing, storage, processing, pests and diseases control.This finding agreed with Rashid *et al.* (2015), who revealed that men were more involved in traditional storage practices of yam in Ekiti State, Nigeria.Results in Table 2 indicated that the mean farming experience of the farmersin Kogi State was 29 years. The findings implied that farmers in the study area had long time experienced and are well exposed which might have equipped their knowledge and skills on post-harvest management which is expected to have positive effect on the livelihood. This findingis in agreement with that of Javed (2013),who reported that majority of farmers had high experience in post-harvest handling of vegetables. Results in Table 2 revealed that the mean years spent in formal education in Kogi State was 9 years, implying slow literacy considering the technical know-how required for proper sorting, grading, packaging, pest and diseases control. This could affect their eagerness to adopt post-harvest management and farmers livelihood. This agrees with Pelemo *et al.* (2019), who reported that bulk of rural farming families in Kogi State, Nigeria had low literacy level.

Table 2: Distribution of the farmers according to socio-economic characteristics (n=160)

Variables	Frequency	Percentage
Age (year)		
≤30	34	21.2
31-40	33	20.6
41-50	57	35.6
51-60	28	17.5
>60	8	5.1
Mean	**43**	

Sex		
Male	132	82.5
Female	28	17.5
Experience in Farming (year)		
1-10	17	10.6
11-20	29	18.1
21-30	40	25.0
31-40	41	25.6
>40	33	20.7
Mean	**28.9**	
Years spent in formal education		
1-6	45	30.8
6-12	63	43.2
>12	38	26.1
Mean	**9**

Percieved effect of post-harvest management on farmers livelihood

Table 3 revealed that improved income and livelihood of rural households ($\bar{X}$ =2.23) ranked 1st, this implies that post-harvest management increase income and livelihood of farmers in the study area. The findings agreed with Anyawu *et al.* (2017), who revealed that the most noticeable effect of adoption of a given technology is increased income and livelihood of the adopters. This was followed by making food available throughout the year ($\bar{X}$ =2.14) ranked 2nd. It is believed that adoption of post-harvest management coupled with proper training will make food available throughout the year, thereby reducing the problem associated with food insecurity. Table 3 further revealed that increase in shelf-life of farmers' produce ($\bar{X}$ =2.10), assist in market information ($\bar{X}$ =2.07) and improved in non-farm expenditure ($\bar{X}$ =2.07) were ranked 3rd and 4th respectively.

Table 3: Percieved effect of post-harvest management practices on farmers livelihood (n=160)

Variables	Mean ($\bar{x}$)	R	D
Improved income and livelihood of rural household	2.23	1st	SE
Increase in shelf-life of agricultural produce	2.10	3rd	SE
Make food available all through the years	2.14	2nd	SE
Assist in market information	2.07	4th	SE
Increase productive assets	2.05	8th	SE
Maintaining quality of farm produce	2.04	9th	SE
Improved non-farm expenditure	2.07	4th	SE
Assist in the procurement of households assets	2.06	7th	SE
Enhance livelihood expenditure	2.07	4th	SE
Settlement of children school fees	2.04	9th	SE
Enhance off-farm activities	2.01	11th	SE
Provision of employment opportunities	1.92	12th	NE

Note: SE=Significant effect, NE=No effect

Constraints Associated with Post-harvest Management Practices

The result in Table 4 showed that Kendall's coefficient of concordance obtained in the analysis was 0. 21% level of probability. This shows a weak on the outcome of ranking. Table 4 showed that nineteen constraints were identified as key problems faced by farmers in the adoption of post-harvest management. The results revealed shortage of fund ($\bar{X}$ =7.74) ranked 1st as the most serious constraint faced by farmers. This was followed by unfavorable price due to low income problem inadequate credit with mean value of ($\bar{X}$ =8.05) and inadequate credit ($\bar{X}$ =8.47) ranked 2nd and 3rd respectively. This finding is supported by Maxwell (2014) showed that shortage of fund and inadequate access to credit were the most serious constraints affecting rice farmers in Sub-Sahara Africa.

Table 4: Distribution according to constraints associated with post-harvest management (n=160)

Variables	Mean ($\bar{x}$)	Ranking
Inadequate credit facilities	8.47	3rd
Poor funding	7.74	1st
High cost of post-harvest materials	8.52	4th
Unfavorable price due to low income	8.05	2nd
Loss in market value	9.20	6th
Lack of farmers participations	10.54	14th
Insect attacks	9.41	7th
Inadequate market information	10.25	13th
Disease attack	9.09	5th
Transportation challenge	9.42	8th
Inadequate technical knowledge	9.65	9th
Knowledge and skills limitation	10.7	12th
Inadequate infrastructure	9.94	11th
Limited knowledge on post-harvest management	9.65	9th

Degree	15	
Asymptotic significant	0.000***	

Source: Field survey, 2018

CONCLUSION AND RECOMMENDATIONS

It can be concluded that majority of the farmers were male in their active age with low literacy level. Improved income and livelihood of rural household and make food available all through the years were the major perceived of post-harvest management practices on farmers livelihood. The major constraints associated with post-harvest technologies were poor funding and inadequate credit facilities. It is recommended that credit and fund should be made available by governments and non-governmental organization so that farmers' could purchase post-harvest tools needed to enhance value addition to agricultural produce.

24 - 28 Oct., 2022

ABSTRACT

Irish potato production in Nigeria has become a pathway in attaining sustainable food security and agricultural development amidst climate change, covid-19 pandemic and general insecurity., This study examined the factors influencing the level of participation of irish potato farmers of the women-in-agriculture and youth empowerment (WAYE) programme in plateau state, Nigeria. A multi-stage sampling method was employed to select 256 respondents. Data were collected through the use of questionnaires and were subjected to both descriptive and inferential statistics. The results of the analysis showed that the mean farming experience was 10 and 16 years for participating and non-participating farmers, while mean farm size for participating farmers and non- participating farmers were 1.4 and 0.5 ha, respectfully. The result findings reveal that, (55%) and (47%) of the participating farmers and non-participating farmers respectively had secondary school education, which constituted the highest level of educational qualification attained in the study area. Factors influencing the level of participation of irish potato farmers in (WAYE)programme in Plateau State are marital status (3.72, P<0.01), sex (2.25, P<0.05), years of irish potatoes production (9.85, P<0.01), household size (10.92, P< 0.01), awareness of WAYE programme (4.93, P< 0.01), a unit increase in these factors will subsequently influence the level of participation of irish potato farmers in (WAYEP) programme. It was recommended that, Government and Non-Governmental Organizations (NGOs) should create more awareness, provide credit, farm inputs at a subsidized rate and, rural markets should be linked to the urban market through extension agent and media to attract good value for food crops thereby enhancing living standard of the farmers.

Keywords: Factors influencing, level of participation, irish potatoes, WAYE, Plateau State.

INTRODUCTION

Irish potato (*Solanum tubersun*) belongs to the solanaceae family. The (*Solanum tubersun*) is a native of western hemisphere and is believed to have originated somewhere between Mexico and Chile possibly in Andes highlands of Bolivia and Peru. It later spread to other places like England and Ireland where it is predominantly cultivated Irish potato was introduced into Nigeria in the later part of the 19th century and early 20th century by Europeans notably the Tin miners in the Jos Plateau (Mado, 2013). It has a high nutritive value and it is grown for food purposes as well as livestock feed. It is also used for industrial purposes (Okeowo, 1999; Burton, 2000. Irish potato is therefore an important crop not only as food crop, but also its social, economic and environmental relationships with the people who grow, sell and consume it (Alimba and Mgbada, 2003). The empowerment of women and youths that are involved in potato production in Plateau State is therefore crucial to poverty reduction. Women-in-Agriculture and Youth Empowerment (WAYE) programme aims at encouraging Irish potato production through participation of the target group as a strategy to combat rural poverty. Therefore, Women-In-Agriculture Programme (WIA) and Youth-In-Agriculture Programme (YIAP) were both initiated and implemented towards reducing poverty, improvement on the income and raising the level of living of rural dwellers to achieve the first goal of the MDGs (Sharma, 2004)

A number of studies have been carried out by different scholars (Shittu, 2012; Kotter and Petras, 2012; Mado, 2013; Shittu and Panan, 2014) to assess the Women-In-Agriculture and Youth Empowerment (WAYE) programme. Their focus, however, was on women and men and only few Local Government Areas were covered, thus limiting the scope on WAYE programme objectives. Similarly, Ifenkwe (2015), in his study on the impact of WAYE programme, concentrated his efforts more on reproductive health (HIV/AIDS and rehabilitation) while the agricultural component and other aspects of the programme were greatly ignored. What is almost lacking in these studies, however, is any direct involvement of youth in the programme and assessment of impact of the programme on the livelihood of the participating farmers. Therefore, their studies have left a knowledge gap on impact of Women-In-Agriculture and Youth Empowerment programme objectives. It is based on this, that the study made an attempt to find solutions to the following research specific objectives: describes the socio-economic characteristics of irish potato farmers in the study area; determine the socio-economic characteristics and factors influencing the level of participation of irish potato farmers in the programme;

METHODOLOGY

This study was conducted in Plateau State, Nigeria. The State was created in 1976 from the defunct Benue-Plateau State. The name “Plateau State” was derived from the State’s spectacular geographical landscape, with the high lands rising from 1,200 meters above sea level at the low lands to a peak of 1,829 meters above sea level. It is located in Nigeria’s middle belt and lies between latitude $80.24^0\,N$ and longitudes $80.32^0\,E$ and $100.38^0\,E$ ofthe Greenwich Meridian. The State is situated in the tropical zone, with a higher altitude ranges from 12 meters, about 400 feet to a peak of 1829 meters above sea level (Plateau Agricultural Development Programme, 2000). Plateau State has a boundary with Bauchi State to the north-east and Kaduna State to the north-west. It is also bounded to the south-east and south-west by Taraba and Nasarawa States, respectively. The State has a landmass covering nearly 53,585 square kilometers with a population of 3,577, 669 people as per 2006 census (NPC, 2006).

A multi-stage sampling procedure was used to select participating farmers for the study. There are nine (9) irish potatoes producing LGAs in Plateau State and they are given a priority consideration for the programme. In the first stage, all these nine Local Government Areas were used for the study. This was because of their high level of production of potatoes in State. In

the second stage, two villages were randomly selected in each Local Government Area and this was based on the level of participation in the programme as well as in potato production. This gave a total of eighteen (18) villages. During a reconnaissance survey of the study area in 2016, the list of WAYE potato farmers in the chosen villages was compiled with the help of the programme coordinating officers in each LGA and the total number obtained was seven hundred and eleven (711) farmers. Therefore, a total number of two hundred and fifty-six (256) Irish potato farmers were selected randomly using the random number table method.
Both primary data and secondary information was used for the study. The primary data were obtained by the use of well-structured questionnaire and administered to the participating farmers and non-participating farmers by the researcher and to be assisted by well-trained enumerators from the Plateau State Agricultural Development Project (PADPs). The secondary information was obtained as base-line information from WAYE head office and the coordinating liaison offices. Also, information from other related studies were used to support the discussion of results of the findings. Data were analyzed using both descriptive and inferential statistics. Descriptive statistics was used to achieve objectives (i)), while inferential statistics (Tobit model) was used to achieve objective (ii).

RESULTS AND DISCUSSION

Socio-economic Characteristics of Participating and Non-Participating Farmers

The results in Table 1 shows that the mean age of the participating farmers was 38 years while that of the non-participating farmers was 43 years. This means that the participating farmers were younger in age than the non-participating farmers. This is in line with the major objective of WAYE programme to engage both young men and women in agricultural activities with the aim of improving the living conditions of households in the study area. Age has been found to be an important variable in agricultural productivity; hence both categories of the farmers were within the agricultural productive age range of 30-50 years quoted by Food and Agriculture Organization (FAO, 2000; 2008). About 65% and 60% of the participating farmers were married and single while (66%) and (17%) of the non-participating farmers were also married and single respectively. The significance of marital status on agricultural production can be best explained in terms of the supply of family labour (Adewale, 2005).

The result of the study shows, that (67%) and (33%) of the participating farmers were males and females while (77%) and (33%) of the non-participating farmers were males and females respectively. This agrees with the findings of Ayandiji and Adeniyi (2011) who reported that males have dominance potato production activities unlike their female's counterparts because agricultural activities are regarded as labour intensive. The result in Table 1 indicated that majority (63%) of the participating farmers cultivated between 1-1.5ha for Irish potato production while (75%) of non-participating farmers used less than 1ha.This mean farm size cultivated by both categories of farmers was 1.4 ha and 0.5ha respectively. According to Adamu (2019) classification of farm size of 0.1 - 5.9 hectares as small farms implies in this study that all the farmers were small scale farmers. This may be due to the inheritance system of land ownership practiced in the study area which results in land fragmentation among farmers, leading to small farm holdings. The implication of small farm size affects the quantities of Irish potato output produced which in turn affect both the income and food security status of the farmers. The result agrees with the finding of (Nwosu, 2007) who reported that majority (82%) of the farmers acquired the farmland through renting with farm sizes ranging from 0.5-4 hetares. Farming experience in Irish potato, the result in Table 1 indicated that, (67%) and (54%) of both the participating farmers and non-participating farmers had Irish potato farming experience between 1-10 years and 11-20years respectively. Abonge (2012) opined that farming experience is an important factor in determining both the productivity and the production level in farming. The result in Table 1 reveals that (55%) and (47%) of the participating farmers and non-participating farmers had secondary school education, which constituted the largest number of educational qualification attained in the study area. Adewale (2005) had identified literacy among other factors as a variable that positively influenced the use of improved agricultural inputs by farmers. According to the distribution of respondents in Table 5.1. The result shows that majority (77%) and (73%) of the participating and non-participating farmers have a family size of 1-10 members respectively. This finding agrees with that of Ifenkwe (2012) reported that the average family size in Africa is between 8 and 9 people in a household. The implication of large number in a household can be a motivation to the adoption of innovations because members will provide the required family labour for Irish potato production. This will reduce the cost of production.

Tobit analysis examines factors influencing level of participation in WAYE in Plateau State. The results in Table 5 indicates that, commutatively about 17.6% of the variation in level of participation is explained by the variable included in the model. It shows that marital status, years in irish potatoes production, household size, awareness of WAYEP were found to significantly influenced the level of participation at 1%, level of probability whereas only sex, is found significantly influence the level of participation at P<0.05. The implication of this finding is that, the level of participation increases by variation in marital status thus as farmers' marital status changes from single to married, the level of participation equally increases from 1 to 27.6%. It was also observed that as years in Irish potatoes production increase by 1unit, the level of participation increases by 34.7%. Thus more experience farmers tend to participate more than new in-experienced farmers. So also as household size increase by 1 person the level of participation increase by 78%. Nonetheless as level of awareness of the existence of WAYE programme increases by 1 the level of participation is equally increases by 30%. Based on these findings marital status, sex, years in irish potatoe production, household size, and awareness are the major factors influencing farmers' participation in WAYEP. Adamu (2021), factors influencing women farmers'-participation in Development Exchange Centre (DEC) microcredit programme of Kaduna State, Nigeria; shows that level of education (1%), age (1%), house size (5%), credit (10%), farm experience (10%), extension (5%) and years of involvement in cooperative society (5%) were significantly related with level of participation in (DEC) microcredit programme.

CONCLUSION AND RECOMMENDATION

Based on the findings, the study concludes that marital status, sex, years in irish potatoe production, household size, and awareness are the major factors influencing farmers' participation in WAYEP programme. It was recommended that, Government and Non-Governmental Organizations (NGOs) should create more awareness, provide credit, farm inputs a subsidized rate and, rural markets should be linked to the urban market through appropriate information channels such as extension agent and media to attract good value for food crops thereby enhancing living standard of the farmers especially those in the rural area.

ABSTRACT

The study examined food insecurity status among farming households in Abeokuta Agricultural zone, Ogun State, Nigeria. Data were collected from 120 farming households with the aid of questionnaire using multistage sampling techniques. Coping strategy index (CSI) and ordered probit regression analysis were employed for data analysis. Results of the CSI revealed that, only 17.5% of the farming households were food secure while majority (82.5%) of the farming households were food insecure. In terms of the status of food insecurity, most (33.3%) of the food insecure households were moderately food insure, 26.7% were severely food insecure. and 22.5% were mildly food insecure in the study area. Age of household heads, education, marital status, household size, number of dependents, farm size, income, extension contacts, off-farm occupation, non-food expenses and membership of cooperative society were the significant determinants of food insecurity status in the study area. Therefore, policies that encourage youth participation in farming activities, increase educational level, farm size, income, extension contact and cooperative membership should be put in place to reduce food insecurity in the study area.

Keywords: Determinants, food insecurity status, farming households, ordered probit

INTRODUCTION

Food insecurity is the inconsistent access to nutritionally adequate and safe food (Food and Agricultural OrganisationFAO, 2006; Mendy, Asongwe, and Nkongho 2020). The United State Department of Agriculture in 2018 describes food insecurity as a “situation in which regular access to adequate food is limited by lack of money and other necessary resources”. According to World Food Programme (WFP, 2012), half of the world’s hungry are from smallholder farming communities, living on marginal lands that are vulnerable to the effects of climate change, despite smallholder farmers producing nearly 90% of the continent’s total food output in Africa (Ojuederie and Ogunsola, 2017). In 2014, the Federal Ministry of Agriculture of Nigeria estimated that 65% of the population is food insecure despite having majority of all employments dependent on agriculture (Ogunpaimo,Oyetunde-Usman and Surajudeen 2021). FAO (2022) reported that about 19.4 million people will face food crisis between June and August, 2022 in Nigeria. According to the report, food crisis will affect 21 states and FCT including, 416,000 Internally Displayed Persons (IDPs). The report identified insecurity especially insurgency in the North-east and North-central states, climate change, high inflation in soaring food commodity prices, reduction in household income due to the long-term effect of COVID-19 pandemic and displacement arising from conflict and armed banditry as factors that will contribute to the hunger crisis.

Recent study by Ibukun and Adebayo (2021) reported that only 12% of the households in Nigeria were food secure, 5% were mildly food insecure and 24% were moderately food insecure while majority of the households (58%) experienced severe food insecurity during the COVID -19 pandemic. Their result from the ordered probit regression identified education, income and wealth status as the main determinants of food security in the country.
Attaining and sustaining food security for all of humanity seems to be an overwhelming global challenge in the face of population growth, environmental degradation and accelerating climate change. Against this backdrop, this study seeks to examine the determinants of food insecurity status among farming households in the study area. The specific objectives were to determine the food insecurity status of the farming households and analyse the factors influencing food insecurity status of the farming households in the study area.

METHODOLOGY

Study Area: The study was carried out in Ogun State, Nigeria. Ogun State is a state in southwestern Nigeria, created in February 3, 1976. Abeokuta is its headquarters. It is bounded in the west by Republic of Benin, south by Lagos State and the Atlantic Ocean, east by Ondo State and in the North by Oyo and Osun States. Ogun State is located on longitude 3^0 35^1 00^{11}E and latitude 7^0 00^1 00^{11}N, and covers approximately an area of 16,980.55 square kilometers and a population of 5,217700,140 people (NBS, 2019). The major food crop grown in the study area include, among others, cassava, yam, cocoyam, plantain, maize and vegetable while cocoa is the major permanent crop. The natural vegetation in the study area is rain forest.

Sampling Procedure and Data Collection: Multistage sampling technique was used to select 120 respondents for the study. The first stage involved the purposive selection of Abeokuta Agricultural zone from the four Agricultural zones in the state. The second stage involved the purposive selection of two Local Government Areas from the zone because of the predominance of farming activities in the areas. In the third stage, simple random sampling technique was used to select 2 communities from each of the LGAs making a total of 4 communities. The fourth stage involved random selection of 30 farming households from each of the selected communities making a total of 120 farming households for the study. Data on socioeconomic and food insecurity characteristics of the selected households were collected with the aid of pre-tested questionnaire and focus group discussion.

Analytical Techniques: Coping Strategy Index (CSI): The CARE International/World Food Programme Household Coping Strategy Index (CSI) was used to measure food insecurity status and identified coping strategies adopted by the farming households. The CSI index was calculated by multiplying the frequency and consensus severity of using a set of eleven coping strategies against food shortage related shocks. The consensus ranking of coping strategies was determined using a focus group discussion. The higher the score the higher the probability of a household level of food insecurity (Maxwell Watkins, Wheeler and Collins (2003); Hussein, Segun and Hassan (2016); Ojo Akin-Olagunju, Yusuf and Yusuf, (2019))

Ordered Probit Regression Model: This was used to assess the factors that influence the food insecurity status of the farming households based on the results of the CSI scores. Following Hussein *et al.,* (2016), the food insecurity status is grouped and ranked based on the level of the CSI score into four ordered values (j = 0, 1, 2, 3). However, these observed values are assumed to derive from some unobservable latent variable Yi*, which is expressed as:

$Yi = Xi\beta + \varepsilon i$ (1)

Yi is the hypothesised predicators of food insecurity, βs is a vector of parameters to be estimated, and ε is an error term which is assumed to be normally distributed (Greene, 2003). The values for the observed variable Yi are assumed to be related to the latent variable Yi* in the following manner: $Y = 0$ = food secure if $Y^* < \mu$ o where $\mu = 0$; $Y = 1$ = less food insecure if $0 \leq Y^* < \mu 1$; $Y = 2$ = moderately food insecure if $\mu 1 \leq Y^* < \mu 2$; $Y = 3$ = severely food insecure if $\mu 2 \leq Y^* < \mu 3$; μ means the unknown threshold parameters. The CSI rank represents the dependent variable; Xi's are the independent variables which include: X_1= Age of household head (years); X_2 = Education (years); X_3 = Marital status (married=1, otherwise=0); X_4= Household size (number of persons); X_5 =Size of dependents (number of persons); X_6 = Farm size (ha); X_7 = Income (₦); X_8 = Access to extension services (dummy), X_9 = Off-farm occupation (dummy); X_{10} =Non-food expenses (dummy); X_{11} = membership of cooperative association (dummy).

RESULTS AND DISCUSSION

Food insecurity status among farming households in the study area

Result in Table 1 reveals that majority (82.5%) of the farming households were food insecure. In terms of the status of food insecurity, a larger proportion (33.3%)of the food insecure households were moderately food insure followed by the severely (26.7%) and mildly (22.5%) food insecure households respectively. Only 17.5% of the farming households were food secure in the study area. This is an indication that food insecurity situation of the farming households was hazardous. According to FAO (2008) and Sileshi, Kadigi, Mutabazi and Sieber, (2019), these households may need special attention in terms of direct food assistance and access to productive resources in form of subsidy which will enable them to improve their productive capacity and help them escape from food insecurity in the near future. This result agrees with the findings of Ayoade and Adetunbi (2013) that food insecurity was about65% among farming households in south western Nigeria. In the same vein, Hussein *et al.,* (2016) reported that only 27% of the households in Katsina State were food secure, 44% were mildly food insecure 17% were moderately food insecure while 12% experienced severe food insecurity. Ibukun and Adebayo (2021) also observed that 58% of the households in Nigeria were severely food insecure during the COVID -19 pandemic.

Table 1: Food insecurity status among farming households in the study area

Ordered value	Food insecurity status	CSI range	Frequency	Percentage
F = 0	Food secure	0	21	17.5
F = 1	Mildly food insecure	1-15	27	22.5
F = 2	Moderately food insecure	16-30	40	33.3
F = 3	Severely food insecure	>30	32	26.7

Determinants of food insecurity status (FIS) among farming households in the study area

Result of the ordered probit model on determinants of food insecurity status among the farming households in the study area is presented in Table 2. The overall model is highly significant (p<0.01) with log likelihood of -125.272 implying that the model provides a good fit for the data. The estimated cut-off points (μ) satisfy the conditions that μ1 < μ2 < μ3. This implies that these categories are ranked in an ordered way. The first cut-off point (Y=0 for "food secure group") was used as a mark for the purpose of comparison. Only the significant variables are presented in the table and marginal effects are used for explanation since estimated coefficients from an ordered logit model are difficult to interpret because they are in log-odds units. The result reveals that age of the household heads had a negative significant relationship with FIS in the mildly FIS group and positive significant relationship with moderately FIS group at 5% alpha levels. This implies that a unit increase in the age of the household heads decreases the probability of farming households being mildly food insecure while it increases the probability of being moderately food insecure in the study area. This result agrees with the report of Opiyo, Wasonga and Nyagito (2014) that older farmers are relatively less productive in farming communities and thus more susceptible to caprice of economic distress. Education was negative and significant with moderately FIS group. The implies that as the level of education of the household increases by one year, the likelihood of being moderately food insecure decreases by 8.2% in the study area. This is in tandem with the findings of Ogunniyi, Omotoso, Salman, Omotayo, Olagunju and Aremu (2021) that higher level of educational attainment provides higher levels of welfare such as food security for the households. Marital status of the household heads negatively influences the probability of households being mildly ($p<0.05$) food insecure. This implies that households headed by married farmers are less likely to be mildly food insecure in the study area. Result on the household size reveals that an additional person to the household will increase the tendency of being moderately food insecure by 3.3% and being severely food insecure by 8.1%.

Also, the size of dependents positively influences the probability of being moderately and severely susceptible to food insecurity at 5% alpha levels respectively in the study area. This implies that the probability of being moderately or severely food insecure increases with the size of dependents in the study area. This result concurs with the report of Ojo *et al.,* (2019) that larger proportion of household resources are directed to dependants who contribute little or nothing towards household welfare leading to food insecurity. The coefficient of farm size positively influences the likelihood of households being mildly food insecure ($p<0.01$) and negatively influences the probability of being moderately food insecure ($p<0.05$). This implies that a unit increase in farm size will increase the probability of households becoming mildly food insecure while it decreases the probability of becoming moderately food insecure in the study area. This negative relationship is similar to the findings of Johnson and Awoseyila (2020) that increase in farm size reduces vulnerability to food insecurity in Ondo state. Monthly income ($p<0.01$) of the households had an inverse significant relationship with mildly and moderately food insecure category. This implies that as the monthly income increases, the likelihood of households being mildly and moderately food insecure decreases in the study area. This result is in agreement with Akukwe (2020) that income is a significant factor in reducing food insecurity. The probability of households becoming severely food insecure decreases with extension contact at 5% alpha levels. This is because access to extension officers exposes the farmers to innovation and good agricultural practices which could increase their output and reduce food insecurity. Furthermore, engagement in off-farm occupation will cause 1.4% increase in probability of the household being mildly vulnerable, 14.1% and 29.3%decrease in the probability of the household being moderately and severely food insecure in the study area. Moreover, a unit increase in non-food expenses was found to increase the tendency of households becoming both mildly and severely food insecure at 10% and 5% alpha levels respectively. This is in concordance with the findings of Ojo *et al.*, (2019) that spending on non-food items reduces the amount of resources available to combat food insecurity. Finally, membership of cooperative society had an inverse relationship with severely food insecure category. This implies that farming household heads who are members of cooperative society are less likely to be severely food insecure in the study area.

CONCLUSION

The study investigated food insecurity status and its determinants among farming households in Abeokuta Agricultural zone, Ogun State. Findings revealed that the farming households were found to be fairly distributed across the food insecurity statuses in the study area. While a larger proportion of the households were moderately food insecure, others were either severely or mildly food insecure. Based on the findings, the study recommends that policies that encourages youth participation in farming activities, increase educational level, farm size, income, Extension contact and cooperative membership should be put in place to reduce food insecurity in the study area.

Agricultural Society of Nigeria
24 - 28 Oct., 2022

ABSTRACT:

One Hundred and fifty (150) participating household in Fadama III project and fifty (50) non-participating households were randomly selected for this study. Data were collected by well-structural and pre-tested questionnaire and analyzed through the use of descriptive and inferential statistical tools. The Double-Different (DD) Estimator was used to compare changes in outcome measures. Findings revealed that the average of respondents was 50 years, while 53.33% and 60% respectively were males. About 52% and 56% respectively were married; with 20.67% and 16% possessing no formal education respectively. 86.67% of the respondents have household sizes ranging from 5-12 members. The average per capita income of the Fadama III user households before project implementation was ₦126,000; while that of the Fadama III non-beneficiaries was ₦127,665. On the average, the real income of Fadama III beneficiaries increased from₦126,000-₦175,000; as a result of participation in the project. By contrast however, average real income of Fadama III non-beneficiaries increased from ₦127,665 –₦163,000. The mean increase in income for participants in Fadama III was significantly different at 1% level. It is therefore recommended that appropriate policy to ensure proper education of rural populace be advocated.

INTRODUCTION:

Nigeria is a country blessed with potentially good and water resources required for sustainable agricultural development. It is a known fact that many government agricultural intervention development programmes in Nigeria have not had lasting impact on agricultural development and many have not yielded the expected results of sustained increase in food production (Omonona, 2009). Agricultural methods have remained undeveloped, despite many years of efforts on technology generation and transfer in Nigeria.

The agricultural sector is not just only the most important non-oil economic activity in Nigeria, but also the single largest employer of labour force (about 70% according to NBS, 2007). Thus, the agricultural sector is often seen as very important in reducing poverty (Agenor et al, 2004). Agriculture and rural development in Nigeria has been neglected for long. However, actions to address the cause of rural poverty often represent the key components of this rural sector strategy (Nwajiuba, 2013). Usually, there is absence of infrastructures (such as water, electricity, and motor able roads) which improve the quality of life. The rural areas are saddled with low purchasing power. Indeed, the ongoing neglect of rural areas continues to widen the gaps between the rural and urban areas with regards to the levels of social and economic opportunities, physical development and available infrastructural facilities (Olayiwola and Adeleye, 2005). In addition, rural financial support are scarce and most rural finance policies implemented previously have hindered, rather than assisted in improving agricultural production (Simonyan and Omolehin, 2012).

However, in an attempt to alleviate poverty among the rural Nigerians and also to increase the incomes and productivity of the rural inhabitants, an approach of meeting up with millennium development goals (MDGs) of food sufficiency and poverty eradication; the Federal Government of Nigeria embarked on several projects aimed at improving the income and productivity of the small-scale rural farmers. These projects have not substantially generated increased income or improve the standard of living of the rural poor farmers in Nigeria. It is to be noted that since independence, the Federal Government of Nigeria in conjunction with the United Nations and other developed agencies, initiated Agriculture Economic Devolvement related projects for the farmers of which the National Fadama Development Programme is one. Its main focus being to finance the development of Fadama lands by introducing small-scale irrigation schemes in states, with Fadama development potentials (Yunana et al, 2013). This was the first phase of the project which was subsequently followed by the second phase:- called Fadama II.

Fadama II implemented an innovative Local Development Planning (LDP) tool and building on the success of the community-Driven Development mechanisms initiated in the first Fadama project. Subsequently, following the success recorded in Fadama II project, the World Bank in conjunction with the Federal Government introduced the Fadama III project. Fadama III is a tripartite funded intervention by the World Bank (1996), the Federal Government of Nigeria and participating states with objectives targeted towards poverty reduction.

Fadama II project came fully into operation from 2009-2013 as a follow-up to the Fadama II project which was assessed to have impacted on the lives of the rural farmers, raising their incomes by 63%. This project just like Fadama II took the Community Driven Development Approach which places beneficiaries in the driver’s seat where local community members under the umbrella of Fadama Community Associations (FCA) and Fadama Users Groups (FUGs)to oversee the design and implementation of the project and are empowered through skills and capacity building to improve their livelihoods by increasing income generating activities.

Fadama III project established standardized procedures and steps to guide the local people on how to take part in the decision making process. It established platforms for participation, such as local consultations meetings to indentify and select the needed infrastructure to be funded by the project. Beneficiaries (participants) were trained to identify the needed infrastructure, execute and manage small-scale development projects in their communities. Community people, through the FUGs and the FCAs were designed to be the executing agencies of local development projects. Capacity building activities were conducted to ensure that they have the ability to manage the different aspects of the project implementation; including financial management, procurement, management and quality control at a level acceptable to the project. Therefore, this study assesses the impact of Fadama III project on the income of beneficiary farmers in Ezza North Local Government Area of Ebonyi State. Specifically, the study described the socio-economic characteristics of Fadama III beneficiaries and non-beneficiaries groups; ascertained the income level of the participants and non-participants before and after intervention programme, determined the effects of socio-economic characteristics of the

Fadama III, Users on their income and, identify the constraints associated with the FADAMA III farming beneficiaries of the project.

METHODOLOGY:

Study Area:

The Study was carried out in Ezza North Local Government Area of Ebonyi State, Nigeria. It lies between latitudes $5^0 41$ and $6^0 45$ North of the equator, and longitude $7^0 31$ and $7^0 43$ East of the Greenish Meridian. It has headquarter at Ebiaji and it is one of the thirteen local Government Area that makes up Ebonyi State.

It has a annual rainfall range of between 1800mm-2000mm, and an annual temperature range of between 28^0-32^0C; and with a relative humidity of 65%. It has a population of 145,619 persons and a land area of $305km^2$;most of which are fertile (NPC, 2006). The main seasons experienced in the area are dry season which starts from April –October, with a short break normally in the month of August, called “August break”. It is inhabitants are mostly farmers, and the common crops grown include maize, groundnut, plantain, banana, cassava, fruits and vegetables. Other economic activities engaged in are artisans, hunting, fishing, vulcanizing, tailoring, fashion and designing, etc.

Sampling Procedure:

A multi-stage random sampling technique was used to select communities, villages and the respondents in Ezza North Local Government Area of Ebonyi State. Firstly, five (5) communities were randomly selected from the fourteen (14) communities that make up the study area; secondly, three (3) villages were also randomly selected from each community already chosen in stage 1. This gave a total of 15 villages. In Stage III, ten (10) households were randomly selected from each village chosen in stage II. This gave a total of one hundred and fifty (150) participating households. In addition, ten (10) non-participating households were randomly selected from each of the communities chosen in stage I; thereby giving a total of fifty (50) non-participating households that were used for the study.

Analytical Techniques:

The data generated were analyzed using descriptive and inferential statistical tools. The descriptive tools used were means, percentages and frequency distribution tables. This was used for objectives (i) and (iv).

Model Specification:

The Double-Difference (Difference in-Difference) Method:

The Double-difference analytical tool is a quantitative method often used to estimate and compare change in outcome, both pre and post program for participants and non-participants (Chen et, al, 2006). In order to use the estimation in question, there must be information on both participants and non-participants, and all individuals must be observed, both before and after the programme (Verner and Verner, 2006). The Double-Difference method which is also known as Difference-in-Difference Method (Duflo et al, 2004), has the formula:-

$$DD = (Yp_i - Yp_0) - (YnP_1 - YnP_0)$$

Where:

Yp_1= Outcome (i.e income) of beneficiaries after the project started.

Yp_o = Outcome of beneficiaries before the project started

Ynp_1 = Outcome of non- beneficiaries after project started;

Ynp_o = Outcome of non-beneficiaries before the project started.

The advantage of the Double-Difference Estimator is that it nets out the effects of any additive factors (whether observable or unobservable) that have fixed impacts on the outcome indicator (such as the abilities of the farmers, or the inherent quality of natural resources) or that reflects common trends affecting project participants and non-participants equally, such as changes in prices or whether (Ravallion, 2005).

In principle, the Double-Difference Approach can be used to assess project impacts without using any other statistical tools (such as the propensity Score Matching (PSM) method as applied by (Philip et al, 2009) as it will produce unbiased estimates of impact, as long as these assumptions hold, hence the adoption of this method in this study for estimating the project impact among the Fadama III beneficiaries in Ezza North Local Government Area of Ebonyi State, Nigeria.

Multiple Regression Model:

This was used to determine the effects of socio-economic characteristics of the FADAMA III users on their income. Linear, semi-log, double-log and exponential functional forms were employed, fitted and tried, and on the basis of economic theory, statistical and econometric criteria; linear functional form was chosen as the lead equation.. The explicit form of the model is presented below:

$Y= b_0tb_1X_1tb_2x_2+b_3x_3+b_4x_4+b_5x_5+b_6x_6+b_7x_7\ldots\ldots b_nx_n+e$

Where:

Y= income of beneficiaries are non-beneficiaries before and after the project.

X_1= Age of the participants and non-participants in years

X_2 = Gender of the participants and non- participants in (male = 1, otherwise = 0)

X_3 = Marital status of the participants and non-participants (married = 1; otherwise = 0)

X_4 = Educational attainment in years

X_5 = Household size in numbers

X_6 = Farm size in hectares

X_7 = Extension contact (contact =1; otherwise =0)

X_8 = Fadama III access (Access = 1, otherwise =0)

b_0 = Constant term

b_i-b_8 = Coefficients to be estimated ei= Error term

RESULTS AND DISCUSSION:

Socio-economic characteristics of respondents

	Benefiting Households		Non – Benefiting Households	
Variables	Frequency	Percentage (%)	Frequency	Percentage
Age in Years:

Source: Computed from the field survey data, 2020.

Analysis of the socio-economic variables of the respondents (Table 1) showed that majority (43.33%) and (50%) of both the Fadama III beneficiaries and Non-beneficiaries were still in their youths. This portends that the youths were much involved in Fadama III project in the study area. This dominance of the middle-aged people in the programme is in accordance with the work of Agwu and Edun (2007) in Ilaro Agriculture zone of Ogun State, Nigeria. Of the 200 households that were involved in the study 80 and 30 of them were males; while 70 and 20 were females. This indicated dominance of male folks in Fadama III project activities in the area studied. A close look at Table I also revealed that 20.67% of the beneficiaries and 16% of non-beneficiaries of the Fadama III project had no formal education. This has great implication on the implementation of the Fadama III project as it might be seen as mere embodiment of paper works. It is also a known fact the education is a key factor in reduction of rural poverty in general; whether the households are headed by men or women (Ike, 2012). Girei et al (2013) also are of the opinion that education has been a factor in the adoption of modern technology innovations.

Large household sizes have been noted to have correlation with food insecurity and poverty; especially when the household head is engaged in agriculture as the main source of livelihood and income (Ike and Uzokwe, 2011). Hence, there is need for efforts to further sensitization of the populace on the need to control births and all cultural beliefs that tend to lead to over-population should be removed through proper advocacy.

Most of the respondents (52% and 56%) of the participating and non-participating households in the Fadama III project are married. This dominance by married people had earlier been reported by (Ike 2012).

The same Table 1 equally revealed that participant and non-participant used some of the provisions of Fadama III project to expand their farm sizes and this agress with the findings of Olaolu et al, (2012).

Table 2(a): Income level of Respondent Households before the inception of Fadama III project.

	Fadama III Beneficiaries		Non – Fadama III Beneficiaries

Source: Computed from the field survey data, 2020.

Considering the income beneficiaries before and after the inception of Fadama III project (Table 2a and Table 2b) about 38.89%/27.68% of the beneficiaries increased their income at least 10% in the first year of Fadama III operations in the area. This finding is the tandem with that of Yunana et al, (2013) who established the fact that Fadama III project had a positive impact on income and wealth of participants in FCT, and also Iwala (2014) found a positive economic impact of Fadama III in small scale community – owned infrastructure on beneficiaries in Ondo State, Nigeria.

The result of the estimated parameters on the effects of socio-economic characteristic of FADAMA III users on their income is presented in Table 3. Of the four functional forms that were fitted and tried with the production function model, the linear functional form was chosen as the lead equation based on the established economic theory.

Table 3: Regression Estimate of the Effects of Socio-economic characteristic of the FADAMA III users on their income.

*;** and *** simply implies significant at 10%5% and 1% level respectively.

The coefficients for education, household sizes, farm size, extension contact and Fadama III Access had direct relationship with the Fadama III users income. However, they were all significant at varied probability levels. In fact, these were all expected and are in accordance with a priori expectations.

Table 4: Constraints associated with the Fadama III farming beneficiaries of the project.

Constraints	Frequency	Percentage	Ranking
Inadequate improved seeds	90	60.00	2nd
High cost and unavailability of farm inputs e.g. fertilizers and agro-chemicals	95	63.33	1st
Clashes with pastorialist	52	34.67	10th
Political and economic instability	68	45.33	6th
Dishonesty and corruption among the Fadama officials	65	43.33	7th
Untimely disbursement of farm inputs	85	56.67	3rd
Pests and diseases infestation	45	30.00	11th
Inadequate power supply	58	38.67	9th
Poor communication network	60	40.00	8th

Poor access to extension services	75	50.00	5th
Poor supporting infrastructure	80	53.33	4th

Source: Computed from the field survey data, 2020.
Multiple responses

Table 4 showcased the main constraints highlighted by the Fadama III beneficiaries in the study area. The average percentage of each constraint across the study area were computed and ranked in the Table. Those factors are shown in Table 4 with average constraints above 50% were the major challenges that needed to be addressed. The remaining problems that scores less than 50% were regarded as minor or non-effective challenges in the execution of FADAMA III Project.

The high cost and unavailability of farm inputs such as agrochemicals and fertilizers in Nigeria; especially the inorganic fertilizers are variously reported among literatures (IRRI, 2015; Ume et al, 2018; Udemezue, 2019) could be correlated to the removal of "Fertilizer Subsidy Programme" by the Federal Government; thereby exposing the farmers to procure this all important resource from the black market to the detriment of their farm profits.

CONCLUSION:

It has been established that Fadama III project impacted positively on the income of project participants. However, it is a known fact that Ebonyi State did not participate Fadama III project, and so the only control group applicable here is the Non- Fadama III communities; not receiving support from the Fadama III project. The study recommends that the project should entrench proper measures towards ensuring proper education of the rural populace.

ABSTRACT

The study assessed the comparison analysis of gender participation in fish production in Ikorodu local government Lagos state, Nigeria. Purposive simple random sampling technique was used to select the fish farmers through well-structured questionnaires. Both descriptive and inferential statistics were used to analyze the data collected. Result show that catfish farming were male dominated (male=96%, female =40%) mostly married, educated, young with large household size. The result of the Liker scale revealed that 97% of the male fish farmers participated in fish pre-production and production activities, while only 1.47% of the female fish farmers sometimes participated. But 95% of the female fish farmers participated in both processing and marketing activities while less than 30% of male fish farmers sometimes participated. Both male and female fish farmers faced with various challenges but more than 90% of the female fish farmers faced the problem of poor water supply especially during the dry season follow by inadequate capital and high rate of fish mortality when compare to male counterpart. In view of the above findings the study recommends that fish farm inputs like feeds, fingerings and credit facilities should be made available and affordable to both genders on time to enhance improved production. Female fish farmers should be trained on fish management to reduce high rate of fish mortality.
Key words: Gender participation, catfish farming, female fish farmers, male fish farmers, high fish mortality rate

INTRODUCTION

Fish farming, a branch of aquaculture is defined as the raising, cultivation, propagation and marketing of fish such as catfish, tilapia and ornamental fish for food security, income generation and livelihood activity (Umunna, 2020). Fish farming provides important services including supporting nutritional wellbeing, provide feed stocks for the industrial sector, increasing export opportunities, employment opportunity suitable for male and female gender in the society (Dagtekin *et*, *al.*, 2007).

Gender concerns in the fishery sector involve the roles and responsibilities assume to male and female as well as their level of participation in fish farming activities (Adam *et*, *al.*, 2021).

While men participate mostly in activities such as selection and supplying of fingerlings and other inputs (fish feeds, drugs), pond construction and liming, stocking and Weighing of fish, women participate mostly in fish feeding, processors, and marketing activities (Adeoye *et, al.*, 2020). Women participation in fish production activities cannot be over emphasized. Subasinghe *et, a*l., (2021) claim that despite women major role in fish farming production as well as their involvement in small-scale fisheries value chains, yet most women lack information on fish farming, lack access to capital and access to land and this has limited their participation. Thus, this study aims to comparatively analyze the gender participation in fish production in Ikorodu local government Lagos State, Nigeria.

RESEARCH METHODOLOGY

This study was carried out in Ikorodu Local Government area of Lagos state, Nigeria. The respondents for the study were catfish farmers in the Fish Farm Estate Ikorodu. The State is very rich in different forms of aquatic ecological zones that support different varieties of fish species and aquatic organisms; thereby providing productive fishing opportunities for fishers (Adesoji and Kerere, 2013). A two stage sampling techniques was employed in this study. First stage involved purposive selection of Ikorodu Local Government area for the study. This is because of the predominant fish farming activities in the area. Second stage involves random selection of 140 fish farmers from the list of registered fish farmers in the Fish Farm Estate Ikorodu area. These were stratified into male and female fish farmers. Therefore, a total number of 136 copies of duly completed questionnaire were collected of which 96 of the fish farmers were males and 40 were females. And these were used for the final analysis. This accounts for a true representation of the population since they do not have equal numbers of farmers in the area. Information elicited from the respondents are socio-economic characteristics (age, educational status, household size, marital status, years of fish farming experience etc), participation levels in the production activities and constraints encountered in fish farming among others. Both descriptive and inferential statistics were used to analyze the data collected. Participation level was captured with Likert-Type Scale using 3 points comprising of always, sometimes and rarely.

RESULT AND DISCUSSION:

The result of the socio-economic characteristics, as presented in table 1, indicates that majority of the fish farmers were males (70.59%) with only 29.41% female this shows that fish farming activities are gender sensitive.This implies that men are more involved in fish farming than the female counterpart which might be attributed to the common believe that fish farming activities are energy-sapping and time-consuming nature in which women may not be able to go through the rigor. The result is in agreement with the findings of Ajala *et, al.,* (2017). Majority of fish farmers were young and energetic and in their productive age with the average age of 42 years across the data. This was similar to Siyanbola *et, al.*, (2020) that fish farmers were still young, agile and could easily adapt to new techniques that could enhance their productivity. It was also revealed that 80.21% and 77.5% of the male and female fish farmers respectively were married. Furthermore, male fish farmers have higher literacy level when compared with the female fish farmers. While 54.16% of the male fish farmers had secondary education only 37.5% of the female had. This was in line with Siyanbola *et, al.,* (2020) that male fish farmers were more educated than female counterparts in Lagos state, Nigeria. The average household size for the male fish farmer was 6 while that of the female fish farmer is 5. More than 60% of the fish farmers had household size between 4-6 persons. The result is similar to the findings of Adebesin (2011) that most fish farmers usually have large family size. In addition, the average fish farming experience for both gender were 13 years which implies that majority of the fish farmers have been in fishery operation for a long time. Afodu *et,al.*, (2016) reported that the higher the years of farming experience of a farmers the higher the level of his productivity and efficiency. This implies that fish farming production in the area has a greater potential to be continued, sustained and expand in scope and reap scale economies in the future.

Table 1: Description of the socio-economic characteristics of the respondents

Source: field survey, 2022

Table 2 shows the comparative analysis of gender participation in different fish farming activities in the study area. These activities were classified into four groups such as pre-production, production, processing and marketing. Under the pre-production activities, it was revealed that male gender had highest participation level in almost the activities except for feed formulation activities. Male gender also had the highest participation level in production activities except the fish feeding activities in which female gender sometime participated.

Furthermore, female gender had the highest participation level on processing activities except the weighing of fish in which most women were rarely participated. It was also revealed that female gender had the highest participation level in marketing activities while many of the male gender rarely participated in the marketing activities in the study area. This shows that female fish farmers participated in the important aspect (marketing)of the production. This implies that female fish farmers participated more than male counterpart in financial aspect of fish farming.

Table 2: Level of gender participation at different activities of fish farming production

Activities	Gender Participation level					
	Male (%)			**Female (%)**		
	Always	**Sometimes**	**Rarely**	**Always**	**Sometimes**	**Rarely**
Pre-production activities						
Selection of fish	96.32	3.68	-	1.47	1.47	97.06
Pond Construction	99.26	0.74	-	1.47	1.47	97.06

Production activities						
Feeding of fish	97.79	1.47	0.74	2.21	97.79	-
Stocking of fish	98.53	1.47	-	0.74	13.97	85.29
Treating of fish	97.79	1.47	0.74	1.47	10.29	88.24
weeding of pond	98.53	1.47	-	1.47	0.74	97.79
Harvesting of fish	98.53	1.47	-	1.47	0.74	97.79
Processing of fish						
Weighing of fish	97.79	2.21	-	1.48	12.59	85.93
Smoking of fish	30.53	21.47	48.00	71.48	0.74	27.78
Salting of fish	44.85	25.15	30.00	91.48	0.74	7.78
Drying of fish	26.67	3.85	69.48	97.48	0.74	1.78
Storage of fish	68.53	1.47	30.00	81.48	9.74	8.78

Marketing of fish						
Wholesaling	20.47	10.58	68.95	95.59	4.41	-
Retailing	2.21	5.15	92.65	95.59	4.41	-
Exporting	26.67	3.85	69.48	95.59	4.41	-

Table 3 revealed that both gender in the study area were faced with various challenges ranges from inadequate capital (92.71%), Poor water supply during dry season (92.18%), Poor marketing system (91.97%), High cost of labour (91.71%) and High fish mortality rate (90.44%). Higher percentage of the female fish farmers faced the problem of poor water supply especially during the dry season follow by inadequate capital, inadequate credit/loan, and high rate of fish mortality and high cost of labour. This implies that female fish farmers were at less advantage in production. This result is in agreement with Abdul *et,al.,* (2017) that women were found to face many of problems while participation in fish farming activities.

Table 3: Constrain to gender participation in fish farming

Constraints	Male (%)	Female (%)	Pooled (%)
	Percentage	Percentage	Percentage
High cost of fingerlings	83.33	82.50	83.09
Inadequate credit/loan	85.42	90.50	86.76
Poor marketing	89.58	87.50	91.97
Inadequate capital	90.63	91.30	92.71
High fish mortality rate	90.63	90.44	90.44
Insufficient Land/space	82.29	90.00	84.56
Poor water supply during dry season	85.00	94.50	92.18
Poor fish health service	71.88	82.50	75.00
Insufficient information on fish farming	75.00	80.00	76.47
High cost of feed	85.42	75.00	75.00
High cost of labour	89.59	90.41	91.71

Source: field survey, 2022

CONCLUSION AND RECOMMENDATIONS

The findings of this study show that catfish farming is male dominated activities which imply that fish farming activities are gender sensitive. Majority were married, educated, and were in their active age which also implies that fish farming production in the area has a great potential to be continued, sustained and expand in scope and reap scale economies in the future. It is clear that male fish farmers participated mostly in fish pre-production and production activities, while female always participated in marketing activities, this implies that female participated mostly in financial aspect of fish production. Both male and female fish farmers faced with various challenges but higher percentage of the female fish farmers faced the problem of poor water supply follow by inadequate capital, high mortality rate more than the male counterpart which implies that female fish farmers were at less advantage in production. The study recommends that fish farm inputs like feeds, fingerings should be made available and affordable to both genders on time to enhance improved production. Female fish farmers should be trained on fish management to reduce high fish mortality rate. Also Government should provide grants and credit access most especially to female fish farmers as incentives to expand their scope of operations and encourage better female participation in catfish farming production in Nigeria. Owing to the fact that majority of the female participated more in the financial aspect of fish production, they should be involved in policy formulation and decision-making relevant to catfish production in Nigeria.

ABSTRACT

This paper examines the major factors constraining the adoption of cocoyam value added innovations among rural women in Abia State, Nigeria. Multistage sampling techniques were used in selecting 120 rural women for the study. Descriptive statistics was used for data analysis while Ordinary Least Squares regression model was used to test the hypothesis. The results showed that majority (78% and 56%) of the women were aware of cocoyam soup thickener and cocoyam flour respectively. However, only 48% of them were aware of cocoyam chips. There was low level (2.18) of adoption of cocoyam value added innovations among the women. Factors constraining the adoption of cocoyam value added innovations as revealed by the study include lack of fund, insufficient knowledge of practices, lack of equipment and lack of follow-up training. Furthermore, the study showed that there was a significant relationship between identified constraints and adoption at 5% (2.39**) level of significance. These findings suggest that there is an urgent need for researchers, policy makers and administrators of the extension service to consider these constraints seriously so as to overcome them to increase the adoption of cocoyam value added innovations among women in Abia state.

Keywords: Cocoyam value added innovations, Rural women, Adoption, Constraints

INTRODUCTION

In Nigeria, cocoyam is used to describe both taro (*Colocasia esculenta*) and tannia (*Xanthosoma sagitifolum*). Cocoyam is a perennial crop cultivated as annuals, for mostly their edible starchy storage underground stems called corms and cormels (Igbozulike, 2015). It is an economic crop that is not only used as food but also as an agro-industrial raw material in pharmaceutical, confectionery, and livestock industries (Kundu *et al*., 2012).

With around 2.86 metric tonnes produced in 2019 (FAOSTAT, 2021), Nigeria is the world's top producer of cocoyam, making up more than 27% of global production (FAOSTAT, 2021). After yam and cassava, it is the third most significant root and tuber crop grown and consumed in Nigeria (NRCRI, 2015). Cocoyam, which belongs to the Araceae family, is one of the six most significant root and tuber crops in the world (Ekanem and Osuji, 2006).

Cocoyam is rich in digestive starch, good quality protein, vitamin C, thiamine, riboflavin, niacin and high content of protein and essential amino acids (Lewu et al., 2009). It can be processed into flour, cake, crisp, and chip (Chukwu *et al*. 2012; Enwelu *et al*., 2014). The flour can be used for soups, biscuits, bread and puddings. The peels can also be used as feed for ruminants (Apata and Babalola, 2012). It has low glycemic index which is why it is highly recommended for diabetics. In terms of nutrition, it is better than most crops because of its digestibility, crude protein content and essential minerals like Calcium, Magnesium and Phosphorous (Green, 2003).

Value addition boosts production, decreases spoilage in storage, and expands the categories of consumers who consume agricultural products (Chukwu et al, 2015). The preference for the production and consumption of other crops, which has resulted in its neglect and under-utilization, is one of the main factors affecting value addition in cocoyam (Utomakili and Agunbiade (2013). In addition, Okorji et al. (2013) asserted that good processing, preservation, and value addition technologies are out of the reach of rural women, which hinders effective value addition to cocoyam. Furthermore, cocoyam is a bulky and, perishable commodity that is exceedingly expensive to transport without any initial processing and value addition (Aniedu and Aniedu, 2015).

As a result, National Root Crops Research Institute (NRCRI), Umudike, which has the national mandate to undertake research into root and tuber crops, has developed several value-added (processing) technologies of root and tuber crops in an effort to reduce their perishability and add value to these crops. Products like cocoyam flour and snacks have been developed and widely disseminated to women's groups around the country. This paper therefore sought to investigate the level of adoption and factors constraining the adoption of cocoyam value added innovations among rural women in Abia State, Nigeria. The study specifically examined the following objectives: ascertain rural women's awareness of cocoyam value added innovations; assess rural women's level of adoption of cocoyam value added innovations in the state; and identify the factors constraining rural women’s’ adoption of cocoyam value added innovations in the state.

METHODOLOGY

This study was conducted in Abia State, Nigeria. The state is situated between latitudes 5°06'60" north of the equator and 7°21'59.99" east of the Greenwich Meridian. The participants in the study were rural women who had received training in cassava value addition from the National Root Crops Research Institute, Umudike in the state. The study adopted a multistage random sampling technique in the selection of respondents. Two agricultural zones from the State were purposefully chosen in the first stage. Two Local Government Areas (L.G.As) from each of the agricultural zones were purposefully sampled in the second stage. The reason for purposive selection is because root and tuber crops' value added innovations have been enormously disseminated in the agricultural zones and LGAs. A list of rural women beneficiaries from each of the selected LGAs was collected from the institute's Women-in-Agriculture Unit. As a result, samples of two women groups were randomly chosen in each of the chosen LGAs, creating a sampling frame for the rural women beneficiaries that resulted in a total of 1200 women beneficiaries. In the last stage, 60 women (10% of the recipients) were randomly selected from each LGA. This gave a sample size of 120 rural women. Structured questionnaire was administered to elicit data from the women. Information was gathered through the internet and various reports that were pertinent to the study. Data were analyzed using descriptive statistics such as percentages, means and inferential statistics like OLS regression model. The level of adoption of cocoyam value added innovations was measured using 4-point adoption score model.

The following scaling point was adopted; Never (1), Sometimes (2), Often (3), Always (4). The mean score was 2.50. The level of adoption was categorized as follows; 3.5 – 4.0 = Very High; 2.5 – 3.0 = High; < 2.5 = Low

Factors constraining adoption of cocoyam value added innovations was measured using 3-point type Likert scale: Not serious (1), Serious (2), and Very serious (3). The mean score was 2.00. To determine the relationship between identified constraints and adoption of cocoyam value-added innovations, Ordinary Least Squares regression was adopted.
Y = Level of Adoption of cocoyam value-added innovations (measured with mean point of the 4-point adoption scale). The independent variables were factors constraining adoption of cocoyam value added innovations (measured with mean point of the 3-point type Likert scale). X1 =Lack of ready market; X2 = Lack of fund; X3=Insufficient knowledge of the practices; X4=Lack of equipments/facilities; X5 = Lack of follow-up training; X6 = Lack of extension contact; X7 = Busy with other activities and thus have no time for processing; e = Error term.

RESULTS AND DISCUSSION

1. Awareness of Cocoyam Value Added Innovations

Table 1 shows distribution of rural women according to their awareness of cocoyam value added innovations. The table reveals that 48.3%, 77.5% and 55.8% of the respondents were aware of cocoyam chips, cocoyam soup thickener and cocoyam flour**.**

Table 1: Distribution of rural women according to their awareness of cocoyam value added innovations

	Innovation	Aware		Unaware	
		Frequency	**Percentage**	**Frequency**	**Percentage**
1	Cocoyam chips	58	48.3	62	51.7
2	Cocoyam soup thickener	93	77.5	27	22.5
3	Cocoyam flour	67	55.8	53	44.2

Source: Field survey, 2021

Except for cocoyam chips, majority of the respondents were aware of cocoyam value added innovations in the State. Awareness of a new technology is a pre-requisite for adoption of the technology. It enables farmers to learn the existence of a technology and this facilitates its adoption. Farmers will only adopt the technology they are aware of.

2. Level of Adoption of Cocoyam Value Added Innovations by Rural Women

Table 2 shows level of adoption of cocoyam value added innovations by rural women in Abia State, Nigeria**.** According to table 2, the respondents had low level of adoption of cocoyam value-added innovations (χ=2.18).

Table 2: Level of adoption of cocoyam value added innovations in Abia State

	Innovation	Always	Often	Sometimes	Never	Total	Mean	Remark
1	Cocoyam chips	18 (72)	9 (27)	39 (78)	54 (54)	231	1.93	Low
2	Cocoyam soup thickener	41 (164)	8 (24)	45 (90)	26 (26)	304	2.53	High
3	Cocoyam flour	23 (92)	12 (36)	38 (76)	47 (47)	251	2.09	Low
	Grand mean						**2.18**	**Low**

Source: Field survey, 2021

Respondents had low level of utilization of cocoyam chips and cocoyam flour but high level of utilization of cocoyam soup thickener. This could be attributed to the fact that Abia State is not a major cocoyam producing in Nigeria.

3. Factors constraining adoption of cocoyam value added innovations

The result on table 3 revealed that the respondents agreed that four out of the eight constraints mentioned in the table seriously affected adoption of cocoyam value-added innovations in the Abia State.

Table 3: Constraints to adoption of cocoyam value-added innovations

	Constraint	Very serious	Serious	Not serious	Total	Mean	Remark
1	Lack of ready market	12 (36)	31 (62)	77 (77)	175	1.46	Not Serious
2	Lack of fund	37 (111)	52 (104)	31 (31)	246	2.05	Serious
3	Insufficient knowledge of the practices	61 (183)	43 (86)	16 (16)	285	2.38	Serious
4	Lack of equipments/facilities	44 (132)	46 (92)	30 (30)	254	2.12	Serious
5	Lack of follow-up training	60 (180)	35 (70)	25 (25)	275	2.29	Serious
6	Lack of extension contact	16 (48)	31 (62)	73 (73)	183	1.53	Not serious
7	Busy with other activities and thus have no time for processing	24 (72)	57 (114)	39 (39)	225	1.88	Not serious
8	Lack of interest	6 (18)	26 (52)	88 (88)	158	1.32	Not serious

Source: Field survey, 2021

Constraints such as lack of funds (χ=2.05), insufficient knowledge of practices (χ=2.38), lack of equipment/facilities (χ=2.12) and lack of follow-up training (χ=2.29) were the major constraints to adoption of cocoyam value added innovations in the State.

4. Effect of Identified Constraints on Adoption of Cocoyam Value Added Innovations

Table 4 showed multiple regression estimates of the relationship between identified constraints and adoption of cocoyam value added innovations among rural women in the Abia State, Nigeria. The four functional forms were fitted in the regression model and based on some econometric criterion, such as the number and level of the significant variables and their conformity to *a priori* expectation, the lead equation was chosen.

Table 4: Regression estimate of the relationship between identified constraints and adoption of cocoyam value added innovations by the rural women

Variables	Linear	Semi-log	Double Log +	Exponential
Constant	1.532 (3.79)***	.359 (1.87)*	.573 (5.08)***	1.981 (8.36)***
Lack of ready market	.132 (0.66)	.009 (0.10)	-.003 (-0.02)	.198 (0.60)
Lack of fund	-.281 (2.01)**	-.146 (2.20)**	-.273 (2.30)**	-.524 (2.10)**
Insufficient knowledge of the practices	.051 (0.28)	.051 (0.60)	.136 (0.86)	.178 (0.53)
Lack of equipments/facilities	.125 (0.92)	.078 (1.21)	.138 (1.17)	.237 (0.96)
Lack of follow-up training	-.230 (-1.34)	-.133 (-1.63)*	-.277 (-1.86)*	-.492 (-1.58)*
Lack of extension contact	-.070 (-0.40)	.014 (0.17)	.077 (0.53)	-.025 (-0.08)
Busy with other activities and thus have no time for processing	-.208 (-1.18)	-.123 (-1.47)	-.248 (-1.73)*	-.435 (-1.45)
Lack of interest	-.395 (1.81)*	-.182 (1.74)*	-.276 (1.64)*	-.607 (1.71)*
F-statistics	2.71**	2.37**	2.39**	2.70**

R^2	0.3632	0.3460	0.3470	0.3629

The Double-log function was chosen as the lead equation. The R^2 value was 0.363 indicating that 35% of the variation in the adoption of cocoyam value added innovations was accounted for by the explanatory variables expressed in the models. The F-ratio was significant at 5% level indicating the goodness of fit of the model used in the analysis..

The coefficients of lack of fund, lack of follow-up training, busy with other activities and lack of interest were significant at 5%, 10%, 10% and 10% levels of probability respectively and inversely related with adoption of cocoyam value added innovations. This implies that lack of fund, lack of follow-up training, busy with other activities and lack of interest significantly impeded the adoption of cocoyam value added innovations in the state. These findings suggest that there is an urgent need for researchers, policy makers and administrators of the extension service to consider these constraints seriously so as to overcome them to increase the adoption of cocoyam value added innovations among women in Abia state. Rural women trainees should be given soft loans so they can start producing cocoyam value added products commercially.

56th Annual Conference
Agricultural Society of Nigeria
24 - 28 Oct., 2022

ABSTRACT

The study reviewed the existing literature on sources of climate change information and their use by small holder rural farmers in Nigeria. It was also found that there was a high level of awareness of climate change information in the state, with the main sources of climate change information including radio, television and extension services. Farmers also use climate change information to make decisions about what and time to plant, as well as to plant improved crop varieties, among other things. Challenges such as decreasing annual rainfall, deforestation, insect pest attacks and high temperatures, to name a few does exit. This paper recommends a more intensive climate change awareness campaign, as well as an increased budget allocation to the agricultural sector for greater mitigation and adaptation capacity for farmers.

INTRODUCTION

The news on the level of awareness, access and capacity building of vulnerable populations for climate change adaptation and/or mitigation around the world, especially in developing countries like Nigeria, is of concern to the ecologists. Over the years, world leaders have held international summits to find solutions to this global threat. According to Stevens *et al*. (2017), the most recent agreement reached by the United Nations Conference of the Parties at the World Climate Change Conference (COP21) in December 2015 was hailed by many as a watershed moment. According to them, the agreement is still strewn with pitfalls. As a result, some world leaders are questioning their full commitment to the principles of the agreement. As our interest is in the availability, awareness, access and, of course, use of climate change information, we will avoid as much technical detail as possible in this work and stick to the basic knowledge of climate change. Banmeke *et al.* (2017) pointed out that the Intergovernmental Panel on Climate Change (IPCC, 2001) defines climate change as statistically significant variation caused by human and non-human activities that lasts for decades or longer. Deforestation, oil spills and gas flaring are examples of human causes, while volcanic eruptions and ocean currents are examples of non-human causes. This definition shows that it is caused both by human activities and by uncontrollable natural circumstances. The West African sub-region would also be more vulnerable. Individually, farmers, fishermen, other rural dwellers and city dwellers are the most vulnerable groups. According to Abdulhamid (2015), some of these policies in the agricultural sector aimed at ensuring food security and self-sufficiency since 1970 included Agricultural Development Project (ADP), Agricultural Establishment and National Accelerated Food Production Program (NAFPP), Operation Feed the Nation. (OFN) etc. Despite all these laudable programs, Nigeria has not been able to achieve food security and self-sufficiency, perhaps due to the various forms of climate change plaguing it. Wakili (2018) reported that the Lake Chard basin has dried up to 10% of its original size. According to an AFP report on August 24, 2010, the Nigerian Meteorological Agency had predicted light rainfall, but it fell in torrents. That doesn't mean the agency wasn't confident in its prediction, but that climate change had an impact on it. According to Rabiu (2014), “information is knowledge communicated or received regarding a specific fact or circumstance, knowledge gained through study, communication and research”. The Nigerian government is working hard to diversify the country's economy, with agriculture as the main focus. The Federal Ministry for the Environment has created a Climate Department. Change with the mandate to drive the federal government's vision to mitigate and adapt to the impacts of climate change. Their mandate includes, among other things, providing leadership in promoting the appropriate adaptation culture, as well as supporting research, education, and awareness. Adapting to the threats of climate change by transitioning to modern climate-smart farming practices is becoming more difficult due to a lack of knowledge (Ibrahim, 2017). Beyioku (2016) reported that one of the solutions proffered by a 2 Day South-South Regional Workshop on Climate Change Capacity Building was raising awareness on issues of climate change that is presently at low level especially amongst vulnerable groups like women, children, even at the grassroots, especially rural dwellers. This indicates that awareness of climate change problems in Nigeria is low, implying that our government has not done enough to address the problem.

Awareness of the term climate change

Akpan *et al* (2012) reported that Nigerians’ understanding of climate change-related issues including the negative effect of the fast changing climate on lives is not encouraging. However, in their study, Abdulkareem *et al*. (2012) recorded that level of awareness of teachers on climate change was high with a high rate of 84% but on the contrary, the awareness rate of the students was very low with only 31% representing their awareness of the phenomenon. It is worrisome that the teachers have such a high rate of awareness while their students recorded a very low awareness level. This is an indication that it is not yet included in our schools curriculum. These children if they are aware of this phenomenon can help in spreading the information. Idoma and Mamman (2016) in their study revealed that 92% of their respondents were very aware of the term climate change and variability. They reported that high rate of their awareness is an indication that climate variability is very evident coupled with the fact that 49.2% of the farmers had over forty years of farming experience.

Climate change information

In the face of the threats posed by climate change to the world especially Nigeria, there is need for sufficient and well-timed information to be given out to the public. This information will help the people especially the susceptible to build capacity for adaptation and or mitigation of the effects of climate change. Idoma and Mamman (2016) in their study discovered that early warning signals, Rainfall Prediction, Drought Prediction, Food aid, Temperature change, Adaptation Technology, Human Health Services and Veterinary services had mean scores above two, placing them on top as needed climate change information. Similarly, Idoma and Mamman (2016) revealed the need for climate information and knowledge sharing between researchers, policy makers and community institutions in order to boost practical adaptation at the grassroots level.

Causes of climate change

Climate change or global warming is assumed to be triggered by both human and natural factors. Agreeing to Intergovernmental Panel on Climate Change (IPCC) in Onu and Ikehi (2017), the causes of climate change can be connected principally to factors such as: Industrial revolution, for instance the activities of automobiles and other industries have led to emission of several gases like carbon dioxide (CO_2) into the atmosphere which over time affects the structure of greenhouse gases leading to altered climate; Burning of fossil fuels by oil producing companies and refineries which emit greenhouse gases into the atmosphere; Land use change such as deforestation and desertification which leads to climate change, and agricultural activities such as bush burning, fertilizer application, fermentation among others, all of which are anthropological influencers of climate change (Odjugo, 2011).

Effects of climate change

Reduced rains have been observed in some parts of Nigeria especially Kaduna State, with the farmers lamenting poorer rice, maize, and vegetable output,(Ibrahim, 2017). He opined that, the long-term forecast is for still dryer conditions across the north, with the potential decline in yields for rain-fed agriculture as high as 50 percent. Low yield is one of the effects of climate change on farmers. This is as a result of irregular/random rainfall, severe heat, desert encroachment, flooding, shrinking of rivers and lakes, soil degradation, landslides, erosions among others. Dadzie *et al.* (2012) in their findings agreed with this when they reported that the production experience of the food crop farmers interviewed stated that flooding, pests and diseases outbreaks, drought and irregular rainfall are the common incidence of events they have been encountering with seasonal shifts due to climate variability and change. Sagoe (2006) also agreed with this in her report on study of climate change and root crop production in Ghana, Factors such as unreliable, irregular and unpredictable rainfall are some of the effects of climate change. Idoma and Mamman (2016) revealed major adverse effects of climate change in the area they studied as flooding of farm land, crop failure and poor harvest, poor performance and high mortality rate of livestock, wilting and decay of farm produce, poor fish harvest and unusual pests/diseases of crop and animal.

Sources of climate change information

Anunobi, and Udem, (2014) defined information as realistic data, ideas, and other knowledge stemming from any society that are acknowledged as being of value, sometimes assembled on a regular basis, organized in some fashion, communicated to others, and used in some meaningful way. This definition reveals that information is meaningless if it is not collected, processed, disseminated and used. Source and dissemination of information on climate change is very essential. Every information has a target audience and there is a right source to get that information to that very audience. It is only then that the information can be said to have been rightly and properly disseminated. Various sources of information dissemination abound, viz; the Mass Media – Print and Non-print media. Newspapers, Magazines and Radio, Television. This days the advent of Information and Communication Technology (ICT) (internet and the World d Wide Web) has provided another powerful means of information dissemination. It uses various platforms such as blogs, social media network – facebook, WhatsApp, imo, Linkden etc. as well as the Libraries, extension workers (for some technical areas), posters and handbills, community channels (town criers), and so on. Annor-Frempong and Nana Acquah (2012) in their study reported that a majority (85.3%) of their respondents used the media

(Television and Radio) for information on climate change, and it is regarded as the most effective sources. Akpan et al. (2012) conducted a study on the Influence of the Nigerian Mass Media on Public Understanding of Climate Change and discovered that Interpersonal communication, internet and television still had an edge over newspapers as sources of climate change information for the respondents. That Interpersonal communication ranked the highest among the sources of information on climate change for the respondents. It was only 19 (4.75%) respondents out of 400 who indicated having ever read a story in a newspaper on climate change. The respondents who had read newspapers did not remember reading up climate change stories. Idoma and Mamman (2016) in their study identified four major channels of climate information communication in their order of acceptance to the respondents. Community channels (extension workers, neighbours/friends) very high significant rate, Mass Media (Radio & Television) came second while Print Media (Newspapers, Pamphlets) ranked third and Electronic Media (internet, SMS) ranked fourth in there study.

Use of information on climate change

Information received becomes relevant only when it is utilized. Climate information is meant to adapt or mitigate the effects of climate change in the environment. Idoma and Mamman (2016) stated that decision on when to plant crop came first (very important), decision on when to harvests fish from ponds ranked second (important), planning mitigation for flooding was ranked third (moderately important) while general daily activities came fourth (of little importance) in there study.

Difficulties in accessing and using climate change information

Idoma and Mamman (2016) reported limited access to radio, television and internet as well as poor translation of climate change technologies with a very high percentage (94%) as barriers to communicating climate information to Agatu. Other obstacles are the technicality of the message (85%), lack of trust in the source of information (82%) and cultural barriers (80%). Their findings were corroborated by Schubert, (2014) and Speranza, Kiteme, Ambenje, Wiesman & Makali (2010) who reported that communicating climate information to support adaptation action in Africa is hampered by several contextual factors, namely socio-cultural, content-related and technological barriers. Meanwhile, most of the challenges faced by farmers, as emerged from discussions and interviews, include reduction in annual rainfall, excessive heat (high temperature), depression of groundwater, gaps between forecast and actual rainfall, soil erosion, reforestation activities, land tenure and the incidence of pests attacking our agricultural products are some of the burning issues requiring climate change information in the study area. Furthermore, besides climate change, other agricultural challenges are lack of budget allocation to support the team farming population, lack of credit facilities and weak market are the major challenges.

CONCLUSION

For the past few years, world leaders have been pondering what or how to deal with the greatest threat of the moment, erratic climate change otherwise known as climate change. These changes negatively affect the overall survival of the human race and other living organisms on the surface of the earth, as the life of all living organisms depends on water, humidity, air and soil. to survive. Air pollution caused by the emission of gases from factories, vehicles, the domestic use of firewood, etc. drastically affects the ozone layer and the earth's crust, leading to reduced precipitation, humidity and an increase in the concentration of carbon dioxide on the earth, which leads to poor agricultural produce. However, the mechanisms put in place by the government at all levels, international organizations and NGOs in the state to sensitize and encourage farmers to use the information provided have yielded good results as the levels of awareness, access and use of climate change information by farmers are high. , therefore, the state has no reason not to be at the forefront of economic diversification of this agriculture-oriented government, thus improving the socio-economic activities of its people who are really farmers.

RECOMMENDATIONS

Based on this study, the following recommendations were made:

1. Due to the threat posed by climate change to humanity in the area of food scarcity, there is an urgent need to provide the public with adequate and timely information on climate change, as this will enable people to build their capacities adaptation or mitigating the effects of this phenomenon

2. Governments at all levels should increase their budgetary allocation to agriculture and provide accessible credit facilities to farmers to enable them to insure their farms to minimize the burden of losses resulting from the effects of climate change.

3. The government and non-governmental organizations should do more to train more personnel and send them to every nook and cranny of the state to create greater awareness about current events regarding climate change; this will help people to be more proactive in managing the results of this phenomenon.

ABSTRACT

This paper investigated the role of gender mainstreaming in agricultural productivity in Wukari Local Government area of Taraba State. It examined gender differentials in terms of roles performed in agricultural production, marketing, access to productive resources. On gender differentials in crop and animal production, men were more involved (45%) than female (15%). Similarly, level of involvement in crop productivity by gender (hectares) and year for the past three years (2019-2021), men were more involved while female mostly engage in processing activities. The study employed in-depth interview, focus group discussions and structured questionnaires for data collection. Findings of the study revealed that women are generally underrepresented in most profitable nodes of agricultural activities. The commercialization of agriculture has led women to lose control over the commodities they traditionally used to control, as these commodities have fallen into the hands of men. Therefore women in this category are either disempowered or at least not empowered by agricultural interventions programmes. Nevertheless, for women of FHHs, gender mainstreaming in agricultural has contributed to improving gender equality, employment, and women's empowerment by boosting their economic, social, and personal empowerment levels, though they still lag behind the men in many aspects of agricultural enterprise. It is concluded that women are less involved in almost all aspects of agricultural productivity because of lack of access to productive inputs. It is therefore recommended that

Improving access to productive resources and market services, provisions of services, loans, subsidies, and capacity development can enhance productivity of particularly women.

Key Words: Role, Gender Mainstreaming, Agricultural Productivity, Wukari Local Government, Taraba State

INTRODUCTION

Gender mainstreaming was established in 1995 as an intergovernmental mandate in the Beijing Declaration and Platform for Action (Ababe *et al.*, 2006). Gender mainstreaming emerged as a response and a strategic solution to the shortcoming of women's- focused policies which failed to significantly address the gender disadvantage. Gender mainstreaming as a strategy "represents a shift of policy focus from women-focused policies to a more strategic attention of mainstreaming gender across all organizations as a means of achieving gender equality and women's empowerment (Elliston, 2006). According to Bera (2015), gender mainstreaming is a means by which the gender equality will be realised, it is more than increasing women's participation as it places gender equality at the centre of planning, policy decisions, program budget, and institutional structures and processes and recognizes the importance of incorporating women's and men's perceptions, experiences, knowledge, and interests into these processes. This section presents historical overviews of gender mainstreaming, strategies and conceptual framework of gender mainstreaming as well as the limitation and critiques of gender mainstreaming. Mainstreaming a gender perspective is the process of assessing the implications for women and men of any planned action, including legislation, policies or programs, in all areas and at all levels. It is a strategy for making women's as well as men's concerns and experiences an integral dimension of the design, implementation, monitoring, and evaluation of policies and programs in all agricultural, political, economic and societal spheres so that women and men benefit equally and inequality is not perpetuated. The ultimate goal is to achieve gender equality. A common example of gender mainstreaming is providing training to strengthen women's skills and capacity. But gender mainstreaming goes beyond increasing women's participation. It means bringing the experience, knowledge, and interests of women and men to bear on the development agenda. The goal of mainstreaming gender equality is the transformation of unequal social and institutional structures into equal and just structures for both men and women in the targeted organizations. The mainstreaming activities specifically target women's priorities and needs, though, for example, legislation, policy development, research and projects/programs on the ground. Women-specific projects continue to play an important role in promoting gender equality. And yet, they are still needed because gender equality has not yet been attained and gender mainstreaming processes are not well developed (Chawa *et a*l., 2001).Nevertheless, gender mainstreaming is still seen as the most "modern" approach to gender equality (Daly, 2005). The study answered the following research questions:

1. To what extent are women benefiting from gender mainstreaming?
2. How women's involvement in agricultural production does contributes to their empowerment?
3. What are the constraints to gender equity and women's participation in agricultural production?

METHODOLOGY

Study Area

Wukari is a Local Government Area in Taraba State, Nigeria. Its headquarters is in the town of Wukari on the A4 highway. The Donga River flows through the area and the Benue River forms a boundary with Nasarawa State to the northwest. It has an area of 4,308 km^2 and a population of 241,546 at the 2006 census. The Wukari Federation is a traditional state in Nigeria, a successor to the Kwararafa state of the Jukun people. The ruler takes the title "Aku Uka" The Jukun were established in Wukari as early as the 17th century. The town was one of the southern centers on a trading route that connected via Bauchi to the northern states of Katsina, Kano and Bornu (NPC, 2006)

Sampling Procedure and Sample Size

Simple random sampling procedure was employed to select 30 male farmers and 30 female farmers bringing a total of 60 respondents used as the sample size for the study

Data Collection

The data collection methods used in the study are structured interviews, focus group discussions, and structured questionnaires.

Data analysis

This study employs qualitative content analysis and descriptive statistics for data analysis from the information collected through in-depth interview, focus group discussion and questionnaire schedule.

RESULTS AND DISCUSSION

Socio-economic profile of the respondents

Table1 indicates the demographic characteristics of the participants who were involved in structured interviews and focus group discussions, out of which 30 were engaged in in-depth interviews. The participants of the research in this study are classified into three groups: male-head of household 33.3%, female head of household 41.7%, and women in MHHs 25%. As indicated in total, women (66.7%) outnumbered men (33.3%). This was deliberate because of the need to include women from MHHs as they are also one of the actors of agricultural productivity. The majority of the

Research participants (68.3%) were between 35 and 60 and the remaining 21.7% and 10% were 18-35 and above 60, respectively. Therefore most of the data were obtained from economically active member of household with longer years of experience of working in the agricultural sector.

Table 1: Demographic characteristics of the respondents

Characteristics	Variables	N	Percentage
Sex	Male	40	66.7
	Female	20	33.3
	Total	60	100
Age	18-35	13	21.7
	35-60	41	68.3
	above 60	6	10.0
Education level (men)	Illiterate	1	5.0
	Primary Edu	12	60.0
	Secondary Edu	7	35.0
	Tertiary Edu	0	0.0
Education level (women)	Illiterate	8	20.0
	Primary Edu	30	75.0
	Secondary Edu	2	5.0
	Tertiary Edu	0	0

Title in household	Male heads	25	41.7.
	Female heads	20	33.3
	Women in male head	25	41.7
	Total	60	100

Source: *Field data 2022*

Table 2 analyses gender roles in agricultural productivity. It is important to note that one participant may be involved in more than one activity in the production process. Therefore the figures indicated are not exclusive of one another. For instance, a producer might perform both production and processing activities or can be into animal production activities. Table 3 shows that the level of involvements of research participants along crop and animal production were highly gendered. The participation of men along the functions of agricultural production nodes are fairly distributed from production to marketing. Women's involvement were largely concentrated in the processing activities as well as to less extent in retailing activities of crops and animals (Bitew *et al.,* 2015).As indicated, women were absent in input provision activities, and other marketing activities such as collecting and wholesaling. Therefore women are primarily incorporated and benefited in crop and animal production. In both crop and animal production, most coordinating activities were run by men. Women are underrepresented in the management positions of agricultural activities. For instance, out of the total men interviewed, 30 percent reported that they are members of agricultural managing committee, while only 2 (5%) out of 40 interviewed women reported that they are member of agricultural management committees.

Table 2: Participants' involvement in Agricultural production and value chains activities by gender

Value chains	Male		Female	
	number	**percentage**	**number**	**percentage**
Input suppliers	4	20	0	0
Crop producers	30	75	5	10
Labour supply	1	5	9	23
Collectors	4	20	0	0
processors	2	10	20	50
Wholesalers	5	25	0	0
Retailers	4	20	10	25
Animal production	6	30	2	5

Source: *Field data, 2022*

Table 3 describes gender differences in crop and animal production. The study assessed household productivity of the main crops and main animals. It was found out that male are more involved in crop and animal production. This is because MHHs have scored higher productivity of quintals per hectare than females. Differences in household productivity between male-headed and FHHs can be related with the differences in access to productive inputs and support services between the households. Limited access to productive inputs such as seeds, and chemical fertilizer as well as production support services will affect the productivity of the farm activities of FHHs. Added to this, the problem of limited access to market and market information, labour shortage and other institutional constraints are also the main cause for the low productivity of FHHs. Evidence from other African countries reveals that differences in productivity per unit area of land between men and women farmers attributes to the difference in the amount of labour and other resources used per plot. Women-controlled plots usually receive less amount of labour and other inputs and consequently produce less amount of yields than men-controlled plot (Carranza, Goldstein and Oseni, 2014).

Table 3. Gender differentials in Crop and Animal production

Agricultural Production	Total participants	Men participants	Women participants	Men owners	Women owners	Men employee	Women employees	Women family La
Crop Production	35	25	10	16	12	2	5	8
Animal Production	25	20	5	14	8	0	3	9
Total	60	45	15	29	20	3	8	17

Source: *Field data 2022*

Table 4 describes gender differences in crop productivity. The study assessed household productivity of the main crops in the last three production years (2019 to 2021). It was found out that for all the main crops, MHHs have scored higher productivity of quintals per hectare for the years indicated in Table 3.Differences in household productivity between male-headed and FHHs can be related with the differences in access to productive inputs and support services between the households. Limited access to productive inputs such as seeds, and chemical fertilizer as well as production support services will affect the productivity of the farm activities of FHHs. Added to this, the problem of limited access to market and market information, labour shortage and other institutional constraints are also the main cause for the low productivity of Female Household Heads. Carranza, Goldstein and Oseni (2014) posits that, evidence from other African countries reveals that differences in productivity per unit area of land between men and women farmers attributes to the difference in the amount of labour and other resources used per plot. Women-controlled plots usually receive less amount of labour and other inputs and consequently produce less amount of yields than men-controlled plot (Bera, 2015).

Table 4. Assessment of the level of crop production of main crops by gender (hectares) and year

Year	Roots and Tubers		Cereals		Pulses		Vegetables	
	male	**female**	**male**	**female**	**male**	**female**	**male**	**female**
2019	40.0	30.0	36.3	28.0	22.5	16.6	54.5	41.4
2020	38.0	27.5	37.0	25.0	24.0	15.0	62.5	45.0
2021	42.0	30.0	35.7	25.5	26.0	18.0	60.9	45.0

Source: *Field data, 2022*

CONCLUSION/ RECOMMENDATIONS

It is concluded that gender mainstreaming in access to and use of resources, productive inputs and agricultural support services should be encouraged due to the socio-cultural and institutional barriers that constrain women's equal access to those resources. In the study area the agricultural development program has largely neglected the gender perspectives mainly due to the rhetoric of male-dominated household headship that obscured women and their contributions in agricultural productivity. The following are some of the recommendations put forward.

- The incentive for agricultural production should be made available to everyone irrespective of gender.

- Improving access to productive resources, market services, loans, subsidies, and capacity development that push the disadvantaged group of farmers, particularly women should be encouraged, reinforced and sustained.
- The delivery of the general agricultural extension services should be designed to target both male and female household heads.

24 - 28 Oct., 2022

ABSTRACT

Agriculture is the sector mostly affected by climate change. This is not unconnected with the fact that the key elements within which agriculture thrives is the climate. The devastating impact of climate change on livelihood and the environment is a cause of concern in the Niger-Delta area of Nigeria and this have had tremendous effect on yam production in the area. The study was to identify response system and adaptation strategies by yam farmers in the study area. A multistage sampling procedure was used and structured questionnaire administered for primary data to yam farmers, with 216 viable questionnaires retrieved for analysis. The Multinomial Logit (MNL) model showed how socio-economic, institutional, households and farm characteristics influenced yam farmers' choice of adaptation measures in the study area. The result revealed that the major adaptation strategies employed by yam farmers were mixed cropping (30.5%), planting different varieties (24.0%) and soil conservation techniques (20.3%). Also, that socio-economic characteristics like gender, marital status, access to extension, access to credit, age, farm size, farming experience, farm income and household size were the major factors influencing the choice of adaptation measures employed by the yam farmers in the study area. It can therefore be submitted that mixed cropping/farming and soil conservation techniques were key adaptation strategies employed by the yam farmers and socioeconomic characteristic (farm income, access to extension, farming experience) were pivotal to adaptation choices used by the farmers.

1.0 INTRODUCTION

Climate change is one of the most serious environmental threats facing mankind worldwide. Ifeanyi-obi, Etuk and Jike-wai. (2012) posited that there are four major causes of climate change: astronomical causes, volcanic eruptions, variations in solar output and changes in earth's environment as a result of human activity. The devastating impact of climate change on livelihood and the environment is a cause of concern in the Niger Delta area of Nigeria. It is important to highlight that Delta region is one of the most volatile coastal regions with some worsening levels of ecological hazards in Sub-Saharan Africa. According to Ugo-Ikem (2015) the Niger-Delta region of Nigeria is characterized by lowlands with most of the Delta being less than 6m above sea level, making the region very much exposed to rise in sea level. The abundant rivers, creeks and streams expose the region to adverse environmental negative impacts with significant flooding resulting from inland surface waters and the boundary coastal shelf. Food production has been adversely hit by the recurring climate change induced flooding in most part of the area.

Study by Woodley (2011) revealed that climate change has untold impact on health, human settlement, energy, agriculture and food security on the coastal area. Similarly, Rural Linkage Network (2013) also noted that Delta State has been experiencing climate change related impact such as: rising temperature, heat waves, more intense rain/wind storms, more extreme rains, including: erosion and landslides, sea level rise, sea surges and coastal inundation.

Yam is an important food and cash crop in West Africa and provides livelihood to over 60 million people in the region (Djana *et al.*, 2014). The issue of Climate change have also had debilitating effect on yam production in the Niger Delta. Ohagwa (2017) quoted that "Climate change is here with us. We have to tackle it. It has a lot of opportunities for us in Niger Delta". Therefore, the need to look at the response system and adaptability measures taken to cushion the effect of climate change in this area becomes imperative.

2.0 MATERIALS AND METHOD

The study area is the Niger-Delta area of Nigeria. It comprises of nine states namely, Akwa-Ibom, Bayelsa, Cross-River, Delta, Edo, Rivers, Ondo, Imo and Abia States. Both primary and secondary data were used for this study. For the primary data, structured questionnaire was administered to yam farmers gotten through a multistage sampling procedure in the study area. In all a total of two hundred and forty (240) respondents for the study. However, a total of 216 viable questionnaires were finally retrieved for analysis.

2.1 Multinomial Logit Model for Adaptation Strategy

Multinomial Logit (MNL) was employed to examine the factors that influence the choice of adaptation measures used by yam famers in the study area. The MNL is a generalization of the logistic regression model to the case where there are more than two outcomes, and where the outcomes are not ordered.

Let Y_1 be a random variable representing the adaptation measure options chosen by any farming household taking on the values {1,2,...J} for J, a positive integer, and

Let X represents a set of conditioning variables which represent household attributes/socioeconomic characteristics.

The question is how ceteris paribus changes in the elements of X affect the response probabilities P(Y =j/X),j = 1.2,...J

Since the probabilities must sum to unity, P(Y = j/X) is determined once we know the probabilities for j = 2,…….J

Let X be a 1 x K vector with first element unity.

The MNL model has response probabilities:

$P\,(Y\,j/X) = \exp\,(X\beta j\,)/\,[1 + \sum_{h=1}^{j} exp(X\beta_h), j = 1,..\,.J]$ ……………………………….. (1)

Where β_j is K x 1,j = 1.. J.
Differentiating equation (1) with respect to the explanatory variables provides marginal effects of the explanatory variables given as:
$\frac{\partial P_j}{\partial X_K} = P_j\,(\beta_{jk} - \sum_{j=1}^{j-i} P_j\beta_{jk})$... (2)
The marginal effects or marginal probabilities are functions of the probability itself and measure the expected change in probability of a particular choice being made with respect to a unit change in an independent variable from the mean (Deressa, Hassan, Alemu & Yesuf, 2008 and; Fatuase & Ajibefun, 2014).
The explicit function of the MNL model is given below:
$Y^* = \beta_0 + \beta_1X_1 + \beta_2X_2 + \beta_3X_3 + \beta 4X4 + \beta_5X_5 \ldots + \beta 11X11 + \beta_{12}X_{12} + \beta_{13}X_{13} + e_1$ .... (3)
Where:
Y* = dependent variables (Adaptation measure options) which are:
1 = Different Planting Dates (DPD), 2 = Practicing Crop Diversification (PCD)
3 = Mixed Cropping (MC), 4 = Soil Conservation Techniques (SCT)
5 = Use of Agro-chemicals (UAC) ,6 = Move to Different Sites (MDS),
MDS was chosen as the base category.
While; the Xis are the explanatory variables, which are:
X_1 = Age of respondent (Years).X_2 = Gender of household head (dummy: 1 = Male and 2 Otherwise) X_3 = Marital status (1 =married and 2 otherwise) X_4= Household size (Number) X_5 = Educational level of household head (years spent in school). X_6 = farm size (ha) X_7 = farming experience (years), X_8 = Access to extension services (yes = 1, 0 otherwise) X_9 Access to credit (yes = 1, 0 otherwise), X_{10} = Farm income (naira),ε= the error term.

3.0 RESULTS AND DISCUSSION

3.1Major Adaptation Measures Commonly Employ by Yam Farmers in the Study Area

The study identified various adaptation strategies to climate change, relevant and engaged by yam farmers in the area. As shown in Table1, about 30.5% of the yam farmers identified “Mixed cropping/farming” as their main means of adaptation strategy used in the study area. The greater use of this adaptation measure is not unconnected to the fact that people tend to resort to a closely complementary alternative when an earlier enterprise they know is threatened. About 24% of the yam farmers adopted “Planting different varieties” as their adaptation measure while 20.3% of them employed soil conservation technique, to guide against uncertainty in the area. Similarly, 16.2% of the respondents adopted “Different planting date” measure as a way of dealing with the challenge of climate change. In addition, 4.3%, 2.6% and 2.1% of the sampled respondents employed “Moving to different site”, “Use of agrochemicals” and “Practicing crop diversification” respectively as adaptation strategies in the study area and this aligns with the findings Bradshaw *et al.* (2004) and Deressa *et al*. (2008).

Table 1: Major Adaptation Measures Employed by Yam Farmers in the Study Area Adaptation Measures

Adaptation Measures	Frequency	Percentage

Mixed Cropping/Farming (MC/F)	64	30.5
Planting Different Varieties (PDV)	52	24.0
Soil Conservation Techniques (SCT)	44	20.3
Different Planting Dates (DPD)	35	16.2
Move to Different Site (MDS)	10	4.3
Use of Agrochemicals (UAC)	6	2.6
Practicing Crop Diversification (PCD)	5	2.1
Total Sample Size	**216**	**100.0**

Source: Computed from field survey, 2018

3.2 Factors Influencing Choice of Adaptation Strategies to Climate Change in the Study Area.

This section presents the results of MNL model that showed how socio-economic, institutional, households and farm characteristics influenced yam farmers' choice of adaptation measures in the study area.

The MNL failed to produce satisfactory results in terms of significance level of the parameters estimates when the seven identified adaptation options were first run. This was thus restructured by grouping closely related choices together in the same category. In this case, Planting different varieties and Different planting dates were grouped together as the same category, labelled "Planting Different Varieties". Similarly, Soil conservation techniques and Use of Agrochemicals were grouped together as same category and labeled "Soil conservation techniques".

The MNL adaptation model with these restructured choices was ran and it showed some significant levels of the parameters estimates. Table 2 showed the results of MNL diagnostic tests. The results revealed that all the parameters showed the goodness of fit. The likelihood ratio statistics as indicated by $\chi 2$ statistics (24.29) are fairly significant ($P < 0.0463$) suggesting the models have a strong explanatory power. The estimated coefficients were compared with the base category/outcome which is Move to Different Site (MDS) in the case of this study.

Table 2: Results of Diagnostic Tests of the MNL Regression Analysis

Parameters	Results
No of observations	102
LR Chi-Square	24.29
Prob > chi2	0.0463
Log likelihood	-145.1804
Pseudo-R^2	0.0772

Source: Computed from field survey, 2018

Therefore, Table 3 presents the marginal effects of the MNL results along with the levels of statistical significance. The results were discussed based on each adaptation options in the study area.

Planting Different Varieties (PDV): Three out of the ten variables examined in the study statistically influenced the likelihood of adopting Planting Different Varieties over the base outcome (Move to Different Site). The coefficient of gender is positive and significant at 1% level. This indicated that the male respondents have a higher chance of adopting Planting Different Varieties than female respondents by 1.02 units. The coefficients of access to extension and credit are positive and significant at 5% level, showing that more access to extension and credit increases the chance of adopting Planting Different Varieties by 0.70 and

0.71 units respectively compared to Move to Different Site (Table 3).This results on gender from the States, is in line with the argument that male-headed households are often considered to likely get more information about new technologies and take more risk than female-headed households (Deressa, 2008 and Deressa et al., 2010).

Mixed Cropping/Farming (MC/F): Three out of the ten variables examined in the study area, statistically affected the likelihood of adopting Mixed Cropping/Farming over the base category. Age and farm size are significant at 1% while farm income is significant at 5%. The coefficient of age is negative and showed that an increase in the age of the respondents reduces the probability of adopting Mixed Cropping/Farming over the base category/outcome by 0.08 units while the coefficients of farm size and farm income are positive, indicating that an increase in the farm size and farm income of the respondents increases the probability of adopting Mixed Cropping/Farming by 0.25 and 3.12e-06 units respectively instead of base category.

Soil Conservation Techniques (SCT):Four out of the ten variables examined, statistically influenced the likelihood of adopting Soil Conservation Techniques over Move to Different Site (base outcome). The coefficient of age is negative and significant at 1% level. This indicated that older farmers have a lower chance of adopting Soil Conservation Techniques than younger respondents by 0.07 units. The coefficients of marital status, farming experience and farm income are positive and significant at 5% level, revealing that married respondents and respondents that have higher farming experience and farm income have better chances of adopting Soil Conservation Techniques by 0.61, 0.03 and 2.88e-06 units respectively compared to base outcome.

Table 3: Result of the Marginal Effect of MNL on Yam-based Climate Change Adaptation Strategies in the Study.

4.0 CONCLUSION

Based on the findings of this study, it can be concluded that the main adaptation strategies employed by the yam farmers are; planting different varieties, practicing crop diversification, mixed cropping/ farming, soil conservation techniques and move to different site. Also, that socio-economic, households and farm characteristics like gender, marital status, access to extension, access to credit, age, farm size, farming experience farm income and household size were the major factors influencing the choice of adaptation measures employed by yam farmers in the study area.

ABSTRACT

This study was designed on examining the socio-economic determinants of adoption of TMS cassava production technologies in Ivo Local Government Area of Ebonyi State, Nigeria. Specifically, the objectives were to identify the TMS cassava production technologies used by smallholder cassava farmers in the study area; examine the socio-economic factors leading to adoption of TMS cassava production technologies in the study area ; identify the cassava production techniques used by smallholder cassava farmers in the study area; identify the TMS cassava production constraints affecting the smallholder cassava farmers in Ebonyi State. Multistage sampling technique was employed to select the local government area, communities, villages and farmers. A total of 84 respondents were identified and selected using this sampling technique. Data from these respondents were analysed using descriptive statistics (frequency, tables) and inferential tools (Binary Probit model).It was however, deduced that high cost of planting materials, lack of fund(credit facilities),lack of labour for farming activities were major constraints affecting farmers production of TMS cassava in the study area.The result showed that the marital status of the farmer, age of the farmer, household size, farming experience and farm size were what significantly influenced the adoption of TMS cassava production technologies by farmers in the study area. It was however recommended that extension institutions in the study area should encourage farmers to adopt TMS cassava production technologies and also financial institutions, both governmental and private institutions should make loans available to farmers at affordable interest rates.

Keywords: Socio-economic, determinants, adoption, cassava production, technology

INTRODUCTION

The adoption of improved agricultural technologies is needed to improve agricultural productivity, which serves as the panacea to food insecurity and economic recovery for a country(Ojeleye et al.,2017).In Nigeria, despite projects, programmes and policies targeted at reducing the problem of hunger in the land, the country is still ranked 34^{th} on the Global Hunger Index(GHI) of 50 countries, with a Global Hunger Index of 25.5 indicating a serious hunger situation(International Food Policy Research Institute,IFPRI,2017).Thus, research and adoption of technological improvement are crucial to increasing agricultural productivity and food security(International Fund for Agricultural Development,IFAD,2011). Nigeria accounts for cassava production of up to 20% of the world, about 34% of Africa's and about 46% of West Africa's(FAO,2017). The national average yield of cassava is estimated to be at about 13.63MT/Ha which is grossly different against the potential yield of up to 40MT/Ha(FAO,2017). Despite the introduction of several government initiatives directed at improving cassava production in the country. Some of these initiatives include and not limited to the president Olusegun Obasanjo's Presidential Initiative(PI) for cassava production of 2002(Ojeleje et al.,2017).This presidential initiative involves the International Institute of Tropical Agriculture(IITA), National Root Crop Research Institute(NRCRI),National Agricultural Research Services(NARs),Agricultural Development Programmes(ADPs) and some other partners to develop and disseminate high yielding and disease-resistant cassava varieties(Ojeleye et al.,2017).Through these initiatives, a number of varieties were released and promoted. Unfortunately, most of the farmers in the rural areas still use the local cassava varieties as planting materials, which in turn gives very poor yield hence, contributing to food insecurity, given the important role cassava plays in the typical Nigerian diet (Ojeleye et al.,2017).The rate of consumption of cassava in the country led to an increase in the demand for this crop both for food and for industrial uses, which exceeded its supply(Agwu and Anyaeche,2007).To reverse this trend, the International Institute of Tropical Agriculture(IITA) and National Root Crop Research Institute(NRCRI) in Nigeria led the development of improved cassava cultivars through their breeding programmes to obtain higher quality cassava roots at relatively shorter time and pest/disease resistant cassava cultivars capable of adapting to a wide range of ecological conditions and farming systems(Agwu and Anyaeche,2007).The general objective of the study seeks to examine the socio-economic determinants of adoption of TMS cassava production technologies in Ivo Local Government Area of Ebonyi State ,Nigeria. The specific objectives are to identify the TMS cassava production technologies used by smallholder cassava farmers in the study area; examine the socio-economic factors leading to adoption of TMS cassava production technologies in the study area ; identify the cassava production techniques used by smallholder cassava farmers in the study area; identify the TMS cassava production constraints affecting the smallholder cassava farmers in Ebonyi State.

MATERIALS AND METHODS

The study was conducted in Ebonyi State, Nigeria.The State has a total number of thirteen Local Government Areas(LGAs) that are demarcated into three agricultural zones namely:Ebonyi North, Ebonyi Central and Ebonyi South Zones. The people of Ebonyi State are predominantly farmers. They grow crops like cassava, rice, yam, cocoyam, maize, vegetables, fruits and as well as keeping of some small ruminants and rearing of cattle(Echiegu,2002).There exit huge salts deposits at Okposi and Uburu salt lakes, the biggest salt deposit in Nigeria.The population for the study was cassava farmers in Ebonyi State Nigeria. Data were collected with the aid of a structured questionnaire that was administered to the respondents. A four stage random sampling technique was used in selecting community, villages and respondents. Firstly, Ivo local government area was purposively selected. This was due to the fact that there was low adoption of TMS cassava production technologies in the local government area. Secondly, three(3) towns were randomly selected out of five(5) towns namely Amonye, Amagu, Akaeze, Okue and Amokwe.Thirdly,four(4) villages were randomly selected from each of the towns. This gave a total of twelve(12) villages. Fourthly, seven(7) farmers were randomly selected from each of the villages.This gave a total of eighty four(84) farmers

The general form of the adoption of binary probit model can be specified explicitly as:

$Y=\beta_0+\beta_1X_1+\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots B_8X_8+\varepsilon_1$

Where

Y= Adoption of TMS cassava production technologies(y=1 if farmer adopts the TMS cassava production technologies,y=0 if otherwise)
X_1=Gender(dummy variable,1=male,0=female)
X_2 =Marital Status (1 if a farmer is married and 0 if otherwise)
X_3 =Age of the farmer(years)
X_4 =Educational level of farmers (number of years of formal education)
X_5 = Household size (number of persons)
X_6 =Occupational status (1=full-time farmer,0=part-time farmer)
X_7 =Farming experience (years of cultivating cassava as disclosed by the farmer)
X_8 =Farm size(hectares)
E_1 =Error term

RESULTS AND DISCUSSION.

Table 1.0: Frequency distribution of respondents according to the cassava production technologies used

Production Technologies	Frequency	Percentage(%)
TMS 30555	50	59.52
TMS 30572	51	60.71
TMS 92/0326	48	57.14
TMS 4(2)1425	47	55.95
TMS 98/0581	48	57.14
Others	43	51.19

Source: Field survey,2022

Multiple responses

Table 1 reveals that 60.71% of the respondents confirmed that they made use of TMS 30572.This implies that majority of the respondents were familiar with TMS 30572 and hence it was highly adopted by the farmers.This however,supports the study of Udensi et al.,(2011) that despite the introduction of TMS cassava production technologies by various research institutes through integrated farming project, there still remained a very low adoption level by farmers.

Table 2.0:Frequency distribution of respondents according to the cassava production techniques used.

Production Techniques	Frequency	Percentage(%)
Land preparation	68	80.95
Planting techniques	51	60.71
Proper spacing	43	51.19
Proper and timely weeding	51	59.52
Use of pesticides/insecticides	50	57.14
Use of fertilizer/manure	48	55.95
Use of TMS planting materials	47	55.95
Use of irrigation	12	14.
Harvesting techniques	60	71.43

Source:Field survey,2022

Multiple responses

Table 2.0 reveals that 80.95% confirmed that they prepared their land before cultivation. This implies that majority of the cassava farmers prepared their farm lands before they planted. This finding supports the findings of Okuthe, (2014) that land preparation is essential for improved output.

Table 3.0: Probit regression estimates on the Socio-economic factors leading to adoption of TMS cassava production technologies.

Variable	Coefficient	Std error	t-value
Constant	--10.4882	4.3012	-2.44**
Gender	-1.0741	0.8151	-1.32
Marital Status	0.0758	0.0561	1.35**
Age	1.4511	0.7618	1.90***
Education Level	-2.1728	0.8027	-2.43
Household Size	-0.1406	0.1905	-0.74***
Occupation	3.1811	1.2551	2.53
Farming Experience	0.1408	0.0588	2.39***
Farm Size	0.00003	0.0000009	3.41***
Chi square	86.26***		
Pseudo R^2	0.7878		

*, ** and *** is significant at 10%, 5% and 1% level of probability respectively.

Source:Field Survey,2022

The results show that the chi square value of 86.26 was highly siginificant at 1% level of probability indicating that the model is a good fit. The R^2 value of 0.7878 also indicates 78.78% variability in examining the socio-economic factors leading to adoption of TMS cassava production technologies as explained by independent variables. The marital status of the farmer, age of the farmer, household size, farming experience and farm size were what significantly influenced the adoption of TMS cassava production technologies by farmers.

Here, the coefficient of marital status was positive and significant at 5% level of probability.The coefficient of age was negatively at significant at 1% probability level. This suggests that as farmer advances in age, the risk aversion increases, and the likelihood to increase the number of improved varieties adopted becomes less. This result agrees with the findings of Donkor and Owusu, (2014) that as a farmer ages, the tendency to adopt improved technologies reduces. The coefficient for household size was significant at there1% and positively related to influence the adoption of TMS cassava production technologies. This matches the findings of Donkor and Owusu,(2014) that an increase in farmer's household size increases the probability of adopting improved varieties.There was positive relationship at 1% between the experience of farmers and adoption of TMS cassava production technologies. Onyebinama(2004) said that previous experiences in farm business would enable the farmer to set realistic cost and time targets, allocate and utilize resources efficiently and identify production risk.Farm size was found to be positively significant at 1% to adoption of TMS cassava production technologies.

Table 4.0: Frequency distribution of TMS cassava production constraints

Constraints	Frequency	Percentage(%)
High cost of planting materials	58	69.05
Lack of fund (credit facilities)	41	48.81
Lack of labour for farming activities	38	45.24
Inadequate planting materials	33	39.29
Small farm size	28	33.33
Poor soil fertility	22	26.19
Prevalence of pests and diseases	19	22.62

Lack of education	18	21.43
Poor quality of planting material	14	16.67
Lack of market for cassava	11	13.10
Drought	10	11.91
Lack of Irrigation facilities	5	5.95

Source:Field survey,2022

Multiple responses.

Table 4.0 shows that majority of the respondents (69.05%) affirmed that their major constraint to TMS cassava production was the high cost of TMS planting materials. This implies that TMS cassava production in the study area was limited because of high cost of TMS planting materials as stated by majority of the respondents. This finding however agrees with Ezeano et al.,(2017) who opined that high cost of planting materials, lack of extension services, high labour cost, unavailability of improved varieties and high cost of fertilizer were the major constraints to cassava production.

CONCLUSION

Several studies have reported issues related to adoption of technologies and factors that influences adoption of technologies. This study revealed that majority of cassava farmers were females and they had attained secondary education. It was however deduced that marital status, age, household size, farming experience and farm size were significantly related to adoption of TMS cassava production technologies. Furthermore, high cost of planting materials, lack of fund(credit facilities),lack of labour for farming activities were major constraints affecting farmers production of TMS cassava.

ABSTRACT

This study was on economics analysis of the profitability in yam production among farmers in Abakaliki Local Government Area The specific objectives were to determine the factors that affects yam production, to estimate the profitability in yam production and to identify the constraints to yam production in the study area. Descriptive and inferential statistics were used as tools for analysing data. Multi-stage random sampling technique was employed to select 120 women farmers. The primary data generated were analysed using both descriptive and inferential statistics such as frequency distribution tables, percentages and Ordinary Least Square(OLS) multiple regression technique. Among the functional forms tried namely the linear, exponential, cobb-douglas and semi-log functional forms, the exponential functional form gave the best fit and therefore was chosen as the lead equation with high R^2 value of 0.712.The profitability estimation of yam production among farmers in the study area reveals that yam production was a very viable enterprise, the result obtained revealed a profit of ₦317,700.The profitability estimation shows that for every ₦1 invested in yam production resulted in a yield ₦1.72.Farmers and yam producers should be encouraged to form cooperative societies in order to have access to improved productive inputs from government at reduced rates. Extension agents should be motivated to efficiently discharge their duties by giving them incentives and paying them out of pocket expenses while performing their duties. Government should help in the development of infrastructure for efficient and effective yam production system.
Keywords: Economics, Analysis, Profitability, Yam Production,

INTRODUCTION

Agriculture, a major resource based activity in terms of capital, and labour utilization has the potential of increasing Nigerian's food self-sufficiency(Bamire and Amujoyegbe,2010).The food crop sector(maize, sorghum, millet, rice, yam, cocoyam and cassava) as the main food crops in the country contributed to about 28% to Gross Domestic Product(GDP) representing 75-76% of the share of the agriculture sectors contribution to GDP(CBN,2012).Yam (Dioscorea spp) is an annual tuber which belongs to the family of Dioscorea species can be grown in nearly all tropical countries provided that water is not a limiting factor.Yam is however, one of the principal root crops in Nigeria both in terms of land cultivation in volume and value of production. Although, yams are grown throughout Africa, but Nigeria is said to be world's largest producer of yam, accounting for over 70-75% of the world's total output(CBN,2012).It is one of the carbohydrate foods that is nationally superior to most roots and tubers in terms of digestible proteins and mineral (calcium,magnesium and potassium)(Ebewore et al.,2013). It is more resistance to drought, pest, diseases and can tolerate different climate and edaphic conditions(Ugwumba and Omojola,2012). The high cost of seed yam was the major problem of yam production in the study area.This necessitated this study which its broad objective is on the economics analysis of the profitability of yam production among farmers in Abakaliki Local Government Area.The specific objectives were to determine the factors that affects yam production,to estimate the profitability in yam production and to identify the constraints to yam production in the study area.

MATERIALS AND METHODS

The study was conducted in Abakaliki Local Government Area of Ebonyi State.Abakaliki is a local Government Area situated at the heart of Ebonyi State.The municipal council is located 64 kilometers Southeast of Enugu State and are predominantly members of the Igbo speaking tribe with a population of 79,280 according to NPC(2006) population census. Abakaliki local government Area of Ebonyi State has a temperature of 27^0C and mean annual rainfall of 1800-2000mm.Majority of the population are farmers, engaging in the production of arable crops like yam, cassava, rice melon,groundnut, maize, millet and sorghum(ESBS,2018).The people are also involved in quarrying and other economic activities like golf course and hotel businesses.Data were collected with the aid of a structured questionnaire that was administered to the respondents.Multi stage random sampling technique was used in selecting respondents from community and villages. Firstly, a community was purposively selected from Abakaliki local government area. Secondly, six villages were randomly selected from the community.Thirdly, twenty farmers were randomly selected from each of the villages and this gave a total of one hundred and twenty(120)farmers. Objective i was analysed using gross margin analysis ,objective ii was analysed using inferential statistics of Ordinary least square regression analysis while descriptive statistics such as percentage, frequency table and mean was used to analyse objective iii.

Model Specification

Multiple Regression Model

Model can be implicitly represented as

$Y=F(x_1,x_2,x_3,x_4,x_5,x_6,x_7,x_8,x_9,x_{10}+ei)$

Where;

Y= yam output(kg)

X_1=Gender(male=1,female=0)

X_2=Age(years)

X_3=Farm size(ha)

X_4=Farm Experience(years)

X_5=Extension(visits=1,No visit=0)

X_6=Labour(manday)

X_7=Seed minisett(Available=1,Not available=0)

X_8=Agro-Chemical(Available=1,Not available=0)

X_9=Household Size(Number)

X_{10}=Educational Level(years)

RESULTS AND DISCUSSION

Table 1.0 Cost and Return Analysis in Yam Production

Item	Unit	Rate	Price/unit	total price(₦)
A.Revenue				
Sales of Yam	1000tubers	5/sett	2500	500,000
Total Revenue	-	-	-	500,000
B. Variable Cost				
Land acquisition(family)	Ha	1.5	15,000	16,500
Labour	Mandays	5	4000	20,000
Yam minisett	250kg	1	33,000	33,000
Fertilizer	25kg/bag	5	5200	26,000
Fertilizer application	Mandays	4	1500	6,000
Staking	mandays	10	1800	18,000
Weeding	mandays	6	1500	9,000
Harvesting	mandays	6	1200	7,200
Miscellanous	-	6	800	4,800
Transportation	manday	-	12000	12,000
C.Total variable cost				152,500
D.Total gross margin				347,500
E.Fixed cost				
Depreciation cost of fixed assets@5% of cost				
Cutlass	-	3	2000	6000
Hoe	-	4	1200	4,800
Rake	-	3	1200	4000
Basin	-	3	1000	3000
Wheel-barrow	-	1	12,000	12,000
F.Total fixed cost	-	-	-	29,800
G.Total Cost	-	-	-	182,300
H.Gross Profit	-	-	-	317,700

Source:Field Survey(2022)

NFI=TR-TC

Where NFI=Net Farm Income

=500,000-182,300

=317,700Return Per Naira invested(RNI) was obtained by dividing the Net Farm Income(NFI) over Total Cost(TC).

RNI=NFI/TC

= 317,000/182,300

=₦1.72

The result reveals that yam production was a viable enterprise as the result obtained revealed a profit of ₦317,700.If you relate it to its benefit cost ratio which means that every ₦1 invested in yam production, there is a return per naira invested of ₦1.72.This means that yam production is a very lucrative agribusiness and may need more participants to increase the quality and quantity of products produced in a year. This is in line with the findings of Jonathan and Anthony,(2012) yam production was a very lucrative business in Nigeria.

Table 2.0:Multiple Regression estimates of the factors that affect the output of yam production

***Significant at 1%,** significant at 5%,* significant at 10%, + indicates lead equation while figures in parenthesis are the t-ratios.The regression estimate of the determinants of the factors that affected the output of yam farmers is presented in table 2. The coefficient of age was positive and statistically significant at 5%. The age of the farmer had a positive and fundamental impact in yam production. The coefficient for farming experience was negative and significant at 1% level of probability. This is against a prior expectation. If there is increase in farmers farming experience this should lead to an increase in their output.The coefficient of extension visit was positive at 1%, the more contact farmers have with the extension agents and the more likely they are to adopt improved practice..Seeds, labour and Agro-chemicals(farm inputs) were positively signed and statistically significant at 1% level of probability. This implies that the more farm inputs the farmers utilizes, it's more likely that it will lead to increase in their output in yam production.There was a positive relationship between household and output of yam.This is particularly so in view of the increasing cost of hired labour and the inability of the farmers to make use of improved mechanical tools either due to high cost or relative small nature of farm sizes.There was a positive relationship between farm size and output of yam produced. This implies that women farmers who had relatively large farm sizes had more output and revenue. According to Onyebinama and Onyejelem(2010),a larger farm size should translate into greater output and higher revenue generation.

Table 3 Constraints in Yam Production

Constraints	Mean Score	Decision
Lack of fertile land	2.12	Accepted

Limited yam minisett	2.15	Accepted
High cost of labour	2.47	Accepted
Pest and diseases attack	2.83	Accepted
Lack of accessibility to market	2.12	Accepted
Inadequate storage materials	1.76	Rejected

Source:Field Survey,2022

The constraints in yam production among the farmers were analysed using likert scale.The table 3 shows the mean scores were defined to propose that if the values were 2.0 and above ,it should be accepted, but if the value of the mean score is below 2.0,it should be rejected.The result reveals that lack of fertile land has a mean score of 2.12(accepted), limited yam minisett had mean score of 2.15(accepted),high cost of labour was the highest mean score of 2.47(accepted),lack of accessibility to market has a mean score of 2.12(accepted)

CONCLUSION

The benefit cost ratio which gave ₦1.72 revealed that yam production is a very lucrative business and will need more participants in order to increase the quality and quantity of products produced in every farming season.The study also revealed that age,extension visits,household size and farm size were positively signed and had a significant impact to yam production.Furthermore pest and disease attacks,high cost of labour and lack of accessibility to market were major constraints affecting the production of yam by farmers.

ABSTRACT

Agricultural activities contributed significantly to carbon emissions and global warming, which in consequence jeopardize efforts to sustainable food production. This study therefore examined the impact of energy consumption and agricultural production on carbon emission evidence in Nigeria between 1971 and 2019. Cointegration and ARIMA models were used to analyze the data. The result shows that there is a long-run relationship between carbon dioxide (CO_2) emission and agricultural activities. ARIMA result shows that electric power (ECE) and fossil fuels (ECF) which were energy consumption in the model are statistically significant at 1% and have negative and positive effects on CO_2 emissions respectively. The study therefore recommended that renewable energy such as hydropower, wind, solar and biomass energy should be used as an alternative to fossil fuels; and minimum or zero tillage, indiscriminate bushes burning, deforestation and encroachment into forest lands reserved for wildlife conservation should be practiced.

Keywords: *Agricultural sustainability; CO_2 emissions; Crop and livestock; ARIMA; Energy consumption; Nigeria*

INTRODUCTION

In most recent decades, change in climatic factors and global warming has become an imperative and pressing matter of concern for the policy and decision makers. The atmosphere concentrations of carbon dioxide (CO_2) are rising annually at about 0.5% due to fossil fuel combustion, particles from cement production and variation in carbon sequestration initiated through the use of land (Mohamad *et al.*, 2016).

Carbon emission results in the combustion of carbon including the fossil fuels, subsequent to the production of CO_2 and incorporating it into the atmosphere, stated as emissions of greenhouse gases. Carbon dioxide emissions ensuing from the ignited fossil fuels such as petroleum oil products and coal are detrimental to agricultural production as they pose risk to global climate changes (Gün, 2019). The determinant factors that influence carbon dioxide emissions include: economic growth, increasing population growth, energy consumption, activities leading to deforestation and per capita national income.

According to Ritchie (2017) livestock occupies about 80% of the universal agricultural land, and still outputs from livestock are below 20% of global source of calories. Mourão and Domingues Martinho (2017) studies in Portugal reported that the increase in the production levels of the livestock and the main typical animal production was significantly heightened by the level of carbon dioxide in Portugal. Appiah *et al.,* (2018), and Hongdou *et al.,* (2018) also reported that agricultural production is significantly and directly correlating with change in climatic factors. Hence, we examined the impact of energy consumption and agricultural production specific determinants (agricultural land use, crop and livestock production) contributions to carbon emissions.

Several studies (Hongdou *et al*., 2018; and Appiah *et al.*, 2018) on the implication of agricultural production on carbon emission utilized agricultural production, FDI, renewable energy, global trade, energy consumption and income per capita as independent variable factors in determinants model of climate change, while some focused on the evaluation of climate change on the theory of Kuznets environmental curve (Och, 2017). However, there exist some studies that assessed the impact of agricultural production directly on carbon emissions (Hongdou *et al*., 2018; Appiah *et al.*, 2018; and Leitão, & Balogh, 2020). In the same way, this study adopted similar approach with emphasis on Nigeria carbon emissions as studies of such are scarcely available in the knowledge vault of Nigeria literatures.

Hongdou *et al*. (2018) used Granger causality, Cointegration, and Vector Error Correlation Model (VECM) and reported that crop productivity has positive effect on climate change, and fertilizer applications was positively correlated with carbon emissions. Appiah *et al*. (2018) used Ordinary Least Square (OLS) and Fully Modified Ordinary Least Square (FMOLS), and reported that energy consumption was negatively correlated with carbon emissions, while population, income per capital, crop and livestock productivity had direct effect on climate change. While Leitão and Balogh, (2020) concluded that agricultural operations and energy consumption had positive effect on environmental pollution, using Autoregressive Distribution lag (ARDL), Granger causality and ARIMA model. Therefore, this study explored the impact of energy consumption and agricultural production on carbon emission in Nigeria. The study examined the correlation and contributory effects of climate change and agricultural production calculated by CO_2 emissions, agricultural land, and crop and livestock production index from 1971 to 2019 in Nigeria. This study will also, fill the existing knowledge gap, serve as a tool to share essential information on the industry, and refocus attention on the prospects of an environmentally friendly agricultural production system.

METHODOLOGY

This study analyses the Nigeria agricultural production factors (crop production, livestock, and agricultural land), as well as energy consumption on climate change between the periods, 1971 to 2019. The study used secondary data extracted from World Development Indicator (WDI) and Food and Agriculture Organization (FAO) database. Johansen Cointegration, and AutoRegressive Integrated Moving Average (ARIMA) model used in this study. Carbon emissions represent climate change. The independent variables selected for this study are: energy consumption from both electric power (ECE) and fossil fuels (ECF), Crop Productivity Index (CPI), Livestock Productivity Index (LPI), and Agricultural Land used (AGL). Adapted from empirical studied of (Hongdou *et al.*, 2018; Appiah *et al.*, 2018; and Leitão, & Balogh, 2020) the equation below established the function as;

$$CO_2 = f(ECE, ECF, CPI, LPI, AGL) \quad (1)$$

In logarithm form as;

$$LnCO_2 = \alpha_0 + \alpha_1 LnECE + \alpha_2 LnECF + \alpha_3 LnCPI + \alpha_4 LPI + \alpha_5 AGL + \mu_t \quad (2)$$

Where; CO2 is carbon dioxide emissions (kt); ECE is electric power consumption (kWh/capita); ECF is fossil fuel energy consumption (kg of oil/capita); CPI is crop production index; LPI is livestock production index (proxy of meat and milk from all sources, cheese, eggs, honey, raw silk, wool, and hides and skins); AGL is agricultural land (proxy of arable, under permanent crops, and under permanent pastures); and u_t is the error term. The data were analyzed using GRETL statistical software. The following hypothesis was tested;
Ho1: Agricultural productivity positively related to climate change via carbon dioxide emissions in Nigeria.

RESULTS AND DISCUSSION

Table 1: Unit root test: Augmented Dickey-Fuller (ADF) test intercept and trend

Variables	**At Level**		**First Difference**	
	Statistic	***P*-value**	**Statistic**	***P*-value**
$LnCO_2$	-2.884	0.181	-5.427	0.000
LnECE	-0.346	0.088	-8.996	0.000
LnECF	-2.620	0.274	-5.592	0.000
LnCPI	-1.531	0.807	-7.954	0.000
LnLPI	-1.324	0.872	-9.690	0.000
LnAGL	-1.742	0.720	-8.204	0.000

Significant at *** 1%
Source: Authors computation, 2022

Table 1 shows the unit root test using ADF intercept with trend. All variables are non-stationary at level and stationary at first difference. Also, all the variables at first difference are statistically significant at 1% level (P-value < 0.01). This implies that all the variables considered are integrates of order *I(1)*. This result agrees with the finding of Leitão and Balogh (2020) in their study in Portugal.

Table 2: ARIMA

Variables	**Coefficient**	**Std. error**	**z**	***p*-value**

***, **, and *are significant at 1%, 5% and 10% respectively.
Source: Authors computation, 2022

Table 2 shows the ARIMA result of the model. The coefficient of multiple determination (R^2) shows that 63% magnitude of CO_2 were explained by the independent variables included in the model, while Adjusted R^2 0.499 illustrates the correct measurement of the model. ECE and ECF which represented energy consumption in the model are statistically significant at 1% and have negative and positive effects on carbon emissions. This agrees with Tan and Tan (2018). Correspondingly, Leitão and Balogh (2020) affirmed that energy consumption, particularly energy consumption from fossil fuels energies increases CO_2 emissions and as result heightens and worsens the climate change. On the other hand, agricultural land (AGL) and livestock production index (LPI) were insignificant contributors to carbon emissions. This finding is in contrast with Hongdou *et al*., (2018); Appiah *et al*., (2018); and Leitão and Balogh (2020) who reported significant role of livestock production and agricultural land via carbon emissions on climate change.
Test of ARCH (P(chi-square (1) > 1.334) = 0.248) and test of normality of residual (chi-square (2) = 0.927), are significant, thus shows the reliability of the model used in the study.

Table 3: Johansen cointegration

Eigenvalue	**Trace test**	***P*-value**	**Lmax test**	***P*-value**
0.970	191.39	0.000	80.72	0.000
0.853	110.67	0.000	44.17	0.001
0.682	66.50	0.000	26.34	0.069
0.642	40.16	0.002	23.65	0.019
0.340	16.51	0.033	9.54	0.249
0.261	6.97	0.008	6.97	0.008

Significant ** at 5%
Source: Authors computation, 2022

Table 3 shows Johansen Cointegration test using the decisive factor of trace and lmax test techniques. According to the test, the hypothesis of no cointegration was rejected at 5% level of significance. The result agrees with the findings of Leitão and Balogh (2020). This means that there is a long-run relationship between CO_2 emission and agricultural activities.
[

Diagnostic Test

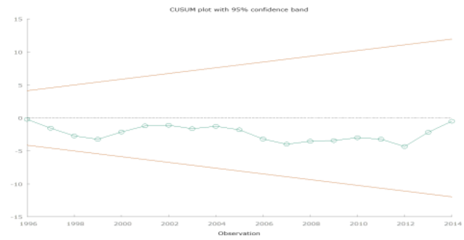

Figure 1: CUSUM Test

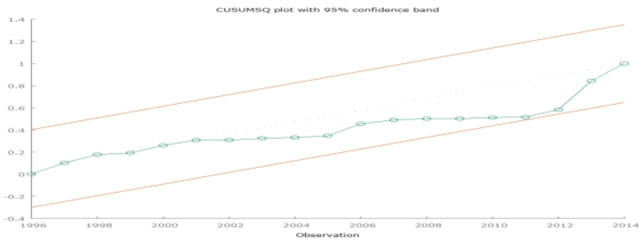

Figure 2: CUSUMSQ Test

Source: Authors computation, 2022

Figure 1 and 2 shows the robustness of the OLS residual, the cumulative sum control chart (CUSUM) and cumulative sum control chart of the square (CUSUMSQ) testing methods were used in this study. Since the broken lines of the data collected shaped by the CUSUM and CUSUMSQ do not extend beyond the boundary at 5% level of significance, then it implies that models used in the study accurately represent the data used in analysis.

CONCLUSION AND RECOMMENDATIONS

This study examined the relationship between Nigeria CO_2 emissions and agricultural activity, energy consumption, using ARIMA and Cointegration for the period of 1971 to 2019. ADF unit root test established that the variables employed in this study were stationary at difference in *I(1)* order. ARIMA result shows that energy consumption (ECE and ECF) are significantly contributing to CO_2 emissions in Nigeria. The indicates that increase in agricultural production activities and energy consumption would result in excessive emissions of CO_2 to the extent of hampering the environment and increasing the already saturated risk propensity in agricultural practice. On the contrary, the resulting increase in food production relates to economic growth. The study, therefore recommended that;

i. In order to minimize the hazards associated with climate change through CO_2 emissions and achieve as well as maintain the sustainability of agricultural productivity, energy from fossil fuels should be substituted with the renewable energy sources like hydropower, wind, biomass, solar energy among others;
ii. Minimum or zero tillage to reduce deforestation, reduction of indiscriminate bush burning for agriculture, incorporating agro-forestry practices into agriculture by planting trees as wind breakers, forest conservation and prevention of urban encroachment into the forest lands apportioned for agriculture and reserved for wildlife conservation should be practiced and enforced; and
iii. Organic farming which is an alternative means to enhance sustainable agricultural practices by minimizing environmental pollution in farming should be adopted.

Agricultural Society of Nigeria
24 - 28 Oct., 2022

ABSTRACT

In recent times, there have been several efforts to achieve sustainable development and increase people's welfare. Financial inclusion has become the policy agenda of many countries especially in developing economies. Therefore, the effect of financial inclusion on welfare outcomes of people living in rural setting in Nigeria where majority of the populace reside has become very important and is therefore, the subject of this study. Hence, this study empirically examines the impact of financial inclusion on rural economy in Kwara State, Nigeria. Primary data was solely used for the study. A two staged sampling techniques was used for the study. A total of 360 respondents comprising of 180 beneficiaries and 180 non beneficiaries of the VADI scheme across the nine (9) communities where VADI operates in Kwara State. A structured questionnaire was used for the purpose of extracting needed information from the respondents. The data collected was analyzed with descriptive statistics, Double hurdle model, food security index and Propensity Score Matching (PSM). However, the results showed that utilization of credit facilities under VADI Scheme is significantly affected by remittance received, monthly income, membership of cooperative society, functional bank account and number of dependents The result also showed that about 70.5% and 50.9% of VADI Benefitting and non VADI Benefitting households are food secure respectively. The impact of VADI on the food security of the rural households that participated in the scheme revealed an average increase of 17018.22Kcalorie intake.However, it is recommended that government and non governmental agencies should look into the opportunities presented through financial inclusion for sustainable economic growing and development

Keywords: Rural, communities, food security and households

INTRODUCTION

Access to financial services is significant for development and the achievement of the 2030 Agenda for Sustainable Development as it serves as a mechanism for supporting inclusive economic growth (Jahan et al., 2019). It plays a key role in the functioning of markets and the economy; and contributes to economic and social development. The relevance of financial services for the economy is manifold as it contributes to output, foreign direct investment (FDI) and employment; as infrastructure services it provides valuable inputs for activities in the primary, industrial, and tertiary sectors and for individuals; through banking, securities and insurance services, it facilitate domestic and international transactions, mobilize, and channel domestic savings and broaden the availability of credit for Small and Medium Scale Enterprises (SMEs) and households especially those in the rural areas.

Despite the benefit of access to financial services and the progress in recent years, a crucial gap remains between developed and developing economies. In 2017, 94 percent adults in developed economies had an account with a bankcompared to 63 percent in developing economies. The poor, less educated, youth and women who are mostly in the rural areas tend to be more excluded. Therefore, financial inclusion has become a key policy agenda of many countries, since it can contribute to poverty reduction.

Financial inclusion is the process of extending financial products to the unbanked and vulnerable populace. This enables individuals and businesses to have access to financial services such as deposit, loans, insurance, payments and fund transfer at their convenience; and to meet economic needs. Better still, it is the bringing home of financial services at an affordable cost to the disadvantage group in the society, particularly the low-income and underprivileged (Gwalani & Parkhi, 2014).

Growing financial inclusion has the capability of helping the poor through various channels, including the ability to accumulate savings and access credit that enable them to have diverse consumption patterns; better manage financial risk and deal with uncertainties; and also invest in productive assets (Demirgüç-Kunt et al., 2018).

Lack or poor access to financial services signifies a major obstacle to income opportunities and economic welfare of individuals, especially the poor, women and youth, as well as firms, particularly the SMEs in the informal sector who are credit constrained, as lenders have little information on their performance and credit worthiness, as many do not have bank accounts to run their business.

The Village Alive Development Initiative (VADI) was initiated by Agricultural and Rural Management Training Institute (ARMTI) as an action-oriented research with the aim of increasing rural livelihood which encompasses farmer's capabilities, assets, income and activities required to secure the necessities of life in rural communities. In Kwara state, VADI activities covers Idofian, Elerinjare, Jimba-oja and Kabba-owode (ARMTI, 2013).

The study accessed the impact of (VADI) credit services on the livelihood of rural dwellers in Nigeria. The objectives are to

- assess the heterogeneity in financial service credit utilization in terms of rural dwellers characteristics;
- determine the food security status of households in rural communities; and
- examine the impact of financial service under VADI schemeon food security of rural dwellers.

METHODOLOGY

Study Area

The study was carried out in North Central, Nigeria. North Central Nigeria consists of six states, namely Plateau, Nasarawa, Benue, Kogi, Niger and Kwara as well as the Federal Capital Territory, Abuja (National Bureau of Statistics, 2012). The region covers a land area of about

298,830 square kilometres which accounts for 37 percent of the total land area of Nigeria; it hasa population of about 29,252,408inhabitants (National Population Commission, 2016) and has a high degree of ethnic diversity. The region is bounded in the East and West by the republics of Cameroon and Benin respectively and in the North and South by the Northern and Southern states of Nigeria (Okpeh, 2008). This region is an area with certain climatic coherence, stretching over two distinct ecological zones namely; the Savannah zone and the Rain Forest zone. The predominance source of livelihood in the area is farming.

VADI programme is currently in operation in three states in the region namely: Kwara, Benue and Nasarawa States.

Data and Sampling Techniques

The study employed a cross sectional research design. A two-staged random sampling was used for the study. The first stage was the random selection of Kwara Statefrom the three (3) states under VADI programme in North central, Nigeria;and the second stage was the selection of 360respondents comprising of 180 beneficiaries and 180 non beneficiaries of the programme across the nine (9) communities where VADI operates in Kwara State.The sampling frame used for selecting beneficiaries of the scheme was the complete list of farmers obtained from VADI office in each of the communities in the state under the Agricultural and Rural Management Training Institute (ARMTI).

Analytical Techniques

Descriptive Analysis

Descriptive statistics which comprises the use of measures of central tendency and dispersion (mean, mode, median and standard deviation), percentages frequency and tabulation was used to capture the socio-economic characteristics.

Double Hurdle model

Double hurdle model was used to analyze drivers of the decisions of rural dwellers to access financial services and determinants of quantity/amount utilized. Drivers of usage decision ofVADI credit is specified using the Probit model

$Z_I^* = \alpha X_i + U_i$; where Z^* is an unobserved latent variable determining a household's decision to use credit, X is a vector of the characteristics hypothesized to affect the usage decision, and u is the random disturbance term distributed with mean 0 and variance 1.

$Z^*=1$ *if* $Z^*>0$, (for users of VADI credit) ; $Z^*=0$ *if* $Z^*\leq 0$, (for non-users of VADI credit) .

The determinants of amount of VADI credit used was analyzed using a Tobit regression equation given as $Y_i = \beta_0 + \beta_1 X_i + \beta_2\lambda + u$; $Y = f(X_1, X_2, X_3, X_4, X_5, X_6, X_7, X_8, X_9, X_{10,} u)$ Where Y = Quantity of VADI credit used (naira) X_1 = Number of dependents ; X_2 = Gender ; X_3 = marital status ; X_4 = Monthly income (Naira) X_5 = Education (years spent in school) ; X_6 = Age ; X_7= membership of cooperative society ; X_8= Having operational bank account ; X_9= Remittance (Naira) ; U = Error term

Food Security Index

The food security (Z) index as applied by Fakiyesi (2001) is given by the formula $\mathbf{Z}=\frac{Yn}{R}$: where Yn is the nth household's daily per capita calorie intake and R is the recommended per capita daily calorie intake. Thus, Zn=1 for Yn>1 (i.e. food secure households) and Zn= 0 for Yn< 1(i.e. food insecure households). $\mathbf{H}=\frac{M}{N}$: where **H** is the headcount ratio, **M** is the number of insecure household and **N** is the total sample. The nutrients content of both produced and purchased food items were used to derive calorie availability. A daily recommended level of 2470kcal per capita and 65g protein per day defines the food security line, used in this study (Omotesho, Adewumi, & Fadimula, 2007).

Propensity Score Matching (PSM)

Propensity Score Matching (PSM) was used toevaluate the impact of access to VADIfinancial services (credit access) on the welfare (food security) of rural dwellers. PSM addresses the differences in groups prior to treatment by reducing the total collection of observed pre-treatment covariates into a single composite score that is then used to create a comparison group that is similar to the treated group with respect to observed covariates using the propensity score.

The average treatment effect on the treated (ATT) can be estimated using these results. $ATT = E\ Y_1(\ |D=1) - E\ Y_0(\ |\ D=1)$ The CIA implies $E\ Y_0(|\ D=1, X) - E\ Y_0(|\ D=0, X)$; $E\ Y_0(|\ D=0,\ X) - E\ Y_0(\ |D=0,\ p(X))$ Combining these results, the Law of Iterated Expectations can be used to show that $ATT = E\ Y_1(|\ D=1) - E\ Y_0(\ |D=1)$
$= E_p(x)\ |D{=}1\ E\ Y_1(|\ D=1, p(X)) - E\ Y_0[\ (|\ D=0, p(X))]$

RESULTS AND DISCUSSION

Socio Economic Characteristics of Farmers

The socio-economic characteristics of respondents considered in the study include sex, age, marital status, level of education, marital status, number of dependents, farming experience, farm size and primary occupation. The study revealed that most (77.2%) of the farmers in the study area are males, this implies that majority of the households were headed by males.The result showed that the average age of household head in the study area was about 53 years while the majority (34.7%) of the respondents fall within the age brackets of (46-55) years, this suggests that majority of the households heads were in their active age. Majority (59.5%) had at least primary education. This implies that the rural households are enlightened and may be willing to adopt innovations that would bring about increase in their economic activities to improve their income and food security. Results from the study revealed that only 16.6% of respondents were single.

The majority (66.6%) of the household heads had farming as their primary source of income while 76.7% of the farmers had above 10years experience of farming in the study area.

Table 1: Socio-Economic Characteristics of Rural Dwellers

Factors that determine farmers' decision to utilizeVADI **credit facility and amount of credit utilized**

The farmers' decision to access and utilizeVADIcredit was tested. Four out of the nine explanatory variables tested were significant in explaining the farmers' decision to utilize of VADI credit. Remittanceand monthly income were significant at 5% and contributed negatively to dwellers' decision to utilize VADI credit while membership of cooperative society,functional bank account and Number of dependent had a positive relationship with farmers' decision to utilize the credit obtained through VADI and were significant at 5% and 10% respectively.

Table 4 presents the households food security status of VADI Beneficiaries and Non- VADI Beneficiaries. About 70.5% and 50.9% of the VADI Benefitting and non VADI Benefitting households were food secure respectively. The mean daily energy and protein available to the food-secure households for VADI Beneficiaries and non VADI Beneficiaries are (17018.22Kcal and 346.41g) and (16015.26Kcal and 331.71g) respectively while the daily per capita energy for food secure households for VADI Benefitting and non VADI Benefitting households are 3550.50kcal and 2950.05kcal respectively.

Table 3: Food Security Status of Rural Dwellers

	VADI Beneficiaries		Non- VADIBeneficiaries	
	Food Secure	Food Insecure	Food secure	Food Insecure
Household Percentage	70.5	29.5	50.9	49.1
Mean Adjusted Household Size	4.72	4.89	5.30	5.71
Household daily energy availability (Kcal)	17018.22	11446.70	16015.26	10402.71
Household daily per capita energy	3605.55	2340.84	3021.75	1821.84
Household daily protein availability (g)	346.41	274.16	331.71	234.70
Household daily per capita protein availability	73.39	56.07	62.59	41.10
Head Count Ratio	0.705	0.295	0.509	0.491

Source: Field survey, 2022

Table 4 reveals that Average Treatment Effect on the Treated (ATT), which measures the impact of VADI on food security of households that Benefitted, showed that the calorie intake increased on the average by 1176 kcal/AE/day. The increment in the calorie intake of the Beneficiaries was significant at 1%. Average Treatment Effect of VADIon the Untreated (ATU) showed that if the non- beneficiaries had utilized thescheme, the improvement in their calorie intake would have been increased by 1089kcal/AE/day while Average Treatment Effect (ATE) shows that if a respondent was to be picked randomly, the calorie intake would increase by 1092 kcal/AE/day, since ATT is greater than both ATU and ATE, it implies that VADIhas impact on the food security of the households benefitting.

Impact of Irrigation Scheme on Calorie Intake of Farming Households

Table 4: Treatment Table

Variable	Sample	Treated	Control	Difference	S.E.	T-Stat
Farm Income	Unmatched	1847.657	972.612	875.045	5572.834	3.64***
	ATT	2281.790	1105.476	1176.314	7261.763	3.85***
	ATU	1965.576	876.079	1089.497	-	-
	ATE			1092.446	-	--

Source: Field Survey, 2022**;** *, **, *** indicate the coefficients are statistically significant at 10%, 5% and 1% level respectively. T-values are based on Bootstrapped standard error.
ATT is Average Treatment Effects on the Treated, ATU is Average Treatment Effect on the Untreated and ATE is Average Treatment Effects.

CONCLUSION AND RECOMMENDATION

From the empirical evidences of this research work, it clear that VADI scheme which is a form of financial inclusion of great impact on food security of rural communities. However, it is recommended that government and non governmental agencies should look into the opportunities presented through financial inclusion for sustainable economic growing and development

ABSTRACT

The study reviewed the significance of utilization of yam technologies to increase yam production and achieve food security in Nigeria. Secondary data were used for the study. Yam plays a very important role in ensuring food security and livelihood systems of people living in Nigeria. The major uses of yam are for human consumption, income generation, and for social, cultural, or religious events. One of the ways small holder yam farmers can achieve sustainability and food security in yam production is by improving their efficiency within the input of existing resource base and technology. Yam production technologies include improved yam varieties, yam mini-set technique, land preparation, appropriate spacing, weed control, fertilizer application, improved staking, and proper harvesting time. The reviewed study concluded that the effective utilization of yam technologies developed and released in Nigeria for yam production have the attributes or characteristics that will promote food security. Major constraints to yam production include access to credit and high production cost. It is recommended that, in order to increase yam production and achieve food security, the effective utilization of yam technologies developed and released by research institutions (IITA Ibadan and NRCRI Umudike) will be maximally utilized by yam farmers

Key words: **Food security, Utilization, Yam Technologies and Yam Production.**

INTRODUCTION

Yams (Dioscorea species) constitute the predominant starchy staple in sub-Saharan Africa where food security for a growing population is a critical issue, Regina *et al.* (2011). According to FAO (2014), the world output of yam is estimated at 68.1 million tones on a total cultivated land area of 7.8 million ha, corresponding to an average yield of 8.8 t/ha. Nigeria is the largest producer of yams with about 45 million tonnes in 2014, representing 66 percent of world output. The most cultivated species of yam (Dioscorea sp.) are white yam (D. rotundata), yellow or Guinea yam (D. cayenesis) and water yam (D. alata). Yam plays a very important part in ensuring food security and livelihood systems of at least 60 million people in West

Africa. It is cultivated mostly in the Derived and Southern Guinea Savanna. About 57 million tons of yams (about 93% of global production) are produced on 4.7 million hectares annually in this sub-region, mainly in five countries namely; Benin, Côte d'Ivoire, Ghana, Nigeria and Togo. Nigeria alone accounts for 47 million metric tonnes of global yam production (Vanguard, 2021), Yams are cultivated for mainly seed yam and ware yam production. Ware yams are intended for consumption, while seed yams are the planting materials used in the field production of ware yams (Eyitayo *et al.*, 2010). The major uses of yam are for human consumption, income generation, and for social, cultural, or religious events. It is eaten in different forms such as *fufu* (the so-called poundo yam and Amala in Nigeria), boiled, fried and roasted (IITA, 2009). They are among major cash and most consumed food crops in West African countries like Nigeria (National Bureau of Statistics, 2012). Its cultivation is very profitable despite high costs of production and price fluctuations in the markets (IITA, 2012; Izekor and Olumese, 2010). Yam place in the diet of smallholder farmers cannot be over emphasized. It contributes over 200 dietary calories per capita per day for over 150 million people in West Africa and have over 21% dietary fibre and are rich in carbohydrates, vitamin C, potassium, manganese and other essential minerals (IITA, 2009). Many yam belt areas in Nigeria continuously proclaimed "yam is food and food is yam" (Maikasuwa and Ala, 2013).

In Nigeria, the scarcity and high cost of seed yam has forced the production of ware yam to fall short of the aggregate demand for ware yam for food consumption and industrial uses. Since the restoration of democracy in 1999, agricultural policies have sought to enhance food security and combat poverty and extreme hunger (Ojo and Adebayo, 2012). As a result, mini tuber yam production by smallholder farmers has assumed great importance for increased supply of mini tuber yam (planting material) to seed yam producers in response to the increasing demand for ware yam. It implies that efficient use of farm resources has strong potential for increasing the profit efficiency of the farmers in the supply of planting material to seed yam producers, as well as reflect an increase in farm employment, income and food security in Nigeria. Increase in farm profit efficiency through efficient use of farm resources is an important part of agricultural sustainability (Anyaegbunam *et al.* 2019). One-way small holder yam farmers can achieve sustainability in yam production is to raise their production, by improving their efficiency within the input of existing resource base and technology (Ajibefun, 2004). Expansion and increasing intensification of yam cultivation have raised the need for ensuring a sustainable availability of high-quality seed yam on a commercially viable basis in yam growing areas. An early adopter of YIIFSWA-promoted improved yam varieties enjoyed "fantastic" yield of 32.6 t/ha (Asiedu), 30.0 t/ha (Kpamyo), and 37.5 t/ha (Swaswa) from which he earned reasonable revenue (Amadi, Anyaegbunam and Amadi (2022). To achieve food security, innovative yam propagation techniques have been developed by international Institute for Tropical Agriculture (IITA) and National Root Crops Research Institute (NRCRI) Umudike for yam farmers to increase output and make food available. Therefore, there is need for this study to review how to achieve food security through utilization of improved yam technologies in Nigeria.

Appropriate Technology

Technology is considered appropriate if it makes optimum use of any given economic environment. Aremu *et al*. (2015) stated that appropriate technology for peasant agriculture should comprise the set of objectives or tools that will unlock new resources, increase productivity and generate new capacities to produce goods and services on farms. To ensure that technologies are appropriate to the actual needs of the farmers, it is suggested that agricultural research in Nigeria should emphasize what is now known as participatory research (Nwosu and Nwachukwu, 2013). According to Ann (2013), the appropriate technology integrates and inter connects sub processes which include delivery of the technology to the targeted farmers and promotion of new technology to the region as follows:

- persuading farmers to adopt the technology;
- enabling the targeted farmers to apply the technology in their farms and giving them the knowledge and skill necessary to do so;
- provision of technical application requirement;
- diagnosis and treatment of problems that may arise during the application and dissemination of new technology and;
- the basic requirements that are reliable in choice of agricultural technology for farmers.

Farmers need proper orientation on appropriate technology to scale up their productivity.

Food security concept

Food security has been defined as physical and economic access, at all times to adequate food for an active and healthy life, which includes access to nutritionally safe foods and an assured ability to acquire foods in socially satisfactory ways (Food and Agriculture Organization (FAO), 2012). The concept of food security includes both physical and economic access to address people's needs and preferences. In that way, a household should have the possibility to consider all its members at all times. FAO (2013) enlisted three main steps towards achieving food security such as; food availability, food accessibility, and food utilization. There are however, some major problems associated with food production and consumption. They are among others the availability and suitability of cultivable land, the method of cultivation, the technology and energy productive effort and equitable distribution of available food resources. Nevertheless, Nigeria still has the potentials for food security if the following technologies on yam farming are adopted and utilized;

- Improved yam varieties
- Proper land preparation
- Yam mini-set technique (for seed yam production)
- Appropriate spacing (1mx1m for ware yam and 0.25mx1m for seed yam).
- Weed control (1st and 2nd weeding).
- Fertilizer application.
- Staking of yam vines.
- Proper harvesting time.

(Roots, 2014).

Improved yam varieties released by IITA and NRCRI Umudike and registered in Nigeria

Variety Name	Outstanding Characteristics / Potential yield	Year Released
TDr 89/02677	Stable yield, very good cooking and pounding qualities, cream tuber parenchyma, 25% tuber dry matter content	2001
TDr 89/02565	Stable yield, very good cooking and pounding qualities, cream not oxidizing parenchyma, 35% tuber dry matter content	2001
TDr 89/02461	Stable yield, very good cooking and pounding qualities, cream tuber parenchyma, 26.7% tuber dry matter content	2001
TDr 89/02665 (Asiedu)	Stable yield, very good cooking and pounding qualities, cream non oxidizing tuber parenchyma, 35.3% tuber dry matter content	2003

TDr 95/01924	Stable yield, very good cooking and pounding qualities, white non oxidizing tuber parenchyma, 32.8% tuber dry matter content	2003
DRN 200/4/2	High yielding, pest and diseases tolerant, very good for fufu, frying and boiling suitable for rainy and dry season yam production. 35t/ha.	2008
TDa 98/01176 (Swaswa)	High yielding, pest and diseases tolerant, good for pounding, frying and boiling. 26-30t/ha.	2008
TDa98/01168	High yielding, pest and diseases tolerant, good for pounding, frying and boiling. 24-28t/ha.	2008
TDa 98/01166	High yielding, pest and diseases tolerant, good for pounding, frying and boiling. 26-30t/ha.	2008
TDr 95/19158	High yielding, pest and diseases tolerant, very good for pounding, frying and boiling. 29.4t/ha.	2009
TDr 89/02602	High yielding, pest and diseases tolerant, very good for pounding, frying and boiling. 31.5t/ha.	2009
TDa 00/00194	High yielding, pest and diseases tolerant, good for pounding, frying and boiling. 37.5t/ha.	2009
TDa 00/00104	High yielding, pest and diseases tolerant, good for pounding, frying and boiling. 30t/ha.	2009
UMUDa-4	High yielding, good for Amala, pounded, frying and boiling 33.3t/ha.	2010
UMUDr-17	High yielding under dry season yam cropping system, 30t/ha.	2010
UMUDr-18	High yielding, pest and diseases tolerant, very good for yam fufu, frying and boiling. 31t/ha.	2010
UMUDr-20	High yielding, 39.9t/ha.	2016
UMUDr-21	High yielding, 43.9t/ha.	2016
UMUDr29 (Super)	Tolerance to yam mosaic disease, slow rate of oxidation (browning) and high dry matter content.	2022
UMUDr30	Tolerance to yam mosaic disease, slow rate of oxidation (browning) and high dry matter content	2022
UMUDa31 (Wonder)	Tolerance to yam mosaic disease, slow rate of oxidation (browning) and high dry matter content, high yield, excellent boiling and poundimg quality	2022
TDa1100201	Good boiling, good taste and good dry matter	2022
TDa1100316	Good boiling, good taste.	2022

ABSTRACT

Human capacity development on catfish production targeting youths and women in Nigeria was carried out by Nigerian Institute for Oceanography and Marine Research from 2017 to 2020. A total of 1366 people were trained comprising of 949 males and 417 females, selected from six geopolitical zones of Nigeria. The modules taught during the training included the different value chains of catfish production. The training programme on catfish farming, the major fish species cultured in Nigeria has further boasted aquaculture production through engagement and empowerment of youths and women as skilled actors in the fish industry in Nigeria.

Keywords: capacity development, youths, women, catfish production,

INTRODUCTION

Capacity development is the process whereby people, organizations and society as a whole unleash, strengthen, create, adapt, and maintain their affairs to achieve set goals. The way of increasing fish production and ensuring that Nigeria is self-sufficiency in fish production by engaging in fish farming especially catfish farming (Adediran, 2002) and Ugwumba, (2005). This is because currently, we need 3.2 Million tonnes of fish but produce 1.1 Million tonnes leaving a deficit of 2.1 Million tonnes with estimated population 187.1 Million (FDF 2015). Fish contributes a significant amount of animal protein to the diet of many people in Nigeria. It is widely accepted, readily available and relatively cheaper when compared with protein from other animal sources (Ugwumba and Ugwumba, 2003, Gabriel et al, 2007).

The need to increase food security especially animals protein in Nigeria culture is by fishery activities to skyrocket in the third world countries (Akinrotimi *et al,* 2007). Youths and women require education and training on aquaculture production in order to provide them with the knowledge to contribute to national and household food supply, security and income (FAO, 2011).

Food and Agriculture Organization (FAO) reported that increased aquaculture activity is key to meeting the demand for food associated with global population growth, and more and more people, especially in poor rural areas, where food often lacks essential nutrients(FAO, 2014),. Aquaculture is the fastest growing food production sector in the world (Tacon, 2020).

According to FAO (2017, 2017b), implementing sustainable aquaculture is therefore central to achieving many of the sustainable development goals (SDGs). This will directly affects the success of SDG 1 (end poverty. Aquaculture can influence poverty alleviation in two main ways: by increasing income for families and by generating jobs, specifically for very low income or poor people producers. In this way, aquaculture offers an effective mechanism to lift individuals and communities out of poverty for those able to enter the sector (Stevenson; Xavier, 2009)

Youths and women needs education and training on Aquaculture in order to provide them with the knowledge to contribute to greater national and household food supply, security and income (FAO 2011).There was a need to equip women and youths with skills in the aquaculture value chain. The Federal government of Nigeria fashioned out the skill acquisition schemes to empower youths and women and give them means of livelihood in order to reduce the high unemployment rate in the country. In 2016, Federal government in conjunction with Nigerian Institute for Oceanography and Marine Research renewed programme on Aquaculture development for training of unemployment youths and women in Aquaculture and post-harvest technology in the six geopolitical zone (i.e North- East, North-West, North-Central, South east, South-South and South-West). This study sees capacity development of the youths and women as a tool to address the constraints and decline in catfish production in Nigeria, identify the number of men and women trained in the six geopolitical zone and know the total number of youths empower from 2017 to 2020 before outbreak of covid- 19 pandemic.

MATERIALS AND METHODS

This study was carried out in Nigerian Institute for Oceanography and Marine Research records from 2017 to 2020 before the outbreak of covid-19 pandemic. The trainees were accommodated for the period of the training. Each training were conducted between one and two weeks. The training utilizes participatory approach which include lectures (30%) hands on practical works (70%), discussion groups and other interactive learning methods. The trainees were chosen by ADP staff of the states from Federal ministry of Agriculture and rural development. And also the trainees were selected by screening from various local government area from the six geopolitical zone through the programme of capacity development by the senators and house of assembly members in their constituencies. The trainees were trained on Aquaculture production and fish post-harvest technology. The resource persons adopted a combination of lectures, class exercises, use of audio visual materials and mostly use of practical demonstrations to impact knowledge efficiently on the participants. At the end of the training trainees were awarded with certificate for participation and training manual provided. The Institute trained 1,366 out of which male are 949 (69%) and female were 417 (31%) from the six geopolitical zone from 2017 to 2020 before the outbreak of Covid – 19 pandemic. Trainees were evaluated and stated their farm location for monitoring. The trainees also formed a WhatsApp group for easier communication. The results of trainees participated were analyze using IBM SPSS statistics 20 and Microsoft excel 2013.

RESULTS

Table 1: Number Youths and women trained by Nigerian Institute for Oceanography and Marine Research (NIOMR) from 2017 - 2020.

Year	Male	Female	Total	Ratio of male : female
2017	53	18	71	0.75 : 0.25
2018	168	59	227	0.74 : 0.26
2019	665	289	954	0.70 : 0.30
2020	63	51	114	0.55 : 0.45
Total	949	417	1,366	0.69 : 0.31

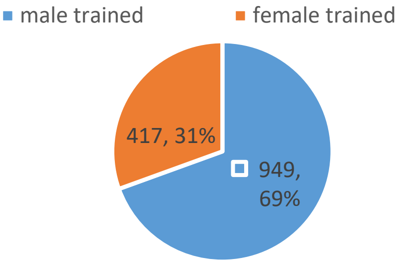

Figure 1: Pie chart indicating Percentage of male and female trained at NIOMR from 2017 to 2020

Table 2: Composition of Starter packs received by trainees from 2017 to 2020

	Quantity	2017	2018	2019	2020
Plastic fish tanks	2	X	X	X	X

DISCUSSION

Empowering youths and women on aquaculture production and fish processing through training could go a long way by eradicating poverty and youth's restiveness. The initiative by Federal government aimed at the development of the agriculture sector as well as youths empowerment in order not to be over dependent on the oil sector and youths depending mostly on white collar jobs. Nigerian Institute for Oceanography and Marine Research trained 1,366 out of which male are 949 (69%) and female were 417 (31%) from the six geopolitical zone from 2017 to 2020 before the outbreak of Covid – 19 pandemic (Table 1 and figure 1) . About 43 training programmes were carried out during this period. This programme is in line with the event organize by African development bank (2012) and World Bank (2014). Table 1 showed number of youths and women trained for four years before the outbreak of Covid – 19 pandemic. The lowest number of male and female were observed in 2017. The highest number of male and female were observed in 2019 (Table 1)

Table 2 indicates unemployed Youths and women trained by the Federal government project were supplied with starter packs in order to establish themselves and also in the future to be an employer of labour. The starter packs comprises of rearing tanks ($3m^3$), fish feed, juvenile fish, scoop net, weighing scale (20kg), kitchen knife, plastic bowls, net for covering of tanks, sieves, log book (for record keeping, salt (1kg), smoking kiln (25kg), table size fish (25kg) and charcoal from 2017 to 2020 depending on the training purpose. The aim is to contribute towards increasing employment of youths and women through skill acquisition, re-orientate their minds to be owners of fish farm and employer of labour in the near future. Also the essence of this provision of the starter pack is to increase means of livelihood, employment creation, and revenue generation from generation to generation. This is also corroborate with project organize by FAO (2011C), IFAD (2010) and IFAD (2011). Investment in sustainable production systems for aquaculture is an alternative that should be encouraged to ensure environmental protection that is also economically viable and socially just. (Marques et al, 2020).

Moehl, (2013) states five challenges facing the aquaculture sector (high quality and affordable seed, feed, capital, market and information. These five factors were made easier through capacity development by Federal government and Nigeria Institute for Oceanography and Marine Research with training, technical and management, issuance of starter packs as well as strong financial and business planning. The trainees were provided with high quality juveniles, fish feed, money and WhatsApp group were open in order to monitor and pass information. At the end of the training certificate were awarded to the trainees.

CONCLUSION AND RECOMMENDATION

It is estimated that Nigeria needs to produce at least 700,000 metric tonnes (Winrock International (2010) of fish annually to eliminate its dependency on fish importation. According to Obiya and Ekubo (2011), Government should encourage more involvement in the fish farming business such that will create an enabling environment to increase investment in fish aquaculture development in Nigeria. Development of youths and women in Nigeria through training will promote the benefits of catfish production, increase employment opportunities and source of animal protein for small income earners, reduce food insecurity and poverty alleviation.

56th Annual Conference
Agricultural Society of Nigeria
24 - 28 Oct., 2022

ABSTRACT

The study analyzed the determinants of access to credit among farmers in Irepodun Local Government Area of Kwara State, Nigeria. Primary data were obtained from a total of 104 selected farmers in 5 farming communities. Descriptive statistics and ordinary least square regression model were used to analyzed the data. The results revealed that the farmers were within the active and productive age with a mean age of 42years. 90% of the farmers had formal education, 75% were male and the average household size and farming experience of the farmers was 8 persons and 16years respectively. Majority of the farmers' source of finance were personal savings, families and friends and cooperatives. Only about 54% of the farmers have access to credit with an average of ₦416,946.50 obtained. The determinants of access to credit in the area were annual income (6.89), interest rate (5.58), farm size (2.29), membership of cooperative (2.92) and age of the farmer (2.23). The perceived constraints to credit access among the farmers were absence of banks in locality, lack of guarantor, distance from financial institutions, lack of awareness and high administrative procedures among others. The study concluded that access to credit facilities among the farmers in the study area is inadequate. Establishment of credit/loan offices closer to the farmers and operated by officials who would be familiar with farmers in the study area to reduce lending procedures and risks was recommended.

Keywords: Credit access, Farmers, Irepodun LGA.

INTRODUCTION

Small scale farmers are an important contributor to the national objective of creating employment opportunities, generating income and providing a source of livelihood for the majority of the low-income households in the country. However, inadequate credit supply is a central problem upon which other production factors exerts negative influence on farmers' output and productivity (Akinola, 2013; Agada, 2017). Limited access to agriculture credits perpetuates poverty and innovation which the farmers wish to adopt may be too expensive to procure if they have restricted access to credit facilities. Lack of appropriate financial services is one of the major problems experienced by small scale farmers and it is a major constraint to small scale commercialization in developing countries (Obisesan, 2013; Ololade and Olagunju (2013). However, there is a consensus on the fact that to increase the level of food crops production in the country, small scale farmers need to be strengthened financially, as agricultural credit has been cited as being used in developed countries to accelerate agricultural production, implying that inadequate flow of credit into agriculture is a critical factor that is militating against incremental food production in Nigeria. Although successive governments have come up with numerous programs to address the inability of agricultural output to keep pace with the country's demand for agricultural products as argued by Salihu *et al*. (2018). However, credit institutions have over the years shield away from lending to the small-scale farmers who form the larger part of the farming population citing reasons such as high default rates, difficulty in monitoring numerous individuals whose loans do not provide much return on investment as well as not being cost effective (Agada, 2017).

Farmers have continued to record low level of productivity due inadequate capital and limited access to agricultural credit facilities for their production activities (Akinola, 2013; Adewumi *et al.*, 2021). There is little or no evidence of research on determinants of farmers access to credit in Irepodun LGA of Kwara State. Following on the problem of credit access elucidated above, the primary objective of this research was to determine the factors that influence access to both formal and informal credit institutions by the farmers. It is in the light of the above problems that this study attempted to examine the determinants of access to credit by farmers in the area.

This research aimed to contribute to the body of literature on determinants of access to credit finances, the constraints faced by small scale farmers in accessing credit facilities and its effect on economic outcomes. It will bring to fore factors affecting farmers in Irepodun Local Government Area as touching the issue of their accessibility to credit facility. In addition, this study will also contribute to the pool of literature on the role of credit in increasing agricultural productivity as a pathway out of chronic rural poverty and household food insecurity in Nigeria. Furthermore, the outcome of this study would be useful in identifying institutional arrangements that would serve as an input for policy makers in formulating rural credit policy. This study will also serve as reference point or guide to study for those who will carry out similar research work in the study area in the future.

METHODOLOGY

The study area

The study was conducted in Irepodun Local Government Area of Kwara State, Nigeria.

Sampling technique and sample size

A multi-stage sampling was used in selecting farmers from the local government area. The local government is divided into eleven (11) wards. At the first stage five (5) wards were randomly selected out of eleven (11) wards. At the second one (1) village was randomly selected from each of the five wards. At the third stage, following Adewumi *et al.* (2018), 10% of the farmers were proportionately selected from each the villages. This gave a total sample size of 104 for the study.

Method of data collection

Primary data were used for this study. The data were obtained from the respondents with the use of structured questionnaire which was complemented with the interview schedule. The researcher was assisted by trained enumerators. For respondents who could not write or understand English language, the questions were related to them in a language (Yoruba) understood by them through the aid of interpreters and their responses were entered into the questionnaire in English language.

Method of data analysis

Descriptive statistics which include frequency distributions, percentages and mean were used to describe the socioeconomic characteristics of the farmers, identify the source and level of access to credit as well as constraints encountered by the farmers. Also, the ordinary least square (OLS) regression model was used to ascertain the determinants of access to credit among the farmers. The model is implicitly specified as follows:

$Y = f(X_1, X_2, X_3, \ldots, X_9)$

The model is explicitly specified as follows:

$Y = \alpha + \beta_1X_1 + \beta_2X_2 + \beta_3X_3 + \beta_4X_4 + \beta_5X_5 + \beta_6X_6 + \beta_7X_7 + \beta_8X_8 + \beta_9X_9 + e$

Where:

Y = Amount of credit accessed by the farmers (₦)
X_1 = Annual income (₦)
X_2 = Interest rate (%)
X_3 = Farm size (ha)
X_4 = Member of cooperative (member = 1, non-member = 0)
X_5 = Access to extension (number of contacts)
X_6 = Age (years)
X_7 = Sex (male = 1, female = 0)
X_8 = Level of education (years of formal education
X_9 = Farming experience (years)
α = intercept
$\beta_1 - \beta_9$ = Regression coefficients
e = Error term

RESULT AND DISCUSSION

Socio-Economic Characteristics of Farmers

The socio-economic characteristics of the selected farmers which included; age, gender, household size, level of education, farming experience, membership of cooperative and access to extension services were presented in Table 1. The results showed that most of the respondents were within the age range of 21-50 years with the mean age of 42 years which suggests that majority the farmers in the study area were young, active and energetic. This group of farmers could be more productive when given access to adequate capital to expand and boost their production. This result is slightly higher than the average of 37 years reported by Ibrahim *et al.* (2019) for farmers in Niger State.

The results further revealed that majority (75.00%) of the farmers in the area were males. The low percentage of women involved in farming in the area could be as a result of cultural and religious belief which limited the outdoor activities of women. This finding lends credence to the argument of Fadairo *et al.* (2015) that male participation in agricultural production is more pronounced than that of female. Also, results in Table 1 showed that the mean household size of the farmers in the area was 6 persons. This suggests that family labour could be readily available to the farmers which could help them reduce financial cost of production relatively in the area. This could help boost farm income thereby increasing productivity.

Findings in Table 1 showed that about 90% of the farmers had one form of formal education or the other ranging from primary to tertiary level. The relevance of education in agricultural production in the views of Ibeun *et al.* (2018) and Salihu *et al.* (2018) is that high educational attainment can help farmers to produce efficiently and boost their livelihoods. It could also boost farmers' chances of accessing agricultural credit formal financial institutions. Results further showed that a typical selected farmer in the area had an average of 16 years of farming experience. The number of years one has been involved in farming helps to build practical knowledge in agricultural production towards improved productivity.

The findings equally revealed that only 43.23% of the farmers belong to cooperative society. This is relatively low and may limit farmers access to financial services from relevant financial institutions. Unfortunately, results also revealed that majority (89.42%) of the sampled farmers had no access to agricultural extension services. This implies that these farmers may not be aware and exposed to networks and opportunities for securing financial assistance in addition to increased access to timely and adequate information on improved and sustainable farming practices towards efficient crop production.

Table 4.1: Socio-Economic Characteristics of the Farmers

Variables	Frequency (n = 104)	Percentage	Mean value
Age range			42.00
Less than 21	4	3.85	
21-30	20	19.23

Farmers' sources of finance

The sources of finance available for farmers is presented in Table 2. It revealed that majority of the farmers' source of capital were personal savings (86.56%) and families and friends

(70.19%). This is an indication that most of the farmers don't have access to formal financial institutions where they can obtain borrowed capital for their farm operations. It also suggests that personal savings and families and friends has helped farmers in the study area in securing capital to facilitate their farming business in the absence of formal credit. Although, results revealed that some got credit from cooperatives (58.65%) and micro-finance banks (25.00%), this is not enough. Local money lenders, nongovernmental organizations and commercial banks were the other source of credit recorded among the farmers. This finding suggests that inadequate access to agricultural credit remains a major issue of concern among farmers in the area and Nigeria as a whole.

Table 2: Sources of finance

Source of savings	Frequency	Percentage
Personal savings	90	86.56
Families and friends	73	70.19
Cooperatives	61	58.65
Micro-finance banks	26	25.00
Local money lenders	5	4.80
Non-governmental organizations (NGOs)	4	3.84
Commercial banks	2	1.92

Source: Field Survey, 2021

Farmers' Access to Credit

The farmers' access to credit were analyzed which include: access to credit, range of amount obtained and summary of the amount obtained as stated in Table 3. Results revealed that 53.85% of the farmers had access to credit in the study area. Which connote that reasonable percentage of farmers still does not enjoy credit facilities in Irepodun Local Government Area. Findings also revealed that 20.19% of the farmers in the study area were able to access from between ₦1.00 to ₦250,000.00, 19.23% accessed between ₦250,000.00 to ₦500,000.00 Naira while 14.42% were able to access above ₦500,000.00. Table 4.3 further revealed that those who had access to credit obtained an average of ₦416,946.50 in the study area.

Table 4.3: Level of Access to Credit

Access to credit	Frequency	Percentage
Access	56	53.85
No access	48	46.15
Total	**104**	**100.00**
Range of amount obtained (₦)

Determinants of access to credit by the respondents in the study area

The OLS regression estimate of the determinants of access to credit is presented in Table 4. The F-ratio of 37.88 which was significant at 1% level of probability implies that the model has a strong explanatory power. The result shows that the coefficient of multiple determination represented as R-square indicated that the independent variables in the model explained a significantly high percentage (about 78.39%) of the total variation in the amount of credit accessed by the farmers. The result shows that the coefficients of annual income at 1%, interest rate at 1%, farm size at 5% and membership of cooperative at 1% levels of significance respectively were positive and statistically significant. This implies that the variables significantly determine farmers access to credit in the study area. Given they were positive, it also implies that an increase in these variables will increase the chance of the farmers getting more access to credit in the area. On the other hand, age of the farmers was negative and significant at 5% level of significance. This implies that as the farmers get older, the chance of getting access to credit reduces. This result is similar to those of Ololade and Olagunju (2013) and Obisesan (2013) who reported that income, age, land area cultivated, membership of farmers group and rate of interest are major factors influencing farmers access to credit in Nigeria.

Table 4: Determinants of farmers' Credit Access

Variables	Coefficient	Standard error	t-value	p-value
Annual income	0.24	0.04	6.89***	0.000

Constraints of Farmers Access to Credit

The constraints limiting farmers access to credit based on their perceived severity is presented in Table 4. The result revealed that absence of banks in the locality was ranked 1st as the most severe constraint faced by the farmers with the mean value of 3.74 in the study area. This was followed by lack of guarantor (3.22), distance from financial institution (3.15), lack of awareness (3.13), high administrative procedure (3.13), small size/inadequacy of credit (3.07) and demand for collateral (3.00) respectively. The result further revealed that the respondents also have other constraints that were perceived not to be severe in affecting their access to credit in the area. These include high interest rate, delay in disbursement, unwillingness to disburse loan, political interference and loan diversion among others. This result is similar to the findings of Agada (2017) for farmers in Federal Capital Territory, Abuja. The inference drawn from this finding is that the farmers are faced will several marauding constraints limiting their access to credit in the area. Apparently, this requires attention from the government and other relevant stakeholders for policy brainstorming and appropriation on how to alleviate limited access to credit among the farmers.

Table 5: Constraints of Farmers to Access Credit

Constraints	Weighted sum	Weighted mean	Remark	Rank
Absence of banks in locality	389	3.74	Severe	1st
Lack of guarantor	335	3.22	Severe	2nd
Distance from financial institute	328	3.15	Severe	3rd
Lack of awareness	326	3.13	Severe	4th
High administrative procedure	325	3.13	Severe	5th
Small size/inadequacy of credit	319	3.07	Severe	6th
Demand for collateral	312	3.00	Severe	7th
High interest rate	309	2.97	Not severe	8th
Delay in disbursement of loan	291	2.80	Not severe	9th
Unwillingness to disburse loan	284	2.73	Not severe	10th
Political interference	280	2.69	Not severe	11th
Loan diversion	280	2.69	Not severe	12th
Bureaucratic bottleneck	278	2.67	Not severe	13th
Gender	271	2.61	Not severe	14th

CONCLUSION AND RECOMMENDATIONS

The study concluded based on the results obtained that many of the farmers still don't have access to credit facilities in the study area. Annual income, interest rate farm size, member of cooperative and age were the determinants of farmers' access to credit. Constraints to credit access among the farmers in the area include absence of banks in the locality, lack of guarantor, distance from financial institutions, lack of awareness and high administrative procedure among others. The following recommendations were made:

1. Government in collaboration with relevant financial institutions should establish credit/loan offices close to farmers and should be operated by officials who would be familiar with farmers in the study area to increase awareness, reduce lending procedures and educate them on modalities of loan repayment.
2. Government should improve on extension service delivery to the farmers in the area so as to keep them abreast with information on financing opportunities as well as on improved farming practices.
3. Farmers should form and join cooperative societies to boost their chances of securing financial assistance for their farming and other livelihood activities.

56th Annual Conference
Agricultural Society of Nigeria
24 - 28 Oct., 2022

ABSTRACT

This study comparatively assessed the rationale and selection criteria for water yam production among water yam farmers in Ebonyi State. Multisatge sampling procedure was used. This involves the use of purposive and stratified sampling techniques at various stage. This was based on sampling frame contact from the ADP.This gives a total of 216 yam produces in the study area. The rationale or the determinant factor R^2 indicated 70.5%, 63.4%, 69.5%, 86.7% and 51.3% variability within the five production season and seven out of eleven variables showed positive coefficient and were significant at 1%, 5% and 10% respectively. Age, gender, educational level, farming experience, and farm size and production rate, market demand and maturity time are the determinant factors in selection criteria and major rationale in water yam production in the study area. Water yam farmers had higher variable sources of planting materials in 2017 (90.7%), 2020 (88.4%) and 2019 (79.6%) than other planting seasons, while moderate sources was recorded in 2018 (68.5%) and 2021 (50.3%). Rationale for selection also include multiple tuber ratio, high yield and high survival rate and together accounted for 93.5%, 93.1% and 87% in 2021, 2018 and 2019, while for resistant to pest and disease, drought tolerance and high yield as well as high market demand recorded for ten water yam accessions grown in 2017, 2018 and 2020 in comparison to others. Accessions of Okwalenwankata, Nvula and Mbula Obiaraohu scored above Likert scale mean and the rationale is good fit model in their production, hence recommended.

Key words: Comparative, assessment, rationale, selection criteria, production

INTRODUCTION

Water yam (*Dioscorea alata*) is one of the multi-species crop that belongs to the genus *Dioscorea* and family *Dioscoreaceae* (Tewodros and Getachew, 2013). Sesay (2013) noted that water yam (*D. alata*) originated in South East Asia, probably in Burma, and from there spread into the main land of East of Africa, *D.rotundata*, *D. cayenensis* and *D.dumetorum* complex originated from Africa, while aeriel yam (*D.bulbifera)* and Chinese yam (*D.esculenta)* originated from Asia, (Muluneh, 2006; Lebot, 2009, Norman *et al*., 2012). Of these species, *Dioscorea cayenensis*, *D. rotundata* and *D. alata* are the most cultivated and of greatest

economic interest in Africa (Norma *et al.*, 2012). In contrast to *D. cayenensis* and *D. rotundata*, that are native to Africa, *D. alata* comes from Asia (Gima *et al*., 2012).
They are now the most widely cultivated species both in Asia, America and have real economic significant in Africa (Norman *et al.*, 2012). These species are also threatened by genetic erosion due to many factors such as pest attacks and farming practices (Ngo Ngwe *et al.*, 2015).

Yam (*Dioscorea spp*) is an important food crop especially in the yam zone of West Africa and ranked the fourth most important world food crop (FAO, 2013). Its production generally has been challenged by many rationale considered to be crucial for effective production. This made yam production a task venture and production is still questionable (Verter and Bečvářová, 2014). Water yam production has been stagnated due to old and crude ideology considered to be fundamental by rural peasant farmers with option of no review on new sustainable production practices. Remarkable changes in water yam production has been ranked to be positive in increase production over the years, but the productivity and sustainable transformation of rural farmers stagnate in the face of skill shortages and some rationale (World bank and IMF, 2015).

Rationale in cultivation of some species are farming or production practices which the farmer considered being fundamental in cultivation of yams within his or her area. Improvement in yam production is dependent on the effectiveness of adoption of production rationale that increases accessions distinctiveness as an added value to the worth of yam (Gima *et al*., 2012). Some water yams are selected for cultivation either because they are highly tolerant to drought, somewhat resistant to pest and disease, has very good yield, early maturity, high multiple tuber ratio and tasteful resulting to real economic significance and this stems wide cultivation in West African countries including Nigeria where it is considered a staple food among southeastern farmers (FAOSTAT, 2011, Norma *et al*., 2012). In this, Nigeria is the largest producer of valued edible yams, accounting for 70% to 76% of total world production, with 35.07 million meteric tones and largest consumers of yams (Ezulke and Nwosu, 2006, World Bank and IMF, 2015). These exceptional qualities of water yam and adopted selection criteria by rural yam farmers encourage its production, reduces opportunistic erosion and guides against world food insecurity (FAO, 2011).

It is noted that the majority of poor smallholder yam farmers are still using traditional methods of farming and storage (Verter and Bečvářová, 2014). In addition, Kleih *et al.*, (2012) observed that all these methods are yam improvement for income and food security in West Africa. However, most of the selection criteria and rationale adopted by major producer of the world food security crop are considered to be crude, lack modern credibility which could outsmart weather vagaries and better livelihood of the farmers. It is on this fact that most of African countries incur huge lost and poor revenue generation accruable to yam production due to climate impact (Ishaku and Maharjan, 2014). The incessant alarm of global food insecurity and dearth of modern production facilities and technologies particularly in Ebonyi State arose the needs to investigate the selection criteria and practices used by water yam farmers in production of yam in the study area. The broad objective of this study is to compare rationale and selection criteria for water yam production within the last 5 planting seasons in Ebonyi State. Specific objectives include (i) identifying the socio-economic characteristics of water yam producers of the study area (ii) comparing the major actors in adoption of selection criteria and choice of rationale and (iii) identifying marketing demand as one of the selection criteria.

METHODOLOGY

Ebonyi State is one of the South Eastern States found in one of the six geopolitical zones in Nigeria. The area lies between longitude $7°30^1$ and $8°30^1$ east and latitude $5°40^1$ and $6^0\ 54^1$ north of equator in the Southeastern part of Southern Nigeria. the population has be approximated to two million,eighty hundred and eighty thousand and four hundred people occupying an area of land totaling 6,488km^2 (NPC and National Bureau of Statistic, 2016). Multisatge sampling procedure was used. This involves the use of purposive and stratified sampling techniques at various stage. This was based on sampling frame contact from the ADP. In the first stage, 3 LGAs each were purposively selected from the 3 senatorial zones based on massive yam production in the area. In the second stage, 2 autonomous communities were selected from each of the 3 LGAs, to give a total of 18 communities. The third stage involved selection of 54 villages with a total of 216 yam produces in the study area. In all, a total of 216 stratified and randomly selected respondents participated in the study. Data were collected using interview schedule to obtain relevant information from respondents and by using questionnaires structured in line with the specific objectives. These were administered in form of oral interview schedule in order to ensure that responses to the questions were correctly filled. Data collected were analyzed using a statistical tools frequency and percentage distribution. Tobit regression was used to establish the socio-economic adoption of the rationale for water yam production, while factor analysis was used to identify factors affecting yam production. The implicit forms of the Tobit regression used to establish the influence of farmers socio- economic factors were represented by age (X_1), gender (X_2), education (X_3), farming experience (X_4), source of farmer income (X_5),source of planting material (X_6), farm size(X_7),production rating (increase, decrease) (X_8), market demand (X_9), maturity rating (late, medium & early) (X_{10}) and access to credit facilities (X_{11}). Level of rationale and selection criteria adoption is represented with (Y) and estimated using the function as:

Y= $f(X_1+ X_2 + X_3 + X_4 \ldots\ldots\ldots\ldots\ldots\ldots X_{11}$ + error term) implicit function. Descriptive statistics such as frequency counts and percentages were used to analyze and compare major actors in adoption of rationale and choice of selection criteria, while 5 points Likert scale = $\frac{5+4+3+2+1}{5}$ = 3 market demand– 1-very poor, 2-poor, 3-fair, 4- good, 5 – very good was used to assess market demand.

RESULT AND DISCUSSION

Effect of socio- economic factors on respondents' choice of rationale and selection criteria on water yam production.

The result in table 1 showed the Tobit regression rationale adopted by farmers in water yam production in the study area. The chi-square values were all significant at 5% level of probability for the five years indicating goodness of fit of the model used. The rationale or the determinant factor R^2 values 0.705, 0.634, 0.695, 0.867, and 0.513 respectively, indicated 70.5%, 63.4%, 69.5%, 86.7% and 51.3% variability in adoption of rationale and selection criteria were explained by independent variables.

The coefficient of age was statistically significant and negative at 1% level probability in the three planting seasons of 2017, 2018 and 2017 respectively. This implied that as the farmer grows older, decrease in choice of rationale is adopted or less concerned on the rationale used in water yam production. This is true as the farmer might not be able to attend seminars or use internet for new information on techniques in water yam production. This leads to shortage of skills and innovation whereby the farmer is stagnated with old skill or experience. However, the coefficient of age in 2016 was statistically significant and positive at 1% level of probability. This implied that the older the farmer the higher the rationale and selection criteria adoption and consequently the output. This is in conformity with apriori expectations and in tandem with World Bank and IMF (2015) reports that the productivity and sustainable transformation of rural farmers stagnate in the face of skill shortages and some rationale.

Furthermore, the coefficients of gender, educational level, farming experience, and farm size and production rate obtained were statistically significant and positive at 5% level of probability, while the coefficients of market demand and maturity time obtained were statistically significant and positive at 10% level of probability. This implied that the earlier the maturity of water yam, the earlier the utilization which increases market demand. However, the higher the number of age male and female farmers, educational attainment and farm size in water yam cultivation the higher the increased production (output). The implication is that there is no gender restriction in growing water yam in the study area and the higher level of education attained with more years in farming experience, the higher the adoption of the rationale and the higher the production (output) which was rated to have increased from 2017 to 2021. This is in conformity with apriori expectations and in tandem with Okoye *et a l*.,(2009) as well as Ada *et al.*, (2007) who revealed that the greater the years of farming experience, the greater the farmers' ability to manage generally specific factors that affect the farm business. The result also collaborated with findings of Omojola (2012) as well as Eyitayo *et al*. (2010) who reported positive effects of higher educational level, farm size and amount of credit obtained by seed yam farmers on output.

Major actors in adoption of rationale and selection criteria for water yam production.
The result in table II revealed major actors in adoption of rationale and selection criteria used in water yam production in the last five in the study area. The result indicated that water yam farmers had higher variable sources of planting materials in 2017 (90.7%), 2019 (88.4%) and 2020 (79.6%) than other planting seasons. However, water yam production witnessed moderate sources of planting materials in 2018 (68.5%) and 2021 (50.3%) respectively. The higher the sources of planting material the lower the cost and the lower the sources the higher the cost. High cost of planting materials increases high cost of production thereby reduce net farm income. There was remarkable increase in water yam production in the study area over the years. However, increase to decrease production of 2021 and 2018 in comparison to other years was attributed to climate and weather impact resulting to flood, high cost of maintenance, and pest and disease attack. This is synonymous with the findings of Ishaku and Maharjan (2014) who noted that most of African countries incur huge lost and poor revenue generation accruable to yam production due to climate impact.

Market demand of water yam had been from very poor to very good demand, the highest demand was recorded in 2021 (60.2%) than other production seasons. This could be as a result of decline in yield attributed to climate and weather vagaries and intense global food demand in recent years. Furthmore, very poor market demand might also arise due bad qualities of water yam listed to include late maturity time, high vegetative growth, soil selectivity, multiple small tubers and non-utilization in social functions. In contrast, good qualities of growing water yam were enumerated to include multiple tuber ratio, high yield and high survival rate and together accounted 93.5%, 93.1% and 87% in 2021, 2018 and 2020 production years respectively. Water yam farmers' engage in production of those accessions of water yam that are resistant to pest and disease, drought tolerant and can yield high as well as high market demand. These was observed in water yam grown in 2017, 2018 and 2020 in comparison to others grown in 2019 and 2021. These are considered as the major determinant of production effectiveness in water yam production enterprise. This is in conformity with apriori expectations and in tandem with Kleih *et al*., (2012) who observed that all these methods are yam improvement for income and food security in West, Africa.

Table III. Marketing demand was rated by farmers using 5 points Likert scale from very poor to very good demand. The highest demand was recorded in in accessions of water yam called Okwalenwankata, Nwawafu or Akoawafu (5.8) across the three senatorial zones and performed above Likert scale mean (3.0), this was followed by other accessions called Nvula or Mbala or Mbula and Mbula Obiaraohu at mean value of 5.5 and 5.1 and at acceptable decision rules of good and very good respectively. The only rejected decision was recorded in water yam accession Akpuruakputu having scored below Likert mean value (2.3). Marketing demand is an additional qualities of water yam production having grown for high multiplication tuber ratio. This observation corroborated with the findings of FAO (2011) who reported that exceptional qualities of water yam and adopted selection criteria by rural yam farmers encourage its production, reduces opportunistic erosion and guides against world food insecurity.

Table III: Farmers' rating of market demand of water yam using 5 points Likert scale

No	**Accession local name best ten selected**	**Farmers rating**	**Mean score**	**Decision rule**
1	Nvula/mbala/mbula	Good	5.5	Accepted
2	Okwalenwankata and Nwawafu	Very good	5.8	Accepted
3	Akpuruakputu	Very good	2.3	Rejected
4	Ajingworo	Fair	3.1	Accepted
5	Egboro-Mbala	Good	5.0	Accepted
6	Igborogidi	Fair	4.4	Accepted
7	Mbula Obiaraohu	Very good	5.1	Accepted
8	Nneonwuka	Good	4.2	Accepted
9	Mbula America	Good	4.2	Accepted
10	Uranium	Good	4.0	Accepted

5 points Likert scale = $\underline{5+4+3+2+1}$ = 3 market demand– 1-very poor, 2-poor, 3-fair, 4- good, 5 – very good

CONCLUSION AND RECOMMENDATIONS

The result indicated that age, gender, educational level, farming experience, and farm size and production rate, market demand and maturity time are the determinant factors been significantly at 1%,5% and 10% in selection criteria and major rationale in water yam production in the study area. Selection of water yam accession without consideration to above factor could amount to low or poor production of water yam in the study area. Having accessions that performed above Likert scale mean with intrinsic qualities for selection criteria, including multiple tuber ratio, high yield and high survival rate, resistant to pest and diseases, drought tolerance and high market demand for some accessions is an indication that these traditional practices of choice of planting material are still good when there is no alternative. However, the rationale and selection criteria goodness fit is challenged by climate and weather impact resulting to flood, high cost of maintenance, and pest and disease attack. The rationale goodness fit is appreciated in some accessions performance and the following recommendation are proffered.

It is recommended that traditional rationale and selection criteria observed and enumerated are good fit model for growing water yam particularly in Ebonyi State, and farmers should be assisted in documentation of the rationale since there is no alternative. There should be a gene bank for improved genotype of water yam which farmers can be assisted with for excellent production to reduce incessant sourcing of planting materials. Water yam producers in the study area can be assisted with extension agents to equip them of adoption of good rationale and selection criteria for higher production (output).

ABSTRACT

This study was to analysis perceived constraints on adoption of traditional conservation methods and storage.
Multistage sampling procedure was used. This involves the use of purposive and stratified sampling technique at the various stages. This was based on sampling frame contact farmers from ADP. This gives a total of 216 yam farmers who participated in the study. The result of multiple regression on the effect of socio-economic characteristic of the farmers had a coefficient determination (R^2) of 73.3% and seven variables out of nine had a positive coefficient and were significant at 1%, 5% and 10%. Farming experience, storage sites, conservation methods, education attainment has positive significant relationship with the adoption and storage site for yams as well as source of farmer's income and farm size. Adoption of conservation strategies utilizable by farmers in the study area include keeping in multiple plots (40.7%), by giving others to plant (33.3%), clean planting materials (26%) and alternatively sold to outsides (37%), sold to one person in the community (36.1%) and gifted to outsiders (26%) and three storage sites identified include storage in the barn (49.1%), storage in the field (37.0%) and garden (13.9%) with mostly species of *Dioscorea alata*, *D. rotundata*, *D.cayenensis*, *D.dumentorum* and *D. bulbifera*. Adoption was constrained by lack of capital, high cost of fertilizer, high cost of herbicide, poor road network, open grazing, lack of grant and subsidy, lack of modern storage facilities and land degradation issue, usage of traditional conservation method and poor innovation. Policy recommendations were proffered.

Key words: Investigation, perceived constraints, adoption, conservation methods, storage media

INTRODUCTION

Yam (*Dioscorea spp*) is an important food crop especially in the yam zone of West Africa and ranked the fourth most important world food crop (FAO, 2013). It is a multi-species crop that belongs to the genus *Dioscorea* and family *Dioscoreaceae* (Tewodros and Getachew, 2013). It

is today cultivated in almost all the continents of the world as yam is found in Africa, India, Southeast Asia, north/southern America and Australia with about 600 described species (Tewodros and Getachew, 2013). West Africa accounts for 90-95% of world yam production with Nigeria the largest single producer. In 2004, global yam production was about 47 million metric tons (MT) with 96% of this coming from Africa. IITA (2010) reported that yams are now farmed/cultivated on about 5 million hectares in about 47 countries in tropical and sub-tropical regions of the world. Yams are the fifth most harvested crops in Nigeria, following cassava, maize, guinea corn, and beans/cowpeas. More so, cassava, yams are the most commonly harvested tuber crops in the country (National Bureau of Statistics, 2012).
Yam being the most common food of African continent is posit with challenges of conservation, preservation both in filed and at home barn or garden. This has made yam farmers in sub-Saharan Africa to source for preservation methods that will keep harvested yam off spoilage at a considerable time pending for marketing and the ones that will be used as planting materials. FAO (2013) reported that on the volume of yam lost in metric tons in Nigeria, Ghana and Côte D'Ivoire between 1961 and 2009; Nigeria lost an annual average of 10% within the period under study. The country recorded the highest yam lost in 2006 with over 3.7 million metric tons. Inadequate preservation, storage and processing facilities, marketing and market access to yam products are attributed to yam waste or lost in the country. There are many indigenous storage structures and methods commonly find in West Africa.

It is noted that the majority of poor smallholder yam farmers are still using traditional methods of farming and storage (Verter and Bečvářová, 2014). Ayanwuyi *et al.*,(2011) revealed that the adoption and no option on the modern conservation methods are the perceived constraint on yam production in some States of Southwestern Nigeria. Similarly, Kleih *et al*., (2012) observed that all these methods are yam improvement for income and food security in West, Africa. The crops stored is associated with these indigenous storage systems, have antecedent problems of postharvest losses including: decay, drying off, rotting; respiration and temperature; sprouting while in storage; and pests like insects, nematodes, rodents and animals. This made yam production a task venture and production is still questionable (Verter and Bečvářová, 2014). It is noted that the majority of poor smallholder yam farmers are still using traditional methods of farming and storage (Verter and Bečvářová, 2014). This conservation and storage structures have made agriculture in rural areas of West Africa countries to remain at subsistence level. Osunde and Orherha, (2009) noted that conservation methods are posit with challenges of sprouting, quick germination, rotting, weight and decay recorded to significant losses at about 12% for a method that doesn't allows six hours air flow. However, due to wide experience of yam farmers, these methods have sustained yam production in Nigeria to a certain level. Okoye *et al*.,(2009) revealed that the more experienced the farmer is, the more efficient in managing factors that affect farming business, including decision making process and associated risks in both adoption and rejection of any innovation in farming business. Similarly, Ada *et al*., (2007) also revealed that the greater the years of farming experience, the greater the farmers' ability to manage generally specific factors that affect the farm business. The major task therefore was to find a suitable and effective storage media, method or technology to keep the excess harvest and to make the crop available all the year round.

METHODOLOGY

Ebonyi State is one of the South Eastern States found in one of the six geopolitical zones in Nigeria. The area lies between longitude $7°30^1$ and $8°30^1$ east and latitude $5°40^1$ and $6^0 54^1$ north of equator in the Southeastern part of Southern Nigeria. the population has be approximated to two million,eighty hundred and eighty thousand and four hundred people occupying an area of land totaling 6,488km^2 (NPC and National Bureau of Statistic, 2016).The climate is tropical with vegetation typical of guinea savannah in the rainforest zone of West Africa. Farming is a major occupation of the people with key arable crops comprising of maize, yam, cassava, cocoyam and rice. Rapid rural appraisal (RRA) involving multistage purposive and stratified sampling technique was adopted for farmers' selection based on sampling frame of contact farmers of the Agricultural Development Programme (ADP) in Ebonyi State, to select a total of 216 yam producers in the study area. In the first stage, 3 LGAs each were purposively selected from the 3 senatorial zones based on massive yam production in the area. In the second stage, 2 autonomous communities were selected from each of the 3 LGAs, to give a total of 18 communities. The third stage involved cluster sampling of the yam farmers. From each community, 3 stratified villages were selected and 4 farmers stratified according to gender per village was randomly involved. In all, a total of 216 stratified and randomly selected respondents participated in the study. Data were collected using interview schedule to obtain relevant information from respondents and by using questionnaires structured in line with the specific objectives. These were administered in form of oral interview schedule in order to ensure that responses to the questions were correctly filled. Data collected were analyzed using a statistical tools of means, frequency distribution and percentage. Multiple regression was used to establish the socio-economic determinants of yam production, while factor analysis was used to identify factors affecting yam production. The implicit and explicit forms of the multiple regression used to establish the influence of farmers socio- economic factors were represented by gender (X_1), age (X_2), marital status, (X_3), storage sites (X_4), conservation methods (X_5), farming experience (X_6), educational status (X_7), source of income (X_8) and farm size (X_9). Level of traditional conservation methods adoption and storage media is represented with (Y) and estimated using the function as:

$Y= X_1+ X_2 + X_3 + X_4$………………..X_9 implicit function.

$Y= a_0 + a_1x_1 +a2_+ x_2 + a_3x_3 + a_3x_4$………………..$a_2x_9$ +ET. Explicit function. Descriptive statistics was used to analyze perceived constraints and adoption determinant, while multiple regression analysis was used to analyze objective (i) and objective (iv) was analyzed using factor analysis.

RESULT AND DISCUSSION

The distribution of the respondents according to their socio-economic characteristics is shown in Table 1. From the table, most of the respondents (91.7%) were male famers who fall within the age bracket of 50-60 years and above. Again, 89.4% were old and middle aged men and women above the age of 50.The implication is that yam cultivation is undertaken by old and middle aged people with low energy to withstand the drudgery of yam production. These farmers preserve their farm produce in the barn/home or field by keeping the in the multiple plots or given other to plant so as to collect and plant in the next season. These farmers have engaged in this methods for long having been long with wide farming experience ranged from 20 to 50 years. On level of educational attainment, majority (59.7%) of yam farmers attained one form of formal education or the other ranging from primary to tertiary education. This farmers solely depend on farming as their only source of income and who cultivate from 1 to 10ha of land annually. This result corroborated with the findings of Okoye *et al*., (2009) who revealed that the more experienced the farmer is, the more efficient in managing factors that affect farming business, including decision making process and associated risks in both adoption and rejection of any innovation in farming business. the result is also synonymous with findings of Ada *et al*., (2007) who reported that the greater the years of farming experience, the greater the farmers' ability to manage generally specific factors that affect the farm business. The farming left in the hand old yam farm who relied on crude preservation method makes yam production questionable. This observation is in consanace with findings of Verter and Bečvářová, (2014) who noted that yam production is questionable in Togo.

Farmers' socio-economic factors on yam conservation adoption methods and storage sites

The multiple regression analysis was used to predict the effect of farmers' socio-economic factors on yam conservation adoption methods and storage sites. A multiple regression model employed indicated that coefficient of determination (R^2) was 73.3%. This implied that the variation in the dependent variable (Y) was influenced by the combined effects of independent variable (X_1-X_9), while the remaining 27.7% of the dependent variable (Y) was due to some other important variables that were not included. The R^2 justified the goodness of fit of the regression model, and this indicates the explanatory variable exerts effects on the explained variable. The result also indicates that age had negative relationship with adoption of conservation methods and choice of storage sites. This implied that as the farmers grow older, less choice of conservation methods are adopted than when they are younger. The farmers might store yam at filed as they have no other modern alternative methods of storage after barn in the farmstead or farmers' resident. An increase in age of farmers is an increase in farming experience which have positive significant relationship. This implies that the more years the farmer engage in yam production the more stable in conservation methods and maintaining a suitable site for storage. This result corroborated with the findings of Okoye *et al*., (2009) who revealed that the more experienced the farmer is, the more efficient in managing factors that affect farming business, including decision making process and associated risks in both adoption and rejection of any innovation in farming business.

Education attainment has positive significant relationship with the adoption and storage site for yams. This implies that the more educated the farmer is the more conversant in adoption of the methods. A unit increase in the level of education leads to 0.567 (56.7%) increased in yam conservation methods of adoptions and storage sites. The source of income had a positive significant effect at 10% level of probability. This was associated with the fact that the more source of income the more land to acquire in cultivation of yam as well the more preservative methods to adopt. Storage site indicated negative significant effect on adoption of conservation. Increase in storage site might be associated with increase in the factors that could cause wastage or loss yam tubers, while positive relationship in the farm size indicates that the more the farm size the more yam and the more methods to adopt to save the yam for next planting season. Conservation methods adoption and storage sites were positively sign and this method are safe methods to preserve yam for future use. This result corroborated with findings of Kleih *et al*., (2012) who observed that all these methods are yam improvement for income and food security in West, Africa.

Perceived farmers attitude and activities of major actors in adoption of conservation methods and storage sites of yam

The result shown in Table 2 indicates that most of the yam farmers (40.7%0 adopted keeping in multiple plots as alternative methods of preservation. This was closely followed by giving others to plant (33.3%). This implied that the most cultivated yam species (*Dioscorea rotundata,;D. alata* and *D. cayenensis*) were preserved mostly by these methods. All the yam species are either stored in the barn or field with few storage made at the garden and can also be sourced number of measures including sold to outsides (37%), sold to one person in the community (36.1%) and gifted to outsiders (26%). These stored yams are perceived to be affected by loss in the weight, pest, low durability and storage media. The adoption of conservation strategies helps to reduce losses incurred in yam storage sites and methods. This result is synonymous to findings of FAO (2013) that on the volume of yam lost in metric tons in Nigeria, Ghana and Côte D'Ivoire between 1961 and 2009; Nigeria lost an annual average of 10% within the period under study. Similar result was observed by Osunde and Orherha (2009) who noted that conservation methods are posit with challenges of sprouting, quick germination, rotting, weight and decay recorded to significant losses at about 12% for a method that doesn't allows six hours air flow.

Factors that necessitated constraints to yam conservation and adoption methods and storage site

Many factors are put forward as major constraints in adoption of yam conservation methods. The constraints are grouped into three factors depending on the factors that loaded high in each case. Factor one was named government policy issue because of the variables that loaded high are related to government policies. These include unfavorable government policies, poor road network, open grazing, lack of grant and subsidy, lack of modern storage facilities and land degradation issues. These factors are rated in descending other .755, .603.569, .544, .509 and .305. Factor two was named institutional management problem, they include the usage of traditional conservation method, poor innovation, low durability, and lack of access to extension service, use of fertilizer, poor road network, flood problem and land degradation, and lack of modern storage facilities. Factor three was named management and market information which loaded high on lack of capital, high cost of fertilizer, high cost of herbicide, and usage of traditional conservation method, poor innovation and low durability. These and many other factors contributed to constraints in adoption of traditional conservation methods and storage site. This is in agreement with the findings Ayanwuyi *et al.*, (2011) who revealed that the adoption and no option on the modern conservation methods are the perceived constraint on yam production in some states of Southwestern States of Nigeria.

CONCLUSION AND RECOMMENDATION

The adoption of conservation methods is dependent on age and education attainment of the yam farmers as the younger farmer have more curiosity to adopt multiple conservation methods than older farmers who considered it stressful. It is concluded that all the yam species are either stored in the barn or field with few storage made at the garden or alternatively keeping in multiple plots amounting to (40.7%) or by giving others to plant (33.3%) and use clean planting materials (26%). It is by extension sold to outsides (37%), sold to one person in the community

(36.1%) and gifted to outsiders (26%) who can be accessible in case of failed production as a result of multiple factors surrounding yam production. Adoption of has been constrained by lack of capital, high cost of fertilizer, high cost of herbicide, poor road network, open grazing, lack of grant and subsidy, lack of modern storage facilities and land degradation issue, usage of traditional conservation method and poor innovation. Adoption and good practices of these methods also have sustained yam production over the years. However, bulk of good policies that would ensure reduction in open grazing, giving of farmers grants and incentives inform of grant, subsidy, fertilizers and improved yam setts or yam seed with modern preservation and storage facilities are recommended.

ABSTRACT

The study examined the socio-economic characteristics of rural women empowered through fish farming and value addition in Cross River Central District of Cross River State, Nigeria. A total of one hundred and twenty five (125) women were selected and empowered through training on fish farming and value addition from five Local Government Areas of the state. The objectives of the empowerment training program was to develop enterprising women in fish production and value addition in processing, packaging and marketing for increased income generation and improve living standard. Structured questionnaire was used to obtain necessary data required. Data was analysed with descriptive statistics such as frequency, mean and percentages. The result revealed the majority (53.6%) of the respondents were youths, who were married (68%) and had secondary education (65.6%) with little value addition experience (66%) and belonged to cooperative society (70%) in the study area. It is recommended therefore that, with the potential and zeal of the women towards the empowerment training program, more other government intervention on food production value addition and value chain will go a long way in enhancing capacity building, increase food security, income and raising their living standard in the study area.

Keywords: Socio-economic characteristics, women, fish farming, value addition.

INTRODUCTION

Fisheries play a major role in the nutritional security and in food production for people around the world. Fish is known for its high nutrition as it has various essential micronutrients, mineral and fatty acids. Fish is an important part of the diet of many communities and large numbers of families earn a living from fish farming/fishing, fish processing and marketing. The nation's fast growing population of about 170million and its very high demand of fish, of 2.66 million metric tonnes, has positioned fish production on a much stronger market-driven patty based on commercial production in peri-urban areas (Onunka, 2022). Tilapia (*Orechromia spp*) and catfish (*Clarias spp)* are the major aquaculture products in Nigeria and these are produce and marketed under different systems along value chains and value addition. In order to improve revenue generated and for the products present reasonable opportunity for additional revenue generation, job creation and effective post-harvest management, value addition concept is required. This helps fish business, fish farmer and middlemen (fish mongers) simply add value to the fish via fish processing (fish smoking etc). This act has created more varieties and forms of fish products which are widely acceptable in the fish market. Not only does value addition give the products high economic value which is consequently brings higher income to the fish managers but also address market competition, post-harvest losses and food security (Karthickumar, Hozen, Karthickumar and Balasundari, 2020). Women are known for their multi-talent tackling both the indoor and outdoor activities without much effort. In the local markets of the coastal regions in Nigeria like the Cross River State, women are tending to be vendors to sell the catch of that day. Most times, the women are forced to sell fresh fish at a lower cost which results low income and living standard, as the fresh fish does not have a long shelf life. In order to prevent these issues and to improve the living condition of the Cross River Central District women, there arose the need for empowerment training on fish farming and value addition in the study area. Hence, the objectives of the empowerment training program were to disseminate information on fish farming (Pisciculture) and to develop value addition enterprising women, who would acquire skills in processing, packaging, and marketing to prevent post-harvest losses, increased food security and improved living standard in the study area.

METHODOLOGY

The study was conducted in the Cross River Central District of Cross River. It examined rural women who were empowered through training program on fish farming and value addition (processing, packaging and marketing) technologies in Ikom area of the States. Twenty-five (25) women were selected from Six (6) Local Government Area of the district which includes: Abi, Yakuri, Obubra, Ikom, Etung and Boki. A total sample size of one hundred and fifty (150) respondents trained and empowered. Structured questionnaire was used to illicit information on the socio-economic characteristics of the respondents. Data collected were analysed with descriptive statistics such as frequency, percentage, table and mean. The objectives of empowerment training program were to disseminate fish farming technologies and develop enterprising women in fishing and value addition who were to acquire skills in processing, packaging and knowledge in fish marketing for increased income generation and improve living standard in the study area.

RESULTS AND DISCUSSION

Table 1 represents the socio-economic characteristics of the respondents. The results showed that the mean of age of the respondents were 33 years. This indicates that the respondents were within the active productive age and great potential to develop enterprise in fishing and value addition. This also implies that the respondents were youth who would address market competition which agree with report of Onunka, Chima and Mbanaso (2016). The result revealed that majority (68%) of the respondents were married and living with their husbands and children. This indicates high level of responsibility. The result showed that most (65.6%) of the respondents had secondary education which implied moderate education level. Mauracher and Ragszzoni, (2005) opined that education obviously influences people's basis for acceptance and acquired processing enterprise in fish production and management of natural resources. The result further revealed that majority (66%) of the respondents had no experience in fish farming and value addition while 4% had experience in such enterprise. Effiong (2005) indicated that freshers in business are prone to efficient utilization of available resources than the experienced ones. Also, the result of the finding showed that majority (70%) of the respondents belonged to cooperative society which indicated great potential in socialization and interaction thereby bringing customers to purchase the processed fish for increased income generation in the study area.

CONCLUSION

The result of the finding revealed that the mean average of the respondents were 33 while 68% were married and had secondary education as their highest level of education. The result also showed that majority (66%) of the respondents had no experience in fishing and value addition while 70% belonged to cooperative society in the study area. It is therefore recommended that, with the potential and zeal of the respondents towards the empowerment training programme, more of other government intervention on food production, value addition and value chain will go a long way in enhancing capacity building, increased food security and income in the study area.

ABSTRACT

This study was conducted, to analyze the effects of HIV/AIDS among men, women and youth in crop production in Jema'a and Giwa local government areas of Kaduna state, Nigeria. Jema'a and Giwa were purposively selected due to the prevalence of HIV/AIDS and the youth and women are predominantly crop farmers. A sample size of 192 respondents was randomly and proportionately selected for the study. Structured questionnaire was used to elicit relevant data from the respondents. Percentages and analysis of variance (ANOVA) were used to analyze the data. The results showed that women were 41.8% and youth58.2%, and 73.0% had secondary education status, about 70% of the respondents earned between ₦1, 000.00 - ₦15, 000.00 monthly with the mean earning of ₦12, 595.1. About 51 of respondents used family labour while 46% had family size of 6-10 members, about 69% were married and 40% had farm sizes of less than one hectare with about 28% having 6-10 years farming experience. Also, about 71% respondents do not have access to credit facilities. The study established that about 84% of respondents agree that HIV/AIDS significantly affects their crops output and income at 5% level of significance. It was concluded that HIV/AIDS has significant economic effects on crops output and income of the respondents implying that there might be a diverted attention, time and money in nursing the HIV/AIDS patients and burial or funeral services instead of on crop production. Consequently, direct support and supply of credit facilities and inputs need promptly at highly subsidized rate, special package and programs towards improving women income and legislation that can protect the land rights of women and children who contribute in a great measure to crop production development in Nigeria.

Key words: Effects, Youth, Women, HIV/AIDS, Crop Farmers, Kaduna State.

INTRODUCTION

HIV/AIDS spread has brought a significant stress on the crop production affecting the crop output, income and level of living of farmers negatively which posed a major challenge to the economic development of the nation and livelihood generally (La'ah, 2003).In spite of all the efforts being put in by government at all levels as well as non-government organizations and religious bodies, there is still increased reported cases of HIV/AIDs related diseases in Kaduna State (Cross Roads, 2001) with a number of people dying daily.study areas; Little work has been done on effects of HIV/AIDS on crop production, for example, La'ah (2003) in a study titled "The Demographic and Socio-Economic Effects of HIV/AIDS in Kaduna State" Therefore, this study aims at analysing the effects of HIV/AIDS on crop production among youth and women in Jema'a and Giwa Local Government Areas of Kaduna State. Given this background, this study to analyse the effects of HIV/AIDS among youth and women in crop production in Jema'a and Giwa Local Government Areas of Kaduna State, Nigeria., with the specific objective to identify the socio-economic characteristics of HIV/AIDS infected youth and women farmers in the study area; and analyse the effects of HIV/AIDS on (crops output, income and level of living) of youth and women in the study area. Hypotheses: There is no significant difference between the effect of HIV/AIDS among youth and women of their crops output in the study area.

METHODOLOGY

Primary data were collected through the use of structured questionnaire.Purposive sampling procedure was adopted because of the presence of HIV/AIDS in the study areas. The population of HIV/AIDS infected men, women and youth for Jema'a = 1,295, for Giwa = 626, i.e. a total of 1,921 victims and 192 were taken as the sample size. Data collected for the study were analyzed using descriptive statistics to achieve objectives i, analysis of variance (ANOVA) was used to test hypotheses i, and achieved objective ii,

RESULTS AND DISCUSSION

Socio-economic Characteristics of the Respondents

The result in Table 2a shows that out of the total respondents of 186, age 35 and above was 41.8% women, while youth who fall between the age of 16 – 34 were about 58.2%. The age range reveals that the youth were the dominant group among the respondents. This agreed with the study of La'ah (2015) who opined that youth were people who are at the stage of their productive or active age (15-34 years) and can engage in any aspect of agricultural production and also active in sex relation.The results in Table 2a revealed that most of the respondents (46.3%) had household size of between 6-10 persons, 32.5% had 1-5 persons and 21.0% had 11-20 persons, therefore the mean of house hold size in this study is 7.7. This implies that the large household size has the capacity to supply some of the labour requirement on farm and the other household activities as affirmed by Solomon (2008) and Banmeke (2003). Farm size is shown in Table 2a. The result revealed that 40,6% of the respondents had farm size of less than one hectare, and farming experience revealed that majority of the respondents (28.9%) had between 6-10 years farming experience,the farming experience of majority of the respondents is about 10 years and may be due to the relatively youthful status of the respondents.This finding is consistent with Igbago (2008) that work experience is not only defined by the length of time work done within the given period. The results in Table 2a indicates that 70.5% earned between ₦1000-₦ 15,000 per month; while 3.2% earned ₦ 61,000 and above per month respectively. The mean in this study is N12, 595.1. This means that the respondents were low income earners, their low income level, may attribute some of them moving into prostitution especially among the females in order to earn a living.

Field survey, 2020.

Effects of HIV/AIDS on crops output, income and level of living of youth and women farmers.

In Giwa, 76.9% of the respondents (male, female and youth) agreed that income, females formed 8.9% of the total sample. Out of this, 70.6% agreed that HIV/AIDS affects their income, level of living and crops output, while 29.4% disagreed. Giwa males form 4.7% of total sample Youth form the majority of the respondents in Giwa with 63%. Agree that HIV/AIDS affects their income, level of living and crops output while only 24% did not agree (Table 3.). In Jema'a, 90.5% of the respondents agreed that income, level of living and crops output were affected by HIV/AIDS, while 9.6% disagreed. Jema'a female form 18.2% of the total sample.

Out of this all (100%) agreed that HIV/AIDS affect their income, level of living and crops output. Jema'a males' form 21.4% of the total sample, 75.6% of them agreed that HIV/AIDS affects their income, level of living and crops output while 24.4% disagreed. Youth from Jema'a form 53.1% of the total sample. 93.1% of them agreed that HIV/AIDS affects their income, level of living and crops output, while 6.9% disagreed (Table 3.). Also, the pooled analysis of variance on effect of HIV/AIDS on crops output result in Table 4 shows that there is a significance difference of crops output among the respondents at 5% level of significances, calculated F = 9.569 is greater than the Table F = 3.33. In the case of income, pooled analysis of variance result in Table 5 shows that there is a significance difference of income among the respondents at 5% level of significances, calculated F = 4.056 is greater than the Table F = 3.33. Whereas, the pooled analysis of variance on effect of HIV/AIDS on level of living result in Table 6 shows that no significance difference in level of living exist among the respondents at 5% level of significances, calculated F = 0.21 is less than the Table F = 3.33. This study agrees with the study of Mather *et al*. (2004) which shows that cash, livestock, assets, total and per adult equivalent income were lower for households experiencing death in Mozambique as a result of HIV/AIDS infection.

Pooled test of the effect of HIV/AIDS on crops output

The null hypothesis which states that "there is no significant difference among men, women and youth infected with HIV/AIDS in their crops output in the study area" was tested and the result is presented in Table 4. It shows that there is a significant difference among men, women and youth crops output at 5% level of significance, this is because the calculated F = 9.569 is greater than the Table F = 3.33. There are two groups of significant difference among the respondents. First, female and youth groups on one hand are not significantly different at 5% level of significance from each other. This is due to the fact that women form the bulk of the youth group. Secondly, on the other hand, the Male group is significantly different from the female and youth groups at 5% level of significance. The male average crops output was 4,516.67kg followed by youth group with average crops output of 1,152.63kg. Female group had the least average crops output, 788.20kg. Although Female and Youth groups are not significantly different, the youth group crops output is higher than that of the female group; therefore, the null hypothesis is rejected

Table 4: Pooled ANOVA Test of crops output among Men, Women, and Youth in the Study Area.

Sources of variation	DF	Sum of Squares	Mean Square	F	Sig
Between Groups	2	33,980,000.00	16,990,000.00	9.569	.001

Total	31	85,470,000.00			

Duncan multiple range test

	Mean	Std. Deviation	Std. Error
Female	788	546.89	46.45
Youth	1,152.63	1,162.55	37.29
Male	4,516.67	3,497.98	287.51

Different superscripted letters: The mean difference is significant at the 0.05 level Df=2/29, F=9.569, Sig=0.001

CONCLUSION AND RECOMMENDATION

Based on the result of the ANOVA test on effects of the HIV/AIDS on crops output, level of living and income, it concluded that HIV/AIDS has significant economic effects on crops output and income of the respondents in the study area It was recommended that,enlightenment campaign on abstinence should be intensified and use of condoms if abstinence is not possible should be the best alternative for this active stubborn group;provision of credit facilities and inputs should be directly delivered to the effected HIV/AIDS farmers in good time and legislation that can protect the land rights of women and children. This may help to improve the income levels of women who in a great measure contribute to crop production development in Nigeria.

PROCEEDINGS
56th Annual Conference
Agricultural Society of Nigeria
24 - 28 Oct., 2022

ABSTRACT
Stemming from twin impacts of climate change and Covid-19 pandemic, food insecurity is expected to worsen globally especially among developing countries unless adequate measures are taken to curb the menace. The study assessed impact of adoption of cocoyam value added technologies on food security status of women farmers in South-east Nigeria. 240 respondents were randomly selected Descriptive statistics, adoption scale index, food security index and z-test were used to analyze data. The results of data analysis showed that there was low adoption of cocoyam value added technologies among women cocoyam farmers. Also, about 58.1% of the women farmers were food insecure, while food insecurity gap and severity values were 0.633 and 0.392 respectively. Adoption of cocoyam value added technologies impacted significantly on women farmers income and food security status. It was recommended that deliberate efforts should be made by relevant government agencies to sensitize women farmers in mass and train them on available value added technologies.
Keywords: Cocoyam, food security, value addition, women

1.1 INTRODUCTION
Food is a basic need of humans and food security is central to sustainable development. The international community has long been concerned about eradication of hunger and undernourishment especially among vulnerable groups. However, despite resolution to enhance food security globally, report on world food insecurity highlighted that number of people suffering from hunger globally has increased every year since 1996 (Ijioma, Osondu and Okoronkwo, 2018). Number of people estimated to face food insecurity globally due to the twin impacts of climate change and COVID-19,was projected to double by the end of 2020 (Rondeau, Brianna and Franque, 2020). In a world that seems to be off-track to achieve sustainable development goals by 2030, the growing problem of food insecurity portends a

significant challenge (United Nations, 2020). Food security and insecurity are terms used to describe whether or not individuals, households or an entire nation have access or not to sufficient quality and quantity of food (Osondu, 2018). Many countries including Nigeria are currently faced with the hydra-headed problem of food insecurity and climate change amid the COVID-19 pandemic (Echendu, 2022). In order to solve the problem of food insecurity in Nigeria, especially in this recent time of rise in food prices, there is need to reduce post harvest losses and ensure supply of basic food products at prices within the reach of consumers. One major staple food among rural and urban dwellers in Nigeria, which much attention seems not to have been given is cocoyam.

Cocoyam (*Colocasia* and *Xanthosoma* spp.) is among the world's six most important root and tuber crops (Food and Agriculture Organization (FAO), 2012). Nigeria is the world largest producer of cocoyam accounting for 34% of the world production (FAO, 2013). Cocoyam ranks third in importance after cassava and yam in extent of production among root and tuber crops of economic value in Nigeria (FAO, 2006). It is an important staple crop cultivated mainly in south eastern part of Nigeria mostly by women who usually intercrop cocoyam with other crops (Ojiako, Asumugha, Ezedinma and Uzokiwe, 2007). Cocoyam is mostly used for human consumption and serves as an important food security crop in times of failure or shortage of other crops. However, as is the case with most agricultural produce, cocoyam is highly perishable, hence cocoyam farmers (mostly women) a times do not get the anticipated reward for their work as some of their produce are lost few days after harvest. Kwagala (2018) noted that in developing countries, post-harvest loss is one of the major causes of low agricultural performance and food insecurity amongst farming communities. High level of post-harvest loss reduce the incomes of producers, especially smallholder farmers, which negatively impacts their households' well-being, making them more vulnerable to food insecurity (Barakat, 2018). Participation of smallholders in value chain markets is expected to contribute significantly to rural economic growth, food security and poverty reduction in developing nations

Acting on its national mandate to research into root and tuber crops, the National Root Crop Research Institute (NRCRI), Umudike has developed and disseminated various cocoyam value added technologies aimed at adding economic value to the crop, reducing associated post-harvest losses and possibly widening its market performance. It is envisaged that adoption of these value added technologies will improve food security status of farmers, as well as ensure that cocoyam can be put to wider uses for generation of income. The added income earned from value addition activities can be used to assess food items not produced by farming households, thus improving food security status of such households. This study intends to: (i) describe socio-economic characteristics of women cocoyam farmers in South-east Nigeria; (ii) assess their level of adoption of cocoyam value added technologies; (iii) assess their food security status; (iv) determine impact of adoption of cocoyam value added technologies on income and food security status of the women cocoyam farmers.

2.1 METHODOLOGY

The study was conducted in South-east geo-political zone of Nigeria where greater percentage of cocoyam production takes place (Ojiako *et al.*, 2007). South-east Nigeria is made up of five states namely Abia, Anambra, Ebonyi, Enugu and Imo States. The study area is located between Latitudes $5^0 06'$N and $6^0 34'$N of the Equator and Longitudes $6^0 38'$ E and $8^0 08'$ E of the Greenwich Meridian. According to National Population Commission (NPC), (2007), the population of Southeast zone of Nigeria was 16,381,729 persons.

Multi-stage random sampling technique was used to select sampling locations and respondents for the study. Firstly, 3 of the 5 states in South-east Nigeria, were selected at random. Secondly, 4 Agricultural Development Project (ADP) blocks were selected from each of the 3 states, to

give 12 ADP blocks. Deliberate effort was undertaken to ensure that the selected ADP blocks were spread across the agricultural zones of the states. Thirdly, 2 extension circles were randomly selected from each of the 12 ADP blocks. to give 24 circles. List of women cocoyam farmers in the selected circles was prepared with the help of extension agents domiciled in each of the circles. Lastly, 10 women cocoyam farmers were randomly selected from each of the circles to give 240 women cocoyam farmers who served as respondents for the study.
The study made use of primary data collected from the respondents using pre-tested and structured questionnaire. Analysis of data were undertaken using descriptive statistics, adoption scale index, food security index and z-test.
Level of adoption of cocoyam value added innovations (objective ii), was determined using adoption scale index. It was achieved with the aid of a 7 point Likert type scale graded thus; unaware = 0, Aware = 1, interest = 2, evaluation= 3 trial = 4, accept = 5 and satisfaction = 6. In accordance with Okoye *et al*., (2009) the mean adoption level was determined as follows:

$$\overline{X_s} = \frac{\Sigma x}{n} \quad \ldots \quad (1)$$

Mean score was computed by multiplying the frequency of each response pattern with its appropriate nominal value and dividing same with the number of respondents to the terms. This is summarized with the equation below as follows: $\overline{X_s} = \frac{\Sigma fn}{nr}$ … (2)

Where: $\bar{X}$ =Mean score; $\sum$ = summation; F = frequency; n = Likert nominal value; nr = Number of respondents

Food security status was estimated as the two-thirds of the mean per capita monthly food expenditure of all the women cocoyam farmers. The women farmers were classified into either food secure or food insecure based on the food security line. Those whose monthly food expenditure falls below two-thirds of the mean monthly food expenditure were classified as food insecure, while those whose monthly food expenditure is above or equal to two-thirds of the mean food expenditure were classified as food secure (Osondu, 2018).
Adopting the method of estimation of the Foster, Greer and Thorbecke poverty index, the food security index was estimated following method used by Osondu (2018) as follows:

$$P\alpha = \frac{1}{N}\sum_{i=1}^{q}\left(\frac{z-Yi}{z}\right)^{\alpha} \ldots \quad (3)$$

Where: $P\alpha$ = Food security index; z = Food security line (2/3 mean food expenditure); yi = Per food expenditure (i = 1, 2 ....q); N = Total number of farmers; q = Number of food insecure farmers; α = is the aversion parameter that takes values of 0, 1 or 2 that is $\alpha \geq 0$
When α = 0, the FGT index P_0 measures food insecurity incidence. When α = 1, the FGT index P_1 measures food insecurity depth of the farmers. When α = 2, the FGT index P_2 measures the severity of food insecurity. Z- test was used to assess impact of adoption of cocoyam value added technologies on the income and food security status of women cocoyam farmers The Z-test model is expressed below as follows:

$$Z = \frac{\bar{X}_1 - \bar{X}_2}{\sqrt{\frac{S_1^2}{n_1} + \frac{S_2^2}{n_2}}} \ldots \quad (4)$$

Where: $\bar{X}_1$= Sample mean of monthly income/food expenditure of adopters of cocoyam value added technologies; $\bar{X}_2$= Sample mean of monthly income/food expenditure of non-adopters of cocoyam value added technologies; S_1^2= Sample variance of monthly income/food expenditure of adopters of cocoyam value added technologies; S_2^2= Sample variance of monthly income/food expenditure of non-adopters of cocoyam value added technologies; n_1=

number of women farmers who adopted cocoyam value added technologies; n_2= number of women farmers who did not adopt cocoyam value added technologies

3.0 RESULTS AND DISCUSSION

3.1 Socio-Economic Characteristics of Women Cocoyam Farmers

Table 1 shows distribution of the respondents according to socio-economic characteristics. The table shows that mean age and farm size of the respondents were 51 years and 0.65 hectare respectively. The mean age suggests that the farmers were still energetic and active and thus, capable of withstanding the physical labour and stress associated with cocoyam farming and value addition activities. The respondents had mean household size of 7 persons. This is good as household members could help in works in the farm enterprise and associated value addition activities if any, thus reducing cost of hired labour. Olagunju (2007) asserted that household size had significant and positive effect on provision of labour and that larger households faced lessened labour constraints during adoption of new technologies. The women farmers earned annual income of 182,241.62 Naira. The income households earn have positive implications on their adoption of innovations, welfare and economic access to food (Osondu, 2018). Meanwhile, 87.08% of the respondents attained diverse level of formal education. Ayode (2013) asserted that education plays positive role in adoption of innovations.

Table 1: Distribution of the women cocoyam farmers according to socio-economic characteristics

Variables	Mean
Age (years)	51.37
Farm size (Hectares)	0.65
Household size (number of persons)	6.78
Annual income (Naira)	182,241.62
Education level	**Percentage (%)**
No formal Education	12.92
Primary education	30.00
Secondary education	50.83
Tertiary education	6.25

Source: Field survey, 2022

3.2 Level of Adoption of Cocoyam Value Added Technologies

Level of adoption of cocoyam value added technologies by the respondents as presented in Table 2 shows that only cocoyam flour ($\bar{X}$ = 3.03) can be adjudged as been adopted. This is not surprising as cocoyam flour is the foremost cocoyam value added technology developed traditionally in South-east Nigeria and often used for soup thickening. Among the cocoyam value added technologies developed by NRCRI none can be adjudged as having being generally adopted by women cocoyam farmers in the area. This result implies that despite the efforts undertaken by NRCRI to disseminate these value added technologies to the rural populace most women cocoyam farmers were still non-adopters.

Table 2: Level of adoption of cocoyam value added technologies by women cocoyam farmers

Value Added Technologies	Unaware (0)	Aware (1)	Interest (2)	Evaluation (3)	Trial (4)	Accept (5)	satisfaction (6)	Total	Mean Score
Cocoyam chips	89(0)	27(27)	19(38)	24(72)	11(44)	29(145)	41 (246)	572	2.38

Cocoyam cakes	151(0)	30(30)	12(24)	5(15)	13(12)	9(45)	20 (120)	286	1.19
Cocoyam bread	174 (0)	8(8)	8(16)	16(48)	10(40)	7 (35)	17 (102)	249	1.04
Cocoyam biscuit	152(0)	20(20)	16(32)	13(39)	18(72)	8(40)	13 (78)	281	1.17
Cocoyam flour	21 (0)	29(29)	45(90)	57(171)	35(140)	22(110)	31 (186)	726	3.03
Croquette	172 (0)	13(13)	10(20)	10(30)	13(52)	9(45)	14 (84)	244	1.02
Chin-chin	132(0)	29(29)	26(52)	20(60)	11(44)	7(95)	15 (90)	370	1.54

Source: Field survey, 2022

Decision Rule: mean score of 1.0 – 1.49 = Awareness stage of the technology; 1.5 – 1.99 = Interest stage; 2.0 – 2.49 = Evaluation stage; 2.50 – 2.99 = Trial stage; and 3.0 and above = Adopted stage of the technology. Figures in parentheses are Likert scores.

3.3 Food Security Status of Women Cocoyam Farmers

Table 3 shows estimates of indices of food security among the respondents. The food security line was estimated to be 4941.88 Naira. Hence, women cocoyam farmers whose household per capita food expenditure was below 4941.88 Naira monthly were classified as food insecure, while those with food expenditures equal or above the food security line were food secure. The food insecurity incidence (P_0) showed that 58.1% of the women cocoyam farmers were food insecure, while the food insecurity gap (P_1) showed that on the average, a food insecure women cocoyam farmer will require additional per capita food expenditure of 3128.21 Naira (0.433 x 4941.88) to exit food insecurity. The value of food insecurity severity (P_2) was 0.392, implying that there was 39.20% inequality among the food insecure farmers.

Table 3: Computed food security indices of the women cocoyam farmers

Food security indices	Women farmers
Mean monthly food expenditure	22512.24
Mean per capita food expenditure (MPCHHFE)	7412.82
Food security line (2/3 of MPCHHFE)	4941.88
P_0 (Incidence of food insecurity)	0.581
P_1 (Gap or depth of food insecurity)	0.633
P_2 (Severity of food insecurity)	0.392

Source: *Field survey, 2022*

3.4 Impact of Adoption of Cocoyam Value Added Technologies on Food Security Status of Women Cocoyam Farmers

The z-test analysis of the impact of adoption of cocoyam value added technologies on the women cocoyam farmers' income and food security status is shown in Table 4. As adduced from the table, adopters of cocoyam value added technologies had significantly higher monthly income and food expenditures at 5.0% and 10.0% alpha levels respectively, implying that adoption of cocoyam value added technologies impacted positively on income and food security status of the women farmers. Findings by Agoh (2018) revealed that adoption of value added technologies had significant positive impact on welfare of sweet potato farmers in Abia State, Nigeria.

Table 4: Impact of adoption of cocoyam value added technologies on income and food security status (number of adopters = 87; non-adopters = 153)

Variables	Individual mean	Mean difference	Standard error	z-value	Sig (2-tailed)
Mean monthly income of adopters	17,714.29				
		5,054.98	3817.62	2.252**	0.033
Mean monthly income of non-adopters	12,659.31				
Mean monthly food expenditure of adopters	9,310.02				
		3, 3794.40	2146.33	1.978*	0.051
Mean monthly food expenditure of non-adopters	5,515.62				

***Source**: Field survey data, 2022*
**, * = significant at 5.0%, and 10.0% alpha levels respectively

4.1 CONCLUSION AND RECOMMENDATION

The study showed that huge gap exists in adoption of cocoyam value added technologies amongst women cocoyam farmers in the area. The few women farmers who were adopters of cocoyam value technologies recorded significantly higher monthly income and food expenditures, implying that adoption of cocoyam value added technologies impacted positively on income and food security status. Based on findings the following recommendations suffice: As part of government effort to curb rise in food insecurity in the country, deliberate efforts should be undertaken by relevant agencies to create more awareness on available cocoyam value added technologies. Women farmers need to be sensitized and exposed to trainings on cocoyam value added technologies. To this end, seminars on value added technologies should be held in designated venues in all rural communities of the study area. Attempts should be made to motivate women farmers to attend in mass. NRCRI, Umudike and Agricultural Development Programme (ADP) should intensify efforts in training women farmers on value added technologies. Women farmers should be encouraged to form and belong to cooperative societies. This will avail them access to various opportunities such as training, credit facilities, inputs and markets.

ABSTRACT
Support services which is part of IFAD programme is a required incentive to increase youths motivation and participation in rice production as well as improve rice production potentials with measurable impacts on the food security status and livelihood of the youth rice farmers. Therefore contribution of International Fund for Agricultural Development Value Chain Development Program (IFAD) to food security status among youth rice farmers in Ogun State was investigated in this study. Multi-stage sampling procedure was adopted to sample 127 youth rice farmers from two randomly selected local government areas. This gave selection of Obafemi Owode and Yewa North Local Government in Ogun State. Lists of registered members (youth rice farmers) in each of the local government were obtained and 50% of members were systematically selected. Structured questionnaire and interview schedule was used to elicit response on respondents' IFAD support services, constraints encountered by youth rice farmer and food security status of youth rice farmers. Data were analyzed using descriptive (frequency counts, percentages, mean and standard deviation) and inferential(Pearson Product Moment Correlation and Regression) statistics at $p = 0.05$. All of the respondents (100%) had access to IFAD support services in terms of farm input, Good Agricultural Practices (GAP), infrastructural support and institutional linkages except farm assets with (99.2%). Scarcity of land ($\bar{x}$= 17.3), bird infestation on the field ($\bar{x}$= 17.2), market price fluctuation and water shortage ($\bar{x}$= 16.5), untimely delivery of input ($\bar{x}$= 16.4) were the major constraints encountered by youth rice farmers. More than half of the respondents (53.54%) were food secured in the study area. Years of farming experience ($\beta = .253$, $p < 0.036$) and benefit derived ($\beta = .223$, $p<0.022$) significantly influenced the food security of farmers. It is therefore recommended that there is need to provide solution to the scarcity of land by producing adequate land for farmers to cultivate.
Keywords: Contribution, Youth, Food security, IFAD.

INTRODUCTION
The rate of unemployment in Nigeria has continued to be on the increase despite the abundant human and natural resources available in the country. In recent times in Nigeria, addressing the challenges of youth unemployment in the region have become a topical discussion. According

to Filmer and Fox, (2014), efforts to accelerate agricultural growth and improve food security cannot be separated from efforts to create job opportunities for the young people. Hence, governments, organizations are making frantic efforts to stimulate investment and promote youth participation in agricultural value chain activities. Rice is a prominent crop value chain with potential for food security, economic development job creation through improved productivity and import substitution. Increasing rice production and upgrading the rice value chain will increase food security, reduce urban migration, reduce reliance on imports, and provide viable employments for the youths (CICIAR, 2018). Rice is the most-demanded food product traded in the highest quantities in Nigeria (Veldeand Maertens,2014). There are several factors that hampers profitability from rice farming such as inefficient and ineffective agricultural support services delivery like input, low cultivation, climate change, low yield gap, poor infrastructural facilities among others. Addressing the challenges of productivity along the rice value chain could unlock the potential for young rice farmers engaged in its production practices to meet their food and income needs. The Nigeria Agricultural Transformation Agenda ATA (2011-2014), Anchor Borrowers Programme (2015-Date) and other agricultural intervention programmes have sought to improve rice farming to stimulate productivity and create jobs opportunities along the value chain in Nigeria. Likewise, the International Fund for Agricultural Development(2015-2021) emphasize that the potential returns of investments in young people includes food security, poverty reduction, job creation, peace and political stability (IFAD, 2016). The IFAD supports the young rice farmers as crucial target group for employment creation, through their involvement in sustainable agricultural entrepreneurship by providing inputs and support services for youths engaged in the production, processing, and marketing of rice (IFAD, 2012). Accessibility to input support services is a required incentive to increase youths motivation and participation in the rice production as well as improve rice production potentials with measurable impacts on the food security status and livelihood of the youth rice farmers. It is expected that with access to input and others supports, the productivity of the young rice farmers should impact positively on the improvement of their food security status and livelihood at large. .Hence, this study. The general objective of the study is to analyse the contributions of IFAD to the food security status of young rice farmers in Ogun State. The specific objectives are to: ascertain the IFAD supports services accessible in Ogun State;identify the constraints encountered by the youth rice farmers in Ogun State and ascertain the contributions of IFAD to food security of the youth rice farmers in Ogun State.

METHODOLOGY

This study was conducted in Ogun State in SouthWest, Nigeria.A multi-stage sampling procedure was adopted in this study. The first stage involved the selection of Ogun state in SouthWest, Nigeria, being the only state in SouthWest that meets the criteria for the implementation of the IFAD in Nigeria. IFAD was implemented in just eight local government areas in Ogun state namely Obafemi-owode, Ifo, Yewa-North, Ijebu North-East, and Ijebu-East, Yewa-South, Obada, Odogbolu local government areas.The second stage involved random selection of twenty five percent of all the eight local government areas which equals two LGAs, where the IFAD was implemented namely; Obafemi-owode and Yewa North local government areas. The two LGAs were selected based on high concentration of IFAD youth rice farmers in the areas. The third stage involved purposive selection of all the communities in the local government areas selected. Eggua, Alapako, Igbogila and Sanwojo in YewaNorth and Kobape, Ajana-Odo, Ofada and Maloko-asipa in Obafemi-Owode. A list of young rice farmers groups was generated from the IFAD and from the ADP office at each local government area. The list presented 71 rice youth farmers in Obafemi-owode and 181 rice youth farmers inYewa North local government areas. The fourth stage involved proportionate sampling of 50% of the respondents to give 36 and 91 respondents in Obafemi-Owode and

Yewa-North respectively. A total number of 127registered IFAD young rice farmers was sampled. Structured interview schedule and questionnaire were used to elicit information from respondents. Data were analysed using descriptive statistics and Regression techniques

RESULTS AND DISCUSSION

IFAD support services

The result of the findings in Table 1 reveals that all the respondents (100%) received support services in terms of farm inputs, good agricultural practices, infrastructural support, and institutional linkage/ extension service while 99.2% of the respondents had farm asset support. The provision of farm inputs/extension services is one of the core objectives of IFAD to educate rice farmers on the improved method of rice farming. IFAD provided input support services (such as certified seeds, fertilizer, sprayer, agro chemical, bird scaring equipment, flash bottom boiler).Good Agricultural Practices (GAP) training (on land preparation, seed planting, rice transplanting, pesticides and fertilizer application, weed control, insect, pest control, proper harvesting, drying, storage practices, use of weights or measure, seed production, book keeping), farm asset (such as tractor, plough, threshers, power tiller, mechanical harvesters), infrastructures such as pipe borne water, water pumps and hose, markets and feeder roads, storage facilities and machineries, institutional linkages such as off-takers/buyers, ADP, IITA, extension service among others which has improved the farming activities of the rice farmers in the study area. This finding shows that the intervention of IFAD has contributed positively in terms of support services to rice youth farmers in the study area. This finding agrees with that of Oruonye *et al.* (2021) who submitted that the support services majorly received from IFAD program were farm inputs and extension services**.**

Table 1: Distribution of IFAD support services

IFAD support services	Yes	
	Frequency	**Percentage**
Farm Input	127	100%
Gap	127	100%
Farm assets	126	99.2%
Infrastructural Support	127	100%
Institutional Linkage	127	100%

Source:Field survey,2022

Constraints encountered in rice production

The findings in Table 2 shows that the major rice production constraint faced by the youth rice farmers was scarcity of land ($\bar{x}$= 17.3) which ranked first. This could be as a result of problem of land tenure system. This result is not in line with the position of Nkechi et al (2020) and Oloyede (2020) who identified the problem of pests and diseases as the most limiting factor in their study. Bird infestation on the field ($\bar{x}$= 17.2) ranked 2nd. Though the farmers are using electrical and biological method to chase the birds away from the farm land but due to shortage supply of electricity and high cost of maintenance, bird attack the rice which one of the major constraints. Market price fluctuation and water shortage ($\bar{x}$= 16.5) ranked 3rd. This could be as a result of instability of market price and low supply of water in the farm land. Untimely delivery of input ($\bar{x}$= 16.4) ranked 5th. This is one of the major constraints encountered which occur as a result of poor road network. The finding is in conformity with that of Odoemenem and Inakwu (2011) who reported that inadequate capital, high cost of input, high cost of labour amongst others were the major constraints militating against rice production in the study area.

Table 2: Distribution of respondents based on constraints encountered in rice production

Constraints	Not a constraint	Mild constraint	Severe constraint	Weighted mean score	Rank
High cost of input	36.2	59.8	3.9	15.2	12th
Labour access and cost	32.3	56.7	11.0	16.2	6th
High cost of transportation	32.3	58.3	9.4	16.1	8th
Market price of fluctuation	27.6	63.0	9.4	16.5	3rd
Water shortage	26.0	66.1	7.9	16.5	3rd
Untimely delivery of input	26.0	65.4	8.7	16.4	5th
Scarcity of land	22.0	65.4	11.8	17.3	1st
Bird infestation on the field	22.0	66.1	11.8	17.2	2nd
Presence of impurities in rice	29.9	66.1	3.9	15.8	11th
Pest and disease infestation					
Poor frequency of extension agents	26.8	67.7	5.5	16.2	6th
Loss of paddy due to inadequate drying platform	29.1	66.1	4.7	15.9	9th
Farmer offtaker conflict of interest	29.1	66.1	4.7	15.9	9th
Crop destruction by herdsmen					
	37.8	61.4	0.8	14.8	14th
	36.2	59.8	3.9	15.2	12th

Source: Field Survey, 2022

Categorization of level of food security

The categorization of youth rice farmers according to their level of food security presented in Table3 shows that most of the youth rice farmers (53.54%) were food secured compared to (46.46%) that were not food secured. This result implies that more than half of the respondents were food secured in the study area. This finding supports Otunaiya and Ibidunni(2014) who reported that seventy percent of the farming households in Ogun state were food secured.

Table 3: Level of food security

Food security	Frequency	Percentage	Mean	Min. score	Max score
Food secure (9-15)	68	53.54	14.95	9	27
Food insecure (16-27)	59	46.46			
Total	127	100			

Source:FieldSurvey,2022

Hypothesis : There is no significant contribution of independent variables to food security of respondents

Regression analysis in Table4 shows the contribution of selected variables to food security of respondents. The R-square (.510) obtained for youth rice farmers indicates that the selected independent variables contributed 51% to their food security. The result reveals that years of farming experience (β = .253, $p < 0.036$) benefit derived (β = .223, $p<0.022$) significantly influenced the food security of farmers. This is in agreement with *a priori* expectation. This is an indication that farmers are well experienced in their various rice production activities and might have acquired knowledge and skills to improve their food security. The Table also shows that benefit derived have significant contribution of 33% to farmers food security. This mean s that the more farmers make use of IFAD support services, the more the benefits they will derive in order to attain better food security status.

Table 4: Regression analysis of contribution of independent variables to food security of respondents

Variables	B-value	t-value	p-value	Decision
Constant		4.385	.000	
Age	.158	1.141	.256	NS

CONCLUSIONS AND RECOMMENDATIONS

Respondents had access to IFAD support services. IFAD youth rice farmers derived benefits such as reduced cost of production, increase productivity, employment generation, reduced post harvest loss and availability and access to adequate input among others. Scarcity of land, bird infestation on the field, market price fluctuation, water shortage were the major constraints encountered by the youth rice farmers. More than half of the respondents were food secured in the study area. Years of farming experience and benefit derived were the independent variables that contributed significantly to food security of youth rice farmers. The study recommends that government should make it easier for farmers to access lands for expanding their farms. Farmers who have proven efficiency should be given lands to rent at reduced cost with the option of purchasing such lands at reduced costs over a period of time. Individuals and organizations who have unused lands could partner with farmers who would farm their lands until such a time when the lands are ready for their original purposes. More methods of chasing birds away should be introduced; chemicals like methiocarb which are non -toxic but unpalatable to birds can be introduced to provide solution to the problem of bird infestation of rice field.

24 - 28 Oct., 2022

ABSTRACT

This study ascertained the various climate change adaptation measures practiced against climate change by the women arable crop farmers in Ika North East LGA of Delta State, Nigeria. A two-stage random sampling procedure was used to select six communities from each of the LGAs and fifteen women arable crop farmers from each of the sampled community, which gave a total of twelve (12) communities and 180 small scale women arable crop farmers respectively. Data were collected by use of questionnaire which were analysed using Descriptive statistical tools. Different strategies were listed for the respondents to indicate and multiple responses were recorded. The result revealed the following adaptation strategies; early planting (97.8%), crop rotation (96.7%), minimum tillage (80.6%), drought resistant varieties (77.2%), intercropping (76.7%) among others. The study recommends more involvement of extension workers to educate the farmers on better adaptation strategies.

Keywords: Adaptation, Arable Crop Farmer, Climate Change, Productivity.

INTRODUCTION

Climate change is defined as statistically significant weather variations that persist for a long period of time. It could take up to decades or even longer. It involves shifts in the rate of concurrency and therefore the degree of intermittent weather events (Ricardo *et al.,* 2018). Climate change have alternative ways of prevalence. These could be changes in average weather conditions, variations in regional environmental condition factors leading to some drier or wetter areas on average, variations in rainfall events which may become additionally erratic in some regions. Climate change is a massive challenge facing humankind these days as it ends up in a rise within the rate and frequency within the prevalence of utmost weather events which continue to cause threat to food security in some regions, as extreme weather events destroy crops and scale back yields. Climate change also have devastating impact on pastoralist communities though the impact of climate change is felt everywhere in the globe, developing countries and States that have fragile landscapes are the worst affected areas. According to Heshmati (2021), climate change has become an additional threat to human existence because it has become a major challenge to the proper development of socioeconomic activities especially Agriculture. Agriculture remains the backbone of Nigeria's economy, with more than 50% of the active labour force engaged within the sector and providing most of the national food needs for the population (Enfield, 2019). Climate change projections across the globe point to increasing temperatures across all ecological zones, with temperatures during the dry season expected to extend by about 3^0C by 2080 and the most challenge remain principally flooding (NOAA, 2022). As agricultural production in Federal Republic of Nigeria is generally dependent on rainfall, any erratic changes in rainfall and temperature can continuously exert adverse result on her agricultural production because the country has only one rainy season that the agricultural production depends on (Assan, *et al.*, 2018). Ike and Ezeafulukwe (2015) explained that among the results of climate change on agriculture are the reduction in yield, losses in farm income, and a decline in the livelihood and sustainability of farm households. These adverse impacts of climate change may conjointly stifle efforts toward poverty reduction among rural dwellers that depend upon agriculture and different climate-sensitive activities for their livelihoods and well-being. Some other studies in Federal Republic of Nigeria have shown that losses due to the temperature change annually is on the average of 5.5% of total output of some major staple crops such as maize, rice, cassava, yams, millet, sorghum, groundnuts, and plantain (Ogbonna *et al.*, 2017).

Delta State is thought to be an associate agricultural State with agriculture employing over 70% of the agricultural manpower (Ofuoku and Okompu 2022). Thus, it is crucial for farmers to undertake applicable adaptation ways to cushion them against the adverse impacts of climate change. According to Perera *et al.* (2020), climate change adaptation methods are ways that enable individuals or communities to comply with or deal with the impacts of changes in climate. Cultivable crop farming is predominant within the north and central agricultural zones of the State with females being the key players engaged within the production of maize, cassava, plantain and foliate vegetables among others. Ike and Ezeafulukwe (2015) discovered that female small-scale farmers are rather suffering from the challenges arising from changes in climate because of inherent inadequacies. There is gender bias in the nature of vulnerabilities to climate change, which leads us to the main focus of this study which is to: ascertain the various climate change adaptation measures practiced against climate change by the women arable crop farmers in Ika North East and Ika South Local Government Areas of Delta State, Nigeria. It is envisaged that the outcome of this study will inform decision making on effective and appropriate strategies to solving the problem of climate variability

MATERIALS AND METHODS

The study was carried out in Ika North East and Ika South Local Government Areas (LGAs) of Delta State, Nigeria. The two local government areas are among the twenty five (25) Local Government Areas that make up Delta State. They are in the North Agricultural Zone of Delta State. The two Local Government Areas were selected for the study because they are the areas where farming is mostly carried out in Delta North zone and are referred to as the food basket of the State.

A two-stage random sampling procedure was used to select six communities from each of the LGAs and fifteen women arable crop farmers from each of the sampled community, which gave a total of twelve (12) communities and 180 small scale women arable crop farmers respectively. Primary source of data collection through the use of a structured questionnaire was used. The different strategies employed by women small scale arable crop farmers to fight against the challenges of climate change were listed for the respondents to indicate. Descriptive statistical tools such as mean, percentages and frequency tables were used to summarize the data.

RESULTS AND DISCUSSION

According to Kim *et al.* (2018), agriculture is negatively affected by climate change, while adaptation reduces the impact and increase resilience to climate change such that those farmers who adapt are less vulnerable to these negative impacts of climate change. Adaptation strategies employed by the respondents are indicated in Table 1.

The results indicate that; 77.2% of the women arable crop farmers in the area were adapting by using drought resistant varieties, early planting as a strategy for averting the consequences of climate change on their farming activities was employed by over 97% of the respondents. This goes to show the importance of this strategy in checkmating the consequences of climate change in the area. The use of early planting as an adaptation strategy against climate change by large number of farming household has also been reported by Shongwe *et al.* (2014) in their study on Cost Benefit Analysis of Climate Change Adaptation Strategies on Crop Production Systems in Mpolonjeni Area Development Programme (ADP) in Swaziland.

The respondents indicated that they took advantage of early rains as compared to late planting. Two other strategies, minimum tillage (80.6%) and crop rotation (96.7%) were alluded to as among the most effective measure of combating the negative effects of climate change in arable crop production by the respondents. The use of crop rotation as an important method of averting the consequences of climate change has been reported by many researchers.

Table 1: Adaptation Strategies Employed by Women Arable Crop Farmers against Climate Change

Adaptation Strategy Used	Frequency (Did Use)	Percentage (Did Use)	Frequency (Did Not Use)	Percentage (Did Not Use)
Drought resistant varieties	139	77.2	41	22.8
Early planting	176	97.8	4	2.2
Late planting	56	31.1	124	68.9
Minimum tillage	145	80.6	35	19.4
Crop rotation	174	96.7	6	3.3
Mulching	20	11.1	160	88.9
Irrigation	35	19.4	145	80.6
Intercropping	138	76.7	42	23.3

***Multiple responses were recorded**

Adaptation strategies that received the least responses were mulching (11.1%) and irrigation (19.4%). Irrigation involves high capital investment, which can be a challenge to most rural households because of poor financial background. The strategy also needs a good, reliable water source, which is not the case in most communities under study in both Ika North East and Ika South Local Government Areas.

CONCLUSION

The study showed that climate variations has adverse effects on agricultural production particularly female small holder farmers, who now take advantage of some adaptation strategies to mitigate the effect. Some of such strategies are planting improved varieties, minimum tillage, crop rotation among others. The study recommends that for consistent growth in agricultural production, Government at all levels should make agricultural extension programme more effective in order to equip rural women farmers with relevant and timely information and technology to improve their production techniques, climate adaptation measures and increase their income and standard of living.

Factors influencing children activities in artisanal fishing in five fishing communities in Badagry

O.O Oluwakayode-Oluyi and B .E .Emmanuel
Nigeria institute for Oceanography Marine Research
kemialiuomoba@gmail.com

PROCEEDINGS
56th Annual Conference
Agricultural Society of Nigeria
24 - 28 Oct., 2022

ABSTRACT

Despite the global effort to reduce and totally eradicate child labour, children are very still involve in fishing activities in most fishing communities visited, there contribution are mostly unrecorded in national income. Children contribution in artisanal fishing was investigated between September 2020 and February 2021 to assess the percentage number of children involved in five fishing communities' in badagry, their roles and the outcome of the activities on their livelihood with the use of questionnaire's was documented. Data collected were collated and analysed using frequency distribution and percentages. During the study, no female child was found fishing while male counterpart were totally involve in active fishing, the total numbers of boat counted in five communities where 1,122 and total people counted on the boat where 198 for the period of six month in the various communities. The percentage of children that attended school are 20.43% in September, 18.82% in October, 16.13% in November, 13.44% in December, 18.82% in January and16.13% in February, and their roles includes paddling, bailing water, sorting fish, casting net, setting fishing gears, mending and cleaning of fishing ears used. Enlighten the fisher folks for continuous education of their children is very important. The effort of the children greatly increase fish production and contribute immensely to the artisanal fishing community. The best way to reduce child labour in artisanal fishing is that government should provide the right supports and infrastructures to fisher folks on the ways of improving fishing methods for sustainable management of the fishery to provide for their children education even to tertiary level.

KEYWORDS: Children, fishing, contribution and Badagry

INTRODUCTION

Artisanal fisheries is fishing carried out at subsistence level, by local people using locally dug out wooden canoes, which are usually not motorized while spears, traps, hooks, nets and other locally fabricated traditional gears characterize fishing at this level (Tobor, 1990) Children's activities in fisheries sector have been observed and recorded as far back as the 1960s in Java (White,1976). Quite a sizeable proportion of the Nigerian population depends on fishing as a source of income (Tobor, 1984). Contribution of children in livelihood activities of their households is prevalent in developing countries and Africa in particular as it is regarded as part of the socialization processes to ensure the sustainability of such livelihood activities. Though experts in developed countries consider children's contribution in income generating activities as a form of child labour, it is gradually been agreed to, that not all child's work can be regarded as child labour (ILO, 2005)

METHODOLOGY

This study covered some fishing communities in Badagry. Primary data for the study were collected between the hour of 09.00 and 14.00 GMT on working days for six months (i.e. September, 2020 – February, 2020. questionnaires were used. Data collected were collated and analysed using frequency distribution and percentages. Factors considered were total number of boats fishing, total number of people in the boat, total number of children in the boat, age and educational background of the children in the boat, the children's roles in the boats and the people targeted were fishermen.

RESULTS AND DISCUSSIONS

Table 1: The activities of children and their age in some fishing communities in Badagry

The activities of the children in their various communities includes, paddling, bailing water, sorting fish, casting net, setting fishing gears, mending and cleaning of fishing gears used

ROLES OF CHILDREN	PADDLING	SETTING OF FISHING GEARS	CAST NET	FISHING WITH HOOK /LINE	BALING OF WATER	Sorting of fish	DOING NOTHING	CLEANING /MENDING OF NETS
AGES OF CHILDREN	12-14years	9-11years	15-17 years	15-17 years	3-5years	6-8years	0-2years	15-17YEARS

Table 2: Children in artisanal fishing in some fishing communities in Badagry

Months	Number of boats counted	Total number of people in all the boats	Total Number of Boys	Total Number of Girls	Total number of children in the boat	Crew size of the children sitting in a boat
Sept 2020	214	42	42	0	17	14

Oct 2020	200	39	39	0	34	18
Nov 2020	203	34	34	0	40	24
Dec 2020	180	28	28	0	36	30
Jan 2021	150	28	28	0	35	26
Feb 2021	175	27	27	0	30	22

The total number of boats counted, number of people in the boats counted, number of boats with children, number of children in the boat, number of boys and girls counted crew size of the children sitting in a boat are shown in table 1. The average numbers of boat counted in five communities where 187and people counted was 33 and 32 for children respectively for the period of six month in the various communities. 198 children were interviewed during the period, 153 children answered by themselves while parents answered for 45 children. During the study, no female children was found fishing, while male was 99.9%. (Fakayode *et al*, 2013) recorded a female child fishing in Lagos lagoon, Girls were assisting their mothers in fish processing and marketing, sometimes the female children stay at home to take care of their younger ones.

Table 3: The age range of the children counted in some fishing communities in Badagry

Age range	**0-2years**	**3-5years**	**6-8years**	**9-11years**	**12-14years**	**15-17years**
Number	1	24	168	173	96	6

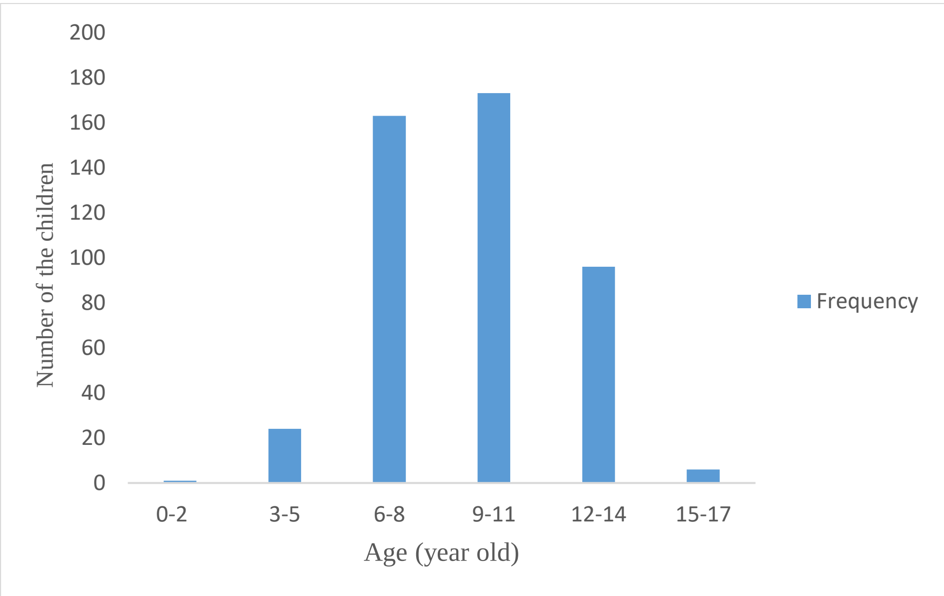

Fig 1: Total number of children at a particular age in the various communities

Table 4: Percentage of children attending School in some fishing communities in Badagry

The percentage of children that attended school were 20.43% in September, 18.82% in October, 16.13% in November, 13.44% in December, 18.82% in January and16.13% in February,

Month	Sept 2020	Oct 2020	Nov 2020	Dec 2020	Jan 2021	Feb 2021
Children attending school %	20.43	18.82	16.13	13.44	18.82	16.13

CONCLUSION AND RECOMMENDATIONS

The study shows that children, in particular the boys are totally active in fishing in their various communities and contribute to the artisanal fisheries sub sector, also helped in alleviating the poverty status of their households. Contribution of children as revealed may not be affecting children's school enrolment and completion negatively in the area. The contribution of children in the artisanal fishery of some fishing communities in badagry, show great potentiality in terms of natural yield which can help the government effort in employment generation, poverty alleviation, food security and supply of animal protein to the people living in Lagos.

It is recommended that government can increase the right support in terms of aids and infrastructures to fisher folks on the ways of improving fishing methods for sustainable management of the fishery also to support their children education. It was observe that no law would stop the fisher folks to involving their children in fishing and it may jeopardize the effort of government on fish production the right way to reduce child labour in artisanal fishing is that government should provide the right supports and infrastructures to fisher folks on the ways of improving fishing methods for sustainable management of the fishery to provide for their children education even to tertiary level

PROCEEDINGS
56th Annual Conference
Agricultural Society of Nigeria
24 - 28 Oct., 2022

ABSTRACT

The study was conducted among farmers in Ebonyi state to assess the level of women participation in yam production. The study also identified the improved technologies used by women in yam production, the yam varieties grown by women,and the factors constraining against women participation in yam production in Ebonyi State. Data were collected from sixty women farmers from Ebonyi South Agricultural Zone with a well-structured questionnaire. Data collected were analyzed with descriptivestatistics.The result showed that the yam production technologies used by respondents were organic manure (91.67%), inorganic fertilizer (78.33%), minisett (71.67%), improved yam varieties (68.33%), herbicide (66.00%) the result also showed a high level of participation of women in yam production in the study area with the mean of (2.82), an indication that women contribute to food security through yam production. The major constraints in yam participation among women were poor access to credit and climate change (100.00%)and(100.00%). unavailability of fund (96.67%), lack of fertilizer (93.33%) and poor yield (91.67%) In recommendation, efforts shouldbe made to handle these major constraints in women participation, for increasedyam production among women. We also recommend that yam will be seen as men and women crop because women are highly involved in the production.

Keywords;Women, Participation,Yam,Production, Farmers

INTRODUCTION

Yams (Dioscorea spp.) is an annual or perennial tuber-bearing plant, a tropical crop with many species, out of which six are economically important in terms of food and medicine (IITA, 2009). Yam originated in South East Asia and was brought to West Africa in the 16th century. It is one of the principal tuber crops in the Nigeria economy. Nigeria is the leading world producer accounted for over 65% of world yam annually, producing an average of 38 million metric tons (Odinwa *etal*,2016) Yam is an important source of carbohydrate for many people of the Sub Saharan region especially in the yam zones of West Africa. It's the second most important tuber crop in Africa, after cassava, with production reaching above one third of the level of cassava. Yam tuber is essentially a starchy food, its principal nutritional function being the supply of calories to the body (Onwueme,2001).Nigeria accounted for over 65%of world yam annually,producing an average of 38 million metric tons (Odinwa *etal*, 2016) . Yam is regarded as men crop in the Southeast Zone of Nigeria, which may be practically true or not, Women are playing a larger role in yam production in some parts of Nigeria. More women are into yam production and processing, but with limited access to resources (Kathryn *etal*, 2012).Research showed that both men and women plant yam in most part of Nigeria, women even grow yam more than men in some areas, while men engage in drinking of palm wine and other alcohol. In parts of Southeastern Nigeria, men and women combine efforts to do the planting; the women carry out weeding about 2-3 times before harvest; and men and women combine efforts again at crop maturity to harvest and even processing(Kathryn *etal* 2012).Despite high involvement of women in yam production, women experience greater constraints in accessing production resources.It will be good to find out the level of women involvement on yam production in Southeast Nigeria, in order to make references and acknowledge the contribution of women to food security and empowerment in Nigeria.

OBJECTIVES OF THE STUDY

1 Describe the socio economics characteristics of the respondents

2 Ascertain the improved yam technologies used by respondents
3 Identify the improved yam varieties used by respondents
4 Assess the level of participation of women in yam production
5 Identify the constraints in the participation of women in yam production in the study area

METHODOLOGY

The study was conducted in Ebonyi State and the population constitutes all yam producers in Ebonyi State. Multi stage sampling technique was used in the study. Ebonyi South Agricultural Zone was purposively selected for the study because of large number of women yam farmersin the area. In the second stage, twoExtension Blocks,Ivo and Onicha were purposively selected. Three Circles were randomly selected from the blocks. A list of all women yam producers in the selected circles were obtained from theextension agents and community leaders in the area, which formed the sampling frame of the study. From the frame, ten (10) yam women farmers were randomly selected for the study which gave a total of sixty (60) respondents for the study. Data were collected from the women using a questionnaire. Data collected were analyzed with descriptive statistics such as frequency tables, means and percentages. Objective four was realized with 4-point Likert type. Where: Strongly Agree (SA) = 4; Agree (A) = 3, Disagree (D) = 2 and Strongly Disagree (SD) =1. Therefore, the Likert mean $=\frac{4+3+2+1}{4}= 2.5$.

Results and Discussion

Table 1: Distribution of Respondents According to Socio Economic Characteristics

Age	Frequency	Percentage
< 20	1	1.67
20-29	5	8.33
30-39	21	35.00
40-49	12	20.00

50-59	15	25.00
Above 60	6	10.00
Total	**60**	**100**
Mean	**42**	
Marital status		
Single	24	40.00
Married	36	60.00
Total	**60**	**100**
Farm size		
< 1	32	53.33
1-2	8	13.33
3-4	14	23.34
Above 4	6	10.00
Total	**60**	**100**
Mean	**1.9**	

Table 1 shows that most (35.00%) of the respondents were within the age range of 30-39 years. However, the mean age of the respondents in Ebonyi State was 42 years, implying that they were middle aged, experienced and productive. This result is in agreement with Okeke and Udeora (2013) who reported that yam farmers in Southeast Nigeria were between the ages of 40 and 60 years. . Majority (60.00%) of the respondents were married while (40.00%) of them were single. This finding reveals that greater proportion of respondents were married, implying that married women are more involved in yam production than single women. This finding is in tandem with Ufondu, *et al* (2021) who reported that married women dominated yam production and processing business in Ebonyi State..Majority (78.33%) of the respondents had household size of 3-6 persons. On the average, the household size of the respondents in Ebonyi State were 5.3 persons This result revealed that the respondents maintained a relatively sizeable household size which could serve as insurance against shortfalls in labour supply and a source of cheap labour. Although very large family size may constitute a social burden, larger families use their labour input as an advantage in yam production and processing activities.Majority of the womenhad farm size of less than 1ha. On the average, the farm size of the respondents was 1.9ha. This result implies that majority of the respondents are marginal farmers because the cultivated less than 1ha of land. This finding is in agreement with Ofondu *et al.*, (2021) who reported that yam farmers in Ebonyi state cultivated less than 2hactares of land.

Table 2: The Distribution of the Respondents According to the Yam Technologies Used

Indicator	Frequency*	Percentage	Rank
Inorganic fertilizer	47	78.33	2nd

Improved variety	41	68.33	4th
Pesticide	14	23.33	8th
Herbicide	40	66.00	5th
Organic manure	55	91.67	1st
Minisett	43	71.67	3rd
Seed yam	31	51.67	7th
Ware yam	34	56.67	6th

Source: Field Survey, 2021 (Multiple response)

Table 2 presents the improved yam technologies used by the respondents in the study area in their order of magnitude include: seed yam (51.67%) and pesticide (23.33%). . This result could imply that the most common improved yam technology used in Ebonyi State, Nigeria is organic fertilizer. Increased utilization of organic fertilizer could be attributed to the fact that it is cost effective and safe

Table 3: The Distribution of the Respondents According Improved Yam Varieties Planted

Yam	Frequency*	Percentage	Rank
Water yam	57	95.00	1st
Yellow yam	50	83.33	2nd
Three leaf yam	30	50.00	5th
Aerial yam	48	80.00	3rd
White yam	45	75.00	4th

Source: Field Survey, 2021 (Multiple response)

Table 3 shows the improved yam varieties planted by the respondents in the study area in their order of magnitude, these include: water yam (95.00%), yellow yam (88.33%), Aerial yam (80.00%), white yam (75.00%) and three leaf yam (50.00%). This result could imply that the most common improved yam being planted among women are water yam, yellow yam, aerial yam and white yam

Table 4: Mean rating of the level of participation of women in yam production

Indicators	Ebonyi State (n =60)		
	Total	**Mean**	**Decision**
Land clearing	142	2.36	Rejected
Ridging/mounding	133	2.21	Rejected
Planting	205	3.42	Accepted
Weeding	212	3.53	Accepted
Stalking	131	2.18	Rejected
Pest control	197	3.28	Accepted
Fertilizer application	192	3.20	Accepted
Herbicide application	134	2.23	Rejected
Harvesting	176	2.93	Accepted
Grand mean		**2.82**	**Accepted**

Source: Field Survey, 2021. Critical mean score = 2.5. **Decision rule:** Mean ≥ 2.5=Accepted

Table 4 presents the level of participation of women in yam production in Ebonyi State. The grand mean score was 2.82 and was accepted because it was greater than the critical mean value of 2.5. This result implies that the women in Ebonyi state participated to a very high level in yam production. This observation could be a pointer to the fact that women are gaining access to agricultural resources such as land, credit and improved input and are considered to contribute immensely to food security status of their families.

Table 5: The Distribution of the Respondents According to the Constraints in Yam Production

Constraints	Frequency	Percentage	Rank	Frequency	Percentage	Rank
Lack of fertilizer	51	85.00	6th	56	93.33	4th
Unavailability of fund	53	88.33	4th	58	96.67	3rd
Poor yield	50	83.33	7th	55	91.67	5th
Poor access to credit	54	90.00	3rd	60	100.00	1st
Climate change	58	96.67	2nd	60	100.00	2nd

Source: Field Survey, 2021 (Multiple response)

Table 5 presents the constraints in yam production in the study area. The common constraints to yam production in Ebonyi State in their order of magnitude include: Poor access to credit and climate change (100.00%), unavailability of fund (96.67%), lack of fertilizer (93.33%) and poor yield (91.67%). This finding is in line with Nahanga (2015) who reported that the most common challenges for yam production in Nigeria were climate change and low financial base of the farmers.

CONCLUSION

There was high participation of women in yam production , Regarding yam as men crop is no longer justified The most common improved yam technologies used by the respondents was organic manure. The improved yam varieties planted by the respondents in the study area in their order of magnitude include: water yam, yellow yam, aerial yam, white yam and three leaf yam .The level of participation of women in yam production in the study area was very high. The constraints to women participation in yam production in Ebonyi State include: Poor access to credit and climate change, unavailability of fund, lack of fertilizer, poor yield and poor marketing.

RECOMMENDATIONS

Based on the foregoing findings, the following recommendations were made.
Government should aim at solving the major constraints of farmers especially in facilitating access to loans to aid production, making needed inputs available in time and, all subsidized rate, provision for all season, and deployment of experienced extension workers to aid the farmers.The Extension agentsshould intimate the farmers on effective coping strategies for climate change, as this will help to mitigate the effect on yam production

ABSTRACT

Agriculture is the main occupation of the vast majority of the population of Nigeria. Producers' organizations can help smallholder farmers participate in emerging high- value markets, such as the export market and the unfolding modern retail sector in Nigeria. Farmer Cooperative Societies (FCSs) strengthens support service for small scale farmers by developing link between farmers, processors, marketers and even consumers of agricultural produce. The study was conducted in Abia state. Well-structured questionnaire were used to elicit data from 80 respondents. The data were analyzed using descriptive statistics. The results revealed that the perception among the respondents ranked 'good to excellent'. The perception on communication behaviour and group orientation indicated the extent of interaction among the members (3.83). Group members are actively participating in FCS meeting and other orientation programmes. The level of perception on usefulness and outcomes revealed that FCS helped members to have better family livelihood activities. The results also indicated that after joining FCSs, their economic wellbeing improved. The FCS are playing major role by dissemination of information on recent technologies and new agricultural practices.

Key Words: Perception; Communication behavior; Farmer Cooperative

INTRODUCTION

Agriculture is the main occupation of the vast majority of the population of Nigeria.Various types of agricultural products are produced in Nigeria and the marketing of all these products is a complex process. Farmers do not have access to direct market and are selling their produce to the intermediaries (Nwafor et al., 2019). Because of intermediaries, their profit margin is reduced and their farming business becomes a non-viable one. Improvement in the status of the farmers is possible only through diversification and commercialization of their agricultural activities. This is possible only through implementation of agricultural policy reforms, introducing sustainable agricultural practices, optimizing input efficiency, bringing about institutional change, developing human resources capital and through participation of the non-governmental sector in agriculture. There is a need to strengthen support services for small-scale farmers by developing a link between farmers and purchasers of agricultural produce. Currently, such types of linkages are either not in existence or very weak. It is well recognized that the commercialization of small-scale, resource-poor farmers is closely linked to higher productivity, greater specialization and higher income (Bernard and Spielman, 2009). Perception in this study referred to the process by which one would have interest of communication and group orientation, outcomes and usefulness and overall level of satisfaction through FCS as member

It is possible to mobilize farmers in groups and build their associations called Farmer Producer Organization (FCSs) to plan and implement product specific cluster/ commercial crop cycles. The FCS is a means to bring together the small and marginal farmers and other small producers to build their own business enterprises that will be managed by themselves. The FCS can help farmers in the production of various agricultural produce as well as during the process of marketing of the crops. Farmers' organizations offer small-scale farmers to participate in the market more effectively and collectively, they are in a better position to reduce transaction costs of accessing inputs and outputs, obtaining the necessary market information, securing access to new technologies and to tap into high value markets, allowing them to compete with larger farmers and agribusinesses (Stockbridge *et al*., 2003). This study therefore assessed the perception of farmers on communication behavior and usefulness of Farmer Cooperative Societies (FCS) in improving the livelihood of farm households.

MATERIALS AND METHODS

This study was conducted in Abia State, Nigeria. Multistage sampling technique was adopted. The first stage was the random selection of Ohafia and Umuahia agricultural zones of Abia State. At the second stage, two local governments area were randomly selected from each of the zones-Aba zone; Ohafia zone; Ohafia and Bende local government areas: Umuahia zone; Ikwuano and Umuahia north government areas. Stage three was the random selection of two communities from each of the four local government areas and the last stage was the selection of 10 respondents purposively from each of the selected communities. These selected 80 respondents were the members of farmers' cooperative societies. Descriptive statistics were used to analyse the data.

RESULTS AND DISCUSSION

Perception in terms of communication behaviour and group orientation

The results obtained on perception in terms of communication behaviour and group orientation are presented in Table 1. The perception in terms of communication behaviour and group orientation were categorized under five criteria namely: the extent of interaction among the members, the assigned group activities and assignments given helped in gaining experience, the overall ability to meet farming related activities, the extent of participation in various community welfare activities, obtained some intellectual challenges. Among the five criteria, extent of interaction among the members (3.83) and the assigned group activities and assignments given helped in gaining experience (3.77) had indicating satisfactory to good level of perception. The respondent's perception on the overall ability to meet farming related activities (3.48), while the extent of participation in various community welfare activities and members who obtained some intellectual challenges had a similar mean perception score of 3.41. This implies that there is a positive perception in terms of communication behavior of the cooperative societies in the area. This is in line with the assertions of Tingchang et al (2021) who asserted that people now share their experiences with others through social networking services by posting on Internet forums, websites, or blogs. For example, people frequently use microblogging platforms (e.g., Twitter) to share their everyday happenings with networked others (e.g., followers). People also use electronic word-of-mouth (eWOM) in the form of online shopping website reviews (e.g., Amazon) to share their experiences with a product or service with unknown others (e.g., Amazon users).

Table 1: Perception in terms of communication behaviour and group orientation

S/No	Perception	Mean score	Rank
1	The extent of interaction among the Members	3.83	1st
2	The assigned group activities and assignments given helped in gaining experience	3.77	2nd
3	The overall ability to meet farming related activities	3.48	3rd
4	The extent of participation in various community welfare activities	3.41	4th
5	Obtained some intellectual challenges	3.41	4th

Source: Field survey, 2018

Perception on the usefulness and outcomes among the respondent

The results of the perception on the usefulness of cooperative societies and outcomes among the respondents are presented in Table 2. As shown in the table, the four criteria viz., FCS helped me to have better family livelihood activities (4.14), FCS acts as a source of socio-economic development to small and marginal farmers(3.96), FCS helps to reduce the loss in farming operations (3.92) and FCS helps in rendering additional revenue through farming activities (3.61) exhibited a higher mean perception score. Whereas effective utilization of available resources of the farmer is highly possible through FCS was the least perceived. This implies that the tendencies for farmers to join cooperative societies are high. This confirms the findings of Bernard and David (2009) that processors and marketers join cooperative societies because of easy access to vital information.

Table 2: Perception in terms of usefulness and outcomes

S/no	Perception	Mean	Rank
1	FCS helped me to have better family livelihood Activities	4.14	1
2	Effective utilization of available resources of the farmer is highly possible through FCS	3.96	2
3	FCS helps to reduce the loss in farming operations	3.92	3
4	FCS helps in rendering additional revenue through farming activities	3.61	4
5	FCS acts as a source of socio-economic development to small & marginal farmers	3.44	5

Source: Field survey, 2018

GENERAL PERCEPTION

It is evident from Table 3 that the following five criteria indicated satisfactory level of perception viz., How do you feel after joining FCS (4.26), Are you interested to continue as a member of FCS (4.10), Did your FCS meet expectations (4.08), and FCS is useful to prepare myself for newer tasks and responsibility (3.52). Whereas FPO helped me in gaining general information and farming knowledge had indicated undecided level of perception with a mean score of 3.48. The findings agrees with Bernard and David (2009).

Table 3: General perception

S/no	General perception	Mean score	Rank
1	How do you feel after joining FPO	4.26	1
2	Are you interested to continue as a member of FPO	4.10	2
3	Did the FPO meet your expectations	4.08	3
4	FPO is useful to prepare myself to newer tasks &responsibility	3.52	4
5	FPO helped me in gaining general information & farming knowledge	3.48	5

Source: Field survey, 2018

CONCLUSIONS

Perception among the respondents ranked ‘good to excellent’. The perception on communication behaviour and group orientation indicated the extent of interaction among the members (3.83). Group members are actively participating in FCS meeting and other orientation programmes. Level of perception on usefulness and outcomes revealed that FCS helped members to have better family livelihood activities. The result indicated that after joining FCSs the members economic impact improved upsurge. FCS are playing major role by dissemination of information on recent technologies and new agricultural practices. The success of these farmers’ cooperative societies is very much dependent on the commitment of the members. The integrity and quality of leadership as well as suitable market environment are the most important factors for the successful growth of such farmer’s organizations. From the findings, farmers perceive FCS to be useful; it is therefore recommended that rural farmers be encouraged to identify with FCS around them for easy flow of ideas and information

ABSTRACT
Market access is increasingly relying on Information and communications technologies (ICTs) like telephony and internet that are only adopted haphazardly. Despite the need for ICTs in Market Information Services (MIS), ICT usage in Africa is low. Little is known about ICTs for use in MIS including, technology, its potential users and characteristics of both entities. The study examined ICT components used and factors influencing the adoption of the components used. Stratified random sampling was used to select respondents and data were collected from them using structured questionnaires. The data collected from 150 farmers and 50 traders were analysed using descriptive and influential statistics with the aid of STATA statistical package. Radio was the most used old ICT, whereas mobile phones were most used new ICT. Expensive handsets, poverty, poor power supply, lack of expertise and poor network coverage limited ICT use. Farmers with knowledge of ICT groups and those thinking that ICTs benefited agriculture were the more likely adopters of ICT-based MIS. Family size and land farmed influenced farmers' adoption, whereas age, trading experience, family size and monthly expenses influenced traders' adoption. Farmers and traders who majorly used ICTs for making profit were more likely to use mobile phone whereas those who stayed further from towns were less likely to use the component.

INTRODUCTION
Access to markets has been one of the major factors that have influenced smallholder agriculture in developing countries. Accessing markets allows smallholder farmers buy inputs and sell surplus of their subsistence and semi subsistence agriculture to enhance household incomes (Barrett, 2008). These markets can be between communities, villages, sub counties or countries. Markets that are often accessed by smallholder farmers who form majority of the poor in developing countries are characterized by poor infrastructure and limited investment capital (Barrett and Swallow, 2006). Market access helps alleviate poverty through commercializing agriculture and result in uniform distribution of incomes in developing countries (DCs).
Income distributions in DCs are biased by corruption tendencies which have hindered improvement in household welfare (Dao, 2008). Progress in household welfare is dependent on increments in productivity of household stocks of land, labour and capital through adoption

of better agricultural technologies that foster economic growth and alleviate poverty (Barrett and Moser, 2003). Even though important innovations continuously occur in many developing countries globally, Africa inclusive, new technologies are only adopted at a slow pace and haphazardly (Singh, 2006). The slow pace of new technological adoption has kept household incomes low.

However, increase in incomes would enable poor households save more financial resources and consequently gain required financial ability to invest in new technologies that are needed in commercial agriculture (Okello, 2005). Most developing countries like Nigeria are characterized by poor infrastructure in roads and poor administrative systems that are ethnic based and usually marginalize sections of poor farmers and traders, hence restricting smallholders' access to markets (Nwafor et al 2019).

ICTs are generally defined as a combination of activities that enhance capture, storage, processing, transmission and display of information by electronic means (Rao, 2004). These Information and Communication Technologies (ICTs) include cellular phones, internet/email, World Wide Web, Print media, and digital radio receivers. Sustainable information exchange in agricultural markets, technology and knowledge is becoming a critical area of agricultural development. Information exchange seems to be given limited priority and in agriculture the bulky load of agricultural information exchange between farmers and agricultural experts and advisors has been left to extension agents. The effectiveness and efficiency of these extension agents have been declining partly due to limited funding from support organizations like government and donor agencies, and the high costs required in maintaining and sustaining the physical movements of these agents between the rural areas where farmers are found, and the urban areas where agricultural experts are mostly stationed (Nwafor *et al.*, 2019).

Majority of factors affecting adoption of ICTs for MIS are generic in nature. For instance cost effectiveness and speed of information transfer, organizational characteristics like business size, system characteristics like availability and access to ICT services, and internal and external characteristics of the business household like education, past experience in using ICTs, attitude towards ICTs, business objectives and incomes among others (Windrum and Berranger, 2002; Dholakia and Kshetri, 2004). Galloway and Mochrie (2005) further opined that usage of ICTs by smallholder households that inhabit mainly rural areas is constrained by limited education and poor technological infrastructure.

With the current need of efficiency in understanding market price trends, accessing inputs and support services, farmers and traders need to use more efficient and appropriate new ICTs to take advantage of the existing opportunities. Timely access to market information, inputs and other necessary information services like weather changes, pest control techniques and others would increasingly enable small-scale farmers and traders make timely, reliable, realistic and economically viable decisions concerning what crops to grow, when to grow them, what products are for sale when and where, what inputs to use and how to use them. The main objective of this study was to assess the adoption of ICT-based market information services (MIS) by smallholder farmers and traders

MATERIALS AND METHODS

This study was conducted in Benue State, Nigeria. The state has a population of about 5,741,800 National Bureau of Statistics (NBS) (2016); its total land area is 34,059km^2 and it is the 11th largest land mass in the country. Benue State falls within longitude $7^0 47^1$, $10^0 0$E and latitude $6^0 25^1$, $8^0 8^1$N, the state shares boundaries with five other states in Nigeria. Benue State is divided into three senatorial districts, namely, North East senatorial district (Zone A) North

West Senatorial District (Zone B) and Benue South Senatorial district Zone (C). Stratified random sampling was used to select the respondents used for the study and data were collected from them using structured questionnaires. The data collected from 150 farmers and 50 traders across the three senatorial zones were analysed with descriptive and inferential statistics with the aid of STATA statistical package.

RESULTS AND DISCUSSION

.
Table 1 presents a focus on some characteristics of the sample considering two broad sample strata; adopters and non-adopters. Means of education, experience in using ICTs, monthly income and distance to nearest town were statistically significantly different between adopters and non-adopters of ICT-based MIS. The class of households' monthly income, costs and distance covered to and from the nearest town were statistically different across groups

Logit model estimates of the determinants of traders' adoption of ICT-based MIS.
Logit model are presented in Table 7 and show that knowledge of existence of ICT groups perceived benefit of ICTs to agriculture and family size and land farmed in previous season significantly influenced adoption of ICTs for MIS by farmers. A one person increase in family size increased the probability of farmers to adopt ICTs for MIS by 60%.
Contrary to *a priori* expectations, an acre increase in land farmed previous season reduced probability to adopt ICTs for MIS for farmers by 15.3%. Farmers who had positive perception towards ICTs and those who had knowledge of existence of ICTs were more likely adopters than their counterparts. Though had a low participation in ICT usage (Table 1), women were more likely to likely to adopt ICTs for MIS than males. Table 8 presents Logit model results of factors influencing Traders' adoption of ICT-based MIS. Age of the trader, trading experience and monthly costs, family size, asset base, later age and better education

significantly influenced the probability of adopting ICTs for MIS by traders. A one person increase in the family size of traders' household increased the probability of adopting ICTs for MIS by 0.09%, as a one year increase in age and trading experience reduced such adoption by 0.08 and 0.03%, respectively. At later age, adoption of ICTs reduced more rapidly. A one shilling increase in monthly costs increased probability of ICT adoption by 0.18%.

Much of small-scale household farming in the study area was mostly practiced by women who had the primary responsibility of farming for household food security as mothers. Therefore males were less likely to devote to the use of ICTs in agricultural market information exchange. Having knowledge of ICT groups' existence availed farmers with an opportunity that attracted them to use and adopt ICTs for MIS. ICT groups were the sources of information and learning on how to use ICTs and benefits of ICTs, thus the positive influence is consistent with (Pickernell et al., 2004). ICTs enabled farmers to access general agricultural information like weather patterns, pests control, mobile money and others that were required in crucial decision making. That was consistent with Opata et al. (2011) and Peansupap and Walker (2005) who found positive perception towards ICTs being positively associated with expansion in ICT use.

Households mainly farmed for household food supply and mainly used rudimentary tools like hand hoes, knives and family labour. The average family size of farmers was small; below six persons (Table 3). Household average incomes were also very small and majority earned below 30 US $ per month (Table 3). Findings were consistent with Njuki et al. (2008) who found that large output proxied by large farm size in this research markets itself hence limiting need for market searches that were largely done using ICTs. However, Warren (2003) found that there was a positive association between farm size and ICT use. Increase in monthly costs on ICTs implied increased use and realisation of economic purpose of ICTs to traders hence traders' attraction to ICT-based MIS as costs increased. Whenever monthly costs increased, traders shifted to more efficient ICTs like mobile phones that gave them quick and more reliable information per unit cost, thus an increase in costs positively influenced adoption of ICTs. Nevertheless findings were contrary to *a priori* expectations and conclusions of Kovacic and Vukmirovic (2008) who found monthly costs to be negatively associated with the likelihood to use and adopt ICTs.

With more age and trading experience, traders mastered business patterns, the trends and tactics of the business environment, thus reduction in need and use of ICTs for MIS. +-Varying locations of family members necessitated more the need of communicating with each other using a more mobile device, thus increasing likelihood of using a mobile phone as compared to pay phone. Knowledge of ICT groups attracted households to gain membership to these groups in which they were more likely to be advised on using modern ICTs like mobile phones, thus a decreasing likelihood to use pay phone as compared to mobile phone. Having ICT groups' knowledge constituted a human capital and consequently a social asset as defined by (Parkinson and Ramirez, 2006). Increased experience in using ICTs enabled households acquire better skills and interest to use more complex ICTs like WWW and internet/email, consistent with Bailey (2009) who established that experience in using ICTs was positively associated with use of modern ICTs particularly the internet. With increasing incomes, households were less likely to use www, CD-ROM and internet/e-mail compared to mobile phone because these components were more capital intensive than mobile phones. Using internet or www required buying a computer and internet services.

CONCLUSIONS

Mobile phone was one of the most important ICT components used by households to access market information services. Family size significantly and positively influenced ICT-based MIS adoption for both small-scale farmers and traders and having knowledge of ICT groups' existence availed farmers with an opportunity that attracted them to use and adopt ICTs for MIS. Therefore, innovation on ICTs should be stended to farmers via ICT groups and farmers organization

ABSTRACT

To understand the varietal traits that attract cassava seed users and their willingness to buy the cassava varieties that possess the desired traits, a study was conducted in four selected states in southeast and south-south geopolitical zones of Nigeria where the activities of Building a Sustainable and Integrated Cassava Seed System (BASICS Project) is currently going on. The study adopted a combination of purposive and random sampling techniques to select 44 cassava farmers who have patronized the cassava seed entrepreneurs. Data obtained were subjected to descriptive statistics and probit regression analysis. Results of the study revealed three distinct trait categories that attracted the interest of the users. These categories include: Agronomic traits, product characteristics and marketability traits. Also, the probit regression output shows that farmers who planted local varieties previously were more likely to be willing to buy improved cassava varieties. Also, there is a varietal preference for TME 419 due to its high starch content and whitish colour including high dry matter content. It was therefore recommended that the identified traits should guide breeders in further varietal developments and the preferred variety (TME 419) should be massively multiplied and distributed to ensure that farmers have access to it at all times.

Key words: Cassava, seed, improved, varieties, farmer, preferred, trait

INTRODUCTION

Cassava is one of the important tropical root crops in Nigeria and Africa as a whole, considering that over 30 million Nigerian farmers, traders and processors are engaged in cassava value chains and agribusiness. Undoubtedly, Nigeria is the world's largest producers of the crop (FAO, 2020). Despite these achievements, cassava production is characterized by over 80% of smallholder farming outlay and dominant use of old and local varieties with traditional production technologies. These account for low yields experienced by the farmers.

National Root Crops Research Institute (NRCRI) Umudike and International Institute for Tropical Agriculture (IITA) Ibadan have developed varieties to meet the needs of the end users and increase demand. Such traits as high dry matter, high yielding, disease resistant, early maturing, high beta carotene content etc., constitute the quality demanded by the farmers.

However, quality content of these traits differs according to variety, therefore will form a major consideration for the farmer to buy such variety. Before now, Teeken et al (2018) had opined that Nigerian cassava breeding programs prioritize traits in setting breeding agenda so as to impact the largest possible number of people through improved varieties. Furthermore, IITA (2021) reported that improved cassava varieties have been subjected to years of preference studies with rural women who plant, process and eat cassava. These varieties resist pests like cassava mosaic disease (CMD), have the right color and texture when prepared as meals.

Willingness to buy certified improved cassava seed is a measure of the ability and preparedness of a farmer or user to exchange a commodity with money payment due to certain accepted criteria that the variety possesses. Certainly, for a farmer to be willing to pay for a preferred variety, his or her perception of the seed should be better than what the farmer is already using and have the ability to give a positive return on investment. The expectation is influenced by quality traits of the variety that meet the criteria for selection by the farmer and at an affordable price. Deal breaker traits are those attributes (phenotypical and genotypical) of a cassava variety that qualifies it for acceptability by the farmer and end users. Such traits include agronomic, processing and marketability qualities of the variety that distinguishes it from other varieties and thus attracts demand from users. In other words, deal breaker traits are those traits that the variety possess as a sufficient condition for a buyer to take decision to buy. This study therefore seeks to identify those traits that a cassava variety should possess that will facilitate farmers' preference and willingness to buy the variety.

METHODOLOGY

The study was carried out in south-east and south-south geopolitical zones of Nigeria. Two states were purposively selected from each zone based on BASICS activities in the states. In South-East, Abia and Imo states were selected while in South-South; Cross River and Akwa Ibom states were selected. The respondents were selected from a list of customers who purchased stems from the key CSEs that sold cassava seed during the 2018 planting season. A total of 44 cassava farmers who are customers to the CSEs were identified and selected. The researchers adopted a snowball method to trace the respondents whose distribution is presented in Table 1 below.

Table1: Distribution of respondents according to states

States	Number
Abia	7

RESULTS AND DISCUSSION

Deal -Breaker Traits of Preferred Improved Cassava Varieties in the study area.

Preference to cassava varieties is pivotal to adoption, utility and commercialization of cassava. Since the varietal traits contained in the seeds cascades down through the product value chain from primary outputs (roots) to secondary products (*gari*, *fufu*, etc). These traits were characterised into three distinct groups based on farmers' responses as shown in Table 2 below.

They include the agronomic traits indicating cassava stems physical features at farm level which forms sources of attraction and a measure of farm level performance of plants amidst diverse climatic conditions. These certified improved cassava varieties show resilience to climate change, soil nutrient and water use efficiency especially during late season farming, they mature early, visibly show good stem architecture which is a good trait for cassava stem entrepreneurs, giving them more value for their labour, good root formation, shape and sizes are some of the best traits identified at farm level as quality agronomic traits.

In addition to this, the second classification of the deal breaker quality traits that leads to increased demand for product is product characteristics at processing level. These varieties show low water content during processing (a proxy for high dry matter), swelling property which is commonly referred to as less-for-better for commercial producers and households with large number of members. For a farmer who is also a processor, an important trait which these improved varieties are renowned for is underground storability. They have proven to have slow deterioration on the field which enables a farmer plan its product marketing regime and possibly take advantage of the off-peak market demand for cassava roots.

Finally, the market-level leading traits as identified from the survey include; brightness of product colour which is a leading property for marketing the product. Products of improved cassava varieties (*Gari*, *fufu*, *Abacha*) does not change colour under the sun or extreme conditions or over time. Its swelling property, draw ability of *gari* and *fufu* (a proxy for good starch content) is a market level leading trait of preference that meets consumer demands. Products of certified improved cassava varieties demonstrates visual and textural satisfaction for consumers and the popularization of these qualities leading traits are a yardstick for increased production and sales to attain maximum utility and overall consumer satisfaction. These findings justify previous findings (Bentley et al 2017, Bechoff, et al 2019).

Table 2. Deal -Breaker Traits of Preferred Improved Cassava Varieties in Southern Nigeria

Agronomic traits	Product characteristics	Marketability traits
High yield	Higher dry matter content	Bright colour of products (garri and fufu)
Early maturity	Considerable starch quantity	Swelling property of processed product
Soil nutrient-use-efficiency	Easy to process (Softens quickly) for fufu	Colour (yellow, Off-white)
Resilient to harsh weather and diseases	Yellow root	Very high demand market for product (stem and roots)
Excellent stem architecture	Underground storability of roots post maturity	Good starch quality for fufu (draw ability)
Good root size and formation	Good for garri processing	Products meet consumers visual and textural preference
Newness of product	Nutritional added advantage	Popularity of products in the area

Willingness to buy certified improved cassava stem in South east and South-South Nigeria

The result of the probit regressions analysis presented in Table 3 reveals a pseudo-R squared value of 0.4148 and chi square value of 31.35 statistically significant at 1% level of probability indicating the goodness of fit of the regression equation. Three (3) out of the eleven (11) independent variables were statistically significant at different probability levels. These include planting of local varieties which had a direct relationship with willingness to buy the certified improved cassava varieties at 5% level of probability. This shows that majority of farmers who are willing to buy improved varieties are those who plant local varieties and are willing to try something new. Furthermore, purchase of variety TME 419 had a positive relationship with willingness to buy, statistically significant at 10% level of probability reflecting an increased demand for the variety. The more they purchase this variety, the higher their willingness to buy more. Those who had purchased TME 419 cassava varieties earlier are more willing to buy, having seen the performance of the cassava variety. This could be because the variety has become popular due to its deal-breaker traits that meets the diverse needs and preferences of different categories of consumers. Conversely, the variable purchase of TMS 01/1368 had an inverse relationship with willingness to pay at 10% level of probability. Which reflects a decline in willingness to purchase the cassava stems. This means that any farmer that purchased the variety will not be willing to pay for it any more, thereby confirming the position of Ayinde (2017) that adoption and consumption of bio-fortified pro vitamin A cassava varieties remain low in Nigeria. Also, in a related study, Onyeneke (2020) identified some constraints to adoption of bio-fortified cassava to include among others, quick root deterioration and high moisture content. These are poor processing qualities that may discourage purchase of seed of the yellow root variety.

Table. 3. Parameter estimates of the Probit regression on willingness to buy certified improved cassava stems in Southern Nigeria

CONCLUSION

Deal breaker traits in a cassava variety plays an important role in determining the preference and willingness to buy such varieties. From the study, cassava varieties that possesses certain agronomic traits (high yielding, early maturing, soil nutrient -use efficiency, resilient to harsh weather and diseases, excellent stem architecture and good root size), product characteristics (high dry matter, considerable starch quality, easy to process (ferments quickly) for fufu, root colour, and nutritional added advantage) and marketable traits (bright colour, good swelling property, high market demand, good starch quality, good visual and textural quality and popularity of product in the area) are considered to possess deal breaker traits that determines the preferences and willingness to buy such varieties. The TME 419 variety is the most preferred variety. The probability of farmers to buy and continue to use TME 419 is significant whereas there is high probability for farmers who have used TMS 01/1368 to stop using it. It is therefore recommended that seed producers should increase the multiplication of TME 419 to meet its increasing demand.

24 - 28 Oct., 2022

ABSTRACT

The study determined the dissemination pathways used by the extension agents. Data was collected from a total of 88 extension agents in Kwara, Niger and Kogi States Agricultural Development Programme via the aid of questionnaire. The data were analyzed using descriptive statistics. The results showed that the mean age of the respondents was 48 years, predominantly male (95.5%) with average of 21 years of experience. The predominant dissemination methods used by the extension agents were farm and home visit ($\bar{x} = \mathbf{1.73}$), result demonstration ($\bar{x} = \mathbf{1.66}$), and method demonstration ($\bar{x} = \mathbf{1.58}$), slide shows ($\bar{x} = \mathbf{0.78}$) and films ($\bar{x} = \mathbf{0.68}$) are rarely used. The study hence recommends that that extension programme managers should understand these methods as the most effective method to disseminate information and provide them with necessary teaching materials. However in cases of large population the dissemination method that are rarely used might be effective, it therefore becomes pertinent that extension personnel are provided with this teaching aids and also trained on its usage.

Keywords: **Extension agents, Dissemination methods, Climate Smart Agriculture**

INTRODUCTION

In West Africa rice has been the region's primary source of calories since the early 1970s, and it is the third largest source of calories (after maize and cassava) (Haggblade, Longabaugh, Boughton, Dembele, Diallo, Staatz & Tschirley, 2012). As at 2016, rice produced locally in Nigeria was estimated at 4.8 million tons (FAO, 2016). According to (Udemezue, 2018), over 8 million tons of rice are consumed annually, with consumption increasing by roughly 6% per year, while a typical Nigerian consumes 24.8 kg of rice per year, according to (Anyaoha, Uba, Onotugoma, Mande, Gracen, & Ikenna, 2019). This implies that the consumption rate is far greater than the production rate.

Rice production faces numerous obstacles, the most significant of which is climate change, as most production activities are carried out in open fields. One of the researches conducted by (Anyaoha et al., 2019, Ronald, Dulle & Honesta, (2014)) pointed out that most rice farmers are faced with the challenges of change in rainfall pattern, pests and weed infestation, flooding which are all attribute of climate change. More so, most farmers lack the information and the resources needed to reduce the impact of climate change on rice production.

An innovation platform is one type of institutional innovation that can aid in climate change adaptation and mitigation (Leeuwis, Hall, Weperen & Preissing, 2013), and this platform is an area where both public and private extension agents can serve as a facilitator and a broker for a variety of tasks, such as bringing farmers together to discuss adoption techniques with researchers and building climate service tools.

However, research has revealed that farmers are responding to shifting climate situations, but the uptake of possibly advantageous measures known as climate smart agriculture is frequently low Arslan, McCarthy, Lipper, Asfaw, & Cattaneo, (2014) and McCarthy, Lipper, Branca, & Security, (2011). This was also ascertained by a number of researchers who have observed limited climate adaptation practices uptake and utilization (Akinnagbe & Irohibe, 2014; Ali & Erenstein, 2017; Tripathi & Mishra, 2017).

Climate Smart Agriculture (CSA) is an agricultural practice that aspires to raise production in a sustainable way, improve resilience (adaptation) wherever possible, reduce/eliminate GHGs (mitigation), and encourage the attainment of development goals and national food security (FAO, 2013). Examples include minimum or zero tillage, construction of water-retention structures, planting crops that enhance ground cover quickly and use minimal water), crop rotation and intercropping by incorporating legumes to promote soil fertility, farmyard composting and adopting farmyard manure management through biogas production, and minimize release of methane amongst others.

There are varieties of literatures as regard extension agents and climate change issues across countries (Oladele, 2011; Dimelu 2016; Kakota, 2017; Olorunfemi et al., 2019). These studies are useful because they assisted in informing us that extension agents have been involved in disseminating CSA practices to farmers. However, there is paucity of literature on the method the extension agents utilize in disseminating CSA practices to the farmers. It is on this note that this study attempt to identify the dissemination method used by the extension agents, so that they can be aware of the best teaching method they can use to disseminate information to farmers thereby increasing the adoption/ uptake of the CSA practice by farmer and thus ensure a sustainable increase of rice production in the study area.

The objectives of this study are to;

i. ascertain the socio economic characteristics of the extension agents in the study area.
ii. determine the information dissemination methods used by extension agents

METHODOLOGY

The study was carried out in the North Central zone of Nigeria. A multi-stage sampling procedure was used in selecting the respondents. The first stage involved a purposive Random selection of Kwara, Kogi and Niger States out of the seven states in North central, Nigeria due to the predominance of rice production in the states. The second stage involved a purposive selection of zone B out of four ADP strata in Kwara State, zone A out of three ADP strata in Niger State, and zone D out of four ADP strata in Kogi State, based on their involvement in rice production. The 3rd stage involve selection o the village extension agents, Zonal Extension Officers (ZEOs) and Block Extension Officers (BEOs) were interviewed totaling 88. This is because all the extension workers mentioned irrespective of their status were involved in disseminating CSA practice to the farmers and the total population selected was due to their small size. The data was analyzed with descriptive statistics.

RESULTS & DISCUSSIONS

The results in Table 1 show that the mean age of the respondents was 48 years, this is in line with (Olorunfemi et al., 2018). The mean number of farmers/ farm families per extension workers was 1936, which is in line with the findings of (Haruna, 2013). The mean years of experience is 21 years with majority been male (95.5%), married (95.5%), had tertiary education (85.2%) as the highest level of education and an average monthly income of ₦74,370.

Table 1: Socio-economic characteristics of extension agents

Characteristics	Mean ± Std deviation	Percentage (%)
Age (years)	48 ± 6.914	
Sex (male)		95.5
Marital status(married)		95.5
Years of experience	21 ± 9.38	
Level of education		85.2
Monthly income(naira)	74,370± 51,869	
Number of farm family/extension agents	1/1936± 6690	

Source: Field survey, 2020

The results in Table 2 present the teaching method used by extension agents in the study area. The table ranked; farm and home visits ($\bar{x} = 1.73$), result demonstration ($\bar{x} = 1.66$), methods demonstration ($\bar{x} = 1.58$), meetings at results demonstrations ($\bar{x} = 1.57$) as 1st, 2nd, 3rd and 4th teaching methods mostly used by the respondents in disseminating climate smart agricultural practices to the rice farmers. This implies that farmers in the study mostly have physical contacts with the extension agents, this could be because farmers prefer having direct contact with the extension agents and this may motivate them to adopt the CSA practices being disseminated to them. This is in consonance with the findings of Ahmed & Adisa, (2017) who reported that rice farmers in Kogi State perceived field demonstration and individual contact methods(result demonstration, farm & home visits) as the most effective teaching methods used by the extension agents. Khatam et al., 2013) stated that individual contact methods like farm visits, demonstration and home visits are the major methods used by extension agents for the farmers. Likewise Abdulshakur, Yusuf, Nnaji, & Haruna, (2020) ranked group discussion and demonstration 1st and 2nd as the most effective methods used by extension agents.

The table further reveals the teaching methods rarely used by the extension agents include: films ($\bar{x} = 0.68$), personal letter ($\bar{x} = 0.78$), slide shows ($\bar{x} = 0.78$), flip charts ($\bar{x} = 0.82$), radio ($\bar{x} = 0.85$), drama ($\bar{x} = 0.85$) and circular letters ($\bar{x} = 0.86$). This could be due to high cost of disseminating information through these media or due to lack of competence in usage of the teaching aids.

Table 2: Distribution of Respondents by teaching/Dissemination methods used

Dissemination methods	Often used Freq (%)	Rarely used Freq (%)	Never used Freq (%)	Mean	Std. Deviation	Rank

Source: Field Survey, 2020

CONCLUSION AND RECOMMENDATION

The predominant dissemination pathway/ method used by the extension agents were: farm and home visits, result demonstration methods, demonstration meetings at results demonstrations while, dissemination pathway/ method rarely used by the extension agents include: films personal letter, slide shows, flip charts, radio, drama, and circular letters. It is recommended that extension programme managers and those concern with agricultural development understand these method as the most effective method to disseminate information and provide them with necessary teaching materials however in cases of large population the dissemination method that are rarely used might be effective, it therefore becomes essential that extension personnel are provided with this teaching aids and also trained on its usage.

ABSTRACT
Climate change has been reported to have been caused by human activities and its impacts on global economy and the citizen is devastating in nature. This paper aims to identify various ways through which farmers in the rural community contribute to climate change. This study intends to contribute to environmental sustainability and farmers' adoption of cleaner agricultural production practices. This research adopted descriptive survey design type. The methodology includes the use of four stage sampling procedure to select 120 farmers from the study area. Interviewed schedule was used to collect data from the respondents, while the data collected were analyzed using descriptive statistics. The findings revealed that majority (92.4%) engaged in bush burning, 96.7% were involved in deforestation,59 % engaged in soil nutrient depletion activitieswhile 92.4% engaged in drainage construction. All these activities contribute to global warming. Therefore, it is recommended that awareness campaign about the cause of climate change should be organized for the farmers in the zone,while policy should be formulated to encourage farmers to use climate smart agriculture in their production process in order to establish environmental sustainability.

Key words: Climate change. Bush burning, Deforestation, Sustainability, Farmers activities Global warming

INTRODUCTION
Climate change is a global issue of concern that puts every nation under pressure to prevent the consequences and the risk through policy making and implementation (United Nations Climate Change Secretariat, [UNCCS], 2019). This unfortunate incidence calls for action in all ramification because neglecting the danger and negative effects of this monster call "climate change" will put the world in jeopardy (International Panel of Climate Change [IPCC],2018). The world is facing a trying time of nature as temperature increases with unpleasant consequences that ravage many sectors of the economy: agriculture, health, social, manufacturing and economic sectors(Nelson, 2009; Oppenheimer *et al.*, 2014; Elum *et al.*, 2017;,Obaniyi*et al.*, 2019, Ugwoke, *et al.*, 2020; Fawzy *et al.*, 2020). Researches in the past have identified major contributors to global warming such as : Natural systems which include forest fires, earthquakes, oceans, permafrost, wetlands, mud volcanoes and volcanoes (Fuss et al,,. 2018:Yue and Gao 2018), but few research focuses on farmers' activities that lead to climate change and that is the area this research paper covered. It is against this background that this research seek to identify the contributions of human beings mostly farmers who

engaged with nature on daily basis. Therefore, the main objective of this study was to assess the farming activities that contribute to climate change in order to provide advisory service in mitigating effect of climate change in the zone.

MATERIALS AND METHODS

The study was carried out in Ekiti State, Nigeria which is located between longitudes 4°5′ and 5°45′ east of the greenwich meridian and latitudes 7°15′ and 8° 5′north of the equator. It lies south of Kwara and Kogi States, east of Osun State and bounded by Ondo State in the west and south. By the 2006 census, the population of Ekiti State was 2,384,212. Ekiti is an upland zone rising over 250 metres above sea level. The total land area is 6,353 km^2 (2,453 sq mi) and ranked 31st of 36 states of Nigeria . It has rhythmically undulating surface and also consist of dome rocks. The State experiences climate of two distinct seasons. These are the rainy season (April – October) and dry season (November – March). Temperature ranges between 21° and 28°c with high humidity. Tropical forest exists in the south, while guinea savanna predominates in the north. The predominant ethnic group in the study areas is Yoruba.

This research adopted descriptive survey type. It involves the use of four-multistage sampling techniques. The population of the study consists of 16 LGAs,out of which 8 LGAs were randomly selected. Two wards were selected from each LGAs. Three villages were selected from each ward, while forty cocoa farmers were selected randomly from each village to give a sample size of 120 farmers. The data on the activities of farmers that contributed to climate change were collected from the respondent using structured questionnaire on how and extent at which the farmers participated in those activities. The categories include Never, Once, Occasionally, Often and All the time ’.

Data Analysis

The data collected was analyzed using descriptive statistics Data collected were coded into a software Statistical Package for social sciences (SPSS version 23) was used after coding, the variable were measured at ordinal level before processing.

RESULTS AND DISCUSSIONS

The involvement of respondents in the activities that contribute to climate change

Involvement in Bush Burning Activities

Bush burning is one of the activities that contributed to climate change through the release of Green House Gases as more carbon is being released into the atmosphere thereby causing global warming(Ritan, 2013; Yue & Gao 2018; Fawzy*et al*., 2020). Also, the smoke from the bush burning can result to a great health challenge for farmers. The results (Table 1) show that majority (84.2%) had occasionally or once burned bush when preparing the land for cultivation while few (9%) still engaged in the habit of burning bushes often and all the time. This call for quick action by the orientation agency and extension agents to campaign against subsequent bush burning as more carbon which result to global warming are being released. Farmers should be taught about the importance of keeping their atmosphere save.

Involvement in Deforestation Activities

Deforestation is a deliberate attempt of cutting tree down in the forest in order to establish cocoa farms and build farm houses. This is one of the major factors that contribute to climate change (Ruddiman, 2003, 2005; Olagunju, 2015; Yue & Gao, 2018; Fawzy *et al.*, 2020) The result (Table 1) shows that 94 % of the respondents engaged in deforestation as following (47.5% cut tree once, 18.3% occasionally, while 29.2% often engaged in cutting tree .on their farm for agricultural purpose. According to FAO (2005), *Nigeria* was ranked the highest*in* terms of the rate of deforestation which result to climate change.This call for quick action by the orientation agency and extension agents to campaign against subsequent cutting of tree as more carbon which result to global warming are being released. Cocoa tree also help to store carbon therefore farmers should be paid compensation from ecological fund for keeping our world.

Involvement in removing dry leaves from the topsoil

The act of parking leaves on the farm is done by some small-scale farmers in order to prevent bush burning disaster as they believe that this will prevent the farm from burning. The results (Table 1) show that 59% carried out the sweeping of the farm during dry season while 41% never engaged in sweeping dry leaves from the land cover of their farms. The implication of removing dry leaves from the topsoil is that it opens the land for erosion and loss of soil nutrient as the organic matter content is reduced. This action calls for extension agent interventions by informing the farmers about the danger of removing dry leaves from their topsoil.

Involvement in constructing drainage to control flood and erosion on their farm

The devastating effects of flood caused by excessive rainfall as a result of unpredictable climatic condition which may have caused rivers to overflow their boundary, and subsequently result into soil degradation and losses to farmers have been documented (Yue & Gao, 2018) . This has been reported to be a major challenge to food security (Ritan, 2013). The results (Table 1) show that majority (93.3%) involved in constructing drainage system in their farm to control excess flooding activities. This will help to safeguard against flood and consequently promoting food security and a peaceful ecosystem. Orientation agency should therefore encourage farmers in the other states to imbibe what Ekiti State farmers have endorsed.

CONCLUSION AND RECOMMENDATIONS

The study concludes that the farmers activities that contributes to climate change in the study area were involvement in bush burning deforestation activities which involve cutting down of trees in the forest in order to establish their farms, the removal of dry leaves from the top soil and Involvement in constructing drainage to control flood and erosion on their farms. The result shows that majority carried out these activities and this is detrimental to the nutrient availability of the soil and consequence low yield from the farms. Therefore, it is recommended that awareness campaign against these practices must be embarked upon and speedy afforestation programme must be established in order to improve carbon sequestration level and consequently reduce Green House Gas (GHGs) emission in the area, thereby reducing the impacts of the climate change in Sub Sahara Africa as a whole. Moreover, Climate smart agriculture should be introduced to farmers to improve their vulnerability level and enhance their economic status. For instance, the used of drought resistant varieties, irrigation technology, weather forecast update and insurance cover can be introduced to farmers.

Table 1: Showing different levels of involvement in activities that contribute to climate change

LEVEL OF INVOLVEMENT	BUSH BURNING F, (%)	DEFORESTATION F, (%)	DRY LEAVES REMOVAL F, (%)	DRAINAGE CONSTRUCTION F, (%)
NEVER	8 (7.6%)	4 (3.3%)	49 (40.8%)	8 (7.6%)
ONCE	15 (12.5%)	57 (47.5%)	14 (11.7%)	44 (36.7%)
OCCASIONALLY	86 (71.7%)	22 (18.3%)	48 (40.0%)	48 (40%)
OFTEN	9 (7.5%)	35 (29.2%)	9 (7.5%)	18 (15%)
ALL THE TIME	2 (1.7%)	2 (1.7%)	0 (0%)	2 (1.7%)
Total	120 (100%)	120 (100%)	120 (100%)	120 (100%)

24 - 28 Oct., 2022

ABSTRACT

This study aims to examine the devastating effects of the Covid-19 pandemic among the human and animals in Nigeria and to proffer a way out of this national attacks through Covid -19 Agricultural Extension Integrated Approach Model (CAEIAM). The recent pandemic has contributed to the downfall of many nations; therefore, there is a need to diversify our resources in fighting this plaque. The truth is that whatever thing that has affected the health status of the production sectors of the economy, has successfully reduce the welfare of the household communities. Agricultural extension is concerned with improving the welfare of the nations through dissemination of new technologies; improvement of crop and animal production system thereby improving their livelihood. Nigeria as one of the developing countries must wake up to the fact that Covid -19 vulnerability can be reduced with integrated approach system known as Covid -19 Agricultural Extension Integrated Approach Model (CAEIAM). Therefore, application of the multifaceted approach which include proper diet, application of faith and supernatural intervention together with strict adherence to Covid-19 Protocols will go a long way in reducing the spread and the impact of Covid-19.

Keywords: Agricultural Extension, COVID-19 pandemic, Integrated approach, Immune system, Model

INTRODUCTION

Covid is a colossal gathering of diseases that may cause infirmity in animals or individuals. (WHO, 2019) to activate respiratory defilements going from the standard infection to more genuine contaminations, for instance, Middle East Respiratory Syndrome (MERS) additionally, Severe Acute Respiratory Syndrome (SARS). This new infection and contamination were anonymous before the flare-up started in Wuhan, China, in December 2019 (World Health Organization [WHO], 2020). A conclusion with Covid 229E, NL63, OC43, or HKU1 isn't equivalent to a COVID-19 finding. Patients with COVID-19 will be evaluated and dealing with uniquely in contrast to patients with customary Covid analysis (WHO, 2019). There is by and by no considerable verification that any food or dietary example can help our safe framework and maintain a strategic distance from or treat COVID-19, anyway helpless sustenance brings about extended contaminations moderate repairing from injury and diseasesand builds weakness to signs and confusions from resistant framework brokenness. The resistant framework is responsible for fighting unfamiliar trespassers in the body, as pathogenic microscopic organisms and infections, and furthermore ends cells inside the body when they become harmful.

Theoretical Framework

A decent nourishment will guarantee a strong invulnerable framework that can help any assault by the infection. Since there is by and by no proof that any enhancement or food can assist our insusceptible framework with treating or forestall viral contaminations aside from Vitamin C. A legitimate eating regimen can likewise assist with guaranteeing that the body is in the most grounded conceivable state to fight and forestall the infection. Nutrient C is significant for keeping a solid insusceptible framework, it is water dissolvable a sign that it can't be put away by the body, this implies you need to supplant it every day by burning-through nutrient C rich fruits(apple, guava, banana, apple, melon, straw berry, pineapple, grapefruit, orange, papaya, blackcurrant, Longman natural product, wallop) including a serving of vegetables(lentils, beans, green ringer peppers, ginger, garlic, lime, kale, coriander (dried), broccoli, green ,stew pepper). It bolsters a decrease in the time allotment and seriousness of indications related with upper respiratory viral diseases, advances phagocytic cell capacities, and backing sound T-cell work, gives cancer prevention agent action to help mending at locales of irritation. The everyday suggested dietary recompense for Vitamin C is 90mg/d for men and 75mg/d for ladies.

This study hereby proposes this framework and model in reducing the impacts of Covid- 19. This is referred to as Covid -19 Integrated Approach.Model(CAEIAM).

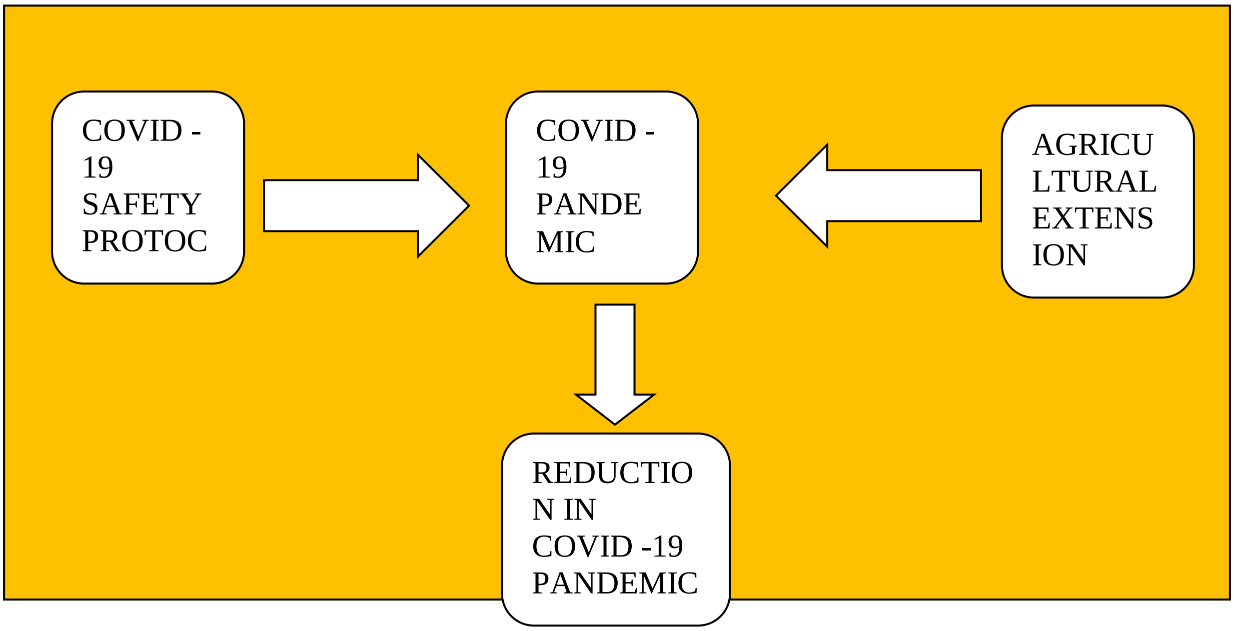

Fig 1: Covid -19 Agricultural Extension Integrated Approach Model (CAEIAM).

Source: Authors' Compilation:

MATERIALS AND METHODS

This study used desk research method and logical thinking to examine the devastating effects of the Covid-19 pandemic among the human and animals in Nigeria and to proffer a way out of this national attacks.The study area is Nigeria, but the research used the past works of authors which are not limited in scope as it covered different research from different authors. This research adopts writing audit method in gathering information .Writing audits can take two significant structures. The most common one is the "writing survey" or "foundation" segment inside a diary paper or a part in an alumni theory. This segment orchestrates the surviving writing and more often than not distinguishes the holes in information that the observational investigation addresses (Sylvester, Tate, and Johnstone, 2013). It might likewise give a hypothetical establishment to the proposed investigation, substantiate the nearness of the examination issue, legitimize the exploration as one that contributes something new to the cumulated learning, or approve the techniques and methodologies for the proposed investigation. The second type of writing audit, which is the focal point of this part, establishes a unique and significant work of research all by itself (Paré, Trudel, Jaana, &,Kitsiou, 2015). This research reviewed different area of intervention by government in reducing risks associated with Covid-19 pandemic and therefore proposes an Integrated Agricultural Extension Model as a way of reducing the impact of Covid-19 .

RESULTS AND DISCUSSION

In the current circumstance, COVID-19 has constrained a novel arrangement of difficulties for the person to keep a sound eating routine. The state of lockdown, social separating and self-segregation are critical measures to fixing the twist of the sickness, despite the way that these measures have extraordinary repercussions on a group life. The demonstration of limitation to one's home affects the well – being of an individual, remembering changes for eating designs, resting propensities, and actual development. It would empower latent practices that impact mental and actual prosperity and lead to an extended peril of heftiness (Khaled and Benajiba, 2020). Dread and strain may likewise cause changes in dietary works on prompting unfortunate dietary examples and less longing to eat or with joy during eating as per (Chen et al., 2020).

Zinc is additionally urgent for the normal turn of events and working of our resistance cells and antibodies. It is ideal to get zinc from food sources as enhancements can meddle with the retention of different supplements like iron and copper. It is essential to keep up satisfactory however not in over-the-top level, overabundance utilization of zinc has additionally shown negative impacts on resistant capacity and can restrain the phagocytic cells. Phenomenal wellsprings of zinc incorporate Spinach, Asparagus, sesame seeds, pumkin seeds, Garbanzo beans, Lentils, cashews, quinoa. Studies have uncovered that absence of top-notch protein can bring about consumption of invulnerable cells, absence of capacity of the body to make antibodies, and other safe related issues. Top caliber, complete proteins are found from numerous sources: eggs, fish, and shellfish, tofu, tempeh and quinoa, numerous vegetables and grains are likewise incredible wellsprings of a significant number of the invulnerable animating amino acids, earthy colored rice, broccoli, mushrooms, nut margarines, seeds and nuts. (Aman, & Masood, 2020)

Keep your liquid admission up, absence of liquid in the body can cause weariness, exasperate cold and influenza indications and hinder your processing, the proposed measure of liquid you ought to drink is around 2 liters each day and this should come essentially from water. Tips for expanding liquid admission include: Make a propensity for continually beginning the day with a glass of water when you awaken. Your body dries out for the time being and needs liquid for rehydration ; Try warm water with a cut of lemon for the duration of the day for a warming method to build your liquid admission ; and Try natural teas like peppermint, jasmine or lemon and ginger teas which are all caffeine free((Aman, & Masood, 2020)

Successive hand washing is essential to secure against Coronavirus, colds and different microscopic organisms that cause ailment. These microorganisms and infections can be available on the surfaces that we contact, while we are outside or inside, the washing of hand is vital to forestall reaching the infection.

Roles of Agricultural Extension and Rural Advisory Services in combating COVID-19

The recent pandemic has contributed to the downfall of many nations; therefore, there is a need to diversify our resources in fighting this plaque. The truth is that whatever thing that has affected the health status of the production sectors of the economy, has successfully reduce the welfare of the household communities. Agricultural extension is concerned with improving the welfare of the nations through dissemination of new technologies; improvement of crop and animal production system thereby improving their livelihood. Nigeria as one of the developing countries must wake up to the fact that Covid 19 vulnerability can be reduced with increase in the food quality taken by the rural and urban populace. Therefore, there is a need to diversify our efforts as a nation to the production of fruits and vegetables that is rich in vitamin c and zinc. Farmers should be trained on the improved practices that will guarantee large production while input should be supplied by the government through research institute such as National Horticultural Research Institute NIHORT, etc. On that note,the future role of agricultural extension and rural advisory services in combating covid-19 include the dissemination of the new technology to the farmers and rural dwellers on the reality of Covid -19. Moreover, the sensitization of rural populace about the prevention protocol of social distance, washing of hands, using of sanitizer, using of Nose Mask, participating in Covid-19 vaccination, and application of religious belief and faith system in reducing the effects of Covid -19 on human being system and ways of lives. Above all, organization of training on the crops and animal production technologies is also fundamental role of extension agents.

CONCLUSION AND RECOMMENDATIONS

In conclusion, this paper call for paradigm shift in our approach to arrest Covid-19 pandemic through changes in our believe system. This paper suggests multifaceted approach which include social distancing, washing of hands, using of sanitizer, Covid-19 vaccine, and application of religious belief and faith system in reducing the effects of Covid -19 on human being system and ways of lives.

Faith and believe system of people have been proved to have tremendous impact on their health, therefore Nigeria and other countries of the world must not shy away from the fact that Covid -19 can be healed supernaturally by the hand of God and indigenously through herbs etc. Therefore, let people have freedom of practicing what they believe in order to be free from this plaque. Churches and Mosque should be opened for people to worship their God in order to gain emotional power to live. There should not be banned on social gathering but rather be moderated.

Above all, building the immune system of people who lived in both the rural and urban area should be our major concerns and that is why the services of agricultural extension personnel should be employed in training the farmers or producers in the best methods of producing vegetables and fruits which will help in this regards. Finally, there should be collaboration between the health workers and agricultural extension professional on the necessary information on the nutrient required in building our immune system.

ABSTRACT

Covid-19 is a twenty-century pandemic that has destroyed many sectors of the economy. Therefore, there is a need to identify several ways of eliminating these global challenges. This study aims to assess the various strategies of reducing the spread of Covid-!9 in Nigeria and in the world. The research method used in this study was quantitative research, while the design type was a survey type. Survey questionnaires were sent out randomly to a specific population of people who are in tertiary institution (Landmark University). The purposive and random sampling technique were adopted. The data collected were analyzed using descriptive statistics. The results show that the majority of the respondents were males (65%) , 40% of the respondents were Master Degree holder (M.Sc.),while 35% with their (Ph.D.) The mean age of the respondent was 39 years, while 82% were salary earners . The result further shows that 82.5% agreed that the consumption of fruits and vegetables serve as a way of boosting immune system against COVID-19.The findings also revealed that 65% of the respondents consumed fruits and vegetables regularly specifically (42.5%) of the respondents also consumed ginger, onion, garlic and turmeric every day. The finding also revealed the COVID-19 pandemic precautionary measures practiced by the respondents in the study area: It was revealed that of 80% of the respondents practiced social distancing, use of face masks, use of hand sanitizer and combination of scientific guideline and indigenous knowledge while 75% practiced good hygiene, consume ginger and garlic, hydroxyl chloroquin and were holding prayer meetings as precautionary measure because they believed their God is a God of protection and can protect them.

This study concludes that the consumption of fruits and vegetables, personal hygiene, prayer to God as well as following precautionary measures are diverse strategies of reducing the spread of COVID-19. Therefore, this study recommends an integrated approach to solving covid-19 pandemic.

Keywords: Nutrition, Fruits and vegetables, Immunity, COVID-19 pandemic, integrated approach

INTRODUCTION

Coronavirus pandemic is at present a main test across the globe (World Health Organization [WHO],2022). This pandemic has caused a lot of damage which has contributed to food insecurity, poverty and economy melt down across the globe (WHO,2022;Schmidhuber, 2020;High Level Panel of Experts [HLPE],2020b). The general view of using vaccination as a preventive measure has been accepted by the European countries. However, Africa is a unique continent with diverse view to the cure and prevention of Covid- 19. In Africa, there is a divergent view to the cure of the pandemic. Some people believe that using herbs can cure Covid, while some people believe that prayer to supreme being (God) can cure Covid-19 (Silveira, 2020 There are much evidence of supernatural healing based on believe and faith of an individual. Another school of thought believed that the effects of Covid -19can be reduced with good diet. It is Important to achieve and keep up with great healthful status to support safe framework that can battle against infection. Wholesome status of individual is impacted by a few factors, for example, our believe, wellbeing status, way of life, what we consume(HLPE.,2020b). Feeble Immune framework, utilization design and healthful status of people have been utilized as strength towards disarray during this COVID-19 pandemic (Aslam , Majeed , Aslam,& Irfan , 2017.On that note, this study aims to assess diverse strategies in reducing the spread of Corona virus in Nigeria. This research therefore examines the view of academicians about the consumption of fruits and vegetables in boosting our immune system.

METHODOLOGY

The study was carried out in Landmark University metropolis. Landmark University is a private owned institution. The University is located at Km 4 Ipetu, Omu-Aran Road PMB 1001, Omu-Aran, Kwara State. (43FP+3V8, Road, 251103, Omu-Aran). Landmark University consist of Four(4) Colleges with over 3,000 students and lecturers and staff who are of different status and academic qualifications and gender. The research method used in this study was quantitative research, while the design type was a survey type. Survey questionnaires was sent out randomly through Google form to a specific population of people who are in tertiary institution (Landmark University). The purposive sampling and random sampling technique were adopted. The data collected were analyzed using descriptive statistics.

RESULTS AND DISCUSSION

The results presented in Table 1 show some of the socio-economic characteristics of respondents selected for the study. The table reveals that more than half (65%) of the respondents were males, while 35% were females, the figure implies that more males work in Landmark University either as a non-academic or academic staff. In terms of age, less than half (37.5%) of the respondents were within the ages of 35-44 years, while 30% were of the ages between 25 and 34years and 22.5% were between the ages of 45 and 54 and 2.5% were between the ages of 55-64 and 65-74 respectively. The mean age was 39.1 years. This is an indication that majority of the respondents were in their active age.In terms of educational status, 40% of the respondent are Master Degree holder (M.Sc.),while 35% with their (Ph.D.) and 25% with only their first Degree. This implies that a large proportion of the respondents had acquired second degree certificate and shows that they are well educated and could follow the COVID-19 pandemic precautionary measures and boost their immune system as education is vital to get informed about the pandemic.

Table 1: The Socio-economic characteristics of the respondents

Gender	Frequency	Percentage (%)
Male	26	65.0
Female	14	35.0
Total	**40**	**100.0**
Age		

18-24	2	5
25-34	12	30
35-44	15	37.5
45-54	9	22.5

Unemployed	0	0
Total	**40**	**100.0**

Source: Field Survey, 2021

Table 2 reveals the perceptions of respondents on the consumption of fruits and vegetables in boosting immune system against COVID-19 pandemic. The results show that more than three-quarter(82.5%) of the respondents agreed that consumption of fruits and vegetables can be used to boost immune system against covid-19. This perception may be as a result of their knowledge about the importance of fruits and vegetables to human health. The finding also reveals that 15% of the respondents were undecided. This implies that they could not really say if the consuming fruits and vegetables could boost immune system to fight against covid-19 pandemic, while a few (2.5%) disagreed. The table also reveals the proportion of respondents that consume fruits and vegetables as an antibody against COVID-19 in which 65% were taking fruits and vegetables regularly whereas 35% were not taking fruits and vegetables. This is an indication that there is heavy consumption of fruits and vegetables to boost immune system against covid-19 in the study area. However, majority (42.5%) of the respondents also consumed ginger, onion, garlic and turmeric every day, 27.5% consumed ginger, onion, garlic and turmeric four times in a week, 22.5% consumed ginger, onion, garlic and turmeric once in a week, 5% consumed ginger, onion, garlic and turmeric once in two weeks and few (2.5%) of the respondents consumed ginger, onion, garlic and turmeric once in a month.

Table 2: Perceptions of the respondents on consumption of fruits and vegetables can boost immune system against COVID-19

Fruits and vegetables can boost immune system against COVID-19	**Frequency**	**Percentage**
Strongly agree	11	27.5
Agree	22	55.0
Undecided	6	15.0
Disagree	1	2.50
Total	**40**	**100.0**
Do you take Fruits And Vegetable regularly		
Yes	26	65.0
No	14	35.0
Total	**40**	**100.0**
How often do you take spices such as ginger, onion, garlic and turmeric		
Everyday	17	42.50
Four times in a week	11	27.50
Once in a week	9	22.50
Once in two weeks	2	5.0
Once in a month	1	2.50

Table 3 shows COVID-19 pandemic precautionary measures practiced by the respondents in the study area. It was revealed that each of 80% of the respondents practiced social distancing, use of face masks, use of hand sanitizer and combination of scientific guideline and indigenous knowledge. The World Health Organization (WHO, 2020a) reported that masks can help prevent the spread of covid-19 from the person wearing the mask to others The result also revealed that each of 75% practiced good hygiene, consume ginger and garlic, hydroxychloroquin and were holding prayer meetings as precautionary measure because they believed their God is a God of protection and can protect them, 62% regularly disinfect contact surfaces such as door handles, furniture etc.50% embraced technology and internet so as to reduce the need for unnecessary movements and small portion (25%) of the respondents believed that apps can be created to make easy the delivery of market and perishable products to people's homes. This result revealed that majority of the respondents were aware and practicing the precautionary measures to prevent COVID-19 pandemic in the study area.

Table 3:COVID-19 pandemic precautionary measures practiced

Idea on how Covid-19 impacts can be reduced in our society	**Frequency**	**Percentages (%)**
Social distancing	32	80
Use of face masks	32	80
Use of hand sanitizers	32	80
High level of personal responsibility		
Good hygiene	30	75
Regular disinfection of contact surfaces such door handles, furniture	25	62
regular consumption of ginger and garlic, hydroxychloroquine	30	75

Embrace technology and internet so as to reduce the need for unnecessary movements.	20	50
Apps can be created to make easy the delivery of market and perishable products to people's homes.	10	25
Prayer as precautionary measure	30	75
Combination of scientific guideline and indigenous knowledge	32	80

Source: Field Survey, 2021

CONCLUSION

The study concludes that the 80% of the respondents practiced the following COVID-19 pandemic precautionary measures: social distancing, use of face masks, use of hand sanitizer. combination of scientific guideline and indigenous knowledge,while 75% practiced good hygiene, consume ginger and garlic, hydroxychloroquin and were holding prayer meetings as precautionary measure because they believed their God is a God of protection and can protect them. Therefore, this study concludes that the consumption of fruits and vegetables , personal hygiene, prayer to God as well as following precautionary measures are diverse strategies of reducing the Spread of COVID-19 . Therefore, this study recommends an integrated approach to solving COVID-19 pandemic.

24 - 28 Oct., 2022

ABSTRACT

This study assess the food consumption pattern and dietary diversity of rural farming households in Kogi local government area of Kogi state, Nigeria. It specifically assess the food security status of households in the area, assessed the dietary diversity of households in the area and examined the relationship between food security and dietary diversity in the area. A three-stage random sampling technique was used to select 120 farming households for the study. Primary data obtained through structured questionnaire were analyzed using descriptive statistics and Poisson regression model. The result also showed that 71.67% of the households were food secure while 28.33% were food insecure. The study further revealed that 58.33% of the respondents fell in the high dietary diversity range, 29.17% had medium dietary diversity, while 12.5% had low dietary diversity levels. The coefficients of age (ß=0.775024), household size (ß=-0.1442771), dietary diversity (-3150306), and access to credit (ß=-2.662027) significantly determined the status of food security among farming households at 5%, 10%, 5%, and 1% level of measurement respectively. The study concluded that rural households with substantial level of educational influences dietary diversity score and improve the number of food secure household in the study area. It is however recommended that in order to reduce burden due to income constraint, food aids intervention should be created to help the rural households to have improved health by diet diversification.

Keywords: Food security, dietary diversity, dietary score, household

INTRODUCTION

Food is a basic necessity of life. Its vital role at the household level is obvious since it is a means of livelihood. Adequate intake of quality food is a key requirement for a healthy and productive life (Victoria and Benjamin, 2012). Dietary diversity is the number of different foods or food groups consumed by the household over a reference period not regarding the frequency of consumption. The reference period usually ranges from one to three days, but seven days is also often used (FAO, 2017), and periods of up to fifteen days have been reported (Administrative Committee on Co-ordination/subcommittee on nutrition, 2005). Dietary diversity is a health indicator to which household nutrition can be assessed and related to the quality of the diet consumed. Dietary diversity does not only ensure the consumption of a balanced diet and good health, it also enhances intake of other components like fiber and antioxidants and helps to reduce the rate of malnutrition in the population. Therefore, increasing dietary diversity most especially at household level is a viable tool to achieving the second sustainable development goals of zero hunger. Household dietary diversity is also used to determine the level of resources available in a household. Understanding household dietary diversity may therefore be an alternative easy pathway to estimate household food security (Ajani, 2010; Valiki *et al.*, 2013). The research was intended to assess socio-economic characteristics of the respondents; determinants of household and dietary diversity and the relationship between household food security and dietary diversity of rural households in the study area. It is against the above background, that this research was undertaken, because it becomes extremely important to analyze the households' food security and dietary diversity among rural food crop farmers in Kogi Local Government Area of Kogi State, Nigeria. The study is significant in the current parlance of development economics, especially in extending similar studies such as Adebayo (2012), Agwu and Oteh (2014); Amao and Ayantoye (2015) among others.

METHODOLOGY

Study Area

This study was carried out in Kogi local government area of Kogi state. The local government has an area of 1,498km² and a population of 115,900 at the 2006 census, projected to 202,670 people in 2016 (NPC, 2016). Politically, Kogi local government area is divided into three (3) zones namely; Zone A, Zone B, and Zone C. The Zones are further divided into two (2) Subzones each namely; Subzones A and B.

Population and Sampling Procedure

The population for this study comprised of farming households in Kogi local government area of Kogi state. Three-stage random sampling technique was employed in selecting the respondents. In stage one; all three Zones of interest were selected. In stage two; one (1) Subzone was randomly selected from each Zone giving a total of three (3) subzones. In stage three; two communities were randomly selected from each of the subzone giving a total of six (6) communities. And finally, twenty (20) respondents were randomly selected from each community giving a total of one hundred and twenty (120) respondents.

Method of Data Collection

The source of collection of data in this research work was primary sources and the main instrument used was a structured questionnaire supported with interview method to take care of respondents with no formal education.

Method of Data Analysis

The data was analyzed using descriptive statistics, inferential statistics and Poisson regression model.

Food security Index: Food security status was used to classify farmers into either food secure or food insecure. The food security line is the recommended daily per capita calorie intake of 2260 kcal (FAO, 1996). Farmers whose daily per capita calorie intake is up to 2260 kcal were regarded as food secure and those whose daily per capita calorie intake is below 2260 kcal will be regarded as food insecure. This method has been applied to several studies whose main focus was on food security (Babatunde *et al.*, 2007). The food security line is given as: $Z = \frac{Yi}{R}$

- - (1)

Where: Zi = food security status of ith farmers; Yi = daily per capita calorie intake of ith farmers; R = recommended per capita daily calorie intake (2260kcal) And, Zi = 1 for Yi greater than or equal to R; Zi = 0 for Yi less than R

Additionally, the shortfall/surplus index and the headcount ratio of food security were calculated for the sampled households based on the food security line. The shortfall index (P) measures the extent to which poor households are food insecure, while the headcount ratio measures the percentage of the population the household that are food insecure/secure.

Shortfall Index (P) = $\frac{1}{M}(\sum Gi) = \frac{1}{M}\sum\frac{(Yi-R)}{R}$ - - - - - - - (2)

Headcount Ratio (H) = $\frac{M}{N}$ … … (3)

Where: M = the number of food insecure households, Gi = per capita calorie intake deficiency for ith household, N = number of households in the sample

Food Dietary Diversity

The Household Dietary Diversity Score (HDDS) was used to determine this. Specification of the HDDS method is given below; the following twelve food groups are used to calculate the HDDS indicator:

A.	Cereals
B.	Roots and tubers
C.	Vegetables
D.	Fruits
E.	Meat, poultry, offal
F.	Eggs
G.	Fish and seafood
H.	Pulses, legumes and nuts
I.	Milk and milk products
J.	Oil/fats
K.	Sugar/honey
L.	Miscellaneous

Each food group is assigned a score of 1 (if consumed) or a score of 0 (if not consumed). The household score will range from 0 to 12 and is equal to the total number of food groups consumed by the household.

HDDS* = ∑ *(A+B+C+D+E+F+G+H+I+J+K+L) - - - - (3)

The average household dietary diversity score for the population of study can be calculated as follows: $\frac{\sum(\boldsymbol{HDDS})}{\boldsymbol{total\ number\ of\ households\ surveyed}}$ - - - - - - - **(4)**

The source of the data for the HDDS is based on a recall of food groups consumed by the household in the previous 24 hours, reported by the person primarily responsible for food preparation in the household.

Relationship between Food Security and Dietary Diversity

Examine the relationship between household food security and dietary diversity among rural households in the area was analyzed using Poisson regression model. The Poisson Maximum Likelihood Estimator requires that the data be Poisson distributed with density function of Poisson regression model as given by (Animashaun, 2012):

F (yi/xi) = $e^{-\lambda(x)}\lambda i(x)^{(y)}$

$$\overline{\Gamma\,(1 + yi)} \quad - \quad - \quad - \quad - \quad - \quad - \quad 1$$

Where;

$\lambda i = \exp(\alpha + X'\beta)$, $yi = 0,1$, i = the number/count of food eaten by the household, X = a vector of predictor variables

Following (Animashaun, 2012) the expected number of events, yi

$$E(yi/xi) = var[yi/xi] = \lambda = \exp(\alpha + X'\beta) \quad - \quad - \quad - \quad - \quad 2$$

For i = 1,2…………..m

Determinants of Household Dietary Diversity

Based on the model above, the implicit functional form of the model estimated to examine the determinants of dietary diversity is specified as:

$$Y = \alpha + \beta X_1 + \beta X_2 + \beta X_3 + \beta X_4 + e \quad - \quad - \quad - \quad - \quad - \quad 3$$

Where;

Y = household dietary diversity; X_1 = food security status; X_2 = Household size; X_3 = Household Income; X_4 = Age of household head, e = error term; α = constant; β = parameter coefficients to be estimated

RESULTS AND DISCUSSION

Food Security Status of Households

Result of food security status of households in the study area is presented in Table 1

Table 1: Food Security Status of Households

Variables	Food secure	Food insecure
Recommended per capita daily intake (R) is 2260 kcal		
Number of households	86	34
Percentage of households	71.67	28.33
Daily per capita calorie consumed	3,322.10	1,673.25
Food security index (Z)	1.46	0.74
Head count ratio (H)	0.72	0.28
Gap/shortfall index (P1)		0.36
Severity (P2)		0.13
Surplus index	0.39	

Source: Computed from Field Survey, 2021

Results in table 1 revealed that the benchmark recommended daily calories intake of 2260kcal (FAO, 2012). However, the headcount ratios shows that 71.67 percent of the households with an average daily per capita household calorie consumption of 3,322.10kcal were food secure. The shortfall/surplus index measures the extent of deviation from the food security line. Hence, households had a surplus index of 0.39 and the least shortfall index of 0.36 indicating that food secure household exceeded the calorie requirement by 39 percent while the food insecure household fell short of the recommended calorie intake by 36 percent. This disagrees with Adeniyi and Ojo (2013) who found that about 70% of rural farmers are food insecure.

Level of Dietary Diversity of Households

The distribution of respondents according to the level of dietary diversity of' households is presented in Table

Table 2: Level of Dietary Diversity of Households

Category	Frequency	Percentage
Low dietary diversity (1-4)	15	12.5
Medium dietary diversity (5-8)	35	29.17

High dietary diversity (9-12)	70	58.33
Total	120	100

Source: Field Survey, 2021. Adapted from Ajani, 2010

Dietary diversity was employed as a qualitative measure of food consumption in the study area. It reflects household access to a wide variety of twelve (12) food groups included in the Household Dietary Diversity Score (HDDS). Dietary diversity indices have been shown to be good proxies for calorie intake and nutritional outcomes (Ruel, *et al.*, 2013). The summary statistics of dietary diversity measures among the sample households revealed that 12.5 percent belonged to the low food diversity category, 29.16% belong to the medium food diversity category and 35.0% belong to the high food diversity category. Most of the respondents were farming households whose major source of livelihood has been drastically affected by numerous challenges in the study area. Households cultivate food crops with significant difficulty. Respondents were forced to consume a particular range of food groups available due to limited income diversification opportunities consequently, reduced economic access to food in adequate quantity and quality when own production depletes.

Relationship between Food Security and Dietary Diversity of Households

Estimates of the binary logistic regression of the relationship between food security and dietary diversity of households is presented in Table 3

Table 3: Binary Logistic Regression of the relationship between Food Security and Dietary Diversity

Food security	Coefficient	Std. Err	Z	p>|z|	Interval
Constant	3.590045	2.263286	1.59	0.113	8.026003
Age	-.0775024	.349707	-2.22	0.027**	-.008961
Gender	-.1106166	.6020095	-0.18	0.854	1.0693
Farming experience	1.236202	.302723	4.08	0.000***	1.829534
Household size	-.1442771	.0874105	1.65	0.099*	.0270443
Educational level	-.0029459	.0322983	-0.09	0.927	.0603577
Dietary diversity	-3150306	.1480308	2.13	0.0338**	.6051658
Access to credit	-2.662027	.6526394	-4.08	0.0007** **	1.382877
Number of obs	= 120				
LRChi2 (7)	= 83.42				
Prob > Chi2	= 0.000				
Pseudo R2	= 0.5080				
Log likelihood	=40.3999				

Source: Computed from Field Survey, 2021

The result of the analysis shows that the Chi square of the regression is 83.42 found to be statistically significant at 1% level. The model has a high Log likelihood of -40.3999; describing a model displaying a good fit, this shows that the explanatory variables in the estimated logit model significantly explain the likelihood of a respondent being food secure. The results show that Pseudo R^2 is 0.5080 (50.8%) of the seven variables explained and included in the model, five were significant. Five variables were significant out of the 7 independent variables namely Age, Farming experience in years, household size, dietary diversity and access to credit. Age and household size, dietary diversity and access to credit facilities were significant at 5%, 10%, 5% and 1% respectively but coefficients negatively signed. This implies that increase in age doesn't necessarily lead to increase in food security status neither dietary diversity of the respondents. Large household size with increased dependents members than the working adults tend to enhance food insecurity. It is pertinent that despite the intervention of the government in provision of credit resources, accessibility of credit from both formal and informal sources food insecurity still sustained which implies that respondents' access to credit facilities doesn't guaranty their food security or ability to diversify their diets. Years of farming experience was significant at 1% and coefficient (1.236202) positively signed. This implies that increase the years of farming of respondents reduce the incidence of food insecurity and tend to improve the dietary diversity of the respondents hence improvement in quality of livelihood. The study found a significant relationship between food security and dietary diversity which agrees with the findings of Faber, *et al.* (2009).

CONCLUSION AND RECOMMENDATIONS

This study concluded that about 71.67 percent of the respondents being food secure having a surplus index of 0.36 indicating that food secure household exceeded the calorie requirement. This reflect a favourable food pattern of households in the study this research extended its scope beyond just rural coverage. It was concluded that, dietary diversity score which is a good proxies for calorie intake and nutritional outcomes of individual households classified majority of the respondents to the medium category which implies, averagely households consumes minimum of 5 – 8 groups of food classes within 12hours basically, they are food diversified. Finally, the study found a strong relationship between the food security status and food diversity among respondents in the study area. The study recommended moderate household sizes be kept as lager household sizes were found to be more food insecure with less food diversified, this can be aided by health extension workers. Finally, intervention programmes like provision of palliative, availability of affordable and accessible loans, grants and subsidized farm inputs will positively influence the welfare of households by the government and relevant stakeholders.

PROCEEDINGS
56th Annual Conference
Agricultural Society of Nigeria
24 - 28 Oct., 2022

ABSTRACT

The inadequate processing technology caused by lack of funds has negative effects on food security. The perception of microcredit use by turmeric processors was assessed in south east Nigeria. A multi-stage sampling procedure was used in selecting ninety six respondents for the study. A well-structured questionnaire was used in collecting data from the respondents. The data collected were analysed using descriptive statistics. The results show that majority of the processors were female and are married. The processors are still in their active age and have a long time experience in processing business. The result reveals that the cost of getting microcredit was high and disagreed that only members in the cooperative assess microcredit. The study concluded that, microcredit should be made easier for assessment to processors. This study therefore recommended that male processors should be encouraged since it is a source of income for household. The cost of getting microcredit should be reduced to support turmeric processers in the business. Also, processers should be encouraged to engage in seminars that will provide information on easy access to micro-credit.

Keywords: Turmeric, Processers, Microcredit and Perceptions

INTRODUCTION

Turmeric (botanically known as Curcuma longa Linn) also known as the 'golden spice of life is a root crop in the same family as ginger. The root receives less attention from Nigerian farmers, despite having huge potential for local industries and export. It is used in the food, cosmetic and pharmaceutical industries. It is used as a spice and it is the major component of curry powder. Turmeric is also used in the cosmetics industry for its brilliant yellow colour and characteristic perfume. It is also used as a dye for colouring fabrics.

Turmeric is a seasonal crop and perishable (USAID 2017). It is an export crop because of its high demand in advanced medical and confectionery industries. Due to the lack of storage facilities, traders are forced to sell the product immediately after collection from farmers.

Microcredit facilities are established to help the rural households to tackle poverty and improve food security. Microcredit provides credit facilities at reasonable terms to the reach of rural dwellers. It increases the productivity of the rural sector, promotes and expands the rural economy in an organized and efficient manner (Sheremenko *et al.*, 2012). Microcredit to a low-income household can create new job opportunities, enable the poor to manage their limited

financial resources in a rational way and reduce unemployment (East and Southern Africa Banking Supervisors Group (ESAF), 2004; Javed et al., 2006; Latif et al., 2011; Stanila et al., 2014).
The objective of the study is todetermine the socio-economic characteristics of turmeric processors and assess the perception of microcredit use in turmeric processing in south east, Nigeria.

MATERIALS AND METHODS

The study was conducted in South-East States of Abia, Ebonyi and Imo of Nigeria. The area lies between Latitude 5^0 29^1, 5^0 32^1, and 6^0 20^1 N of equator and 7^0 01^1, 7^0 29^1, and 8^0 06^1 E Longitude of Greenwich meridian respectively. The states have a total land mass of 10,952,400ha. The South-East zone has over 16 million resident's populations (NPC, 2016). The zone is made up of five states, namely: Abia, Anambra, Ebonyi, Enugu, and the Imo States. It also has a rural population density of 173 persons per square kilometer (Iloka and Anuebunwa, 1995). About 60-70% of the inhabitants are engaged in agriculture, mainly crop farming, animal rearing, food processing, and farm produce marketing. The climate can be described as tropical with two clear, identifiable seasons namely, the wet and dry seasons. Farming, processing, and marketing are the predominant occupations of the people. The economy of the zone primarily depends on agriculture and commerce.

A multi-stage sampling procedure was used in selecting the respondents for this study. The target population was turmeric processors. The turmeric processors were randomly sampled. The first stage involved purposive selection of three states, namely Abia, Imo, and Ebonyi out of the five states in the South-East geo-political zone. These states were chosen based on their high-level activities onturmeric processing. In the second stage, four LGAswere purposively selected from each of the selected states, giving a total of twelve LGAs.These local governments are Isiala Ngwa South, Osisioma Ngwa, Umuahia North and Ikwuano LGAs from Abia state, Ivo, Afikpo North, Ebonyi and Ikwo LGAs from Ebonyi State and Mbaitolu, Ngor Okpala, Onu Imo and Okigwe LGAs from Imo state, giving a total of twelve LGAs.
In the third stage, two communities were purposively selected from each LGA based on the presence of microcredit activities, giving a sample of 24communities. In the fourth stage, one market was purposively selected from each community to give a total of 24 markets. In the fifth stage, multi-stage random sampling technique was used to select 4turmeric processors from each community. It was compiled with the aid of the community resident, extension agents and turmeric processors in the areas. This gave 96 turmeric processors in the areas.
Primary data were collected using well-structured questionnaires administered on turmeric processors that use microcredit. The data collected from the turmeric processors was analyzed using descriptive statistics such as percentage, frequencies distributions, mean and five point likert scales.

RESULTS AND DISCUSSION

The socio-economic characteristics of turmeric processors such as sex, age, marital status, level of education, processing experience, household size were discussed under this section.The result of the socio-economic characteristics of turmeric processors for microcredit users are presented in Table.1.

Source: Field Survey, 2021

The result in Table1 shows that majority (77.08%) of the turmeric processors who used microcredit were females and (22.91%)of processors are male. This could be that processing of turmeric requires less effort and not tedious for women to engage on. This is in line with the findings of Ezra *et al.*, (2017) which indicated that the domination of women in turmeric processing is due to low demands of time and efforts required to work in the enterprise.

The result shows that the mean age of microcredit users of turmeric processors was 46.14years. It was observed that the majority (65.62%) of the microcredit users of turmeric processors are in the age bracket of 31-50 years. This implies that turmeric processors are within the active working bracket. They are young people who can withstand stress involved in the processing of turmeric, and they are matured to take credit decisions that sustain the business.
The results obtained are in line with the findings of Kantiok, (2007) who opined that the majority of the agricultural enterprise actors are in their working age. Also, this is in line with the results of Udoh and Nyienakuma (2008). They opined that agriculturist within the active age groups would be able to withstand stress and put more time in various agricultural operations.
The result in Table 1 showed that the majority (56.25%) of microcredit users of turmeric processors were married. This result indicates that turmeric processing can be used to sustain the basic needs of families involved in the processing. This result agrees with Ojo and Jibowa (2008) that reported that married people being responsible, their views are likely to be respected within the rural communities as they decide on the use of agricultural inputs.

The result shows that the majority (83.33%) of the turmeric processors of microcredit users had one form of formal education or the other. The result shows that the majority of the processors are highly educated. This will enhance the management of turmeric processing in the study area. In processing, formal education allows the turmeric processors to understand the proper management of resources in processing. This finding agrees with the fact that high literacy level, western education facilitates the adoption of modern technologies and improved practices (Shehu *et al.*, 2014 and Offor and Nse-Nelson, 2015).

Experience is expected to have a significant positive impact on the managerial ability of the processors. The result in Table.1 shows the years of experience the processors had acquired over the years. The mean years of experience of turmericprocessors of microcredituser are 11.32years. This result is an indication that the ginger processors have been in processing over a long period and can be said that there are experienced. This implies that the more experience, the more committed and confidence they have in the processing. The finding also shows that the processors were aware of the merits and demerits associated with the business because of the long years of experience.
The study also shows that the majority of the processors in the study area had a household size of between 4-6 persons. This means that the processors in the study area have a large household size. This implies that the processors have the advantage of family labour. Higher household size is advantageous in processing as the members of the household aid in the processing activities (Effiong, 2005 and Idiong, 2005). However, higher family size does not necessarily translate to higher use of family labour, because some of the able young men may prefer other jobs.

Table 2:Perception of Microcredit Use of Turmeric Processors

Perception	SD	D	U	A	SA	Total	Mean
Cost of getting microcredit is high	11(10)	27(54)	10(30)	24(96)	24(120)	311	3.24
Only members in the cooperative assess microcredit	39(39)	43(86)	6(18)	3(12)	5(25)	228	1.88

Microcredit takes a lot of time to process	18(18)	24(48)	11(33)	14(56)	29(145)	300	3.13
Bureaucratic bottleneck for credit	14(14)	16(32)	20(60)	23(92)	23(115)	313	3.26
Microcredit is for the rich	45(45)	30(60)	10(30)	6(24)	5(25)	184	1.92
Microcredit is too hard to understand	25(25)	30(60)	10(30)	17(68)	14(70)	253	2.64
Availability of microcredit to market is too hard	28(28)	14(28)	14(42)	29(116)	11(55)	269	2.80
Microcredit operation is similar to other borrowing methods	28(28)	20(40)	17(51)	19(76)	12(60)	255	2.66
Microcredit is for the poor only	40(40)	31(62)	12(36)	8(32)	5(25)	195	2.03
The culture of your community tolerate microcredit	9(9)	9(18)	18(54)	26(104)	34(170)	355	3.70

Grand Mean: 3.0. Five point Likert scale: 1,2,3,4 and 5
Source: Field Survey Data, 2021

From the result on Table 2, it was discovered that the turmeric processors using microcredit agreed that cost of getting microcredit was high(M=3.24).The result also disagreed that only members in the cooperative assess microcredit. The respondents strongly opined that the culture of their community tolerated microcredit (M=3.70) use. This reveals that community are aware of the important of microcredit in the processing activities. Also the majority of the processors using microcredit show favourable attitude to microcredit use. The result also, agreed that they had overbearing bottleneck during the process of obtaining microcredit. Also, the availability of microcredit to market was too hard. The result also disagreed (2.03) that microcredit is for the poor and this agrees with previous research studies in literature opined that microcredit increase per capita household income (Imai and Azam, 2012). It also enhances households' multidimensional well-being and improves the living standards of rural dwellers (Adjei *et al.*, 2009 and Imai *et al.*, 2010). Finally, the result agreed that microcredit takes a lot of time to process. This means that the impression people have about getting microcredit is true and efforts should be made to reduce the processing time.

CONCLUSIONS

The study examined the perception of microcredit use of turmeric processors in south east, Nigeria. The result of socio-economic characteristics of turmeric processors using microcredit shows that the majority of processors are females and are married. The literacy levels were high among them and could enhance processing technology. The result also agreed that cost of getting microcredit was high and has overbearing bottleneck during the processing of the microcredit. Equally it disagreed that microcredit was for the poor. It is therefore recommended that male counterparts should be encouraged in the processing of the root since it generates huge income for household and serves as a means of livelihood. The cost of getting microcredit should be reduced to encourage more participation by turmeric processers. Turmeric processers should be encouraged to engage in seminars that will provide information on easy access to micro-credit.

ABSTRACT

The conventional agricultural extension practice due to several factors is not effective in capturing the interest of the younger generation. Given the prevalence of digital and social media platforms among young people, these channels can be used to pique their interest in agriculture. The general objective of the study was to assess smallholder farmers' participation in a digital-based extension advisory service with a focus on MyFarmbase Africa while the specific objectives include: to describe the socio-economic characteristics of the farmers under MyFarmbase Africa, examine the farmers' awareness of MyFarmbase Africa programmes, identify the benefits farmers derive and determine the perceived constraints to participation. A total sampling procedure was proposed for the study however, only 121 responded from which data was collected using a questionnaire via Google form survey. Descriptive statistical tools and Chi-square was used to analyze the data. Majority of the respondents were young, tertiary education farmers. Majority were aware of only four of the nine programmes while the farmers awareness of the programmes had significant relationship with their participation. Quick access to agricultural information, support from other participants in the group, information about the latest, up-to-date agricultural innovations, great networking opportunities with key stakeholders, and a ready market were the top five benefits enjoyed by the respondents. The major constraints to participation were Epileptic or poor power supply which ranked 1st, Poor telecommunication service (Bad network) 2nd, and the high cost of data to access online information which ranked 3rd.

INTRODUCTION

Agricultural Extension also referred to as agricultural advisory services is an informal out of school education provided to farmers to boost their agricultural production. It helps to progressively bridge the gap between key actors such as organizations, research services, and agribusinesses and farmers (World Bank & OECD, 2013). Although pregnant with prospects, the conventional agricultural advisory service has been faced with challenges over the years (Nwalieji & Nnabueze, 2018; Ogunniyi, Babu, Balana, & Andam, 2020). However, in recent times, there have been the emergence of private agricultural extension advisory organizations that have greatly complemented the conventional extension services by providing services at better conditions in terms of mode of information dissemination, international partnerships and mentorships, easier funding and ICT usage among others (Barber, Mangnus, & Bitzer, 2018). MyFarmbase Africa is one of such private agricultural advisory organization that leverages digital technology to assist farmers and agripreneurs with easy accessibility to agricultural information, technology and skills while also connecting them to markets to sell their products (MFB, 2020). Particularly the youth whose strength and plausible innovative ideas can help boost productivity and replace the older farmers who are gradually been eased out by reason of their old age. Therefore, utilizing these digital platforms and devices could greatly capture the interest of young people as well as sustain the interest of young farmers currently in agriculture. The specific objectives were to:

1. describe the socio-economic characteristics of the farmers under MyFarmbase Africa
2. examine the farmers' awareness of MyFarmbase Africa programmes
3. determine the farmers' benefits from MyFarmbase Africa programmes
4. determine farmers' perceived constraints to participation in MyFarmbase Africa programmes

Hypothesis

H01: There is no significant relationship between socio-economic characteristics of smallholder farmers and their participation in MyFarmbase Africa.

H02: There is no significant relationship between smallholder farmers' awareness and their participation.

METHODOLOGY

Survey research design was employed for this research to assess smallholder farmers' participation in a digital-based extension advisory service with specific focus on MyFarmbase Africa. A total sampling procedure was proposed for the study to survey farmers under MyFarmbase Africa, hence the link to the google form was sent to all the cohort groups as at the time the research was carried out. However, only 121 respondents responded to the survey. Primary data were gathered from the farmers through the use of questionnaire disseminated via Google form. Descriptive statistical tools frequency tables, percentages, mean, standard deviation, and ranking were used to analyze the objectives. While the hypothesis were tested using Chi-square and Pearson correlation.

Results and discussion of findings

Table 4.1 Percentage distribution of respondents' Socio-economic characteristics

Variables	Percentage	Mean

AGE 21-40	 65.3	36.9
41-60	33.9	
60 Above	0.8	
SEX		
Male	62.8	
Female	37.2	
EDUCATIONAL LEVEL		
Primary education	1.7	
Secondary education	0.0	
Tertiary education	98.3	
INCOME (₦million)		1884223.7
<1	44.2	
1-5	51.2	
6-10	3.5	
11-15	0.0	
16-20	1.2	
PREFERRED MODE OF COMMUNICATION		
Physical contact	24.8	
WhatsApp	63.4	
Instagram	1.0

All of the above	5.9	
All of the above except physical contact	1.0	
PARTICIPATION		
Low	58.7	
High	41.3	

source: field survey, 2022

The table above shows that the mean age is 36.9 and that majority 65.3% of the respondents were within the age bracket 21-40. This revealed that most of the farmers were young adults who were IT inclined, hence their access to and usage of digital devices for various purposes. The table reveals that majority 98.3% of the farmers had Tertiary education. Majority of the respondents are literates and have tertiary education. The table reveals that majority (51.2%) of the respondents made an income of 1-5 million naira a year. The mean income of the respondents for a year is ₦1,884,224 is probably high due to higher literacy levels. The more literate farmers are, the more knowledgeable they are to utilize more improved technology to boost agricultural productivity which in turn results in increased income.

The table revealed that majority of the respondents (63.4%) preferred WhatsApp platform a digital medium for receiving Extension information and Advisory service quickly. Although, a considerably significant 24.8% from the table above indicated that they would prefer if physical contact and one-on-one extension services could be provided too.

As revealed in the table above, majority (58.7%) of the smallholder farmers in MyFarmbase Africa had low participation in the programmes of MyFarmbase Africa despite their tech-savviness.

Table 4.2 Percentage distribution of Farmers awareness of MFB programmes

Programme	Yes (%)	No (%)
MFB Global Agricultural Development Programme (2 weeks Intensive online Boot Camp Training)	90.1	9.9
MFB Value Chain Specialization programme	72.7	27.3
MFB Backyard farm challenge	47.1	52.1
MFB Climate Smart Agriculture Programme	48.8	50.4
MFB Master Class	71.1	27.3
MFB Youth Annual Conference Programme	29.8	68.6
MFB Yearly Hangout	49.6	50.4
MFB Social Media Week Programme	30.6	69.4
MFB Market Square Programme	77.7	22.3

As shown in the table, majority of the farmers were aware of MFB Agricultural Development Programme (2 weeks intensive online Boot camp training) (90.1%), MFB Market Square (77.7%), MFB Value chain specialization programme (72.7%) and MFB Master Class (71.1%). Hence, more efforts need to be done to increase the farmers' awareness of these five (5) programmes.

Table 4.3: Percentage distribution of Smallholder farmers' benefits and constraints

Benefits	S.D	Mean	Rank
I get easy access to funding opportunities	1.12301	2.5868	6th
I get quick access to agricultural information	0.79148	3.9174	1st
Great networking opportunities with key stakeholders to move my business forward	0.87599	3.5372	4th
Ready market by selling my produce on the cohort group	0.94585	3.1736	5th
I share and get support from other participants	0.78071	3.8760	2nd
I get information about latest, up-to-date agricultural innovations	0.86372	3.7686	3rd

Constraints			
Epileptic or no power supply to power my gadgets	0.81267	2.0583	1st
Cost of data to access online information from MyFarmbase Africa is expensive	0.71707	1.9504	3rd
Poor telecommunication service (Bad network) in my area	0.73593	1.9917	2nd
I don't know how to use online platforms very well	0.36946	1.1157	5th
Extension services and Information given at MyFarmbase Africa do not meet my needs	0.55608	1.3388	4th

source: field survey, 2022

The result from table revealed that among others, there were five major benefits enjoyed by smallholder farmers' in MyFarmbase Africa and three main constraints faced by farmers under MyFarmbase Africa which affect their participation

Table 4.4: Chi-square analysis indicating the relationship that exists between Participation and socio-economic characteristics at 0.1 level of significance

Independent Variable	Chi-square (X^2)	DF	P	Decision
Age	1.5731	2	0.666	NS
Sex	0.7223	1	0.697	NS
Educational level	1.5208	3	0.467	NS
Income	53.3569	4	0.613	NS

source: field survey, 2022

Testing the hypothesis of smallholder farmers' socio-economic characteristics: The result shows that there was no significant relationship at the 0.1 level of significance, hence we will accept the null hypothesis I.

Table 4.5: Chi-square analysis indicating the relationship that exists between Participation and Awareness of the farmers at 0.1 level of significance.

Independent Variable	Chi-square (X^2)	DF	P	Decision
Awareness of MFB Global Agricultural Development Programme	6.1345	1	0.013	S
Awareness of MFB Value chain Specialization Class	3.6236	1	0.057	S
Awareness of MFB Backyard Farm Challenge	3.7935	1	0.150	NS
Awareness of MFB Climate smart Agriculture	2.5705	1	0.277	NS
Awareness of MFB Master Class	5.4598	1	0.065	S

Awareness of MFB Youth Annual Conference	4.4568	1	0.108	NS
Awareness of MFB Yearly Hangout	8.9449	1	0.003	S

Source: field survey 2022

The result of the table shows that there was a significant relationship between Participation and the farmers Awareness of MFB Global Agricultural Development Programme, Value chain specialization class, Master class, Yearly Hangout with values less than 0.1 level of significance, hence we will reject the null hypothesis.

CONCLUSION

The outcome of this study explained that majority of the respondents (65.3%) were young farmers who are well educated with tertiary education and have a high mean income of ₦1884223.7. Majority of the farmers (63.4%) farmers preferred WhatsApp, which is a digital mode of communication. However, a significant (25%) which is one-fourth of the respondents indicated that physical contact should be included too. Majority of the farmers were aware of only four programmes out of the nine programmes of MyFarmbase Africa while 58.7% of the farmers had a low Participation in MyFarmbase Africa programmes. The smallholder farmers under MyFarmbase Africa enjoyed quick access to agricultural information, support from other participants in the group, information about latest, up-to-date agricultural innovations from MyFarmbase Africa, great networking opportunities with key stakeholders as well as ready market by selling produce on the cohort group platforms. The top three constraints identified that affected their participation include Epileptic or poor power supply to power gadgets, followed by Poor telecommunication service (poor network) and then the high cost of data to access online information from MyFarmbase Africa. Finally, the farmers' awareness of MFB Global Agricultural Development Programme, Master Class, Value chain specialization and Yearly hangout had a significant relationship with their participation in the various programmes.

RECOMMENDATIONS

I. The farmers should look into alternative sources of power generation such as solar power to complement the current means of generating electricity to power their digital devices/gadgets.

II. Also, government and local community leaders should make demands on private telecommunications companies to improve their network coverage and network services to ensure fast and easy access to network.

III. Furthermore, MyFarmbase Africa should organize their farmers into groups to take advantage of bulk data purchase to reduce the cost of data and give more internet access to their farmers

IV. Private Agricultural extension advisory organizations should increase the awareness of their new and existing programmes among farmers so they can be fully aware to enable them to participate effectively in programmes that can improve their agricultural productivity. This can be achieved via jingles on WhatsApp, radio, adverts on television and posters on bill bards.

V. Finally, Private agricultural extension advisory organizations should include physical meetings and one-on-one contact with the digital extension services they provide to make the service more robust and effective.

ABSTRACT
The work on the effect of adoption, socio – economic institutional technological factors and the level of adoption of improved cassava processing technologies by women in WashitaLocal Government Area of Niger State. Purposive]y choose three communities for this work. The 20% of the respondents from sampling frame of 760 was employed. The mean age was 35 years and 84% have formal education, 26% had extension contacts while 20% had access to loan facilities and 22% were in different associations. The average adoption level was 53% and regression analysis showed that age, household size, processing experience and membership of association were significant to the adoption. The coefficient of determination (R^2) was 0.47 which implies that 47%. The Z-stat (20.04) for output was greater than the Z-critical (1.98) while the Z-stat (24.30) for income was greater than the Z-critical (1.98) and both were significant at p<o.o5. The result of the Z-test statistics shows that adoption of improved cassava processing technologies brought higher output and income for the women cassava processors.
KEY WORDS: Adoption: Cassava: Processing: Technologies: Women:Wushi

INTRODUCTION
Cassava (*Manihotspp*) is starchy root crop in the family *euphorbiaceae* cultivated in West Africa. Nigeria was the highest producer of cassava in the world with 54 million tones oftuberous roots (FAO, 2014). Cassava is major raw material for small scale businesses such as cassava flour mills, bakeries, fast food firms, restaurants, gari processing firms and presently wealth generating activity (Odii, 2012).According toFAO (2004), Cassava farming continuous to expand formore years in both areas cultivationand yield per hectare. Cassava performs well in all parts of Nigeria. This is due to the improved, high yielding, pest and disease resistant varieties bred through research in collaboration with International Institute of Tropical Agriculture (IITA), Ibadan, National Root Crop Research Institute (NRCRI), Umudike and other research to mention but few. Some of the areas where the cassava is cultivated are the coast in the south to the middle belt. North central zone grows about6- 7 million tons of cassava in a year. Benue and Kogi states in the north central Nigeria are the largest producers of cassava

in the country (IITA, 2004).Women play major role in processing basic foodstuffs and also do 60-90% of the rural marketing; thus constitute more than two third of the workforce in agricultural activities(FAO, 1995; Rahman, 2004

METHODOLOGY

The research was conducted in Wushishi local Government area of Niger State.The research work was only on women that take cassava processing as occupation in Wushishi Local Government Area. Purposive samplings were used to select villages. The villages sampled are shown in the Table

1. The sampling was due to the active participation of women in cassava processing and 20% sampled.

Table1: Distribution of Respondents according to villages showing sampling frame and proportionate sampling size of respondents

Villages Selected	Population of women cassava processors	Sampling size 20%
Tsadozhiko	150	30
Lokogoma	160	32
Dukunsakun	196	39
Tangwagi	254	31
Total	**760**	**152**

Data was collected using enumerators that moved round the communities to locate the women processors. Information obtained from the women processors includes socio-economic status like age, educational status, marital status, household size and processing ideas. Institutional factors like number of contact with extension agents, loan collected and whether member of association or not. Analytical tools used were descriptive statistic like mean, frequency distribution, tables and percentages, regression analysis and Z- test statistics.

The model is specified as linear production function.

$Y = a + b_1 X_1 + b_2 X_2 + b_3 X_3 + \ldots\ldots + b_{11} X_{11} + e$

Where Y = Adoption of improved cassava processing technologies

X_1 = Age (in years)

X_2 =Marital status (married=2, single and other = 1)

X_3 = Educational status (years spent in school)

X_4 = Household size (number of persons)

X_5 = Processing experience (years spent in processing)

X_6 = Contact with extension agents (No. of visitation)

X_7 = loan obtain (amount in ₦)

X_8 = Membership of cooperative society (No. in years)

X_9 = Affordability of technologies (5- point Likert scale)

X_{10} = Compatibility of technologies (5 – point Likert scale)

X_{11} = Complexity of technologies (5- point Likert scale)

$b_1 - b_{11}$ = regression coefficients

a = Constant

e = error term

Z - Test statistic.

Z – Test is to examine the effect of adoption of improved cassava processing technologies on respondent's output and income before and after adoption of the technologies. The Z – test come in this form

$$Z = \frac{\overline{X_1} - \overline{X_2}}{\sqrt{\frac{S_1^2}{n_1} + \frac{S_2^2}{n_2}}}$$

Where

Z= the calculated Z – value

$\overline{X_1}$= Mean income of women after adoption.

$\overline{X_2}$= Mean output/income of women before adoption.

S_1^2= Standard deviation of output/income of women after adoption

S_2^2 =Standard deviation of output/income of women before adoption.

n_1= No. of women cassava processors after adoption.

n_2= No. of women cassava processors before adoption.

RESULTS AND DISCUSSION

Adoption of improved cassava processing technologies level

Processor's level of adoption of improved cassava processing technologies is shown in bar chart form in fig 1 below.Improved cassava processing technologies adoptionmay have wide acceptance with more income projection in return. Technologies consider in this research work include mechanical grater, screw press, mechanical sifter as well as the fryer (toaster) which the processors were trained on. Mechanical grater 98%, mechanical sifter 83%Screw press and fryer (toaster) recorded 20% and 9% adoption level respectively. The mean level of 53% adoption was above average indicating improvement in adoption level of the improved cassava processing technologies.

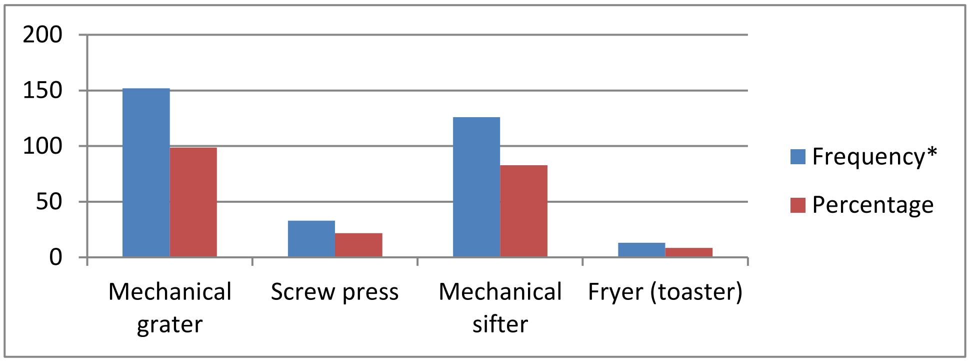

Figure 1: Respondents distribution based on level of adoption of improved cassava processing technologies.

Socio - economic, institutional and technological factors influencing improved Cassava processing Technologies adoption by Women in the Study Area.

The socio-economic factors viewed were age, marital status, educational level, household size and processing experience. The result in table 2 indicated three out of the five socio-economic factors chosen had significant effects on improved cassava processing technologies adoption. Age shows negative regression coefficient of 0.048 and proof to had significant effect on the improved cassava processing technologies adoption at 1% level of probability. The implication is the adoption level of the improved cassava processing technologies reduces with an increase in age. Household size indicated a positive regression coefficient of 0.118 and had significance effect on improved cassava processing technology adoption at 10% level of probability. The implication is that the adoption of improved cassava processing technologies increases with more number of household sizes. The increase in household size means efficient and easy division of labour.

In the study area the experience acquired by the respondents shows significantly a positive regression coefficient of 0.086 and significantly affected the adoption of improved cassava processing technologies at 1% level of probability. This means that adoption of improved cassava processing technologies increases as the years ofexperience increases too. Marital status proof to have no significant effect and has coefficient of 0.070. This means that being single or married has no influence on adoption of improved cassava processing technologies. Educational level gave positive regression coefficient of 0.019 but do not affect the adoption of improved cassava processing technologies. This means that be educated or not does not in any way affect processing of cassava. Age, household size, and processing experience had significant effect on adoption of improved cassava processing technologies.

Table 2Effects of socio-economic, institutional and technological variables on adoption

Variable	Coefficient	Standard error	t-value
Intercept	3.427	0.570	6.01***
Socio-economic variables			
Age	-0.048	0.017	-2.84***
Marital status	-0.070	0.081	-0.86NS
Educational status	0.019	0.017	1.14NS
Household size	0.118	0.064	1.83*
Processing experience	0.086	0.029	2.99***
Institutional variables			
Credit received	1.42e-06	1.46e-06	0.97NS
Membership of association	0.036	0.017	2.02**
Extension contact	0.131	0.083	1.57 NS
Technological variables			
Affordability	0.049	0.017	2.76***
Compatibility	0.017	0.018	0.96NS
Complexity	-0.051	0.023	-2.17**

$R^2 = 0.47$ NS=Not significant
$R^{-2} = 0.41$
F value = 4.778***

*** P<0.01, ** P<0.05, * P<0.10

The institutional variables in this research were loan taken, be a member of association and extension contact. Membership of association gave a positive regression coefficient of 0.036 and significantly has a direct effect on adoption of improved cassava processing technologies at 5% level of probability. Indicating that the adoption of improved cassava processing technologies increases with been a member of association. Loan taken and extension contact does not have any effect on adoption.
The technological factors in this research work include affordability, compatibility as well as complexity. Affordability gave a positive regression coefficient 0f 0.049 and show significant motivation on adoption of improved cassava processing technologies at 1% level of probability. This meaning that adoption continues to increase with the processors acquiring more equipment for these technologies. Compatibility also proofs a positive regression coefficient of 0.017 without significant impact on adoption of improved cassava processing technologies. Complexity will always give negative regression coefficient. The 0.051 coefficient shows significant influence on adoption at 5% level of probability. This means that adoption reduces as technologies become more complex.
The coefficient of determination (R^2) was 0.47. This implies that about 47% of the variations observed in the adoption of the improved cassava processing technologies were explained

by the selected socio-economic, institutional and technological variables, output and income included in the model. The remaining 53% could be attributed to other factors that were not included in the model.

Improve cassava processing technologies adoptions on product output and wealth of processors.

Paired t-test was employed comparing the mean product output and mean wealth before and after adoption of technologies by women processors in the study area.

Table 3: Shows the effect of adoption of technologies on the output of respondents.

	Output Before Adoption	*Output After Adoption*
Mean	71.052	163.158
Standard deviation	30.868	62.703
Observations	152	152
Pearson Correlation	0.685	
Hypothesized Mean Difference	0	
Df	151	
z Stat	-24.045	
P(Z<=z) one-tail	8.511E-54	
z Critical one-tail	1.655	
P(T<=z) two-tail	1.702E-53	
z Critical two-tail	1.98*	

*P<0.05

Table 3.Shows that average outputs before adoption was 71.05 .However, average output after adoption stand at 163.16. The standard deviation for both output before and after adoptions were 30.87 and 62.70 respectively. The calculated Z – value gave 24.04 and is greater than critical value Z - critical that gave 1.98 at 5% level of probability

Table 4.Show the influence of adoption of improve cassava processing technologies on the wealth of processors

	Income Before Adoption	*Income After Adoption*
Mean	298315.789	678736.842
Standard deviation	124204.1	260845.1
Observations	152	152
Pearson Correlation	0.713	
Hypothesized Mean Difference	0	
Df	151	
z Stat	-24.296	

P(Z<=z) one-tail	2.431E-54
z Critical one-tail	1.6550
P(Z<=z) two-tail	4.861E-54
z Critical two-tail	1.98*

*P<0.05

Table 4 the average wealth before adoption was₦298, 315.79 and after adoption gave N673, 736.84. The standard deviation before and after adoptions was N124204.1 and N2608451 respectively. The Z – cal was 24.30 and was greater than Z-critical of 1.98. For both output and wealth, the Z – cal gave greater figure than the Z critical. There exist significant difference between the product output and wealth before and after adoption of improved cassava processing technologies in the study area and corroborates the findings of Bakut (2013.

CONCLUSION

The work revealed that women cassava processors were young, 68% were married and all the factorsplay good role in the adoption of cassava processing technologies.

Agricultural Society of Nigeria
24 - 28 Oct., 2022

ABSTRACT
The study investigated the factors influencing adoption of fertilizer usage among cassava farmers in Delta State, Nigeria. The specific objectives were to: ascertain the factors influencing the adoption of fertilizer usage among the farmers determine the constraints working against fertilizer usage by the farmers and examine farmers' suggested strategies to improve the constraints working against fertilizer usage in the study area. Multistage sampling techniques were used in this study. However, 200 cassava farmers were used as the sample size. Findings of the study indicated that greater proportions (60%) of the farmers were male, while 40% of them were female. Results also showed that the majority (42.5%) of the farmers who cultivated cassava were married, 31.5% were single, 16% were divorced and only 10% were widowed. The average mean age of the cassava farmers was 39 years while the average household size was 8 persons. The mean year of cassava farming experience was 18 years while the average farm size for cassava farmers was 1.21ha. Out of the 13 variables investigated as the factors influencing the adoption of fertilizer usage among cassava farmers in the State, six (6) variables were found to be statistically significant in the study. The variables were educational level, farm size, farming experience, level of soil fertility, training received and extension service. The identified constraints in the study area were disease/past infestation, inadequate government support, high cost of cassava stems, weed infestation, bad road network, scarcity and high cost of land, lack of modern storage and processing, poor access to institutional credit, and inadequate extension services to farmers. In terms of strategies, finding also showed that a majority of the cassava farmers was of the opinion that having appropriate and effective information on fertilizer usage would improve fertilizer usage among farmers in the study. In view of these, this paper recommended that: More extension workers should be recruited by the state and federal governments to fill in the gap of inadequate agricultural extension workers in the study area. Government should help to provide storage and processing equipments to farmers.
Keywords: Cassava, adoption, farmers, influence, fertilizer.

INTRODUCTION

One of the major problems facing agricultural productivity in Nigeria is illiteracy. This has over the years posed great challenges to agricultural development as well as productivity. The level of literacy of farmers in Nigeria generally affects agricultural practices especially in the rural areas(Okpachu,Okpachu and Obijesi,2014). Although farmers usually have rich knowledge of local conditions and valuable practical knowledge or experience of how best to successfully exploit their environment, they require innovation, information generated from research and development to boost their productivity (Paltasingh and Goyari, 2018).They also observed that Agricultural messages could enhance the productivity of farmers when they have access to it. This could be achieved through well equipped adult literacy scheme designed for farmers not only to access the information but having potency to interpret and utilize them for optimum productivity.

Increased agricultural productivity depends primarily on accepting cultural and technological changes at rural farm level. Peasant farmers can achieve higher farm yields if they adopt improved farming techniques; but some new practices are sometimes complicated, making adoption difficult for non-literate farmers. To adopt and successfully use improved farming techniques, peasant farmers must understand them. This requires effective teaching by the agricultural extension service (Oduro-Ofori , Aboagye and Acquaye,2014). Therefore, extension education provides practical learning opportunities for rural people to acquire the necessary knowledge and skills that would enable them choose wisely, act productively, and grow individually while contributing to national progress.

Cassava (*Manihot esculenta*) is perennial woody shrub with a starchy edible root. It grows in tropic and sub-tropic regions of the world. The most commonly used part of cassava is the starchy root, which is rich in carbohydrates, about 20-30% dry matter. Cassava leaves can also be consumed and are rich in protein (14 - 40% dry matter), minerals, Vitamin B1, B2, C and carotenes (Mtunguja , Beckles, Laswai, Ndunguru and Sinha,2019). Cassava's growth characteristics make it a suitable food security crop, particularly due to its resilience growing in conditions that become unfavorable for other crops, such as periods of erratic rainfall. Due to this resilience to adverse environmental conditions, cassava has been named as an ideal climate change crop.

The basic goal of agricultural development organizations is to influence farmers to adopt agricultural innovations (Udemezue and Agwu,2018). The transfer of innovation and knowledge from research unit to farmers will bring about development. Therefore, the basic role of agricultural extension agent in the transfer of technology is to assist farmers in putting the readymade technologies into practice. Adoption is the decision to make full use of an innovation as the best course of action available. Adoption of agricultural innovations in developing countries attracts considerable attention because it can provide the basis for increasing production and income (Udemezue and Agwu, 2018).

There are several constraints to the adoption of technologies by farmers. Here an attempt has been made to outline the major constraints to adoption. According to Iwuchukwu,Obazi,Opata and Madukwe (2022), crop production in Nigeria is still plagued by myriads of setbacks ranging from difficulty in land acquisition, paucity of agricultural information and communication, inadequate training, issues of inappropriate technology, environmental constraints, pests and diseases, inadequate manpower, storage problems and irregular supply of improved seeds, inadequate supply of inorganic fertilizers and other production inputs (Mohammed, Ibrahim, Hayatu and Mohammed, 2019)

According to Carolyn,Afolam , Abiodun Obayelu and Vaughan(2015),Low adoption of modern agricultural technologies amongst farmers in Nigeria has been identified as one of the main reasons for the low agricultural productivity and increase in poverty level.To increase productivity, technology must be adopted in the production process and the rate of adoption of a new technology is subject to its profitability, degree of risk associated with it, capital requirements, agricultural policies and socioeconomic characteristics of farmers .

Soil infertility and low use of chemical fertilizer have been seen as two major factors inhibiting productivity growth of agriculture in Africa(Udemezue,Nwalieji and Nnena,2017). Fertilizer is one of the most essential farm inputs for increasing food production in the universe (Jaja & Barber, 2017). It is the quickest practical way to provide sufficient plant nutrients to restore nutrient-depleted in the soils (Raimi, Adeleke & Roopnarain, 2017).

In recent time, it has been observed that farmers in the state rejected application of fertilizer on their cassava farm despite the information disseminated to them on the need of application the innovation for higher productivity by extension worker. In view of this, the study investigated the factors influencing adoption of fertilizer applications by cassava farmers in Delta State, Nigeria. The specific objectives are to; ascertain the factors influencing the adoption of fertilizer usage among the farmers determine the constraints working against fertilizer usage by the farmers and examine farmers' suggested strategies to improve the constraints working against fertilizer usage in the study area.

Methodology

The study area is Delta State of Nigeria. The State covers a landmass of about 18,050 km^2 (6,970 sq mi), of which more than 60% is land. The State lies approximately between 5°00' and 6°45' E and 5°00' and 6°30' N. It is geographically located in Nigeria's mid-west, bounded in the north and west by Edo State, the east by Anambra, Imo, and Rivers States, southeast by Bayelsa State, and on the southern extreme is the Bight of Benin which covers about 160 kilometres of the state's coastline. The state produces crops like maize,yam,cassava,water melon etc and other economic trees. There are 25 local government in the state with head quarter at Asaba(Isorhovoja,2015).

Multistage sampling techniques were used in this study. Four (4) local governments out of the 25 local governments in the State were used for the research based on their activities on cassava production. Here, Aniocha North, Aniocha South, Ndokwa East and Ndokwa West were selected. These gave a total of four local government used for the study. Five communities per L.G. were purposefully selected due to their active participation in farming activities.Isele Asagba,Isele Ukwu,Onicha-Ugbo,Anioma and Uburubu from Aniocha North;Nsukwa,Abo Oguashi,Ewulu,Isheagwu And Ejeme From Aniocha South;Obi-Igbo,Umutu,Ashaka,Iseogboko And Ossaissa From Ndokwa East; And Amoji,Ogbe-Ogume,Umuchime,Ogbeani and Obodougwa From Ndokwa West were used. This gave a total of 20 communities used for the study.Ten (10) farmers each was randomly sampled from each community and this gave a total sample size of 200 farmers that were used for the work. Data used for this research were collected through a structured questionnaire. Data collected were analyzed using, frequency, percentage,mean score and regression model.

RESULTS AND DISCUSSIONS

Socio-economic characteristics of cassava farmers

Table1 shows that greater proportions (60%) of the farmers are male, while 40% of them are female. The implication is that males dominated their female counterpart in cassava production activities in the study area. This finding is in line with that of Diana(2015) who reported that women were found to contribute less in cassava production activities.

Entries in Table1 show that 47.59% of the farmers are within the age range of 46-55 years while 35% of them are within the age range of 25-35 year. Those who were within the age range of 46-55 were 12.5% while others who were within the age range of 56-75 were 12.5%. The average mean age of the cassava farmers was 39years. This implies that young people of active age dominated the activities of cassava production in the area.

Results also show that the majority (42.5%) of the farmers who cultivated cassava were married, 31.5% are single, 16% divorced and only 10% are widowed. Majority of the farmers who married could be an indication that they relied heavily on cassava for several household needs such as food, school fees for education, and health services for their families. Married people engaged more in cassava production activities than unmarried people because they have more responsibilities than unmarried ones. However, another implication of the married people engaged more than the unmarried could be that the couples are likely to be more productive than the single person due to labour supply in farm activities and access to productive resources in agriculture. This result is in consonance with that of mende kyanize and MW atawala(2015) that married people were likely to be more productive than single persons due to supply in farm activities.

Table1 shows that the majority (42.5%) of farmers completed secondary school education, 29% of the farmers completed primary school education and 14.5% of them stopped their education at first degree and above. The remaining 14% of the cassava farmers obtained OND/HND respectively. Education has always been known to play a good role in the adoption process, because people who are educated are more likely to adopt an innovation more readily than uneducated ones. In the same vein, a literate household head will be relatively less technophobic to adopt a new agricultural practice than one headed by an illiterate. Therefore, low level of education among the farmers imposes serious implications on their ability to access information, use new technological innovations and even access to get credit from formal financial institution (Mende,2015).

Finding shows that 41.5% of the cassava farmers had family size ranging between 6-10 persons, 37.5% of them had family size ranging between 1-5 persons, 11%of the farmers had family size between 11-14 and 10% of the remaining cassava farmers had family size ranging between 15-19 persons. The average household size was 8 persons. This means that the cassava farmers had relatively large family size and this may afford them the opportunity to increase their farm size and adopt more innovations exposed to them, since they will be able to make full use of family labour that can reduce the cost of hired labours for cassava production activities. This result agreed with that of Asmelash(2014) that the number of people in a household is the factor that influences the adoption of the technology, the bigger the size of the family in a household, the higher the chance of adoption as labour accessibility increase, adoption is also expected to increase. On the other hand, a large household size could also worsen the poverty situation of farming household especially if it was composed of a large number of the dependents, which means the family had more mouth to feed. A greater proportion (46.5%) of the cassava farmers cultivated between 1-2ha, 29% of them cultivated less than 1ha, 12.5% of the farmers cultivated between 3-4ha and 7.5% of the cassava farmers cultivated between 5-6ha respectively.

Similarly, 4.5% of the interviewed farmers cultivated between 7-8ha, while the average farm size for cassava farmers was 1.21ha. This implies that all the interviewed cassava farmers in the state were small-scale farmers. This could also help the respondents to have more access to a relatively large farm land that could be used in cultivation of crop to guard against failure that may arise from sole cropping. This result is in line with that of Mba, Saror and Agada (2016) that small scale farming offers the respondents an opportunity to have access to a relatively large farm land which may be used in cultivation of other crops in Venue state.

On the other hand, the majority (34.5%) of the cassava farmers had between 5-8years of farming experience while 34% of them had between 9-12years of farming experience. Similarly, 24% of the cassava farmers had between 1-4years of farming experience, 5% of the farmers had between 17-20years of farming experience, while 2.5% of the remaining cassava farmers had between 13-16years respectively. The mean years of cassava farming experience were 18years. This implies that the farmers had a very long period of farming experience and this will as well help them to acquire experience that will enable them to improve their activities in family farming.

A greater proportion (49%) of the cassava farmers had family and hired labour as the main source of labour in the farm, while 42.5% of the farmers used hired labour as their source of labour. On the other hand, 60% of the farmers got their farm land through renting while 25% of them got farm land through inheritance. Since majority of the cassava farmers sourced their farm land through rent, this could reduce the farmers capacity to increase farm size and this could as well impairing the adoption of new technologies disseminated to farmers. Majority (62.51%) of the farmers belonged to social organization while 60% of the farmers did not have access to credit loan. However, a greater number (65%) of the cassava farmers did not have access to agricultural extension services while some (35%) of the cassava farmers had access to agricultural extension services.

Access to credit loan is one way of improving farmers' access to new production technologies, according to one of the respondents, he said that farmers who have access to credit loan can reduce their financial constraints and be able to buy input more readily at the prevailing price. Therefore, it is expected that access to institutional credit can increase the taste of adopting improved technologies. However, since majority of the cassava growers in the study area did not have regular contacts with an extension agent, this could make them miss some vital information and technologies associated with cassava production activities. Those farmers that had contacts with extension services are expected to be more exposed to relevant technologies such as new released of improved cassava varieties or other technologies relevant to their family farming. In terms of social organization, participation in social organization could be advantageous to farmers, because farmers' social organization offers an effective channel for extension contact with large number of farmers as well as creating opportunities for interactions with organizations. This could also increase farmers' update of new practices such as cassava production technologies. More so, the majority (56%) of the farmers sourced cassava items from their harvested previous farms (owned farm) while 26% of them sourced from their fellow farmers. Similarly, 15% of the farmers sourced cassava stems from ADP while 3% of the remaining farmers sourced cassava stems from extension agents. Access to agro input could increase the probability of adopting an improved technology. It shows that even if a farmer is aware of a technology, access to it is also of paramount in adoption process.

Table1: Socio-economic characteristics of cassava farmers

Variables	Frequency	Percentage	Mean

Factors influencing adoption of fertilizer usage among cassava farmers in Delta state.

Liner regression model was conducted to predict the factors influencing adoption of fertilizer usage among cassava farmers in Delta State. The socio-economic variable used were age, educational level, sex, family size, farm size, farming experience, level of soil fertility, income, perceived constraints, training received, farming system practiced, extension services and types of tillage system used.

Out of the 13 variables investigated as the factors influencing the adoption of fertilizer usage among cassava farmers in the State, six (6) variables were found to be statistically significant as the factors influencing the adoption of fertilizer usage among cassava farmers in Delta state. The variables were educational level ($p<0.009$), farm size ($p<0.001$), farming experience ($p<0.004$), level of soil fertility ($p<0.000$), training received ($p<0.000$), and extension service ($p<0.007$).The decision was based on the value of R^2 (0.751) and adducted R^2 (0.642) that supported the claim of the dependent variable at 95%levels confidence.

Education level

Level of education is one the positive variables in the adoption of improved technology. Formal education helps the farmers to obtain useful information from radio, internet, agricultural news letter and other sources. Former education usually aids famers and lead them to accept new farm technologies more readily to increase their income than those farmers without a formal education. In developing countries, a general characteristic of famers is that they are tradition bound. They are afraid of taking risk and will not take until they are convinced that the new methods are safe, will pay and will not violate their values. However, most famers are tradition bound because of their low levels of education. Farmers are responsive to change provided it paid them and did not conflict with their value system. Hence literate farmers tend to adopt innovation more readily than illiterate farmers. In the light of the above, this finding is in line with the result of Okeke, Mbah, Madukwe and Nwaliej,2019) which saw education as one of the factors that trigers farmers' participation in improved sweetpotato farming. According to Okeke,*et al* (2019) the level of education attained by a farmer is not only increased his farm productivity but also enhanced his ability to know and evaluate more about the new technologies exposed to him.

Farming experience

Years of farming experience was positively significant and related to the factors influencing adoption of improved technologies in the study area. The implication is that the high level of farming experience among the farmers is expected to bring about a positive influence on adoption. That is, the more their farming experience, the higher the probability of adoption of the recommended improved production practices. Farming experience is an important determinant of the farmers' level of farm income. Farming involves a lot of risks and uncertainities, so to be competent enough to handle all the vagaries of agriculture, farmers must have a long farming experience(Garba,2016).

Farm size

The coefficient of farm size was found to be negative and statistically influenced the adoption of improved technology practices. This implies that as the farm size increases,adoption of the recommended improved technology practices also increases. According to Garba(2016),farm size has bearing on the capacity of farmers to adopt improved technologies and new farm practices. Farmers who have large farm size can afford to allocate part of their farm for yam production without significantly affecting the total land left for the production of the staple food crops compared to small land holder. This corroborates the findings of Tijjani,Tijjani and Audu (2018) which suggests a positive relationship between awareness and farm size among farmers in Jere LGA of Borno State.

Training received is positively and significantly related to the determinants of fertilizer usage among rice farmers. This implies that the contribution of explanatory variables is inversely proportional to dependent variable. Therefore, the more training received on fertilizer technologies, the higher the adoption of it. Farmers who receive adequate training on an innovation are more likely to adopt it than those who did not attain training. This finding agreed with that of Udemezue ,Nwalieji and Nenna(2017) who found training to be positively significant to adoption of fertilizer usage among rice farmers in Anambra State. This is because training improves farmers' level of knowledge and having agriculture as the main occupation will also help the farmers to seek for productive improved technology like fertilizer to increase productivity.

Level of soil fertility has a negative influence on determinants of fertilizer utilization among rice farmers. This implies that the more fertility land is the lesser fertilizer application on it. It is also could be that the farmers have exhausted all the available nutrients in the soil due to constant farming practice on one piece of land without fallowing. Therefore, if the fertility of soil is high, less fertilizer will be applied on it. The result agrees with that of Udemezue ,Nwalieji and Nenna(2017) which regard soil fertility as significant to the determinants of fertilizer adoption by rice farmers in Anambra State, Nigeria.

Extension contact has a positive influence on the determinant of productivity level among farmers. This shows that frequent contact with extension agent by farmers gives them the opportunity to know about the use of new farming techniques to increase their productivity level while negative contact with extension workers will affect their productive rate due to the fact that they might have missed information or the basic inputs needed to increase production. Regular contact with extension agents makes farmers being aware of new techniques and how they can apply them to increase production. This finding agrees with Udemezue and Nwalieji (2017) who found extension visit to be statistically significant to determinant of productivity level among cassava farmers in Anambra State, Nigeria.

Constraints to cassava production in Delta State.

Entries in Table 4 show the identified constants to cassava production in Delta State, Nigeria. The decision was based on the mean cut-off of 2 and above for 3-points Likert-type scale. Using mean score to rank the constraints items according to their order of severity were disease/past infestation (M=4.73), inadequate government support (M=4.52), high cost of cassava stems (M=4.51), weed infestation (M=3.95), bad road network (M=3.81), scarcity and high cost of land (M=3.55), lack of modern storage and processing (M=2.89), poor access to institutional credit (M=2.35), and inadequate extension services to farmers (M=2.13)

Table4: Constraints to cassava production in Delta State

Variables	Mean
Diseases/pest infestations	4.75
Inadequate government support	4.52
High cost of cassava stems	4.50
Weed infestations on the crop	3.95
Bad road network	3.81
Scarcity and high cost of land for cassava farming	3.55
Lack of modern storage and processing facilities	2.89
Imitated extension services to farmers	2.13
Long life cycle of the crop	1.81
Poor soil fertility	1.63
High cost of information to farmers	1.55
Age of the farmers	1.43

Low output from the crop	1.40
Use of local variety instead of the improve ones	1.35
High cost of inputs and labour	1.32
Too much attention on other crops like maize and yam	1.29
Low knowledge of the farmers on the multiple use of cassava crop	1.10
High perishability of the crop	1.09
Poor marketing outlet	1.05

Suggested Strategies to Improve Fertilizer Application among Cassava Farmers in Delta State.

Table3 shows that a majority (95%) of the cassava farmers was of the opinion that having appropriate and effective information on fertilizer usage would improve fertilizer usage among farmers. High cost of fertilizer has been reported by the farmers as a barrier to fertilizer usage in that area. In this case, 82% of farmers suggested that reducing the cost of it would help farmers to apply fertilizer on their farm. Also, 80.3% of the farmers were of the view that decentralization of training on fertilizer application among cassava farmers cannot only induce farmers to make use of fertilizer in their farms but also will place farmers on the platform of technical-knowledge of the technology. However,75% of the cassava farmers pointed out that administering training on farmers on the right application rate will encourage farmers to use fertilizers on their crops. Farmers were afraid to use it may be because some of them lacked the knowledge of its application rate and this can cause substantial disadoption of the innovation by the farmers. On the other hand,73% and 70% the interviewed farmers were of the opinion that conducting training on time of fertilizer application and strengthening the existing farmers organization through proper coordination and linking them to financial institution for loan assessment could help farmers to adopt fertilizer application in their farm. More so, 59% and 55% the farmers suggested the constraints to fertilizer application could be improved through the establishment of input centers at the village level for easy assessment. However, ministry of agriculture and other agencies involved in fertilizer packages should play active roles in coordinating and supervising of fertilizer released to farmers by government to get the right hands of the end-users this is because agricultural inputs released to farmers by government are sometimes being diverted and hijacked by politicians without getting to the appropriate farmers. Based on this, it is of utmost important to keep supervision of fertilizes released to farmers by the government.

Table4: Strategies to improve fertilizer usage among cassava farmers in Delta State

Variables	Percentage
Having appropriate and effective information on fertilizer usage on cassava farming	95

Reducing the high cost of fertilizer	82
Decentralization of training on fertilizer application among cassava farmers	80
Training on the right application rate	73
Payment of fertilizer subsidies by the government	38
Fixing of official price per a bag of fertilizer by government	28
Use of unbiased tax force to monitor price fixed by the government	42
Strengthening the existing farmers'cooperatives through proper coordinating and linking them to financial institutions for easy access to credit	70
Encouraging farmers to increase farm size	25
Establishment of input centre at the village level for easy access to fertilizer	59
Establishment of village information centre for current information on fertilizer usage	90
Encouraging farmers to commercialize their farming system	35
Regular and timely release of fertilizers to farmers	20
Increasing the number of extension staff for winder coverage and effective performance	45
Ministry of agriculture and other agencies involved in fertilizer packages should play more roles in coordinating and supervising of fertilizers released to farmers	55
Due process advocacy has to be accelerated	15
Farmers should be acquainted with the soil knowledge analysis before planting of crop	32

Source: field survey, 2022.

CONCLUSION AND RECOMMENDATIONS

Increased agricultural productivity relies on accepting cultural and technological changes at rural farm level. Peasant farmers can achieve higher farm yields if they adopt improved farming techniques; but some new practices are sometimes complicated, making adoption difficult for non-literate farmers. To adopt and successfully use improved farming techniques, peasant farmers must understand them, this requires effective teaching by the agricultural extension service. Based on these, findings of this indicated that greater proportions (60%) of the farmers were female, while 40% of them were female. The average mean age of the cassava farmers was 39years. This implies that young people of active age dominated the activities of cassava production in the area. The average household size was 8 persons. This means that the cassava farmers had relatively large family size and this may afford them the opportunity to increase their farm size and adopt more innovations exposed to them, since they will be able to make full use of family labour that can reduce the cost of hired labours for cassava production activities. The mean years of cassava farming experience were 18years. This implies that the farmers had a very long period of farming experience and this will as well help them to acquire experience that will enable them to improve their activities in family farming.

Out of the 13 variables investigated as the factors influencing the adoption of fertilizer usage among cassava farmers in the State, six (6) variables were found to be statistically significant as the factors influencing the adoption of fertilizer usage among cassava farmers in Delta state. The variables were educational level, farm size, farming experience, level of soil fertility, training received and extension service.

On the other hands, the identified constraints in the study area were disease/past infestation, inadequate government support, high cost of cassava stems, weed infestation, bad road network, scarcity and high cost of land, lack of modern storage and processing, poor access to institutional credit, and inadequate extension services to farmers. However, finding showed that a majority of the cassava farmers was of the opinion that having appropriate and effective information on fertilizer usage would improve fertilizer usage among farmers.

RECOMMENDATIONS

More extension workers should be recruited by the state and federal governments to fill in the gap of inadequate agricultural extension workers in the study area.

Government should help to provide storage and processing equipments to farmers. When this is done, it will reduce the high perishability of the product.

Rehabilitation of the existing roads by the government is necessary; this will help to transport the goods from the farms to markets.

Distribution of farm inputs such as cassava stems in the area is necessary; this will reduce the scarcity of cassava stems by the farmers.

Trainings should be organized by extension workers to teach farmers on how to ward off weed infestation using herbicides.

Fertilizer producers/industries should research critically on the active ingredient that caused weed infestations and correct the abnormality to make it acceptable by the farmers.

ABSTRACT

This research was conducted in Egbeda local govt, Oyo state on the causes of post-harvest losses and the effects on the maize value chain. Data was collected using questionnaires and was analyzed using descriptive statistics and ordered probit analysis. A total of 120 farmers were interviewed. The post-harvest losses of maize were grouped into four categories; Low loss, minimum loss, medium loss and high loss. Results showed that the majority of post-harvest losses among the maize farmers occurred during harvest, de-husking, transportation, shelling, selling and storage. Education, marital status, farm size and external training on postharvest loss management were also observed significant variables that affected post-harvest losses. The study recommends that farmers should be properly educated on improved methods of harvest and processing so as to reduce these losses and the farmers should adopt improved practices that can minimize post-harvest losses

INTRODUCTION

The most widely cultivated grain crop in the Americas is maize (*Zea mays L*), sometimes known as corn, which was domesticated by native peoples in Mesoamerica in prehistoric times. The United States alone produces 332 million metric tons of maize annually (Raouf, 2011). Maize has several uses, such as a source of food, alternative medicine, chemicals, biofuel, and Sornaments. Food production cannot meet the rising food demand, according to the FAO (FAO, 1998), unless post-harvest losses are reduced. As a result, there will be a chance to produce a sizable amount of food for consumption and other purposes. While most of the increasing food production is happening in wealthy countries, the majority of post-harvest losses are happening in underdeveloped countries.

SAMPLING METHOD

Multistage sampling was used to collect data. Purposive sampling was then used to select Oyo state that is well known for maize production. One local government (Egbeda) that is prominent in maize farming was selected using purposive sampling. Six communities namely; Egbeda, Osegere/Awaye, Olodo, Owobaale, Ayede/Alugbo and Erumu with the highest population of maize farmers were selected using purposive sampling. Twenty (20) Maize farmers were randomly selected from each of the six communities making a total of 120 respondents.

METHOD OF DATA ANALYSIS

The Ordered Probit model is a widely used approach to estimating models of ordered type which almost employs the Probit link function. Y* is a linear combination of some predictors, X, plus a disturbance term that has a standard Normal distribution:

$$Y_i* = X_i\beta + \Sigma$$

The latent variable Yi* exhibits itself in ordinal categories, which could be coded as 0, 1, 2,…, k. The response of category k is thus observed when the underlying continuous response falls in the k-th interval as:

$Y* = 0$ if $Y* \leq \delta 0$

$Y* = 1$ if $\delta 0 < Y* \leq \delta 1$

$Y* = 2$ if $\delta 1 < Y* \leq \delta 2$ (2)

Where Y* (i=0, 1, 2) are the unobservable threshold parameters that was estimated together with other parameters in the model. When an intercept coefficient is included in the model, Y= 0* is normalized to a zero value (Green, 2000) and hence only k-1 additional parameters are estimated with Xs. Like the models for binary data, the probabilities for each of the observed ordinal response which in this study had 3 responses (0, 1, 2,) will be given as:

$$prob(Y = 0) = P(\beta' X + \Sigma_i \leq 0) = \phi(-\beta' X)$$

$$prob(Y = 1) = \phi(\delta_1 - \beta' X) - \phi(-\beta' X)$$

$$prob(Y = 2) = 1 - \phi(\delta_1 - \beta' X)$$

where $0 < Y1* < Y2* <...<Y*_{k-1}$ …n is the cumulative normal distribution function such that the sum total of the above probabilities is equal to one. The specification of the orderedProbit model is as follows.

Let Y_i denote the categories: No loss (Y_i=0), Presence of loss (Y_i=1), Category of loss i.e Low loss, Minimum loss, Medium loss, High loss (Y_i=2)

In this study, the post-harvest losses of maize farmers is specified as follows;

$$Y_i^{\text{loss or no loss}} = b_0 + b_1X_1 + b_2X_2 + b_3X_3 + b_4 X_4 + b_5X_5 + b_6X_6 + b_7X_7 + b_8X_8 + b_9X_9 + \mu_i$$

Where:

$Y_i^{\text{loss or no loss}}$ = 0, 1 or 2

X_1= gender

X_2= age

X_3= years of education

X_4= farm size
X_5= farming experience
X_6= household size
X_7= area of residence
X_8= post-harvest training received

RESULTS AND DISCUSSION

Descriptive Statistics of Categorized Post Harvest Losses

The loss estimates were recorded as an ordered range of percentage of quantity losses and were stored as a categorical variable. Farmers loss estimates were then grouped into four ordered ranges; minimal loss (quantitative loss between 0 and 0.99%), low loss (between 1 and 2.99%), moderate loss (between 3 to 7%), and high loss (higher than 7%). The results present the percentage of respondents reporting four loss categories in WFSP (Wisconsin Food System Partnership) processing chain. At the harvesting stage, minimum loss was reported by 47.5% of the maize farmers, low loss was observed by 21.7% of the farmers, moderate loss of was experienced by 10% of them and a high loss was experienced by 12.5% of the farmers. At the Dehusking stage, 47.5% of the farmers experienced minimum loss, 28.3% of the farmers experienced low loss, 18.3% of the farmers reported moderate loss and 5.8% of the farmers experienced high loss. At the transportation stage, 68.3% of the farmers experienced minimum loss, 21.7% of the farmers had low loss, 11.6% of the farmers observed moderate loss and 3.8% of the farmers had high losses. At the shelling stage 51.7% of the farmers reported minimum loss, 24% of the farmers had low loss, 12.5% of the farmers observed moderate loss and 10.8% of the farmers had high losses. At the storage stage, 52.2% of the farmers observed minimum loss, 28.3% of the farmers experienced low loss, 10.8% experienced moderate loss and 6.7% had high loss. At the selling stage, 46.7% of the farmers reported minimum loss, 32.5% of the farmers had low loss, 12.5% of the farmers observed moderate loss and 8.3% of the farmers had high loss. Transportation is the stage where the highest proportion (68.3%) of the respondents reported their losses to be in the 'high loss' category.

Descriptive Statistics of Categorized Post Harvest Losses

Maizeloss category	Harvesting (%)	Dehusking (%)	Transport (%)	Shelling (%)	Storage (%)	Selling (%)
Minimum loss (0-0.99%)	57 (47.5)	57 (47.5)	82 (68.3)	62 (51.7)	65 (52.2)	56 (46.7)
Low loss (1-2.99%)	26 (21.7)	34 (28.3)	26 (21.7)	29 (24)	34 (28.3)	39 (32.5)

Determinants of Post-Harvest Losses along Processing Chain

The findings indicate that the coefficient of years of education is statistically significant and in the negative direction, indicating that more educated farmers are less likely to perceive they have bigger losses during the drying, shelling, and transporting phases. Therefore, raising awareness and enhancing education will be a key policy intervention for loss reduction at all levels of the maize processing chain. The coefficient indicates that education level is significant at the 1% level of significance and is negative for drying and shelling, indicating that better educated farmers are less likely to suffer greater losses at these stages. This suggests that for every 1% gain in education, losses due to drying and shelling will decrease by 0.0309 and 0.0591 units, respectively. The coefficient of level of education is significant at 1% level of significance and positive, which suggests that losses due to transportation will increase by 0.0486 units for every 1% increase in level of education.

The coefficients of the external training obtained on postharvest losses are negative and significant for the transport, storage, and milling stages, indicating that farmers who got training on postharvest loss management are less likely to experience severe losses at these stages. The coefficients of external training at the storage and milling stages are significant at the 5% level of significance, which means that for every 5% increase in external training, the losses resulting from storage and milling will decrease by 0.0459 and 0.772 units, respectively. Transport losses will decrease by 0.4006 units for every 10% rise in external training, according to the coefficient of external training at the transport stage, which is significant at the 10% level of significance and negative. Typically, farmers that lack postharvest management training and expertise are more likely to suffer postharvest losses.

Post-harvest losses are influenced by the techniques utilized at each stage of the processing chain. Using knives, machetes, etc. during the de-husking stage is more likely to result in larger reported loss than using bare hands. When drying, using plastic sheets is more likely to result in greater loss than using tarpaulin. When compared to transportation by motorbike, transportation to markets by truck is more likely to cause greater loss. Comparing shelling with fingers or physical rubbing of maize cobs against one another, bashing cobs in sacks with sticks is more likely to result in larger loss. In comparison to keeping corn in a room in the house, silos and the use of hermetic storage bags are more likely to result in fewer loss during the storage stage. When milling, human milling is thought to be more likely to result in lesser losses than using industrial milling equipment. Additionally, selling in a local market is more likely to incur a loss than selling at the farm gate since there is a chance that a loss could happen when the product is being transported from the farm to the market.

The coefficient of farm size is seen to be significant at the 1% level of significance and positive during the drying stage. This means that drying losses will increase by 0.607 units for every 1% increase in farm size. This suggests that the yield expected from a farm will increase with farm size, increasing the amount of maize susceptible to postharvest loss at the drying stage and vice versa.

Marginal Effects of Post-Harvest Losses in Categories

Since it is consistent with the main parameter estimates for all stages of the processing chain. According to the four sets of marginal effects educated farmers are 5.64% more likely to suffer a very high loss. Marginal effects of the respondent's education level reveal that the likelihood of being in the very high loss category increases by 5.64% for every additional unit of education. With each additional farm unit, the likelihood of being in the low loss category increases by 30.7 %, the likelihood of being in the moderate loss category decreases by 4.77 %, the likelihood of being in the high loss category decreases by 13.6%, and the likelihood of being in the very high loss category decreases by 6.95 %. Farmers are 32.9 % more likely to suffer low losses during harvest than mild losses, 30.2 % less likely to suffer moderate losses, 12.8 % less likely to suffer high losses, and 11.4 % less likely to suffer very high losses.

CONCLUSION

From the results of this study, the variables impacting postharvest losses at each node of the processing chain were identified. Using cross-sectional data from the study area, smallholder farmers' perceptions of postharvest losses in each level of maize processing chains were evaluated. Through careful estimation, the variables impacting postharvest losses at each node of the processing chain were found. The findings demonstrate that socioeconomic variables as well as the currently used postharvest techniques have an impact on physical losses following harvest at various points throughout commodity processing chains. Higher levels of education and training in post-harvest loss control are associated with lower post-harvest losses at critical stages of processing chains, according to socioeconomic characteristics. The number of years spent in school is linked to a lesser chance oflosses during the drying and shelling processes but a higher chance of loss during transportation. Farmers with postharvest loss training are less likely to experience substantial losses throughout the storage, milling and transportation processes. Farmers who are married are less likely to experience loss at the point of drying.

ABSTRACT

The study was on fish consumption among households in Lagos State. A multistage sampling technique was used to select 400 households from Lagos Island, Eti Osa, Surulere, Shomolu, Kosofe and Oshodi/Isolo Local Government Areas. A structured questionnaire was used to collect the data needed for the study. The data were analyzed using the descriptive statistics The result indicated that the study area had more male-headed households (52.5%). The average monthly expenditure on fish by household was ₦3,640 Result of the descriptive statistics further shows that a large number of consumers had preference for fresh fish (60.7%) and smoked fish (54.7%). The study recommends the improvement of the market for fish by creating value through packaging processing and storage and better storage facilities is pertinent. This can be achieved by government provision of steady power supply and agro processing industries which must be linked to production for household consumption.

Keywords: Fish, Consumption, Household, Lagos-State.

INTRODUCTION

Fish is an important component of a modern healthy diet and also a critical food source for developing countries Fish provides key macro and micro nutrients, protein and are low in saturated fat .(Lynch & Macmillan, 2017). Fish consumption has been linked to a wide array of health benefits for infants and adult including the developing foetus (Millen et al, 2015). According to Nesheim and Taktine (2007), fish can supply up to 50 percent or more of high quality protein, mineral elements(B6, B12, niacin, thiamine, riboflavin, Vitamin E) and essential fatty acid such as oleic acid and omega3 fatty acid.

The united nation food and Agriculture organization noted that world population growth has outweighed fish production due to increased fish consumption. Fish consumption per capita across the world has increased from 9.0kg in 1961 to above 20.5kg in recent times as a result of the upsurge in population growth, urbanization and demographic dynamics(FAO, 2018, Falaye & Jenyo-Oni, 2009). Fish consumption (demand) raises enormous challenges for economies. Utilization of fish varies for food and non-food purposes across countries and regions. More importantly, the utilization of fish for direct human consumption increased significantly over the years from 67 percent to 88 percent in 2016 (Vannuccini et al., 2018). Hence, the consumption pattern for fish have peculiar implications for the sub-sector in various economies.

Fish plays a vital role in feeding the world's population and contributing significantly to the dietary protein intake of hundreds of millions of the populace. In Nigeria, 50 percent of total average intake of animal protein is attributable to fish. (Liverpool-Tasie et al., 2021.The quality of the fish/seafood freshness is the prime determinant. In this regard frozen fish are treated as non-fresh, bad quality, tasteless, watery and boring (Olsen, 2001). Other attributes like price and convenience also have impact on fish consumption attitude formation. However, Olsen (2004) found price, value for money and household income not barriers to seafood consumption, while Verbeke (2005) reported that price negatively affect fish consumption attitude because of complex preparation and cooking procedure, fish is treated as an inconvenient food item (Verbeke *et al*, 2006).

Despite the importance of fish in Africa, particularly for addressing malnutrition, examination of fish demand has been limited. There are few survey-based analyses of the demand in Africa, though exceptions include: Abdulai and Aubert (2004) for Tanzania; Tambi (2001) for Cameroon; and local area studies such as Amaoet al. ,(2006) for Lagos State in 'Nigeria. Zhou and Staatz (2016) used Living Standards Measurement Study (LSMS) data from around 2012 to estimate income elasticities for fish as a general category compared with other food categories tor West Africa. Desiere et al (2018) also used LSMS and FAO data to assess current and future meat and fish consumption, in a group of countries in sub-Saharan Africa. Gen-schick et al. (2018) analysed urban Zambian fish consumption patterns of the poor strata.

Moreover, there has been little research globally on the determinants of the form in which fish is purchased. 'Traditional forms' include dried/salted, smoked, and fresh, all of which were common prior to the advent of refrigeration, and freezing. The main non-traditional product form is frozen, fish, which is thawed after purchase for use at home or in restaurants.

Fish consumption analyses have often treated fish (and 'sea food') as a homogeneous group of products and few studies differentiate either species or form. There are some exceptions: Toufique et al (2018) distinguish fish originating from capture or aquaculture. Dey et al. (2008) distinguish dried fish from other fish in Asia. In Europe and the US, Trondsen et al (2004) distinguish processed from fresh,and Verbeke et al. (2007) distinguish traditional presentation styles versus fresh. In the United States, Muhammad and Hanson (2009) distinguish fresh and frozen cat-fish- In Africa, studies of demand for different fish forms are either of a locality, or of one species, or limited product forms (Kumar et al, 2005: Jimoh et al, 2013; Dauda et al., 2016).

The African literature has not had a systematic analysis of: (i) consumption of domestically produced versus imported fish; (ii) consumption of different forms of fish, such as frozen, fresh, dried and smoked; (iii) consumption of fish over spatial categories such as agro ecological zones, and regions with different levels of development. These gaps are important for the following reasons. First, unlike Asia, food imports are among the top policy concerns in Africa (African Development Bank, 2016) due to their viewed foreign exchange burden and their competition with the domestic fish sector. In Africa, the share of imports in total apparent consumption of fish more than doubled over the four decades 1970s – 2000s, to a high of 39% by 2017. This compares to the import share (derived from FAOSTAT) in all food for 2017 of 13% (Liverpool-Tasie et al., 2020.

At the household level consumption pattern may depend on the availability of the income, price of the commodities, primary activities of the household, social structure and customs. The actual quantity of fish consumed, the price paid by consumer for 1kg of fish and other factors like education level, age, gender, household size and income affects the consumption of fish are however poorly documented, particularly in Lagos state, besides the empirical evidences emerging from few studies on fish demand at the household level which has yielded mixed result that is inconclusive and contradictory. Thus, the questions on how household consumer is still worthy of further research such as the one being undertaken in this study. Also, empirical evidences largely scanty, isolated and devoid of in depth analysis of the combined effects of socio-economic and micro economic factors on fish consumption in the context of their significance and size in Lagos state, Nigeria. This creates gap in literature.The Objectives of this study include: examine the socio-economic characteristics of the household, determine consumers' preference for fish, identify the various types and forms of fish consumed by the respondents and identify the constraints for fish consumption in the study area.

METHODOLOGY

Study Area

The study was carried out in Lagos State Nigeria. Lagos State is located in the south-western part of the Nigerian Federation. On the North and East it is bounded by Ogun State. In the West it shares boundaries with the Republic of Benin. Behind its southern borders lies the Atlantic Ocean. 22% of its 3,577 km^2 are lagoons and creeks. It lies within the latitude 6 and 24^1 and 6 31^1 N, longitude $3^0 16^1$ and $3^0 37^1$ Lagos State has 20 local Government Areas out of the 774 Local Government Areas in Nigeria. It Comprises of three senatorial district(Lagos east, Lagos west and Lagos central).It has a population of 9,013,534 as at 2006 National population census (NPC).The highest maximum temperature ever recorded in Lagos was 37.3^{o}C (99.1^{o}F) and the minimum 13.9^{o}C (57.0^{o}F) (Lagos Meteorological Organization 2012). Multi-stage sampling technique was used in selecting the respondents for the study. The first stage in the sampling procedure was the stratification of the study area into cells of high, medium and low density areas Oluwole Samuel Ojewale (2014). With respect to Lagos, areas of high population density are usually populated by low income class. This sampling technique was to ensure that each income group was adequately represented in the sample. In the second stage Lagos Island and Etiosa local government area were selected for the low density areas, while Surulere and Shomolu LGA represented the medium density areas. For the high density areas, Kosofe, and Oshodi/Isolo LGA were selected (these LGA were selected using convenience sampling).The third stage involved the selection of households via random sampling procedure. A complete list of all the households in each of the LGA was obtained from the National Population Commission Census list. A total of 400 households in these areas were randomly selected with sample size distributed proportionate to size.

RESULT AND DISCUSSION

Socio-Economic Characteristics of fish consumer household

The socio-economic characteristics analyzed include: gender, age, marital status, family size, household income, occupation and forms of fish consumed.

Table 1 Distribution of Household by their socio economics

Variable	Category	Frequency N= 400	Percentage
Gender	Male	210	52.5
	Female	190	47.5
Marital Status	Single	155	38.75
	Married	215	53.75
	Widowed	30	7.5
Age	Less than 20 years	68	17.0
	21 – 30 years	80	20.0

Gender of the household heads is an important factor that has significant influence on the preference and consumption pattern of fish by households. The distribution of household by gender and forms of fish is presented in Table 1 and shows that although the percentage of male headed households (52.5%) are more than female headed household (47.5%), the number of female headed household is very substantial. This is in line with result of Chianu &Tsujii (2007) where 99.7% of the surveyed household were male headed. The distribution of the household by marital status is presented in Table 1. The result shows that 53.75% of the households were married while 38.75% are singles and 7.5% are widowed. This shows that there is the tendency for more purchase of fish and increased consumption by households headed by married people than singles due to expansion in family size and greater responsibilities in terms of expenditures on food items. Therefore, there is a tendency for more purchases of fish~~.~~ (Amao & Ayantoye 2014). There is a tendency for the age of the household head to affect the consumption pattern of a household and may determine to an extent the type, quality and nutrition of a given household. This in agreement with Aminu, Adebanjo and Mohammed (2016). Further results show~~s~~ that a large number of household heads (103) fell within the age group of 41-50 years and represented about 25.75% of the respondents. Age could be an important determinant in the quality and quantity of protein requirement of an individual and households (Amao et al., 2006). Education changes taste over time and usually affects consumption pattern, preference for food items and nutrition of a household. This is because consumers become aware of the nutritional value of protein rich food items like beef, eggs and fish and subsequently enhance their consumption. The distribution of household head by level of educational attainment, as presented in Table 1, shows that household heads with secondary education had the highest percentage of 25.75%. The majority of the respondents (50.5%) belong to an extended family in the study. Family size have a significant effect on the consumption pattern for fish as with other food items. As the family size increases, there is tendency for the household to consume more food generally, fish inclusive. Majority of the households in the study area (53.25%) had between 2-5 members. The literacy level of the respondents might have contributed to the relatively small household size. Education has been reported as one of the key determinants of the awareness and use of family planning measures (Babalola, Babalola & Oladimeji, 2012). Information on demographic patterns in Nigeria also shows that urban households are usually smaller than rural households (Statista Research Department, 2021). The frequency distribution of income determines the type of income distribution most prominent in the study area. Table 1 shows that the majority of the respondents fall within the low income group while those in the high income class are relatively few. Low income may affect overall fish consumption and further determine the form of fish consumed by households. Table 1 shows that majority of households sampled (218) were non salary earners, accounting for about 54.5% of total sampled respondents while (182) were salary earners, accounting for about 45.5% of total sampled respondents. A priori expectation is that the probability for salary earners to have a more planned and consistent consumption pattern than the non- salary earners is higher. This may also influence an increase in household purchasing power. However, most of the household in the study area are non-salary earners. In particular, the majority of the respondents are traders (33%). Most of the respondents spend the average monthly expenditure on fish by the household in the study area was ₦3,640.

Health Reasons	41	27.3

***Multiple Response**

Source: Computed from Field Survey (2021)

The result in Table 2 reveals that majority of households sampled (342), accounting for about 85.5% of total sampled respondents, consume fish as their major protein source. This suggests that there are more fish consuming household in the study area. Also, majority of households sampled (88.0%) gave nutrition as the major reason for consuming fish. Other reasons given include taste (74.0%), low cholesterol (58.7%), availability (51.3%) and affordable (46.7%). Increasing fish availability will likely increase fish consumption among the study population? More than half of the respondents (60.7%) prefer fresh fish to frozen, smoked or dried fish. About 50.7% of households indicated their preference for frozen fish, while 54.7% and 52.7% of the households sampled had preference for smoked and dried fish respectively. The most preferred forms of fish by households are further presented in Table 2. A large proportion of households (106) accounting for about 70.7% of sampled households consumed Hake (Panla) compared with any other type of fish, 52% had preference for Mackerel (Titus) while about 60% consumed Horse Mackerel (Kote). Some 50.7% of households preferred Clarias (catfish), 56% of households had preference for Croaker, and 45.3% preferred Tilapia. The result in Table 2 reveal that majority of the household sampled (70.7%) purchase their fish from the open wet markets. Furthermore, majority of households sampled (315) fish consuming household accounting for about 78.75% of total sampled respondents store their fish. This corroborates with their high preference for fresh fish. From Table 2, Majority of the respondents (76.7%) indicated that they consume egg as alternative protein source to fish. This shows that egg is a close substitute for fish in the study area. The relatively low price of egg may also be responsible for this reference. The result in Table 2 shows that a higher proportion (80%) of the sampled household chooses availability as the reason for consumption of other protein source. The result in Table 2 reveals that majority of households sampled (104) fish consuming household accounting for about 67.3% of total sampled respondents gave rapid fish spoilage as constraint because they consume fresh fish and preserve by refrigerating or sun drying. Rapid spoilage of fish could be as a result of poor power supply to power the refrigerator used for preservation of the fish. Some 101 sampled fish consuming household accounting for 67.3% gave distance from the market as their challenge, other constraint include high price of fish (64%). High prices of the product could be as a result of high transportation, high cost of production and high cost of preservation. Low level of consumer income (41.3%), health reasons (27.3), religious belief (25.3%) and low traded volume (12%).

CONCLUSION AND RECOMMENDATION

This study examines fish consumption pattern among consuming households in Lagos metropolis with a view to analyzing the trends of fish consumption, consumers' preference for fish and the functional relationship between the quantity of fish consumed and selected variables. The variables examined include income of the household, taste, price of fish, occupation, household size, level of education and age of the household head which were found to influence households fish consumption expenditure. The food and fish consumption expenditure analysis of households revealed that the average monthly expenditure on food and fish tends to increase with increase in household income, but the percentage of income spent on food and fish decreases with increase in the income of the household in accordance with Engels law. For the average monthly expenditure on fish by household size, it was observed that the average monthly expenditure on fish increases as the household size increases. This was found to be true for the average monthly expenditure on fish by the age of the household head. As the age of the household head increases, their average monthly expenditure on fish also increase. Fresh fish is the highest form of fish in the consumer market, whereas smoked fish is the lowest priced. As the income of the consumers increases, they buy only a little more smoked and frozen fish because most smoked fish consumed in the metropolis are perceived to be of low quality. Wealthier consumers tend to buy more of fresh fish and dried fish (such as stock fish) which consumer perceived to be of better quality in terms of nutrition and safety. The dried and fresh forms of fish are substitute mainly because the most common type of fresh fish in the area (the cat fish) is also the dried fish in the market. The socio economics characteristics reveal that the consumers are not poor. These categories of the population are mostly educated and well exposed and are well within their regular intake of fish protein. However, there is need for further research to disaggregate consumption groups and account for the fish protein intake level in the study area. There is a need therefore to increase domestic fish supply in the country and ensure fish supplies to consumers at affordable prices in all market in the metropolis. Facilitation of supply of fresh and frozen fish is recommended because it attracts higher preference especially in the open market. Finally, there is a need to create consumer awareness of nutrition information through education and media promotion.

24 - 28 Oct., 2022

ABSTRACT

An experiment was conducted at the screenhouse of Federal College of Horticulture, Dadin-Kowa Gombe State, Nigeria during 2021rainy season. The aim of the experiment was to evaluate farm soils of tomato fields for Fusarium wilt pathogen. The treatments consisted of soil samples collected from 6 different locations in the study area namely;- Dadin-Kowa, Deba, Gwani, Kwadon, Shinga and Zambuk which served as inocula source. . Five grams of each soil sample collected was dissolved in 10ml of distilled water and stirred thoroughly to obtain inoculum. This was sprayed on the transplanted seedlings to the point of runoff while the control was sprayed with water. .. Data were collected on percentage disease incidence, severity of Fusarium wilt infection, yield and percentage yield loss per plant. Data collected were subjected to analysis of variance and means were separated at $p<0.05$ using SNK with Genstatth Edition statistical software. The result revealed significant differences in Fusarium willt incidence, severity, yield and percentage yield loss among the locations where samples were collected. It can be concluded that the farms where tomato is cultivated in Yamaltu Deba local government were infected with Fusarium wilt pathogen. There was variation in the intensity of infection and consequent yield loss which ranged from 19-60%. Tomato farms of Dadin-Kowa, Deba and Kwadon were more severely infected. The yield loss was more pronounced in Dadin-Kowa and Deba. High yield loss in Shinga could be due to other soil-borne pathogens. Fusarium wilt pathogen is not a serious disease of tomato in Zambuk.

Keywords. Incidence, severity, Fusarium wilt and tomato

INTRODUCTION

Tomato (*Solanum lycopersicon* L.) is one of the most popular and widely grown vegetable in the world. It is one of the important food and cash crop for many low-income farmers in the tropical countries. It is very rich in vitamin C and minerals, especially phosphorus, potassium and calcium (Taylor, 1987). This reference is too old). Diseases are major limiting factor for vegetables, causing serious yield reduction and leading to severe economic losses. The average global crop losses caused by plant diseases is about 12.8% (). Losses attributed to diseases on tomato alone was estimated be 21.8% (Melese and Samul, 2018). Several diseases **affect** tomato during its growing season. Fungi are the most common cause of infectious plant diseases and can be very destructive. One of the most common fungal diseases that infect tomatoes is *Fusarium* wilt (Rangaswamy 1999).

Fusarium. oxysporum (causative organism of *Fusarium* wilt) is a widespread soil-borne fungal pathogen. *Fusarium* wilt is cosmopoliatan and there is currently no resistant tomato variety to the disease. The pathogen persists for many years in the soil without a host (Rangaswamy, 1999). Most infections originate from the fungus associated with infected tomato debris. Root knot nematode infection makes *Fusarium* wilt-resistant varieties more susceptible to the fungus because of physiological changes in the root. Disease development is favoured by warm temperatures (27–28 °C), dry weather, and acidic soil (pH 5–5.6). Succulent tomato plants exposed to fertilization with ammonium nitrate are especially susceptible to the disease. The fungus can be disseminated by infected seed or by transplants grown in infected soil. The fungus can be introduced into a field on contaminated equipment, stakes, packing crates or shoes. Soil particles from infected fields may be blown into disease-free fields.

The initial symptoms are yellowing of the foliage, beginning with the lower leaves and progressing upwards. Yellowing often begins on one side of the vine. Infected leaves later show downward curling, followed by browning and drying. The top of the vine wilts during the day and recovers at night, but wilting becomes progressively worse until the entire vine is permanently wilted. Vascular browning can be seen in infected stems and large leaf petioles (Brammall and Higgins, 1988). Affected plants and their root systems are stunted. The degree of stunting depends upon the time of root infection. Plants infected early are more severely stunted than plants infected at a later stage. Soil-borne and foliar fungal diseases are a major limiting factor for tomato production. Yamaltu-Deba local government area of Gombe State Nigeria was well known for massive dry season tomato production in previous years but nowadays the production is very low. Abdulkadir et al. (2019) reported that among the major factors limiting dry season tomato production in the area, pests and diseases are the most serious. Hence a study to investigate tomato field for soil-borne pathogen, especially, *Fusarium* wilt cannot be over emphasized. The research was aimed to determine the incidenceand severity of *Fusarium* wilt pathogen in tomato farms at different locations in Yamultu Deba local government of Gombe state and ascertain yield loss of tomato due to the pathogen.

MATERIALS AND METHODS

The experiment was conducted in the rainy season of 2021 at the screen house nursery unit of Research and Training Farm of Federal College of Horticulture, Dadin-Kowa, Gombe State, Nigeria. The experiment consisted of 6 soil samples collected from 6 different tomato farms within Yamaltu Deba Local Government Area of Gombe State.: - Dadin-Kowa, Deba, Gwani, Kwadon, Shinga, and Zambuk. The design of the experiment was Completely

Randomized Design (CRD) with 4 replications. To prepare the medium, the top soil was sterilized at a temperature of 90°c for 3 hours. This is to ensure free germ medium so that the only source of the pathogen was the inoculum. The sterilized medium was used to raise the seedlings in a plug 2 seed per chamber and later thinned to one plant per stand. The seedlings were transplanted at 3 weeks after sowing into plastic containers containing the sterilized soil. A spacing of 5cm was left at the top of the container to promote water retention. Watering and weeding were carried out to ensure moisture stress and weed free conditions, respectively. NPK 15:15:15 fertilizer was applied at the rate of 450kg/ha. The soil samples were collected using W sampling method from 3 tomato cultivated soil in each location, bulked to form a single sample and labeled accordingly. To prepare the inoculum, 5g of each soil sample collected was dissolved in 10ml of distilled water and stirred thoroughly**.** The inocula prepared were sprayed on the transplanted seedlings untilto the point of runoff using hand sprayer at 2 weeks after transplanting. The control plot was sprayed with water. Thereafter, the seedlings were covered with polythene bags for 24 hours to promote ideal humidity for infection.

Data were collected on the following parameters at 2, 4, 6 and 8 Weeks after Inoculation (WAI)**:**

Disease Incidence (DI): This was calculated using the formula below:-

$$DI = \frac{\text{Number of plants infected}}{Total\ number\ plants} \text{ x } 100$$

Disease severity: The plants were scored using the rating scale of 1-5 modified from Owolade *et al*, (2006), as follows:-1= no symptoms. 2= Up to 20%, 3= 21 to 40%, 4= 41-60%, 5= > than 61% . **The** fruits were harvested at maturity from each experimental unit, weighed and the average taken and expressed as yield per plant in kg. Percentage yield loss was calculated as the ratio of the difference between yield of the control and yield of treatment multiplied by 100. The data collected were subjected to analysis of variance (ANOVA) using SNK Genstatth Edition statistical software and means were separated using SNK at 5% level of probability.

RESULTS AND DISCUSSION

The result of percentage incidence is presented in Table 1. There was nosignificant difference between the locations at 2WAI. However, Deba, Kwadon and Shinga recorded higher incidence than the grand mean. At 4WAI, Shinga recorded the highest percentage incidence but at par with all other locations, except Zambuk. The control was significantly lower. At 6WAI, Deba had the highest disease incidence but this was at par with all other locations, except Dadin-Kowa which in turn was statistically similar with the other locations except Shinga and Dadin-Kowa. At 8WAI, Kwadon had the highest *Fuasrium* wilt incidence but at par with all other locations except Dadin-Kowa. Zambuk recorded the lowest incidence among the locations but at par with Dadin-Kowa while control is significantly lower. The intensity of *Fusarium* wilt pathogen among the locations differed at different periods after inoculation. This suggests variation for managing the disease based on locations. Abdulkadir (1998) also reported different time of intensity of disease incidence among locations on anthracnose pathogen of sorghum. It worth to note that the control (un-inoculated) recorded lower *Fusarium* wilt incidence (0.4-1.4%). This could be attributed to the inability of the spore to be blown by air and infect the plants in the control plots. Scarlett *et al*., 2015 identified both micro and macroconidia of *Fusarium oxysporum* f.sp *cucumerium* as air-borne.

The result of severity of *Furasrium* wilt infection as indicated in Table 2. It revealed non-significant differences among the locations evaluated at 2WAI. However, Kwadon and Shinga registered severe infection more than the grand mean. At 4 WAI, there was a significant difference (P<0.05) in the severity of *Fusarium* wilt among the treatments. The control had lower severity while there was no significant difference among the locations. At 6WAI, there was a significant difference of severity of *Fusarium* wilt infection on tomato among the locations. Deba recorded the highest severity which was statistically similar to Dadin-Kowa and also at par with all locations except Shinga which in turn was at par with Gwani, Kwadon and Zabuk. The control treatment had the lowest severity

Table 1: Percentage Incidence of *Fusarium* Wilt Pathogen on Tomato

Treatments **Source of inoculation**	**2WAI**	**4WAI**	**6WAI**	**8WAI**
Dadin-Kowa	5.4	16.6ab	23.5b	34.9bc
Deba	9.4	16.6ab	30.3a	47.2ab
Gwani	3.1	12.3b	25.1ab	44.7ab
Kwadon	9.0	16.8ab	25.7ab	50.0a
Shinga	9.1	21.6a	29.6a	43.1ab
Zambuk	2.5	10.9b	25.3ab	28.3c
Control	0.4	0.6c	0.9c	1.4d
Grand mean	**5.6**	13.6	22.9	35.7
p<F	NS	**	**	**
SE±	3.22	4.0	2.56	5.72

Means followed with the same letter in a column are not significantly different using SNK at 5% level of probability.

of *Fusarium* wilt infection. Similarly, there was a significant difference (P<0.05) in severity of *Fusarium* wilt infection at 8WAT where Kwadon recorded the highest severity but it was at par with all other treatments except Zambuk and the control. The ocntrol had significantly lower severity of *Fusarium* wilt infection, followed by Shinga which was at par with all other locations except Kwadon. Kwadon was found to register both the highest incidence and severity of *Fusarium* wilt at the end of the sampling period (8WAT).

The result of fruit yield as shown in Table3 indicated that the control produced the highest fruit yield but it was at par with Zambuk which in turn was statistically similar with Deba, Gwani and Kwadon. Dadin-Kowa recorded the lowest fruit yield per plant but it was at par with Shinga which was also at par with Deba, Gwani and Kwadon. These results confirmed the report by Melese and Samul (2018) that strains of the pathogen, climate, and/or soil characteristics present in each location impact infection or resistance of *Fusarium* wilt pathogen. The result of percentage fruit yield loss due to infection of *Fusarium* milt pathogen differed significantly ($p<0.01$) where Dadin-Kowa was significantly higher, followed by Shinga, Deba, Gwani, Kwadon and Zambuk, respectively. Several authors reported yield loss due to *Fusarium* wilt infection within the range found in this research. Fravel *et al*. (2005) reported that *Fusarium* wilt caused caused yield reduction of up to 25%. Bowyer (1999) also reported that *Fusarium* wilt caused 25% yield loss in western countries and almost 50% in the developing countries. *Fusarium. oxysporum* f. sp. *lycopersici* is highly destructive both in greenhouses and field grown tomatoes, yirld loss of 10-50% (Mao *et al*., 1998). In Tamil Nadu, wilt incidence up to 25% was reported (Kapoor, 1988) and yield loss of 10-50% was reported by Lukyanenko (1991). A yield loss of up to 45% was recorded in northern and Southern states of India (Kalaivani, 2005). Kirankumar *et al*. (2008) reported 30-40 % yield loss in tomato due to *Fusarium* wilt.

Table 2: Severity of *Fusarium* Wilt Pathogen on Tomato

CONCLUSION AND RECOMMENDATION

Fusarium wilt pathogen was recorded in all tomato farms in Yamaltu Deba local government. However, there is variation in the intensity of infection and consequent yield loss. Tomato farms of Dadin-Kowa, Deba and Kwadon were more severely infected. Yield loss due to *Fusarium* wilt is more pronounced in Dadin-Kowa and Shinga. *Fusarium* wilt pathogen is not a serious problem of tomato in Zambuk. To boost production of tomato in Yamaltu Local Government, *Fusarium* wilt resistance tomato varieties should be cultivated in Dadin-Kowa, Deba and Kwadon. Tomato farms in Shinga and environs should be investigated for other soil-borne pathogens.

ABSTRACT

An experiment was set up to examine the performance of cocoyam (Colocasia esculenta L. Schott) to varying levels of cow dung and potassium fertilizer in 2018 and 2019 cropping seasons under field conditions at the Research Farm of the Agricultural Science Education Unit of the Delta State University, Abraka, Nigeria. The experiment was a 4 × 2 factorial arrangement in a randomized complete block design with three replications. The treatments were four levels each 6 of cow dung (0, 10, 20 and 30 t ha^{-1}) and potassium fertilizer (0, 20, 40 and 60 kg K_2O ha^{-1}). Application of cow dung at the highest rate of 30 t ha^{-1} significantly ($P < 0.05$) enhanced plant height, leaf area index, number of suckers and yield of cocoyam (23.6 t ha^{-1}) in both cropping seasons relative to the lower rates and the control. In general, potassium fertilizer application did not exert much influence on growth parameters of cocoyam as significant effect was observed in both cropping seasons. The results of this study have shown the effectiveness of cow dung in improving the growth performance of cocoyam which is a reliable indicator of yield.

Keywords: Organic and mineral Fertilizer, Cocoyam, Growth Parameters

INTRODUCTION

Cocoyam (*Colocosiaesculentus L.*) is one of the major root tubers produced in large quantity in Nigeria, which is the highest producer in the world. Nigeria produces 40% of the total world output, while Ghana which comes behind produces 31% (Nwite *et al.*, 2020). According to Eke-okoro *et al*. (2005), cocoyam is classified into 6 cultivars namely Coco-India (NCY004), Green Ede ofe (NCY005), Purple Ede ofe (NCY006), Giant Ede ofe (NCY007), Ukpong (NCY008), and Ghana (NCY009). Cocoyam contains easily digestible starch as well as vitamin C, riboflavin and thiamine. The leaves are also edible and used for delicacies in many families in Igbo land and some parts of Delta and Edo States. Cocoyam is known to have so many therapeutic values in the treating of potentially allergic infants and persons with gastro-intestinal disorder and for diabetic patients (Eke-Okoro *et al.*, 2005).

The crop requires 2-4 months of rainfall per annum, average temperature of about 21^{o}C and it grows on a wide range of soils.

The current level of cocoyam production in Nigeria estimated at 15 million metric tonnes in 2016 (FAO, 2017) is grossly inadequate to satisfy the increasing demand for the crop as alternative food crop (Shiyam et al., 2017). This low level of cocoyam production is attributed to increasing decline in soil fertility levels and lack of soil management practices for continuous cocoyam cultivation (Agbede & Adekiya, 2016). The use of organic and mineral fertilizers are the two major and common ways in which soils are managed since the extinction of shifting cultivation as well as reduction in bush fallow periods (Makinde et al., 2011).

In recent years, however, the focus on soil fertility has shifted towards the combined application of organic and inorganic fertilizers for judicious management of resources and soil conservation under intensive cropping (Fening et al., 2011). Sole use of organic manures to sustain cropping has been reported inadequate especially in the year of application (Patel et al., 2000). They are required in rather large quantities to meet crops' nutrient supply because of their relatively low nutrient content (Palm et al., 1997). Efficient use of chemical fertilizer and organic manures in crop production are measures that has been shown to enhance and increase plant growth and nutrient uptake, which forms the basis for higher crop yield (Anjorin, 2013). The objective of this study was to determine the organic and mineral fertilizer effects on growth parameters of cocoyam

MATERIALS AND METHODS

The location of the field experiment was the Research Farm of the Agricultural Science Education Unit of the Delta State University, Abraka, Nigeria (latitude 50 46'N and longitude 60 5'E). The area has a bimodal rainfall with annual rainfall of 2323mm and a mean temperature of 26.70C. The area is characterized as a humid rainforest zone and the soil is sandy loam. The total annual rainfalls for 2018 and 2019 were 1902.8 and 2210.0 mm, respectively while the total rainfalls during the period of experimentation in 2018 and 2019 were 1775.6 mm and 2009.0 mm, respectively.

The cocoyam (*Colocasia esculenta*var NCe001) cormels used in this study were sourced from National Root Crops Research Institute, Umudike, Abia State. The cow dung was obtained from local cattle ranches in Abraka, Delta State while the potassium fertilizer (60 % muriate of potash, K2O) was obtained from the fertilizer unit of Delta State Ministry of Agriculture, Asaba. Composite sample of the cowdung was air dried, crushed, sieved and then analyzed in the laboratory for its nutrient compositions.

The experiment was a 4 × 2 factorial arrangement in a randomized complete block design and replicated three times. The treatments comprised four rates each of cow dung (0, 10, 20 and 30 t ha^{-1}) and potassium fertilizer (0, 20, 40 and 60 kg K_2O ha^{-1}). A total of sixteen treatment combinations and three replications were used. The cow dung was incorporated into the soils of the experimental plots in a single application based on the treatment combinations, at two weeks before planting to allow decomposition while the potassium fertilizer was applied to the cocoyam stands according to treatment allocation at 3 weeks after planting (WAP) using band placement method. One cormel (1.5 cm) was planted per hole at a depth of 15 cm and at a spacing of 0.5 m x 1.0m resulting to about twenty-four plants per plot and a total of about 20,000 plants per hectare. All plots were kept weed free by manual weeding.

Five cocoyam plants were randomly selected from each of the net plots, tagged and then used for the determination of plant height (cm), number of leaves and leaf area index (LAI) at 1, 2 and 3 months after planting (MAP).

The leaf area was determined using the formula of Biradar et al. (1978) as:

Leaf Area of Cocoyam = 0.917 (LW).

Where L and W are length and width of the cocoyam leaf. The leaf area index was then calculated by dividing the total leaf area by the area occupied by the plant (Biradar et al., 1978). Number of suckers and number of corms were counted. Mean values of Leaf Area of Cocoyam = 0.917 (LW). Where L and W are length and width of the cocoyam leaf. The leaf area index was then calculated by dividing the total leaf area by the area occupied by the plant (Biradar et al., 1978).

Soil sample analysis

The analysis revealed that the cowdung used in this study is composed of 2.54, 1.34, 1.16, 1.56, 0.46 and 50.70%, N, P, K, Ca, Mg and organic matter, respectively in 2018 and 2.24, 1.67, 0.65, 2.80, 0.61 and 30.76%, N, P, K, Ca, Mg and organic matter, respectively in 2019.

LSD (0.05)	NS	NS	4.0	NS	2.5	4.3
C x K	NS	NS	NS	NS	NS	NS

NS = not significant.

In 2018 cropping season, differences in plant height due to application of cow dung were significant ($P< 0.05$) at 2 and 3 MAP (Table 1). All cases of cow dung application significantly increased plant height of cocoyam compared to the control at 2 MAP. However, at 3 MAP, incremental application of cow dung up to 20 t ha^{-1} significantly increased plant height. In 2019, cocoyam plant height increased with application of cow dung at 10 t ha^{-1}, above which significant reductions in height occurred at 1 and 2 MAP. At 3 MAP, plant height increased at the highest rate of 30 t ha^{-1} compared to the lower rate of 10 t ha^{-1} or no application in both seasons.

At 3 MAP in 2018 cropping season, application of potassium at 40 kg K_2O ha^{-1} increased significantly cocoyam plant height than no potassium application (Table 1). On the other hand, at 2 and 3 MAP in 2019, application of potassium at 20 kg K_2O ha^{-1} resulted in higher plant height than the control. All cases of applied potassium produced similar plant height values.

In both years, application of cow dung had no effect on LAI at 1 MAP but effect was more apparent at 2 and 3 MAP (Table 2). Application of cow dung at different rates resulted in significant ($P < 0.05$) increase in LAI relative to the control at 2 MAP in 2018 and at 2 and 3 MAP in 2018. LAI increased steadily with plant age. Application of potassium produced significant effects on cocoyam LAI at 3 MAP in 2019 (Table 2). Application of potassium at 20 or 40 kg K_2O ha^{-1} resulted in significantly ($P < 0.05$) higher LAI than no application while application of the higher rate of 60 kg K_2O ha^{-1} recorded higher LAI value than the lower rate of 20 kg K_2O ha^{-1}.

DISCUSSION

In general, application of cow dung resulted in increase in cocoyam plant height, the number of leaves produced per plant, LAI and number of suckers produced per cocoyam stand especially at 2 and 3 MAP. The higher growth following cow dung application would be attributed to the probable effects of the manure in improving soil physical, chemical and biological properties (Balemi, 2012; Khalid et al., 2014), which are important for crop performance.

The effects of cow dung on cocoyam appeared more pronounced later in crop growth at 2 MAP, due to the slow release of nutrients by the manure. This result is consistent with the findings of Miyasaka et al. (2001) who attributed the enhanced growth parameters and yield response of the crop to organic amendment to slow release of nutrients by the organic manures, which tied the crop over the long duration of its growth.

CONCLUSION

This study showed that both cowdung and potassium fertilizer improved growth parameters of cocoyam with cow dung having a better improvement than potassium fertilizer especially the application 30 t ha^{-1} cow dung.

24 - 28 Oct., 2022

ABSTRACT

Growth and yield performance of Bambara groundnut treated with brassinolide at different growth stages was evaluated in the early cropping season of 2015 at the University of Calabar Crop Teaching and Research Farm, Calabar (4.5 – 5.2^o N and 5.3^o E; about 39 meters above sea level) grown under screenhouse and field conditions in the Southern Cross River high rainforest zone of Nigeria. The treatments were application of brassinolide at the seedling, vegetative and flowering growth stages of Bambara groundnut corresponding to 3, 6 and 9 WAP, while the control plants were not sprayed. Results obtained indicated that plants treated at 3 WAP were significantly (P = 0.05) superior to plants in other treatments, irrespective of the environmental conditions though field plants were better than those in the screenhouse. At this growth stage, field plants were tallest (82.20 cm) with more leaves/plant (463) and highest LAI (0.680), whereas the screenhouse plants had longer petioles and wider canopy spread (68.9 cm) and attained flowering earlier in 48.10 DAP. Screenhouse plants produced few large seeds (10.8 mm) while field plants produced more (9.60) large (13.48 mm long) pods, high seed weight (11.36 g/plant), high dry matter (34.04 t /ha) and highest seed yield (1.92 t/ha). Spraying Bambara groundnut at 3 WAP was more favourable and is therefore recommended for increased productivity of the crop under field conditons in the humid environment.

INTRODUCTION

Bambara groundnut also known as Bambara nut (*Vigna subterranea* (L.) Verde; *syn Voandzeia mbtermnean* Thousars) is an annual crop and an important member of the family *Fabaceae*. The crop has different local names according to the tribes in the various areas of production and in Nigeria the crop is known among the Yoruba as 'Epa- Roro' while the Ibos call it 'Okpa' and the Hausas call it 'Kwaruru' or 'Gurjiya' (Bamshaiye *et al.*, 2011; Mabhaudhi *et al*. 2018). Bambara nut seeds are nutritious containing high amounts of protein (17 – 27 %), making it relevant to pro-poor households that can not afford the expensive animal proteins (Ndidi *et al.*,2014; Murevani-hema and Jideani, 2013).

Bambara nut has great socioeconomic impact and consumption in the semi-arid Africa where the crop is mostly grown as the third-ranking and most important grain legume crop after groundnut *(Arachis hypogaea*) and *cowpea Vigna unguiculata*) (Rowland, 1993). It is a strong and extremely adaptable plant that is well tolerated to marginal soils and hot dry climate where annual rainfall is below 500 mm and conditions are too dry for the successful cultivation of some crops like maize, groundnut and even sorghum (Rowland, 1993; Azam-Ali *et al*, 2001; Mabhaudhi *et al*., 2018). The crop also exhibits high tolerance to pests and diseases, and can be produced easily with minimal inputs, making it a suitable food security crop for the peasants in moisture-deficient areas (Ntundu *et al.,* 2006).

The cultivation of Bambara nut is being explored in the humid areas outside its traditional home in the Savannah environment due to increased demand as a food crop.

In the rainforest zone, research on foliar fertilizer application is not common due to heavy rainfall compared to the savanna areas. The effectiveness of foliar plant nutrients depends on optimum absorption of the nutrients which depends on the growth stage of the crop as well as the prevailing weather conditions during the period of application. The focus of this trial was therefore to determine the best crop growth stage to maximize the effectiveness of brassinolide, a foliar micronutrient complex under field or screenhouse conditions for optimal performance of Bambara nut in the humid agro-ecological environment.

MATERIALS AND METHODS

2.1 Experimental Site

Screen house and field experiments on bambara groundnut were conducted at the University of Calabar during the 2015 late cropping season (August - December). Calabar is located in the southeastern rainforest agro-ecological zone of Nigeria on Latitude 04° - 57'N and Longitude 08° - 19'E, 37 m above sea level. The area has a bimodal annual rainfall distribution that ranges from 3,000 mm to 3,500 mm with mean minimum and maximum temperatures of 27 °C and 35 °C, respectively and relative humidity of between 75 and 88 % (Effiong, 2011). The soil at the site was sandy with 73, 16 and 11 % sand, silt and clay respectively and ECEC 7.14 cmol/kg.

2.2 The Screenhouse Experiment

The screenhouse experiment was done using medium size plastic buckets with brim circumference of 96 cm wide, bottom circumference of 73cm and depth of 32 cm. The buckets were perforated at the bottom and filled with 6.5 kg top soil collected from the site of the field experiment, leaving about 5cm to the brim of the buckets.

The cream coloured Bambara groundnut landrace (Black eye) obtained from the Department of Crop Science, University of Agriculture, Makurdi Benue State, Nigeria was used for the experiment. This landrace consistently had a higher seed yield than other landraces in the previous trials in the area (Shiyam and Bello, 2012; Shiyam *et al*., 2016). Two seeds were sown in each bucket and thinned to one per bucket one week after emergence. The buckets were watered adequately with twenty liters of tap water and left overnight before planting the following day. A group of six buckets arranged in three rows of two buckets each constituted a unit plot in the screen house experiment and the middle row was used for sampling. Watering with twenty-five liters of water every seven days was carried out to prevent moisture stress since the experiment was not exposed to natural rainfall.

2.3 The Field Experiment

The field experiment which ran concurrently with the screenhouse was sited at the Crop Science Research Farm. The site had been under intensive cultivation for some years and the vegetation was a mixture of grasses and broad leaf weeds.

A total plot size measuring 14.0 m x 11.5 m (161 m^2) and was used for the field experiment. The vegetation was manually cleared with a machete and the debris packed. The land was then tilled manually using a spade after which three blocks were mapped out and four unit plots measuring 2 m x 3 m (6.0 m^2) within the blocks with alley ways of 1.0 m wide demarcated. There were twelve experimental plots in all.

Before ploughing, composite soil samples for pre-planting routine soil analysis were obtained from the experimental site by random soil sampling technique. Sampling was done using soil auger at 0 - 30 cm depth. Composite samples were also taken for post-harvest soil analysis. The composite samples were air-dried in the Soil Science Laboratory. The dried soil was crushed in a mortar using a pestle and sieved through a 2.5 mm mesh sieve to produce the final sample used to analyze for physico-chemical properties (Udo *et al.* 2009). All buckets and experimental plots were maintained weed-free throughout the duration of the experiment. Weeds were removed manually by hand-pulling in the buckets and by using hand-held hoes in the field.

2.4 Treatments and Experimental Design

There were four treatments comprising the control where brassinolide was not applied and spraying at different growth stages namely: spraying at the seedling, vegetative, and flowering stages which corresponded to 3, 6 and 9 weeks after sowing (WAS), respectively. Treatments were laid out in randomized complete block design replicated three times to give twelve experimental units.

2.5 Establishment of Experimental Plots

Clean healthy seeds were sown at 30 cm x 30 cm spacing, two seeds per hole and later thinned to one plant per stand one week after emergence, giving a population of 111,111 plants per hectare. Four tagged plants in the net plot at centre of each plot constituted the sample population.

2.6 Mixing and Application of Brassinolide

A solution of brassinolide micronutrient fertilizer containing Zinc, Manganese, Boron, Ferrum (Fe), Molybdenum and Copper was prepared and applied according to the manufacturer's specification. A spray solution was made by dissolving 12.5g of the nutrient in 10 litres of clean tap water. Spraying of both field and screenhouse plants was done between 8 am and 9 am each time using a knapsack sprayer. Spraying was done in such a way that sprayed plants were completely drenched.

2.7 Maintenance of Experimental Plots

The first weeding was carried out manually at 2 WAP and subsequently at two weeks intervals in the screenhouse and field.

3 Data collection and Analysis.

Data collection on growth performance was done at 15 WAP, while the yield parameters were assessed at harvest. Six plants in the net plot in each replicate were tagged and used for data collection. The data collected were analyzed using analysis of variance (ANOVA) procedures using the GenStat Package Version 8.1. Significant means were compared using the Least Significant Difference at 5% level of probability.

4 RESULTS AND DISCUSSION

The physico-chemical properties of the soil at the experimental site before planting and after harvesting are shown in Table 1. The soil at the site had high sand content with a sandy texture but the silt and clay fractions were low in both samples. The soil initially had low nutrient content which is characteristic of sandy soils.

However, total Nitrogen, organic matter, exchangeable k, Ca, and ECEC contents except available Phosphorus increased in the post-harvest soil sample, indicating favourable influence of legumes on soil fertility due to nitrogen formation and decomposition of litter fall.

Brassinolide significantly (P = 0) improved the vegetative growth parameters of Bambara groundnut at 15 WAP in the screenhouse and in the field presented. The best growth was obtained in plants sprayed at 3 WAP, followed by 6 WAP, and then 9 WAP while unsprayed plants were the least (Table 2). Wide canopy spread, long leaf petioles and early flowering were recorded in the screenhouse, while tall plants with more leaves and high leaf area index were observed in field plots. This shows clearly that early spraying of brassinolide is more advantageous for enhanced growth of Bambara groundnut whether grown in the screenhouse or in the field.

Table 3 shows that spraying Bambara plants at 3 WAP also had more favourable effect on the seed yield parameters than those sprayed at later growth stages. Large seeds were produced only in the screenhouse whereas field plants produced heavyweight seeds, high dry matter and high seed yield similar to the yield obtained by Shiyam *et* al., (2016) in the same environment.

The vegetative growth and seed yield variation at the different stages of application of brassinolode to Bambara groundnut showed that sprayed plants were superior in all parameters evaluated with the best plants being those sprayed early at 3 WAP. However, the effect of the plant growth hormone became progressively less effective as the growth stage increased. This is a strong indication that plant growth hormones are more effective when applied at early crop growth stages than when they become more mature. Applying brassinolide at 3 WAP was more effective and could be adopted to boost the productivity of field grown Bambara groundnut in the humid areas.

ABSTRACT

Field experiments were conducted in the 2018 and 2019 cropping seasons to assess the infestation and damage caused by adult flea beetles (*Podagrica uniforma* and *P. sjostedti* Jacoby) on four genotypes of *Abelmoschus caillei* (A. Chev.) Stevels, and to evaluate the efficacy of cypermethrin in controlling the pest. The set up was a split-plot design. The main plot factor consisted of sprayed and unsprayed portions, while the subplot factor was the four genotypes of *A. caillei* [NGB 01200, NGB 01204, NGB 01205, and MKD-local (check)], each replicated four times. Results showed that the insecticide reduced ($P < 0.0001$) infestation and damage by both beetles in all genotypes of *A. caillei* tested. Infestation and damage caused by beetles were higher ($P < 0.0001$) in the local variety (local) compared with other genotypes. There were no chemical application × genotype interaction effects for all the parameters evaluated. However, NGB 01205 had the lowest infestation, damage, and the highest yield values when compared with the other genotypes. We conclude that the use of NGB 01205 of *A. caillei* will minimize infestation/ damage by *Podagrica* spp. and maximize crop yield.
Keywords: *Podagrica*, okra, insecticide, field pest, pest management

INTRODUCTION

The West African okra, *Abelmoschus caillei* (A. Chev.) Stevels belongs to the family Malvaceae and is one of the most important and widely utilized crop species. The leaves, fruits, flowers, seeds, stem (fibre), and roots have been subjected to a wide variety of food, therapeutic, aesthetic, and industrial uses (Ekoja *et al*., 2022).

Production of okra in Africa is faced with several biotic and abiotic constraints. Insect pest infestation is one of the important biotic factors limiting okra production. The economic losses depend on pest density, degree of damage inflicted, environmental conditions, stages of growth, and the parts of the plant damaged by pests (Pitan and Ekoja, 2011). Some of the yield-reducing species reported in West Africa include but are not limited to the shoot and fruit borer (*Earia vitella* Fabricius), flea beetles (*Podagrica* spp.), whitefly (*Bemisia tabaci* Gennadius), leaf roller (*Sylepta derogata* Fab.), aphid (*Aphis gossypii* Glover), cotton stainer (*Dysdercus* spp.), green stink bug (*Nezara viridula* Linnaeus) etc (Obeng– Ofori and Sackey 2003, Pitan and Ekoja, 2011). Most damage to okra in Nigeria is inflicted by the flea beetles, *Podagrica uniforma* and *P. sjostedti* Jacoby. Their population could be greater than 90% of the total insects infesting okra at the vegetative growth stage. They are responsible for the characteristic buckshots (round feeding holes) on the leaves of okra (Odebiyi, 1980, Pitan and Ekoja, 2011) which is known to cause significant loss in crop yield (Obeng-Ofori and Sackey, 2003; Ekoja *et al*. 2012).

Quantitative information on infestation and damage caused by *Podagrica* spp. on different varieties of *A. caillei* is still scanty. Most studies conducted in the last decade focused on infestation and damage done to *A. esculentus* genotypes. The increasing demand for *A. caillei* in Africa makes it imperative to direct research on factors that could limit the production of this okra type. Such information will also help our understanding of the damage potentials of flea beetles as well as their economic status on *A. caillei*. Therefore, this study was carried out to assess the infestation and damage induced by adult *Podagrica* spp. on four varieties of *A. caillei*, and to assess the efficacy of cypermethrin in managing the pests in the field.

MATERIALS AND METHOD

Experimental site

The experiment was conducted at the Crop Production Unit of the Teaching and Research Farm of Federal University of Agriculture Makurdi (FUAM) during the rainy season (June – September) of 2018 and 2019 (coordinates: Latitude 7º45’03.4"N Longitude 8º37’43.6"E, elevation: 92 m above sea level, agroecology: Southern Guinea Savannah).

Source of planting materials

NGB 01200, NGB 01204, NGB 01205 genotypes were obtained from the National Centre for Genetic Resources and Biotechnology, Ibadan (NACGRAB), while the MKD-local was obtained from the Department of Crop and Environmental Protection, FUAM.

Experimental procedure

The design was a split-plot arrangement. The main plot factor consisted of sprayed and unsprayed plots while the sub-plot factors are the four genotypes of *A. caillei*. Field infestation by *P. uniforma* and *P. sjostedti* was natural in both seasons. The field was cleared and ridged manually. About 4 cm deep holes were made and three seeds were planted directly in each hole and later thinned to two plants per stand. Seeds were planted on the ridges at 40 cm between each stand and 60 cm between ridges. Cyperkill® (cypermethrin 20EC) at 1.0 ml/ L was applied as from 2 weeks after sowing (WAS). NPK 20:10:10 was applied at the recommended dose at 3 weeks after sowing (WAS). Weeding was done manually at 3, 7 and 10 WAS. Harvesting was also done manually at 4 days intervals. The number of *P. uniforma* and *P. sjostedti* per plant was counted at 9 WAS (n = 10 plants per plot). Other data collected were the number of damaged leaves per plant at 9 WAS, damaged leaf area (cm^2) per plant at 9 WAS, number of fruits per plant, number of damaged fruits per plant, and yield (t/ha).

Insect count (x) and data in percentages were transformed to log (x + 1) and arcsine values respectively before analysis of variance was conducted using the 9.2 version of SAS Institute (2009). Where *F*-statistics was significant, means were separated using Fisher's least significant difference at 5% level of probability. Pearson's correlation analysis between the flea beetle infestation, damage, and yield parameters was also carried out on data in both years.

RESULTS AND DISCUSSION

In both years, the use of cypermethrin reduced flea beetle infestation significantly ($P < 0.0001$) in all the varieties of *A. caillei* tested (Table 1). This was consistent with the report of Singh *et al*. (2015). The high infestation and damage observed and the resultant effect on yield further showed that the insects are major biotic constraint of okra production as reported in previous studies (Odebiyi, 1980; Pitan *et al*, 2007; Obeng Ofori and Sackey, 2003; Pitan and Ekoja, 2011; Ekoja *et al*. 2022). All the genotypes of *A. caillei* tested were susceptible to infestation and damage by both *P. uniforma* and *P. sjostedti*. In addition, the population of *P. uniforma* was higher than that of *P. sjostedti* all through the growing period in 2018 and 2019.

Flea beetle-induced damage was significantly higher ($P < 0.0001$) in the local variety than in other *A. caillei* genotypes (Table 2).

Table 2: Effect of cypermethrin and different varieties of *Abelmoschus caillei* (A. Chev.) Stevels on damage induced by adult *Podagrica* spp. and okra yield at Makurdi, Nigeria

Table 3: Pearson's correlation coefficients showing the association between the flea beetle infestation, damage and yield parameters evaluated

Infestation/ damage parameters	Flea beetles population		Fresh fruit yield (t/ha)	
	2018	**2019**	**2018**	**2019**
Flea beetle population	1.000	1.000	-0.867**	-0.848**
Percentage of damaged leaf	0.906**	0.874**	-0.879**	-0.870**
Damaged leaf area	0.966**	0.963**	-0.867**	-0.845**
Percent damaged fruits	0.952**	0.934**	-0.868**	-0.888**

** = $P < 0.0001$

Most phytophagous insects are known to discriminate among hosts as a result of differences in morphological features or chemical changes brought about by phagostimulants and other secondary metabolites (Pitan and Adewole, 2011).

The treated plots had higher ($P < 0.0001$) fruit yield than the untreated. Apparently, the continuous leaf feeding by the beetles caused significant defoliation and reduction in the photosynthetic capacity of the plants leading to a negative impact on fruit production. This is in consonance with the findings of Pitan and Ekoja (2011) and Ekoja *et al*. (2012) who reported significant impact of leaf feeding by the beetles on chlorophyll concentration and yield of okra. However, infestation and damage were significantly lower ($P < 0.0001$) in NGB 01205 and its yield was significantly higher compared with other varieties.

There were no chemical application × genotype interaction effects ($P > 0.05$) for all the infestation and damage parameters evaluated. Pearson's correlation results showed strong positive associations between flea beetle infestation and damage ($r > 0.870$; $n = 32$; $P < 0.0001$) while the correlations between yield and flea beetle infestation/ damage were negative ($r > -0.840$; $n = 32$; $P < 0.0001$) (Table 3)

CONCLUSION

The study showed that *P*. *uniforma* and *P*. *sjostedti* are important insect pests of *A. caillei* at Makurdi, Nigeria. However, the use of cypermethrin 20EC could reduce infestation and damage significantly in all the genotypes tested. Infestation and damage were lower in NGB 01205 variety and the yield from plots with the genotype was significantly higher compared with other genotypes. Therefore, the use of NGB 01205 genotype of *A. caillei* at Makurdi, Nigeria will minimize infestation/ damage by *Podagrica* spp. and maximize okra yield.

ABSTRACT

Computer seed digital imaging was utilized in this study to evaluate the differences in seed metric traits in thirty accessions of pigeon pea and the extent of associations among these traits. Hundred seeds in each of the pigeon pea accessions were subjected to digital imaging analysis using the inSEEDLE™ software to differentiate the seed metric characters. For every replication, hundred seeds were placed on lighting hood in such a way that embryo axis of seed faces image analysis system and longitudinal axis running parallel to the surface of the scanner. Seeds were automatically analyzed by the scanner and the image of the seed recorded by the 'WinSEEDLE™'. The procedure was repeated three times. The parameters observed were total projected area, average projected area, projected area, straight length, curve length, straight width, curve width, volume circle, surface area circle and projected perimeter. Data collected were subjected to ANOVA,principal component analysis and Pearson's correlation analysis. Accessions NSWCC-34 and NSWCC-32 showed superiority in most of the seed metric traits. Most of the trait examined showed positive and significant relationship among one another. The principal components result indicated that seed projected area, seed straight length, curve length, straight width, curve width, volume circle and surface area circle were traits that contributed highly to the variation within the pigeon pea accessions examined. The two identified superior genotypes as well as those traits with high contribution to the major variation could be included in the seed improvement programme for improved seed quality in pigeon pea.

INTRODUCTION

Pigeon pea {*Cajanus cajan*) is a perennial legume from the family Fabaceae. It has been domesticated in South Asia at least about 3,500 years ago and since then its seeds have become a common food grain in Asia, Africa, and Latin America (Singh and Singh., 2016). Pigeon peas are now widely cultivated in all tropical and semi-tropical regions of the world. It can be perennial in nature, in which the crop can last three to five years or an annual variety more suitable for seed production (Gyulai *et al*.,2015).The different seed metric measurements on seed are very essential quantitative variables for determining size and shape of seeds (Arapa and pardon.,2014). Seeds size and shape are major determinants of seed dispersal and probable loss (Gyulai et al.,2015), moisture imbibition and germination of seeds and grain grading quality. In addition, demand for seed grains for human consumption could have relationship with size and shape of seeds. However, the use of morphometric characteristics of seed may provide a useful management strategy for increasing establishment count in pigeon pea, thereby leading to higher yield.

Image analysis has become a very important laboratory tool for cultivar description for a long time. Smith *et* al (Mandel., 2012) has reported micro computerized video image analysis as an effective research tool for the study of genetic expression in *Zinnia elegans.* Apart from the use of image analysis for genetic comparison, it has been used in various ways to determine seedquality. Shende and Rant (2013) used image analysis system to study the process of imbibitions in white cabbage *(Brassica oleracea*L.) seeds. Also, Nune and Escobedo., (2015) described computer image analysis as a very promising technique to determine mechanical damage in seeds because the method is precise and examines seeds individually using enlarged images in which damaged areas as well as their exact location and extension can be found and examined in detail. Since this test is a nondestructive method, analyzed seeds can be submitted to other physiological tests to establish the relationship between the result of the image analysis and other physiological tests. The study was initiated to evaluate differences in computer determined seed physical (metric) characteristics in some pigeon pea accessions and extent of associations among these traits.

MATERIALS AND METHODS

This experiment was conducted at the laboratory of the Department of Plant Breeding and Seed Technology, Federal University of Agriculture, Abeokuta, Nigeria. Seeds of 30 accessions of pigeon pea obtained from International Institute of Tropical Agriculture, (IITA), Ibadan and Institute of Agricultural Research and Training (IAR&T), Ibadan were used for the study.
An EPSON scanner was connected to a computer device to acquire image and the Regent Instrument (Regent Instrument Inc, Canada) was used for the image analysis by running the custom written software WinSEEDLE^{TM} (Pro Version). For every replication, hundred seeds was placed on lighting hood in such a way that embryo axis of seed faces image analysis system and longitudinal axis running parallel to the surface of the scanner. Seeds were automatically analyzed by the scanner and the image of the seed recorded by the 'WinSEEDLE™'. The procedure was repeated three times.

The parameters that were recorded include: total projected area, average projected area, projected area, straight length, curve length, straight width, curve width, volume circle, surface area circle and projected perimeter.

DATA ANALYSIS

The data collected were subjected to Statistical Analysis System (SAS™, 2017) procedures for Analysis of Variance (ANOVA), Principal component analysis (PC A) and Pearson's correlation analysis.

RESULTS

The accessions differed significantly with respect to total project area, project area, straight length, curve length, straight width, volume circle, surface area circle, width length and projected perimeter (Table 1).

Table 1: Mean square values of morphometric traits evaluated in pigeon pea genotypes

Character	Replicates	Genotype effect	Error
Total projected area	3288892-6.81	1158534.87**	358064.16

Significant at 1% probability level * Significant at 5% probability level ns Not significant

Table 2 shows the mean values for the morphometric performance of thirty pigeon pea genotypes. In terms of total project area, Tcc 8127 had the highest mean value of 4243.65mm^2 which differed significantly from all the other genotypes while genotype Tcc811 recorded the least performance. For project trait, all the genotypes had statistically similar values except Tcc 8127 which had the least mean valve of 3677.75mm. In terms of project area, genotype NSWCC-34C and NSWCC32 recorded the highest menmean values of 28.74 and 28.35mm^2 , respectively.

Mean value of straight length was highest in Tcc 8127 but TCc 6 recorded the least value (4.65mm). Also, Tcc8127 recorded the highest value of curve length (11.69mm) while genotype TCc-6 recorded the least value (4.65mm). For straight width trait, NSWCC32, NSWCC-19 AND NSWCC-34 showed values of between 5.10 and 5.23mm while Tcc6 had lowest value of 3.07mm. Projected perimeter of ICPL87 seed recorded the highest value (33.77m) while TCc-6 had the least value.

Table 3: Correlation coefficient among seed morphometric characters in pigeon pea.

	B	C	D	E	F	G	H	I
Total projected	-0.51**	0.03	0.93**	0.91**	-0.05	-0.07	-0.01	-0.05

Seed Curve							0.85**	0.23*
Volume circle(H)								0.08

Correlation significant at 1% level * correlation significant at 5% level

Total project area recorded a positive and highly significant correlation with straight length (r=0.93) and curve length (r=0.91) (Table 3). However, seed projected area had a highly significant and positive correlation with straight length (r=0.33),curve length (r=0.28),straight width (r=0.91), volume circle (r=0.91), and projected perimeter (r=0.27). Similarly, the straight length of the seed had a highly significant and positive correlation with curve length (r=0.98) but also had significant and positive correlation with the curve width(r=0.22). Curve length on the other hand, had a f highly significant and positive correlation with •i the seed projected perimeter (r=0.27), seed straight width (r=0.87), volume circle (r=0.78). Also, seed curve width had a positive and highly significant correlation with seed volume circle (r=0.85), but had a positive and significant correlation with projected perimeter (r=0.23).

DISCUSSION

The result showed variability among the thirty genotypes for all the metric characters except volume circle, surface area, thereby providing performance opportunity for selecting pigeon pea accessions with superior seed physical traits. Wendel and Grover.,(2015) in cotton, Kehinde (2016),Gotmare*et al.,2018* in cotton, all reported genetic diversity in some seed morphometric traits in using seed digital imaging analysis.The principal components result indicated that seed projected area, seed straight length, curve length, straight width, curve width, volume circle and surface area circle were traits that contributed significantly to the variation within the pigeon pea accessions examined. These traits with high contribution to the major variation could be included in the seed improvement programme for improved seed quality in pigeon pea.

The study showed strong and positive associations among mapping of seed morphometric characters, implying that selection for one morphometric character will lead to improvement in the others. Conversely, there was negative association between seed projected and characters such as seed curve length and seed straight length, suggesting that increase in one character will lead to decrease in other characters and the relationship is therefore worthless in seed improvement if the relationship could bring a desirable improvement. Earlier study by Lee and Frang., (2015), Sangseok, (2018), Zavinon*et al.*,2018 observed positive and strong association among some morphometric characters in kenaf after seed digital images analysis.

ABSTRACT
A field study was conducted in Ishiagu during the 2021 rainy season to determine the silvicultural response of oil palm to effective micro-organisms (EM) and different sources of organic media. The experimental design was a Complete Randomize Design (CRD) with the treatments replicated four times. The four (4) treatments with their specified rates were: T_1 = Fermented Effective Micro-organism at 10 t/ha, T_2 = Poultry Manure at 10 t/ha, T_3 = Gmelina pruning at 10 t/ha and T_4 = Control (No treatment). The following silvicultural (growth) parameters was taken: plant height (cm) per plant, number of leaves per plant and plant girth. Data collected was subjected to statistical analysis using analysis of variance (ANOVA) and treatment means was separated and compared using Fisher's least significant difference (F-LSD) at 5% probability level. The results indicated that there were significant differences between the treatments in relation to the silvicultural parameters measured. In all, the treatment with effective micro-organism (EM) {T1} performed better than other treatments. This was followed by the treatment with poultry manure (T2). Treatment with {T3} (Gmelina mulch) ranked third while the control was the least (T4) in all the parameters measured. Given the results from this study, the application of effective microorganisms in crop production is highly recommended to farmers, followed by poultry manure and *Gmelina arborea* mulch in that order.

Keywords: *Silvicultural response, effective micro-organisms (EM), fermented plant extract, organic media*

INTRODUCTION
The consumers outcry over the residual effect of the utilization of synthetic agro-chemicals in agriculture and forestry production on the health of human being and the agroecosystems has elicited research into alternative, eco-friendly and sustainable agro-inputs (Balogun, Ogbu, Umeokechukwu and Kalejaiye-Matti, 2016)). In an effort to salvage the situation, several technologies are being researched upon focusing among others on the development of short duration and high yielding varieties of crops that are more resistant to pests and diseases; organic manure trials on soil,

agroforestry approaches *et cetera*. These technologies have been certified to markedly improve soil productivity and suppress pest. Other less unexploited alternative is the use of effective micro-organisms (EM). Such amendments has been reported to significantly increase the numbers of beneficial microorganisms in the soil thereby improving the overall health status of the agroecosystem. This is where the use of effective micro-organisms (EM) on trials in crop production comes handy.

Effective Microorganisms (EM) consist of mixed cultures of beneficial and naturally occurring microorganisms (cultured from matured forest) that can be applied as inoculants to increase the microbial diversity of soil, plant, livestock and the ecosystems for sustainable performance. Though, EM is not a substitute for other management practices; but it basically act as a catalyst in agriculture/forestry and environment equilibrium. It consists of these symbiotically existing micro-organisms either in dried or liquid form as against the use of monocultures (Balogun *et al.*, 2016): The beneficial micro-organisms include: Lactic acid bacteria: *Lactobacillus plantarum; L. casei; Streptococcus Lactis*. Photosynthetic bacteria: *Rhodopseudomonas palustris; Rhodobacter sphaeroides*. Yeast: *Saccharomyces cerevisiae; Candida utilis*. Usually known as *Torula, Pichia Jadinii*). Actinomycetes: *Streptomyces albus; S. griseus*. Fermenting fungi: *Aspergillus oryzae; Mucor hiemalis*.

MATERIALS AND METHODS

Location Description

The experiment was conducted at the research and teaching farm of Federal College of Agriculture, Ishiagu, during the 2018 cropping season. The study area, Ishiagu lies within at longitude 07^0 41^1E and latitude 05^0 56^1N in the derived savanna zone of South Eastern, Nigeria. The area has a mean annual temperature of about 30 ^{0}C and rainfall of 1350 mm (Nwite, Igwe and Wakatsuki, 2008).

Experimental Design and Treatment

The experimental design was Complete Randomized Design (CRD) with the treatments replicated four times. The four (4) treatments with their specified rates includes: T_1 = Fermented Effective Micro-organism at 10 t/ha, T_2 = Poultry Manure at 10 t/ha, T_3 = Gmelina pruning at 10 t/ha and T_4 = Control. The test crop used was sprouted palm seedlings which was obtained from National Oil Palm Research Institute, Benin; Edo State. After pre-nursery germination (about 3 inches in height with 2 leaves). The nursery section of the experiment commenced at FCA, Ishiagu research farm.

Agronomic Practices

The experimental site was cleared, stumped, marked and the potted oil palm seedlings were arranged into plots. Each plot consisted of 6 potted oil palm seedlings with a total of 16 plots. Each plot was represented as the net plot. The different soil amendment materials as treatments was applied to each specified plot with the exception of the control plot. The treatments was incorporated into the potted polybags and left for one week to decompose before planting.

Palm seeds was planted directly into the potted polybags at a depth of about 2cm. Weeding operations was carried out manually and hand pulling after planting. More weeding operations continued at intervals of two weeks for proper maintenance of the crop till the termination of the project work at 16 weeks after planting. Plants were randomly selected and tagged on which the following silvicultural (growth) parameters will be taken: (i) Plant Height (cm) per plant: This was determined by measuring the height of the main plant with ruler from the base to the tip of the plant at 2 weekly interval; (ii) Number of leaves per plant: The total number of leaves per plant was determined by counting at 2 weeks interval; (iii) Plant girth: The plant girth is measured using caliper at 2 weeks interval. The data was subjected to statistical analysis using analysis of variance (ANOVA) according to the procedure for complete randomized design (CRD). The treatment means was separated and compared using Fisher's least significant difference (F-LSD) at 5% probability level.

RESULTS AND DISCUSSION

Plant Height of oil Palm seedlings

Table 1 showed the Mean plant height at 2, 4, 6, 8, 10, 12, 14, 16 and 18 weeks after planting. The result of the table above, revealed that T_1 (EM) recorded the highest mean plant height at weeks 2 till 18 after planting with the following figure: 24.13, 24.82, 25.51, 25.72, 26.06, 26.20, 26.50, 27.42 and 27.62 respectively. This was followed by T_2 (poultry manure) with mean plant height of 23.16, 23.56, 23.70, 24.81, 25.04, 25.15, 25.58, 25.78 and 25.98 respectively. Equally, T_3 (*Gmelina mulch*) followed with these values: 22.84, 22.99, 23.56, 23.86, 23.97, 24.67, 24.91, 24.98 and 25.17. The control recorded the least mean plant height as indicated on the table. The results LSD showed that there were significance differences ($P < 0.05$) among the treatments. The results of this study conforms to similar studies by Balogun *et al.*, (2016), Zhang, Han, Li, Liu, Gao, Hou, and Chang, (2005), Khaliq, Abbasi, and Hussain, (2006), Daiss, Lobo, and Gonzalez, (2008) where they recorded increased plant heights in their studies.

Table 1: Mean Plant Height of oil Palm seedlings

	Weeks After Planting

Number of Leaves of oil Palm seedlings

Table 2 above showed the Mean number of leaves at 2, 4, 6, 8, 10, 12, 14, 16 and 18 weeks after planting. From the results of the table above, it was revealed that T_1 (EM) recorded the highest mean number of leaves at weeks 4, 6, 8, 10, 12, 14, 16 and 18 after planting with mean number of leaves of 5.04, 5.06, 5.50, 6.26, 6.38, 6.75, 7.88, 8.81 and 9.94. Treatment 2 (poultry manure) followed with the following values: 4.38, 4.56, 4.96, 5.13, 5.44, 6.06, 7.06, 8.00 and 9.00. Treatment 3 (gmelina mulch) followed with the following values: 4.06, 4.20, 4.36, 4.49, 5.06, 5.13, 5.43, 6.08 and 6.88. The control (T4) had the least values and performance. The LSD results also showed that there were significance differences ($P < 0.05$) among the treatments. The results of this study conforms to similar studies by

Silvicultural response, effective micro-organisms (EM), fermented plant extract, organic media

Balogun *et al.*, (2016), Zhang *et al.*, (2005), Khaliq *et al.*, (2006), Daiss *et al.*, (2008) where they recorded increased number of leaves in their studies.

Table 2: Mean Number of Leaves of oil Palm seedlings

Girth of oil palm seedlings

Table 3 above showed the Mean plant girth at 8, 10, 12, 14, 16, 18 and 20 weeks after planting. From the results of the analysis, it was revealed that T_1 (EM) recorded the highest mean plant girth across the weeks with the following values: 3.29, 3.86, 4.45, 4.87, 5.20, 5.70 and 6.20. This was followed by T_2 (poultry manure) with mean plant girth of 2.93, 3.46, 4.13, 4.27 and 5.03, 5.44 and 5.96.

Furthermore, T_3 (Gmelina mulch) recorded the mean plant girth with the following values: 2.60, 3.01, 3.70, 4.12, 4.49, 5.03 and 5.55. The control recorded the least values across the weeks of study. The LSD results showed significance differences ($P < 0.05$) among the treatments. The results of this study conform to similar studies by Balogun *et al*., (2016), Zhang *et al*., (2005), Khaliq *et al*., (2006), Daiss *et al*., (2008) where they recorded enhanced girth of plant in their studies.

CONCLUSION AND RECOMMENDATIONS

The study entitled "silvicultural response of oil palm (*Elais guineensis*) seedlings to effective micro-organisms (EM) and other organic media was investigated in Ishiagu during the 2021 rainfed cropping season. The results indicated that there were significant differences between the treatments in relation to the silvicultural parameters measured. In all, the treatment with effective micro-organism (EM) {T1} performed better than other treatments. This was followed by the treatment with poultry manure (T2). Treatment with {T3} (Gmelina mulch) ranked third while the control was the least (T4) in all the parameters measured. Given the results from this study, the application of effective microorganisms in crop production is highly recommended to farmers, followed by poultry manure and *Gmelina arborea* mulch in that order.

ABSTRACT

Eight cassava roots varieties were processed into *gari* (six white fleshed and two yellow fleshed roots). Wet residue fibre obtained during the sieving operation of dewatered mesh cake, were dried and milled into flour. Percentage yield of each *gari* and residue fibre flour samples were determined. Significant differences ($p<0.05$) were observed in all the cassava roots varieties investigated. Cassava root variety TME 419 recorded the highest percentage yield (28.129%) in *gari* having no significant difference ($p>0.05$) with NR 87184 (27.7345%), while the lowest was obtained in Umucass 45 (14.845%). NR 01/0004 (7.470%) was the highest in residue fibre flour yield and Umucass 44 (2.529%) the least

Keywords: Cassava variety, *gari*, residue fibre, flour.

INTRODUCTION

Cassava has to be processed in various ways to reduce its cyanide content to safe levels for human consumption. One of the traditional forms the root is processed is a granular starchy product called *gari*.. The dewatered cassava mesh cake is sieved to remove large fibres and roasted in large shallow open pots to get *gari*. Cassava roots processed into several traditional methods, varies from region to region. These products include cassava, chips, *gari*, lafun and foo-foo (Kayode, 2015). *Gari* is a fermented cassava product (Sandra, 2010) and is of the major products obtained from cassava in the West Africa sub region (Onabolu, *et. al.*, 2002 ,Oduro, *et. al.*, 2000). *Gari* is a partially gelatinized (Sanni, *et. al.*, 2008), free-flowing granular flour with a slightly fermented flavor and sour taste (Olanrewaju,2017, Oti et al 2010, Nwabueze, and Anoruoh, 2009). In West Africa, it is the most consumed and traded of all food products made from cassava roots. Cassava varieties influences the physical, chemical and sensory qualities of *gari* (James*et. al.*, 2012). Cassava already provides livelihoods of more than 5 million farmers and processors (often poor rural women) in Nigeria (Oti, *et. al.*, 2010), as well as to numerous equipment manufacturers, wholesale, retail traders, and transporters. In addition, small-scale *gari* processing has gradually become the main source of non-farm rural employment in many countries (Onyenwoke and Simonyan,2014). Residue fibre incurred from the processing of cassava roots into *gari* and starch often lead to reduction in *gari* and starch yield, thereby leading to high cost of these products. Therefore it is imperative to investigate the residue fibre flour, comparing it with *gari* produced to ascertain if it is varietal dependent. Hence this study was aimed at comparing the varietal effect on *gari* and residue fibre flour from selected cassava root varieties in South East Nigeria.

MATERIALS AND METHODS

Cassava roots (TME 419, TMS 30572, NR 01/0004, TMS 950505, NR 87184, Nwageri, Umucass 44 and Umucass 45) were peeled, washed and grated, the resulting mash was put in a porous sack and allowed to ferment for 3-5 days under atmospheric temperature. the mash was dewatered with screw press. After fermentation, dewatered mesh cake was pulverized, sifted and roasted in iron pan to obtain *gari* (Agunbiade and Adanlawo, 2007). Each wet solid residues obtained from the cassava *gari* processing was weighed and dried in an electrothermal oven (model; DHG) at temperature 60 degree celsius, then weighed again before milling using Thomas Willey mill and Binatone blender model BLG-401.*Gari a*nd residue fibre flour samples were each weighed respectively. Flow chart of the processing of cassava roots into *gari* and residue fibre flour is shown in figure 1.

Percentage yield of cassava *gari*.

Percentage yield of the *gari* produced from each of the cassava varieties roots were determined as described by Oluwole *et al.,* (2004) and Karim *et al*(2009). *Gari* produced were each weighed on a weighing balance respectively. The weight of *gari* obtained was divided by the weight of the cassava variety root before peeling and multiplied by hundred (100).

$$\% \text{ yield of } gari = \frac{\text{Weight of gari sample}}{\text{Weight of cassava roots sample}} \times 100$$

Percentage yield of residue fibre flour.

This was determined using the same method described above. Residue fibre flour obtained was weighed on a weighing balance. The weight obtained was divided with the weight of the cassava variety root before peeling and multiplied by hundred (100) to get the percentage yield of the residue fibre flour

RESULT AND DISCUSSION

The trend in the processing of the harvested cassava root into *gari* in Table 1 showed significant (p<0.05) differences in the results recorded. Residue fibre can be obtained from all the cassava root varieties investigated and processed into flour. However, from the result recorded, there were variations in the percentage yield of both the *gari* and the residue flour, showing varietal dependent. Percentage *gari* yield were from 14.845 % (Umucass 45) to 28.129% (TME 419). Residue fibre flour was from 2.803% (Umucass 45) to 8.312% (NR01/0004). Umucass 44 that had the lowest residue fibre flour of 2.803% should have been the highest in *gari* yield; however it was not the case. Umucass 44 had 18.332% yields as compare to the highest yielded 28.129% (TME 419). This was also the case in Umucass 45 that had the least g*ari* yield (14.845%), also 4.003% residue fibre flour compare to the highest value 8.312% (NR01/0004). Therefore in selecting cassava root for production of *gari* and to obtain its residue flour from the sieving operation of the dried cassava root mesh cake, the variety of the cassava root need to be considered. Baafi and Safo-Kantanka (2007) in their work on the effect of genotype, age and location on cassava starch yield and quality, observed varietal effect on the yield of the cassava starch studied. This residue fibre flour had been used to produce *fufu* and fibre rich cake in Nigeria (Ohuoba *et. al.*, 2019a& b).

CONCLUSION

Residue fibre flour obtained during the sieving operation of dewatered mesh cake in the processing of cassava root into *gari* varies with variety. Results obtained in this study could be a benchmark for the breeder and processor of cassava. In addition these findings had shown the trend in one of the post harvest waste incurred in the processing of cassava roots and the possibility of processing it into flour. This could aid in cassava waste management that is geared towards reduction in post harvest waste and increase food security in Nigeria.

ABSTRACT

The use of alternative pesticides in crop production reduces environmental pollution and solves pest resistance problems to improve biodiversity. Crop production practices that ensure environmental conservation, economic viability and social acceptability will result in sustainable agriculture. Bio-pesticides have shown to substitute synthetic pesticides with a possible increase in crop productivity. In order to achieve an optimum increase in crops' productivity, bio-pesticides are used in an integrated pest management (IPM) scheme, which goes in line with the aims to achieve minimal use of chemical pesticides at the lowest cost. To improve agricultural sustainability and create environmental pollution free which bring about food security to a nation regarding the application of bio-pesticides, extension of knowledge and skill based on the use of bio-pesticides by the farmers, low cost availability of bio-pesticides and farmers adoption should be the primary task to be dealt with. In view of the above, this paper used analytical approach to reviewthe following: the concept of bio-pesticides,bio-pesticides and their Characteristics,why bio-pesticides are advantageous in agriculture,challenges in the use of conventional pesticides andbio-pesticide and its sustainability in agriculture To maintain agricultural sustainability and environmental pollution free which bring about food security to a nation regarding the application of bio-pesticides, extension of knowledge and skill based on the use of bio-pesticides by the farmers, low cost availability of bio-pesticides and farmers adoption should be the primary task to be dealt with. Governmental organization and private agencies have to make a joint effort cooperate towards manufacturing and sale of bio-pesticides.

.**Keywords: bio-pesticides, key Measures, agriculture,sustainabilities**

INTRODUCTION

Increasing food production is the primary objective of all the countries, as the global population is expected to reach 10 billion by 2050. To feed the ever-growing global population, we need to produce more food from less per capita arable land and available water. Providing enough foods is only the first part of the challenge, and the most important challenge is to produce them in a safe and sustainable manner (kuma,2015). Since most of the cultivated crops have reached their yield potentials, protection of crops to harvest maximum and store them safe are important to meet the increasing food demands as to attain global food security. A large number of pests damage agricultural crops and a significant portion of agricultural inputs is required to protect the crops from them.

Pesticides have been extensively used in the intensive agriculture to reduce yield losses and maintain the product quality. The extensive use of synthetic pesticides has certainly provided protection to the crops; it has also raised concerns about pesticide residues in the food and the environment (Kumar,2013). Chemical pesticides adversely affect beneficial organisms; leave harmful residues in food, feed and fodder, and causes environmental pollutions. More so, human exposure to pesticides occurs primarily through application of pesticide on the crops, contaminated food, feed and drinking water. Their adverse effects depend on toxicity of pesticides, method of application, the dosage applied, their adsorption on soil colloids, the weather conditions prevailing after their application, and how long the pesticides persist in the environment.

The current pest management strategy centres heavily on chemical pesticides which cause adverse effects even on beneficial organisms, leave pesticide residues in food, feed and fodder, and increase environmental pollutions.Intensive agriculture has provided sufficient food grain production so far but it has several environmental consequences. Due to the problems of resistance development in pests and withdrawal of some products for either regulatory or commercial reasons, only a fewer chemical pesticides are available in the market(kumar,2015; Geraldin,Lengai and Muthomi,2018). Out of the 215 pesticides registered for use in India, 39 have been banned for use or withdrawn from the market and this occationed by the adverse effects characterized those chemicals (Geraldin,Lengai and Muthomi,2018).There are rising concerns for the loss of biodiversity and endangered species,and this brings about the requirement to increase agricultural production without excessive reliance on chemical pesticides.

Development of bio-pesticides has largely followed a chemical pesticide model that does not exploit fully the favorable biological properties of the biological agents. While there is commercial pressure from the manufacturing side to develop products, based on a single strain that are broad spectrum in order to control a range of pests on different crops and may not be endemic to the areas of application.Environmentalists prefer narrow spectrum products based on the strains from the area of use. To reconcile these divergent demands, bio-pesticides in the market have been maintained at minimal negative impact, if any, on the environment. This increased public concerns about the potential adverse environmental effects associated with the use of synthetic pesticides which prompted search for the products based on natural resources.

Bio-pesticides are made from naturally occurring substances that controls pests by non-toxic mechanisms and in eco-friendly manner. They are materials with pesticidal properties that originate from natural living organisms, including microorganisms, plants, and animals.

Bio-pesticides may be derived from animals (e.g. nematodes), plants (Chrysanthemum, Azadirachta) and microorganisms (e.g. Bacillus thuringiensis, Trichoderma, Nucleopolyhedrosis virus), and include living organisms (natural enemies), their products (phytochemicals, microbial products) or byproducts (semiochemicals)(kumar,2015;Udemezue *et al*,2021). Bio-pesticides are anything that kills a pest and is biological in origin as opposed to being synthetic chemical. In the potato industry, the best known biopesticide is referred to as Bt, Bacillus thuringiensis. This is an example of a microbial biopesticide. B. thuringiensis is a soil bacterium, toxic to many insect larvae. There are several Bt-products registered on potatoes for foliar applications such as DiPel, Du-Ter and Javelin. Insect-killing genes of B. thuringiensis have also been introduced into the genome of several crops including potato, for example the New Leaf clones of several cultivars. As such, Bt has shown to be most effective. There are also biochemical biopesticides that are structurally related to natural substances and function identically to them. Their actions are non-toxic, so in a literal sense they are not pesticides. Examples are pheromones used to attract (trick) insects into thinking that they are with a mate thereby confusing their mating cycle or to attract them into traps. Bio-pesticides pose less threat to the environment and human health. They are generally less toxic than chemical pesticides, oien targetspecific, have little or no residual effects and have acceptability for use in organic farming. Bio-pesticides generally fall into three major categories: (i) microbial, (ii) biochemical, and (iii) plant-incorporated protectants (PIPs).Their use is best as part of an Integrated Management Program (IPM). They are natural pesticide choice, natural microbial and biochemical pesticides type commonly used by farmers and growers to control an existing pest problem, because they can be applied like synthetic pesticides but without the toxic damage (Soil Technologies Corp, 2021).In view of the above, the broad objective of the study was to review bio-pesticides: a path way for agricultural sustainability in developing worlds. The specific objectives were to review:bio-pesticides and their characteristics, why bio-pesticides are advantageous in agriculture, challenges in the use of conventional pesticides and bio-pesticide and its sustainability in agriculture

Bio-pesticides and their Characteristics

According to SoilTechnologiesCorp(2021),biopesticides are classified into major types:

Microbial pesticides: These biopesticides are produced by microorganisms, including bacteria, viruses, and certain fungi. Each type of micro,bial pesticide targets a specific species or small group of species. It is common that microbial pesticides control a large variety of pests.

Biochemical/herbal pesticides: These are substances naturally occurring in the environment that control pests. This could include plant extracts that lure and trap insects or insect pheromones that interfere with mating. It may include botanical extractions that are active against plant disease pathogens and other pests.

Plant-Incorporated Protectants (PIPs): These pesticides are produced from plants as a result of another genetically incorporated material added to that plant (aka GM crops). While this application of pesticides originates from natural material, it also interferes with the natural biochemistry of the target organism and is thus widely contested.

Generally, all bio-pesticides exhibit the following characteristics (CROPWATCH,2021):

- Highly specific mode of action
- Suppress pests, not eliminate
- Critical timing of application
- Limited field persistence
- Short residual effect
- Safer to environment
- Safer to people

Why bio-pesticides are advantageous in agriculture?

Bio-pesticides have simply been known and understood by many scholars. This implies that plants are well familiar with and responsive to bio-pesticides, without major adverse side effects. Also, natural microbial and biochemical materials are common to our global ecology and are easily processed in our ecology with minimal probability of environmental imbalance. There is the significant difference from synthetic pesticides. Plants and other living organisms are not accustomed or responsive to synthetic molecules, and this unfamiliarity results in rejection or negative reaction and side effects. The plants lack the capacity to store these synthetic chemicals, so its cells can become cancerous, growing abnormally and causing mistakes in normal biological function (CROPWATCH,2021).Bio-pesticides show a number of other advantages over synthetic pesticides, including:

- **Biodegradable and Can be more effective in the long-term**:Effective in small quantities and quickly decompose, avoiding pollution, which is a major problem with synthetic pesticides

- .**Can be less expensive:**Affect only targeted pests, unlike broad spectrum synthetic pesticides that can take effect on other unintended insects, birds, and mammals, including humans

- **Have a host of natural compounds** which may be active against disease and pest, thus minimizing the capacity of pathogenic and invasive organisms to adapt to the molecules, thus rendering them ineffective.

- Bio-pesticides prove to be a predictable and less toxic form of pest control compared to the less predictable and more toxic conventional synthetic pesticides.

Challenges in the Use of Conventional Pesticides

There are harmful effects associated with the use of synthetic pesticides such as toxicity and poisoning(Damalasand Koutroubas,2015).Synthetic pesticides application also lead to environmental pollution due to the un-biodegradable nature of their constituent compounds(Kekuda, Akarsh,Nawaz, Ranjitha,Darshini,and Vidya, 2016) . According to geraldin,lengai and muthomi(2018) , degradation of metham sodium and other fumigant residues were reported to persist up to over six months after application , metham sodium pollutes the air and soil thereby affecting the population of natural enemies in the soil. Methyl bromide has been banned from agricultural use due to its negative impact on the environment. It is associated with depletion of ozone layer which contributes significantly to climate change(Geraldin,Lengai and Muthomi,2018) . The constituent compounds of chemical pesticides contaminate soils rendering them unsuitable for crop production(Kumari, Kumar and Rao, 2014) . They also pollute surface and ground water, killing aqua life after inhalation and consumption(Maksymiv, I2015) . Use of dichloro diphenyl trichloroethane (DDT) for instance led to poisoning of birds, marine species and humans. It has been reported to have carcinogenic properties leading to its ban from agricultural use(Harada, Takeda, Kojima and Tomiyama,2016) .

In a study by Xavier, Chandran, Naseema, Mathew, George,Vijayasree, Pratheeshkumar, and Kumar,2016), application of Fenpyroximate on chilli peppers (Capsicum annum L) resulted in retention of its residues even after sun drying and processing. Similarly, spinosad (spinosyn A and spinosyn D), Indoxacarb and Deltamethrin containing insecticides used to control Rhizoctonia dominica, Sitophilus oryzae and Trogoderma granarium were found to be persistent for up to 120 days after application(Pandey, Gill and Mandal,2016). Continuous use of synthetic pesticides leads to development of resistant plant pathogen strains leading to their resurgence. Farmers apply more chemicals in an effort to eradicate such pests(Halimatunsadiah, Norida,Omar and Kamarulzaman,2016).In the process of managing target pests, synthetic pesticides kill non-target beneficial organisms such as pollinators, predators and antagonists thereby disrupting biodiversity(Ndakidemi,Mtei, and Ndakidemi,2016) .After application, the active compounds of the synthetic pesticides are taken up and retained by crops. Consumption of such crops poses chronic health problems to humans due to the accumulated toxic chemical residues(Jantasorn,Moungsrimuangdee and Dethoup,2016) . Exposing pesticidesto the human population, adversely affects populations and environment. For example, pesticides containing Malathion and Trichlorfon have been reported to cause reproductive complications in humans (Ghorab, and Khalil, 2015) . Exposures to some pesticides have also been reported to retard growth, induce chemical and structural changes in body organs as well as disturb immune responses. They also reduce resistance of animals to disease-causing pathogen infections (Maksymiv,2015). Continuous exposure to pesticides such as chloropyrifos cause gene mutations, genetic damages, reproductive health problems and chronic diseases such as asthma, hypertension and cancer(Dey, Choudhury and Dutta,2015;Geraldin,Lengai and Muthomi,2018).

Horticulture sector in many developing countries has been particularly adversely affected by the use of synthetic pesticides. The European Union (EU) set out strict regulations regarding levels of pesticide residues and safety of agricultural produce exported to their markets. The use of pesticides containing Dimethoate on vegetables was banned by EU. Failure to comply with this regulation led to rejection and destruction of fresh vegetable consignments containing chemical residues above the required limits (Business Daily,2014; Geraldin,Lengai and Muthomi,2018) . Residues of the restricted chemicals should not exceed 0.02 parts per million (ppm) in a sample of vegetables. The percentage of inspection was increased to 10% on fresh produce at ports of entry into the European Union. According to Geraldin,Lengai and Muthomi(2018), Maximum Residue Levels (MRLs) of unknown pesticides should not exceed 0.01mg/Kg and there was imposed a 10% sampling per consignment in fresh beans and pods. Interceptions of fresh produce almost ruined Kenya's export market reputation due to presence of traces of banned pesticides (Business Daily,2014). Following the guidelines made by the EU and the losses incurred due to rejection and destruction of fresh vegetable consignments, there was a reduction in volumes of horticultural exports. This negatively affected the livelihoods of small holder farmers who are the major producers of vegetable crops (Daily Nation,2014) . This led to introduction of a cloud-based traceability system which uses a quick reference (QR) code and GPS coordinates to pinpoint the individual farmer whose consignment fails to comply with regulations(Daily Nation,2016). This has resulted in increase of the cost of production and several farmers opted out of the export business.

Bio-pesticide and its Sustainability in Agriculture

Plant protection is one of the key factors in agricultural production to ensure food security and bio-pesticides appear to be the best alternatives to synthetic chemicals that imposed threat to environment and health. Though there is increasing use of bio-pesticides nowadays but for sustaining the availability of food to feed over growing population, whole system of agriculture across the world should be mechanized and adopt bio-pesticides as control agent of pest. Bio-pesticides have the capacity and potential to replace synthetic chemicals used in pest control. Consequently, it has attracted global attention in recent times for several positive reasons highlighted previously in this paper. Apart from being green molecules, more active substances are discovered through research thereby raising the stance of their potential as innovative pest control agents(Pavela and Benelli, 2016).

Sustainable agriculture systems are those which are economically viable and meet society's need for safe and nutritious food while maintaining or enhancing natural resources and the quality of the environment for future generation. It is in harmony with the environment while maintaining buoyancy and dynamism in agricultural growth for meeting basic human needs and conserving natural resources. It aims at producing food that is both nutritious and safe to human health(Lal,2000; Udemezue,*et al*,2021). Since, all of the materials are of natural or biological origin, it is very safe to use bio-pesticides as potential source of pest control in sustainable agriculture for the benefit of mankind.

Sustainability in agricultural production system is must to meet the growing demand of food with limited availability of resources. Plant protection is one of the key factors in agricultural production and bio-pesticides seems to be the best alternatives to synthetic chemicals(Udemezue,*et al*,2021). Though there is increasing use of bio-pesticides day-by-day but for sustaining the availability of food to increasing population, whole system of agriculture across the world should adopt bio-pesticides as control agent of pest. It is clear that the bio-pesticides are the key for sustainable agriculture and there is urgent need to put more scientific efforts to identify the thrust area of research for the development of eco-friendly production technology with the use of bio-pesticides as a pest control agent.

For this research regarding pest specificity of particular types of bio-pesticides, extension of knowledge and skill regarding use of bio-pesticides to the farmers, low cost availability of biopesticides and farmers acceptance are the primary task to be followed. Both private and governmental organization should make a joint effort in developing, manufacturing and sale of biopesticides(Udemezue,*et al*,2021). Regulation regarding registration of bio-pesticides needs to be made easy so that the commercialization and availability of bio-pesticides in the market is enhanced. Various molecular and biotechnological tools and techniques are being used for producing bio-pesticides in a safe and sustainable manner. DNA recombinant technology is also being used for enhancing efficacy of bio-pesticides. Fusion protein is being designed to develop next-generation bio-pesticides. The technology allows selected toxins (not toxic to higher animals) to be combined with a carrier protein which makes them toxic to insect pests when consumed orally, while they were effective only when injected into a prey organism by a predator(Udemezue,*et al*,2021) . Likewise various innovative tasks are going on to increase the efficacy of bio-pesticides and make it acceptable globally.

Globally, there are 175 registered bio-pesticides active-ingredients and 700 products available in the market. The commonly used bio-pesticides are from neem and Bt derivatives (Moosavi and Zare, 2018; Emmanuel, Grace and Tonderayi,2020). Bt pesticides are the most popular and diversified biopesticides. They are components of most PIPs, biochemical and microbial bio-pesticides. Most recent research indicates that 75% of bio-pesticides used consist of Bt-based products and Neem has proven to be the most widely used botanical bio-pesticide (Pavela, 2014;Pavela and Benelli, 2016; Emmanuel, Grace and Tonderayi,2020).Neem has demonstrated multiple modes of action by acting as an anti-feedant, sterilant, ovicidal and insecticide. However, owing to its instability in environmental conditions, such as sunlight, its effectiveness is short-lived.

To maintain agricultural sustainability and environmental pollution free which bring about food security to a nation regarding the application of bio-pesticides, extension of knowledge and skill based on the use of bio-pesticides by the farmers, low cost availability of bio-pesticides and farmers adoption should be the primary task to be dealt with. Governmental organization and private agencies have to make a joint effort in developing, manufacturing and sale of bio-pesticides. Regulation based on the registration of bio-pesticides has to be easy, so that the commercialization and availability of bio-pesticides in the market is highly sensitized and promoted. Since bio-pesticides are the key for sustainable agriculture, there is urgent need to put more scientific efforts to identify the thrust area of research for the development of eco-friendly production technology with the use of bio-pesticides as a pest control agent. In order to facilitate the market penetration of bio-pesticides, there is a need for cooperation among researchers, venture capitalists, investors, producing companies and farmers with greater considerations placed on long term gains (Rezaei,Safa and Damalas 2019).

Researchers should also consider the alternative ways of using available technologies at the production to scale-up with objectives based on cost reduction, efficiency and reliability of commercial bio-pesticides. This will positively affect the efficacy and reliability of bio-pesticides when integrated into a flexible IPM programme. The programme will ensure the protection of the ecosystem through the use of minimal synthetic pesticides at the most reasonable cost (Emmanuel, Grace and Tonderayi,2020).Training and awareness of bio-pesticides should be organized and implemented among the stakeholders. It should be acknowledged that strict compliance with biological control has more chances to fail and thus should be supported with other variants of pest control options that require awareness and training. The holistic adoption of bio-pesticides and their variant forms including their roles in IPM requires awareness and training among the different stakeholders to sustainably control insect pests and vectors. Researchers should therefore work together with engineers in the government and industry as well as farmers to provide stable and durable formulations of bio-pesticides that will stand the test of time.

CONCLUSION

Pesticides have been extensively used in the intensive agriculture to reduce yield losses and maintain the product quality. The extensive use of synthetic pesticides has certainly provided protection to the crops; it has also raised concerns about pesticide residues in the food and the environment. Chemical pesticides adversely affect beneficial organisms; leave harmful residues in food, feed and fodder, and causes environmental pollutions. More so, human exposure to pesticides occurs primarily through application of pesticide on the crops, contaminated food, feed and drinking water. Their adverse effects depend on toxicity of pesticides, method of application, the dosage applied, their adsorption on soil colloids, the weather conditions prevailing after their application, and how long the pesticides persist in the environment. Sustainable agriculture systems are those which are economically viable and meet society's need for safe and nutritious food while maintaining or enhancing natural resources and the quality of the environment for future generation. It is in harmony with the environment while maintaining buoyancy and dynamism in agricultural growth for meeting basic human needs and conserving natural resources.

Sustainable agriculture can be achieved through the adoption of bio-based pesticides. The use of alternative pesticides in crop production reduces environmental pollution and solves pest resistance problems and improves biodiversity, including natural enemies. Crop production practices that ensure environmental conservation, economic viability and social acceptability will result in sustainable agriculture. As green compounds, bio-pesticides have shown to substitute classical pesticides with a possible increase in crop productivity. In order to achieve an optimum increase in crops' productivity, bio-pesticides are used in an integrated pest management (IPM) scheme, which goes in line to achieve minimal use of chemical pesticides at the lowest cost. With the right education, skill, research on how to improve shelf life and stability problems, and partnerships among stakeholders, bio-pesticide-driven IPM can make chemical pesticide- free agriculture a reality and create a link between socially acceptable economic viability and environmental safety. To maintain agricultural sustainability and environmental pollution free which bring about food security to a nation regarding the application of bio-pesticides, extension of knowledge and skill based on the use of bio-pesticides by the farmers, low cost availability of bio-pesticides and farmers adoption should be the primary task to be dealt with. Governmental organization and private agencies have to make a joint effort in developing, manufacturing and sale of bio-pesticides.

56th Annual Conference
Agricultural Society of Nigeria
24 - 28 Oct., 2022

ABSTRACT

Diseases constitute a major challenge to watermelon production in Nigeria through fruit yield and quality reduction. The diseases render the fruits unmarketable and inedible. Hence, this study identified the fungal pathogens associated with the leaves and fruits of watermelon using molecular characterization. The study also evaluated the potential antimicrobial activities of ethanol extracts of three selected plants: (leaves of *Vernonia- amygdalina, Piliostigma- reticulatum and Spondias- mombin*) against the fungal species.

The statistical analysis of the study was done using analysis of variance (ANOVA) and means were compared by using Duncan's Multiple Range test (DMRT).

The results showed that all the plants materials have antifungal potentials on the fungal species with *P. reticulatum* extracts having the highest antifungal activity (100%) at 50mg/ml, 100mg/ml and 200mg/ml. The diameters of inhibition zone varied according to leaf extract and concentration *Vernonia- amygdalina* and *Spondias- mombin* also showed significant zone of inhibition (100%) at 100mg/ml and 200mg/ml.

The study concluded that the plant extracts used have varying anti-fungal reactions on the three fungal pathogens detected and as such can be used as natural antibiotic and antimicrobial agents against plant diseases.

Keywords: plant extracts, fungal, antimicrobial, zone of inhibition.

INTRODUCTION

Watermelon (*Citrullus lanatus)* belongs to the family Cucurbitaceae (Koocheki *et al*., 2007) is a tropical fruit that grows in most parts of Africa and South East Asia. Besides its high nutritional value, it is gaining a high level of economic importance in income generation. Watermelon flesh is an excellent source of vitamins, minerals and anti-oxidants that help in preventing human diseases by acting as oxygen radical scavenger (Reetu *et al.*, 2017). The sweetness of watermelon is due to the

presence of sucrose, glucose and fructose. Sucrose and glucose account for 20-40% and fructose for 30-50% of total sugars in a ripe watermelon (Bianchi *et al.*, 2018).
Diseases such as blossom-end rot, bursting and rind necrosis reduce the yield and quality of watermelon fruit thereby making it unmarketable and inedible which in turn causes loss to the farmers (Donald et al., 2015).

The use of plants extracts is gaining momentum in the last few years in managing plant diseases. Many plants have been used because of their antibiotic and antimicrobial traits, which are due to compounds synthesized during secondary metabolism in the plants. These natural plant products are cheap, readily available, has little or no toxicity to humans (eco-friendly) and are easy to prepare. Therefore, the objectives of this study are to:

- identify some fungal pathogens associated with *C. lanatus* leaves and fruits.
- assess the efficacy of three plant extracts in the management of these fungal pathogens.

MATERIALS AND METHODS

Collection of plants materials

Fresh leaves of *Vernonia- amygdalina, Piliostigma- reticulatum and Spondias- mombin* were collected from Ago Iwoye, Ijebu North Local Government Area, Ogun State in Nigeria. The leaves were collected in polyethylene bags and transported to the Postgraduate Plant Science Laboratory of the Department of Plant Science, Olabisi Onabanjo University, Ago-Iwoye, Ogun State.

Botanical identification

Botanical identifications were carried out at the Elikaf Herbarium, Department of Plant Science, Olabisi Onabanjo University, Ago-Iwoye, Nigeria.

Collection of infected fruits and leaves of *C. lanatus.*

Eighteen infected fruit samples and forty-two infected leaf samples were collected from eleven field in Ijebu North Local Government Area of Ogun State. They were packed into sterilized transparent bags, labeled and transported to Post Graduate Plant Science Laboratory of the Department of Plant Science Olabisi Onabanjo University, Ago-Iwoye, Ogun State, Nigeria.

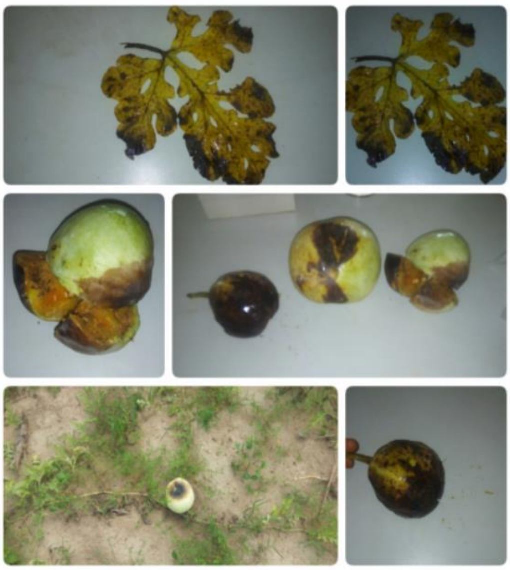

Figure 1: Infected watermelon fruits and leaf samples

Preparation of Culture Media

Potato dextrose agar (PDA) was used as the medium for the growth and maintenance of the fungi isolates.Nineteen and half gram (19.5g) of PDA powder was weighed and dispensed into

500millilitres of distilled water in a conical flask. The mixture was stirred vigorously to dissolve. The conical flask was covered with a foil paper and sealed with a masking tape. The content was sterilized in an autoclave at 121°c for 15 minutes and allowed to cool at room temperature.
The medium was poured into sterile Petri-dishes and allowed to solidify before inoculation was performed.

Isolation of Pathogens from Infected leaves and fruits of *C. lanatus*.

The infected fruits and leaf samples of *C. lanatus* were rinsed in sterile distilled water and small pieces of the rotten parts were picked using a sterile scalpel and placed directly on sterile PDA. The plates were incubated for 3 days at room temperature and sub-culturing was done to obtain pure cultures of the isolate. After incubation, different growths of mycelia colony were sub-cultured with the aid of sterilized inoculating loop into newly prepared PDA plates. The plates were incubated at room temperature for 3-5 days. Several sub-culturing was done, thus purifying the mixed culture plates. The purified fungi were transferred into McCartney bottles of broth agar and stored for characterization.

Identification of Fungi Isolates

The fungal strains were identified using molecular sequencing analysis. The genes (DNA extraction) of the fungal isolates were sequenced with universal primer of (ITS4TCCTCCGCTTATTGACATGS and ITS5GGAACTAAAAGTCGTAACAAGG) and the results are *Fusarium equiseti, Lasiodiplodia theobromae* and*Choanephora cucurbitarum.*

Preparation of Plants Materials

Five hundred grams each of mature fresh leaves of *V. amygdalina, P. reticulatum* and *S. mombin* were thoroughly rinsed in running tap water and air dried at room temperature. The samples were oven dried at a temperature of 55˚C for 30 minutes before grinding into powder with pestle and mortar to facilitate extraction. The samples were ground separately. The leaves were macerated (soaked) in an air-tight plastic container containing 1000ml of 99.9/100% ethanol at room temperature and was stirred using a sterile aluminum rod of 50cm length for 5days to allow for maximum extraction of the plants components and to encourage homogeneity of the plants extract and the solvent used. This was followed by filtration with what-man filter paper and the filtrate was concentrated using water bath. The residue was put into sample bottles as the crude extracts of the test plants and stored.

Concentrations of Crude Extracts

Serial dilutions of the crude extracts were prepared using 0.2g in 1ml of 99.9/100% ethanol and concentrations of 25mg/ml, 50mg/ml, 100mg/ml and 200mg/ml were prepared.

Preparation of Biological Assay

Potato dextrose agar was prepared according to manufacturers' instruction and allowed to cool. The different concentrations of the extracts (25mg/ml, 50mg/ml, 100mg/ml and 200mg/ml) were dispensed into the Petri dishes. The prepared PDA was dispensed into the extracts of the different concentrations, the plates were gently mixed to dissolve the contents using agar dilution method. Four-millimeter diameter of mycelia incubated from old culture of each test fungi was inoculated centrally into the medium using cock borer(4mm) and was incubated for 48 hours to 120hours. The inhibition rate of the plant extracts was observed and measured. The control consists of Petri plates with the organisms but with no plant extract. The inhibition rate was recorded starting from day 2 to day 5. The rate of mycelia growth inhibition (MGI) was calculated using the formula (Jeum *et al.*, 2015):

GI% = dc-dt/dc×100

where dc is mean colony diameter of control sets and dt is mean colony diameter of treatment sets.

Statistical Analysis

Test for significance in the zone of inhibition was done using analysis of variance (ANOVA) and means were compared using Duncan's Multiple Range test (DMRT).

RESULTS

Antifungal effects of the plants extracts on *F. equiseti* at different concentrations

Table 1 shows the percentage inhibition of the plant extracts concentration. On *Fusarium equiseti*, *S. mombin* extracts had percentage mycelia inhibition of 52.80%, 70.30%, 100% and 100% for concentrations of 25mg/ml, 50mg/ml, 100mg/ml and 200mg/ml respectively while the control was 0.00%. For *P. reticulatum*, the percentage mycelia inhibition was 70.53%, 100%, 100% and 100%, while *V. amygdalina* showed the percentage mycelia inhibition of 35.70%, 100%, 100% and 100% respectively.
Ethanol extracts of *P. reticulatum* and *V. amygdalina* at 50mg/ml, 100mg/m and 200mg/ml completely inhibited the growth of *F. equiseti* (100%) while *S. mombin* showed complete inhibition at 100mg/m and 200mg/ml on *F. equiseti*. Thus, the test plants extracts showed no significant difference ($P \geq 0.05$) on *F. equiseti* at 100mg/ml and 200mg/ml while at 25mg/ml and 50mg/ml showed significant difference ($P \leq 0.05$).

Analysis of variance on percentage of *F. equiseti* of the three plants extracts showed significant difference ($P \leq 0.05$) between plant extracts and concentrations of the extracts on *F. equiseti*. The table also shows that the inhibitory effects of the test plants increased with concentrations of the extracts. In comparison, the inhibitory effect of *P. reticulatum* extracts is higher than other extracts at all concentrations.

Antifungal effects of plants extracts on *L. theobromae* at different concentrations

Table 2 shows the percentage inhibition of the plant extracts. The percentage inhibition of the plant extracts was concentration dependent on *Lasiodiplodia theobromae*. *S. mombin* extracts had percentage mycelia inhibition of 23.72%, 84.21%, 100% and 100% for concentrations of 25mg/ml, 50mg/ml, 100mg/ml and 200mg/ml respectively while the control was 0.00%. For *P. reticulatum*, the percentage mycelia inhibition was 54.27%, 100%, 100% and 100%, while *V. amygdalina* showed percentage mycelia inhibition of 23.63%, 44.67%, 74.83% and 100%.

Ethanol extracts of *P. reticulatum* and *S. mombin* at 100mg/m and 200mg/ml completely inhibited the growth of *L. theobromae* (100%) while *V. amygdalina* showed complete inhibition at 200mg/ml on *L. theobromae.* Thus, the test plants extracts showed no significant difference ($P \geq 0.05$) on *L. theobromae* at 100mg/ml and 200mg/ml of *P. reticulatum* and *S. mombin* while at 25mg/ml and 50mg/ml showed significant difference ($P \leq 0.05$) on the extracts.

The inhibitory effects of the test plants increased with concentrations of the extracts. In comparison, the inhibitory effect of *P. reticulatum* extracts is higher than other extracts at all concentrations. Analysis of variance showed significant difference ($P \leq 0.05$) between plant extracts and concentrations of the extracts on *L. theobromae.*

Antifungal effects of plants extracts on *C. cucurbitarum* at different concentrations

The percentage inhibition of the plant extracts was concentration dependent on *Chaonephora cucurbitarum*. *S. mombin* extracts had percentage mycelia inhibition of 22.40%, 32.73%, 42.53% and 100% for concentrations of 25mg/ml, 50mg/ml, 100mg/ml and 200mg/ml respectively while the control was 0.00%. For *P. reticulatum*, the percentage mycelia inhibition was 83.70%, 100%, 100% and 100%, while on *V. amygdalina* showed the percentage mycelia inhibition of 21.33%, 27.10%, 58.83% and 89.46% (Table 3).

Ethanol extracts of *P. reticulatum* and *S. mombin* at 200mg/ml showed a complete inhibition on *C. cucurbitarum* (100%), while *V. amygdalina* showed no complete inhibition at all the concentrations on *C. cucurbitarum*. Thus, the test plants extracts showed no significant difference ($P \geq 0.05$) on *C. cucurbitarum* at 200mg/ml of *P. reticulatum* and *S. mombin* while at 25mg/ml, 50mg/ml and on *V. amygdalina* showed significant difference ($P \leq 0.05$) on the plant extracts.

The inhibitory effects of the test plants increased with concentrations of the extracts. In comparison, the inhibitory effect of *P. reticulatum* extracts is higher than other extracts at all concentrations. Analysis of variance showed significant difference ($P \leq 0.05$) between plant extracts and concentrations of the extracts on *C. cucurbitarum* (Table 3).

DISCUSSION

This study shows three different fungal isolates associated with infected fruits and leaves of watermelon distributed among the seven locations within Ijebu North Local Government Area, Ogun State. *Lasiodiplodia theobromae* appeared in more locations than other fungal isolates on infected fruits and *Fusarium equiseti* appeared in more locations than other fungal isolates on infected leaves of watermelon.

The antifungal effects of *V. amygdalina, P. reticulatum and S. mombin* leaves extracts against; *F. equiseti, L. theobromae and C. cucurbitarum* at different concentrations obtained in this study drastically reduced the mycelia growth of the three fungi strains over a period of 4-5days at (96-120hours) of incubation.

This study revealed the fungal pathogens affecting *C. lanatus* in Ijebu North Local Government Area of Ogun State. In a similar study, Garba *et al*., (2014) reported isolation and identification of bacteria and fungi associated with rots of *Citrullus lanatus* and *Capsicum frutescens* in Sokoto market in Nigeria. List the pathogens detected in Sokoto market. Ratul *et al*. (2010) reported molecular detection and identification of *Fusarium oxysporum* as the fungal species as identified in this study.
Vernonia- amygdalina have been reported to have antifungal activities against some fungal pathogens (Bazie *et al*., 2014; Aondo *et al*., 2016). Stangarlin *et al*. (2011) reported that control of plant diseases using some plant extracts and at different concentrations of *P. reticulatum* on the fungal strains showed a great result of inhibition against the tested pathogen and this could be attributed to the antibiotic properties of the plant. It is therefore a botanical with potential antifungal property (Aderogba *et al.*, 2006). The plant contains very active biological agents that could be used to control fungal diseases of plants.
According to Ngoci *et al*., (2015), *P. reticulatum* extracts show significant antimicrobial activities against some fungi. *Pilostigma reticulatum* had higher antifungal potential compared to other plant extracts used which justified the report of Akomolafe *et al.* (2013), which showed that ethanol and aqueous extracts of *P. reticulatum* have been widely used as herb and also as antibiotic owning to several bioactive constituents it contains. The findings showed that ethanol and aqueous extracts of this plant had strong antioxidant properties.

Garuba *et al.* (2014) reported the ethanolic extracts of *V. amygdalina* showed antifungal potential against *Aspergillus. niger, A. clavatus, A. oryzae, Paecilomyces varioti and Saccharomyces cerevisae*. It was also reported that water extract of *V. amygdalina* leaves have inhibition effect on the growth of *Fusarium moniliforme* and mycelial and conidial growth of *Collectotrichum gloeosporioides* (Owolade *et al.*, 2000; Ogbebor *et al.*, 2007; Suleiman *et al.*, 2008). Nkaa *et al*. (2016) also reported that leaf extract of *S. mombin* reduced the radial mycelial growth of *Proteus-mirabilis* and *Staphylococcus aureus*. Report also showed that ethanol leaf extract of *S. mombin* plant has antifungal activities against some fungal pathogens (Osuntokun *et al.*, 2018) as observed in this study.

CONCLUSION

Findings from this study, showed that the plant extracts used have varying anti-fungal activities on the three fungal pathogens detected.
The observed inhibition zone of *F. equiseti, L. theobromae* and *C. cucurbitarum* suggests that *P. reticulatum* possesses compounds containing antifungal properties that can effectively suppress the growth when extracted with ethanol. Therefore, *P. reticulatum* leaves exhibit the potential of being a good natural antibiotic agent against plant diseases caused by *F. equiseti, L. theobromae and C. cucurbitarum.*

ABSTRACT

Potato production in Nigeria have suffered due to lack of new high-yielding and resistant varieties among other problems. There is a need to develop or introduce new potato varieties that will increase yield, productivity and well being of farmers in a way that can be sustained. In other to increase yield at farmers level some potato varieties were introduced in 2013. On-station and multi-locational trials were conducted on this varieties a high yielding and early maturing cultivar was identified. On-farm trials were conducted in some villages to evaluate the yield performance of the variety along with other variety with farmers using farmer managed on-farm research approach. The new potato variety was distributed to farmers. Twenty-four farmers were selected from eight villages cutting across four and one Local Government Area each of Plateau and Taraba states. The result indicated that based on tuber yield the variety perform better than the varieties which the farmers are using in all locations. Marit Dutse in Barkin Ladi L.G.A and Vwang in Jos South L.G.A recorded the highest tuber yield of 21.29 t/ha and 20.70 t/ha respectively. Based on this result, marabel and the stability analysis of bertita are recommended for production.

Key words: on-farm, evaluation, cultivar, stability, mid-altitude adoption.

INTRODUCTION

Low yield and unavailability of new improved high yielding potato varieties to farmers constitute a major constraint to potato production in Nigeria. Most of the varieties introduced over the last 3 decades have declined in yield due to virus, fungi, bacteria and many other biotic and abiotic problems. (declining soil fertility) resulting in Nigeria recording the lowest yield of 3.7 t/ha as against the African world average of 7.2 tons/ha and 16.4 tons/ha respectively (F.A.O, 2012). Varieties commonly found in Nigeria includes, Nicola, Diamant, Bertita, among others.

The newly introduced variety marabel has spread to many villages and local government areas of plateau and Taraba states. The adoption rate is low, even though they recognize that it is better than the old varieties in maturity and yield, part of their difficulty is the socio-cultural preference for adapted varieties which they are more familiar with.

Stability performance of crop varieties across contrasting environments is essential to the successful selection of high yielding and consistently performing varieties. A number of techniques have been employed to achieve this goal but regression techniques have been most prominent. Although the usual analysis of variance detects genotype and environment (GXE) interaction when genotypes are evaluated in different environments, only the joint regression analysis is able to furnish the response of varieties. Despite the criticism of this technique (Baker, 1969, Hill, 1975, Powel et al 1986; Ariyo, 1987), it has proved valuable in cultivar development for a number of crops (Breese, 1969) in grass; Ntare and Akeni'ova (1985) in cow peas.

The objectives of the study were:

1. To evaluate the performance of the new variety on-farm against other varieties earlier introduced and are available with farmers and
2. Determine the effect of environment on the varieties

MATERIALS AND METHODS

This study was conducted in 24 farms covering five local government areas of Plateau and Taraba states of Nigeria. The fields where the trials were conducted have not been planted with potato for the past 5 years. Each farmer prepared the plot according to the prevailing local practice which generally, consisted of clearing, burning, packing and making of ridges for both plateau and Taraba states respectively. The treatment consists of four varieties including the new variety supplied by the national root crop research institute potato programme Kuru and Syngenta Nigeria limited, farmer management approach was adopted. Three farmers each from Jos south, Bassa(plateau state) and Sardauna local government (Taraba state). Nine and six farmers each from Barkin Ladi and Mangu respectively. Trial was laid out in a randomized complete block design (RCBD) with four treatments and three replications in each location. Each farmer was used as replication, the plot size was 6m x 5m. Planting was done in the second week of May in all villages. The potato varieties were planted at a spacing of 100cmx30cm on the crest of the ridges. Cultural management such as weeding and earthing-up were carried out according to farmers' practice. Compound fertilizer NPK 15:15:15 were applied at the rate of 500kg\ha (10 bags) at planting.

Data were collected on tuber yield. Data collected in each trial were subjected to individual and combined analysis of variance to examine genotype x environment interaction effect. Joint regression analysis was also performed according to the procedure of Eberhart and Russel (1966) by regressing individual means on the environmental indices to determine the pattern of response. According to this method a genotype with average sensitivity will have a unit regression coefficient (b=1.0) or greater than unity. While a stable genotype will have a low slope (b<1).

RESULTS

The analysis of variance for each location is shown in Table 1. Mean squares for all the locations shows that significant differences exist on all the varieties in each location on tuber yield.

Table 1. Analysis of variance for each location

Locations		Kwi		Foron		Vwang		Merit dutse		kwall		kerang		Ampang west		Gembu

Eight locations are presented in Table 2. Locations Marit Dutse, Vwang and Foron were equally favorable for the varieties as they produced 21.29 t/ha, 20.7 t/ha and 18.54t.ha respectively. The lowest yields were produced in Kerang and Kwi 13.60t/ha and 13.18t/ha.

However, KWI had a CV of 2.85% while Ampang west recorded a CV of 5.57%

Table 2: Mean tuber yield and co-efficient of variation for varieties evaluated in 8 locations.

Location	Yield	CV
Kwi	13-18	2.85
Foron	18.54	3.67
Vwang	20.70	3.84
Merit Dutse	21.29	3.63
Kwall	14.19	3.30
Kerang	13.60	5.17
Ampang west	14.69	5.57
Gembu	14.83	5.51
Mean	16.38	4.19
L.S.D	0.70	--

The mean yields of the genotypes are presented in Table 3. The average tuber weight of 13.28t/ha was recorded. Among the entries only Marabel and Diamant produce above average yield. Also varieties Nicola and Bertita had above average co-efficient of variation (cv) and all varieties which produced above average yields had below average cv. In all, marabel with a yield of 21.24t/ha was the most desirable.

Table 3: Mean tuber yield and co-efficient of variation (cv) for Potatoe varieties evaluated

Variety	Mean tuber Yield(t/ha)	cv (%)
Nicola	11.20	7.60
Diamant	13.57	4.95
Bertita	9.30	10.04
Marabel	21.24	2.88
Mean	13.28	6.37
L.S.D	0.78	-

The combined analysis of variance for the varieties are presented in Table 4. Mean squares for all planted varieties were significant. Variety mean square was the largest while varieties x environment was the lowest.

Table 4: Combined analysis of variance for tuber yield of Potato varieties evaluated.

Source	DF	MS
Variety	3	666.400l
Environment	7	5.5936
Reps. Within environment	16	3.1527
Varieties x environment	21	2.6316
Error	48	0.9569

The Joint regression co-efficient (b) and the deviation from regression (s^2d) of the varieties are presented in Table 5. Marabel had the largest regression co-efficient of 1.99, while Bertita had the lowest regression co-efficient of 0.1136. Since the mean square due to variety x Environment (linear) was significant, the regression co-efficient were different from each other. Marabel was sensitive or responsive to the environment and perform better in good environments. While Bertita was stable across all the environments. The deviation mean squares were not significant except for marabel.

Table 5: Regression co-efficient (b) and deviation mean square of the potato varieties.

Variety	Regression	Deviations
Nicola	0.8683	5.8971
Diamant	1.1408	8.4809
Bertita	0.1136	3.0625
Marabel	1.9860	19.4912

DISCUSSION

An essential step in variety development is the evaluation of lines in contrasting environments to determine their desirability or otherwise. It is expected that varieties will respond to increment in environmental conditions. Such responsive varieties are productive especially in good environments. Varieties with average responses over environments had a wide scope of cultivation. With respect to the present study, Marabel and Diamant shows that these varieties are responsive while Bertita and Nicola are productive in varied environments. Successful evaluation of varieties is possible through genotype x environment interaction analysis. Eberhart and Russel (1966) emphasized the need to consider both linear regression co-efficient and non-linear components of genotype x environment interaction analysis.

Samuel et al (1970) and Paroda and Hayes (1971) reported that linear regression co-efficient which could simply be regarded as a measure of the response by a particular genotype is a linear function of the environmental changes. When the sensitivity of a genotype is a linear function of the environment, the yield of that such genotype can be predicted (Ariyo, 1995).

The fact that variety x environment was significant in this study indicated that the varieties responded differently relative to each other in the eight locations. The findings are similar to that of Rajendran et al (1987) who made similar observation in cassava. Also, the significant variety x environment interaction for tuber yield shown by two varieties in this study indicates that breeding potato for improved stability across locations is possible. The results clearly showed that environment and genetic variations mostly accounted for the variation in tuber yield.

CONCLUSION

Breeding potato for high productivity and stability across environments is possible as one variety in this study showed good level of yield and yield stability across diverse locations. Some locations gave better yield than others indicating the possibility of breeding varieties for specific locations.

ABSTRACT

The experiments were conducted at the Western experimental field of National Root Crops Research Institute, Umudike, Abia State during the 2021 cropping season in the rainforest agro-ecology of Southeastern Nigeria with the following objectives: to produce 10,000 botanical seeds for progeny development and increase genetic diversity, to assess current breeding lines for high storage root yield and compatibility as parents for crosses and to evaluate the sweet potato parents for reaction to biotic stresses. Data collected include: total number of capsules harvested per parent, total number of seeds harvested per parent, total number of good seeds, total number of storage roots, number of commercial roots and number of small roots. Weight of total storage roots, the weight of commercial roots and weight of small roots. Data collected were subjected to Analysis of Variance and means were separated using Standard error of difference (S.E.D). Data were also collected on biotic stresses. Results obtained indicated that the objective of realizing 10,000 botanical seeds were not realized due to the fact that most genotypes in the crossing block were not as prolific as was expected. Genotypes with high number of storage roots, heavy weight of fresh matter accumulation and high number of botanical seeds were selected as parents for use in crossing blocks. The high number of seeds produced was an indication of high compatibility with other genotypes. Higher number of botanical seeds produced indicated high genotype diversity since each seed is a new variety. The genotypes selected for use as parents were immune to most of the field biological stresses and therefore were recommended for use as parents in the hybridization plots. The genotypes are: NWA/OP/241 (9.4t/ha) NWA/OP /226 (9.7 t/ha), NWA/OP/231 (13.1 t/ha) and Smiles (16.1 t/ha).

Keywords: Parents, botanical seeds, weight of roots, crossing block and diversity.

INTRODUCTION

The development of new genotypes involve setting breeding objectives, generating the required genetic diversity through hybridization, recombining the first generations, followed by various forms of selection in subsequent generations to increase the frequency desired characteristics and to fix these, leading to a new variety that is reasonably uniform and stable (Gruneberg et al., 2007; Gibson, 2007). Sweetpotato improvement programmes have been even less successful for the extreme arid and high altitude areas of the country partly because of the allocation of limited research resources by national and international programmes and partly due to Gasura et al, 2008; Lebot, 2009). Nigeria has many genetically diverse, sweetpotato landraces but little use has been made of them in the national breeding programmes. Concerted efforts should be considered for the use of alternative approaches to address the problems of the limited sweet potato varietal choice available to farmers. Traditionally, the development of sweet potato varieties has been the task of breeders, and farmers are merely the recipients of finished products.

Technology arguments. To develop better adapted varieties for the marginal complex environments and, in some cases, for highly productive environments, plant breeders have become increasingly aware that their initial primary concern with yields was not always sufficient to guarantee broad adoption by farmers. Gurmu (2015) indicated that it has become apparent that breeding objectives need to incorporate other criteria, such as local consumption preferences. This has led to farmer-participatory evaluation aimed at establishing what additional characteristics were required, such as taste, colour/appearance and other household requirements, e.g. ease of cooking and of storage. The principal objective of the sweetpotato breeding programme was to generate botanical seeds through which variation in sweetpotato plants could be developed, and this will act as raw material for selection (Akoroda, 2021). Seedlings could then be evaluated to select genotypes that merited utility traits for various end-users. Therefore the breeding objectives were to:

1. To produce 10,000 botanical seeds for progeny development and increase genetic diversity
2. Assess current breeding lines for high storage root yield and compatibility as parents for crosses and
3. To evaluate the sweetpotato parents for reaction to biotic stresses.

MATERIALS AND METHODS

The experiments was conducted at the Western experimental field of National Root Crops Research Institute, Umudike, Abia State during the 2021 cropping season in the rainforest agro-ecology of Southeastern Nigeria. The site for the experiment was slashed, ploughed, harrowed and ridged. The area was then divided into plots and the plots were grouped into blocks. Each of the 20 varieties comprised of 17 current breeding lines at AYT (Advance Yield Trial stage) and 3 Varieties (UMUSPO/3, Erica and Tio–Joe) were used as parents and were planted on the crest of the ridge 0.3m within row and 1.0m between rows in a plot size measuring 3m x 3m and replicated three times which gave a total of 60 plots.

Two months after planting, the plots were staked to enhance the flowering, ease of pollination, reduce soil borne diseases and ease in dry capsule collection from the parent plants. The plots were kept weed free throughout the trial. The parents were subjected to diaelle crossing and all seeds collected from each of the parents were packed in a well labeled envelope. No fertilizer was applied to prevent the crop from growing too luxuriantly and delay flowering. The following data were collected: total number of capsules harvested per parent, total number of seeds harvested per parent, total number of good seeds, Total number of storage roots, number of commercial roots and number of small roots. Weight of total storage roots, weight of commercial roots and weight of small roots. Data collected were subjected to Analysis of Variance and means were separated using Standard error of difference (S.E.D). Data were also collected on biotic stresses and scored on severity scale of 1 to 9 and the data collected were scored using the scale of 1 to 9 (Toker *et a*l., 1999).
Where: 1 = Immune , 2 = Highly Resistant, 3 = Resistant, 4 = Moderately Resistant, 5 = Tolerant, 6 = Moderately susceptible, 7 = Susceptible, 8 = Highly susceptible and 9 = Highly susceptible.

RESULTS AND DISCUSSION

The result on the total number of capsules collected, total number of seeds and total number of good seeds is presented in Table 1.

Table 1: Number of capsules and seeds generated through genetic recombination for the development of new sweetpotato genotypes for varied end-users

UMUSPO/3 (chk)	319.0	653	14.0	4.8	3.0	1.0	1.0
Total	**6576**	**9196**	**426.0**	**163.4**	=	=	=
Mean	328.8	459.8	21.3	8.2	=	=	=
Range	109-733	76-1107	7-41	2.5-16.1	=	=	=
CV%	34.2	38.2	31.3	41.2	=	=	=

The result in Table 1 showed that the total number of capsules with seeds harvested from the sweetpotato genotypes varied greatly from 109 to 733 capsules with mean of 328.8 capsules and coefficient of variation of 34.2%. The genotype that gave the highest number of capsules was Tio-Joe with total number of harvested capsules numbering 733 followed by NWA/OP/266 with total of 634 harvested capsules while the least number of harvested capsule was obtained from the genotype SPO/50 which gave a total of 109 harvested capsules. Capsules contain botanical seed for the development of sweetpotato progenies which will give rise to new sweetpotato genotypes which individually possess different characteristics desired by various end-users. For the fact that most of the new genotypes flowered is an indication that they are out crossing and could be used as parents for sweetpotato hybridization block.

However, total number of botanical seeds collected was 9196 with mean of 459.8 seeds. This varied greatly from 76 seeds as produced by NWA/OP/227 to as high as 1107 as was produced by Tio-Joe with coefficient of variation of 38.2% which indicated a high degree of variation. High number of capsules results into high number of seed yield. Not all pollinated capsules produce the same quantity of seeds. From the results obtained, genotypes that produce high number of capsules produced high number of seeds. High number of seeds and capsules is an indication of high compatibility of the parents with other genotypes in the same crossing block. Therefore genotypes with number of seeds above the grand mean were selected for use as parents in the hybridization block. These genotypes included the following: NWA/OP/226 (968 seeds), Tio-Joe (1107 seeds), SPO/3/11 (1032 seeds), NWA/OP/231 (852 seeds), Smiles (972 seeds), UMUSPO/3 (653 seeds) and NWA/OP/598 (598 seeds).

Number and weight of storage roots: Total number of storage roots varied greatly from 7.0 (NWAOP/227) to 41.0 roots (Smiles) per plot with mean of 7.4 number of roots per plot with 31.3% coefficient of variation. High number of storage roots per plot is a function of yield. Parent genotypes with high number of storage roots could transfer such desirable trait to their progenies. Also high number of storage roots leads to heavy weight of fresh matter accumulation.

The result in Table 1 showed that total weight of storage roots ranged from 2.5t/ha (Erica) to as heavy as 16.1t/ha (Smiles) with mean of 8.2t/ha and coefficient of variation of 41.2% which was an indication of high variation in total storage root weight. Heavy storage root weight is an indication of high dry matter accumulation. Genotypes with high storage root weight plus high number of seeds were selected for as parents for inclusion into hybridization block. The genotypes selected were: NWA/OP/241 (9.4t/ha) NWA/OP/226 (9.7t/ha), NWA/OP/231 (13.1t/ha) and Smiles (16.1t/ha).

Pathological Reactions: The pathological reactions of the genotypes indicated that the genotypes had a mean severity score of 1.0 for *SPVD*, *alternaria* and nematode infestation. Based on the pathological score the genotypes selected were assumed immune to field pathological infectious diseases. However, the SPVD did occur in the field. One of the check varieties UMUSPO/3 had SPVD severity score of 3.3 although (the check variety) was resistant to the SPVD attack.

CONCLUSION:

The objectives of producing 10,000 botanical seeds were not realized due to the fact that most genotypes included in the crossing block were not as prolific as was expected. However, those genotypes with high number of storage roots, heavy weight of fresh matter accumulation and high number of botanical seeds were selected as parents for use in crossing blocks. The high number of seeds produced was an indication of high compatibility with other genotypes. The high number of botanical seeds produced indicated high genotype diversity since each seed is a new variety. The genotypes selected for use as parents were immune to most of the field biological stresses and therefore were recommended for use as parents in the hybridization plots. The genotypes are: NWA/OP/241 (9.4t/ha) NWA/OP /226 (9.7t/ha), NWA/OP/231 (13.1t/ha) and Smiles (16.1t/ha).

ABSTRACT

Cocoyam is known to be cultivated by the minority groups in nearly all States of Nigeria, thus gradually leading the tuber crop into extinction. The few cocoyam farmers often suffer loses both on-farm and in storage due to fungi disease which causes low yield. However, the need for increased yield to meet the demands for consumptions and make sales has made cocoyam farmers to resort to the use of fungicides for combating pest and diseases on-farm and in storage. The objective of this study is to evaluate the effect of fungicides (Benomyl and Tecto-40 EC) on mineral and phytochemical compositions. Cocoyam tubers were harvested from the Western experimental field of the National Root Crops Research Institute Umudike, Abia State. Various samples of the harvested cocoyam tubers, both fungicide treated and non-treated were peeled, washed, ground into powder, stored in 2kg packs and analyzed for mineral and phytochemical contents using the appropriate laboratory measures. Data collected were analyzed using SPSS Version 23 and the difference in means at $p<0.05$ was considered significant. Results obtained showed that the crude protein of samples treated with both Benomyl and Tecto-40 EC at 16_WAP were significantly higher than the non-treated samples. The moisture content of the fungicides treated samples at 16_WAP were significantly lower than those of the non-treated samples, an indication of the resistance to microbial attack. Results indicated that the mineral content of the fungicides treated samples were significantly higher than the non-treated samples at 16_WAP, with Tecto-40 EC showing higher values than Benomyl. The results of the investigation showed that the use of Benomyl and Tecto-40 EC increased the mineral and phytochemical compositions of the tuber crops compared to the non-treated samples. It is also recommended that more work is required to determine the bioaccumulative effect of the fungicides on experimental animals.

Key words: Benomyl, Tecto-40 EC, Mineral and Phytochemical compositions.

INTRODUCTION

Colocasia esculentum (L). Schott (cocoyam) is one of the two food crops in the *Araceae* family. It is a perennial tropical plant primarily grown as a root vegetable for its edible, starchy corms. The plant has rhizomes of different shapes and/sizes. The tubers could be roasted, baked or boiled to minimize the toxin (calcium oxalate) it contains in its raw form. The tubers could also be peeled, dried and ground into flour for pastry that can be stuffed with meat or other fillings. The young leaves can be boiled and consumed as vegetable. Thus, provides a substantial contribution to nutritional requirements, for energy, protein and other macro- & micro- nutrients (Adelekan, 2012 and Ikwele et al; 2008). Diseases are the most limiting factors in cocoyam production resulting in significant yield loses. Fungal diseases of cocoyam are usually managed with synthetic fungicides (DoctorFungus, 2012 and Ajima et al; 2011). However, the use of fungicides in the control of diseases (Daisy, 2000 and FAO, 2012) and their effect on the nutrient compositions of the food crop need to be evaluated. Therefore, the present study was carried out to determine the effect of two fungicides (Benomyl and Tecto – 40 EC) on the mineral and phytochemical composition of both the treated and non – treated cocoyam.

MATERIALS AND METHODS

Sample collection and Preparation: Cocoyam tubers were selected from those harvested from the experimental fields of NRCRI, Umudike after 9 months of planting. The tubers were hand peeled using stainless steel knife, washed thoroughly and sliced into tiny pieces. The sliced samples were placed on a stainless steel tray and sun – dried for 5 days. The dried chips were ground using a Warren blender to convert into flour. Then the flour (2kg) was filled in polythene bags, packed and kept in desiccators until analyzed for contents of proximate, minerals and anti-nutritional factors.

DETERMINATION OF PROXIMATE AND MINERAL COMPOSITIONS

The proximate compositions (total moisture content, crude fat, crude protein, crude fibre, ash, total carbohydrate and gross energy values) mineral compositions were determined using the procedures described by the Association of Official Analytical Chemists (AOAC, 2005).

Analyses of the anti-nutritional factors were carried out by the method described by Fana et al; (2015).

STATISTICAL ANALYSIS

Analyses were carried out to determine the difference in proximate compositions, mineral contents and anti-nutritional factors of the Benomyl and Tecto-40 EC treated and non-treated samples. The analyses were performed using SPSS Version 23. Difference in means at $p < 0.05$ was considered significant.

RESULTS AND DISCUSSIONS

The results of the proximate analyses (%) showed that the crude protein in samples treated with Tecto-40 EC at 8WAP and 16WAP (11.34 ± 0.5 and 13.54 ± 0.02, respectively) were significantly higher than the crude protein of samples treated with Benomyl at 8WAP_ (10. 50 ± 0.02 and 11.35 ± 0.04). The crude protein of the non – treated sample at 8WAP (12.23 ± 0.02) was significantly higher than that of 16WAP_ (7.45 ± 0.02). The moisture content of samples treated with Benomyl at 8WAP_ (6.34 ± 0.31) differed significantly from Tecto-40 EC at 8WAP_ (5.61 ± 0.47), while there was no significant difference at 16WAP. Crude fat of both Benomyl and Tecto-40 EC treated showed no significant difference at 8_WAP and 16_WAP. The carbohydrate content of both Benomyl at 8_WAP (78.21 ± 0.26) and Benomyl at 16_WAP (79.86 ± 0.06) were significantly different from that of Tecto-40 EC treated samples (Tecto-40 EC 8_WAP 77.58 ± 0.42 and 77.95 ± 0.16). The dry matter of all the samples were relatively high, an indication of a high nutritional value.

Table 1: Proximate compositions (%) and dry matter content of the Benomyl and Tecto-40 EC treated and non-treated cocoyam.

Samples	*DRY MATTER*	*MOISTURE*	*CRUDE FAT*	*CRUDE FIBRE*	*CRUDE PROTEIN*	*ASH*	*CARBOHYDRATE*	*ENERGY VALUE (KCAL/100g)*

Sample + Tecto 40 16 WAP	96.53 ± 0.15	3.47 ± 0.15	0.42 ± 0.02	1.70 ± 0.03	13.54 ± 0.02	2.92 ± 0.02	77.95 ± 0.16	369.71 ± 0.76

Mineral composition and Anti-nutritional Factors (mg/100g)

Six different elements and three anti-nutritional factors were analyzed for concentrations (mg/100g) in dry weight basis. The results of the comparative analysis showed that nitrogen content at Benomyl applied 8_WAP (1.68), Benomyl at 16_WAP (1.82) and Tecto-40 EC at 8_WAP (1.82) were not significantly different. However, Tecto-40 EC at 16_WAP, the nitrogen content increased (2.17); the same was observed for phosphorus which significantly increased to 10.20 at 16_WAP with Tecto-40 EC. The magnesium content at Benomyl 8_WAP and Benomyl 16_WAP (1.84 and 1.23) were similar to that observed in Tecto-40 EC 8_WAP and Tecto-40 EC 16_WAP (1.84 and 1.23). The sodium content at Tecto-40 EC 8_WAP (1.34) and Tecto-40 16_WAP (1.35) were significantly higher than that observed in Benomyl 8_WAP (0.90) and Benomyl 16_WAP (0.63).

The anti-nutritional factor tannin was not significantly different in the four treatments. However, phytate at Tecto-40 EC 8_WAP (56.99) and Tecto-40 EC 16_WAP (56.47) were much higher in Benomyl 8_WAP (49.49) and Benomyl 16_WAP (50.11). Oxalate was much lower in Tecto-40 EC treated samples (Tecto-40 8_WAP 45.34 and Tecto-40 EC 16_WAP 45.55) when compared with Benomyl 8_WAP (49.85) and Benomyl 16_WAP (50.19).

Table 2: Mineral compositions and anti-nutritional factors (mg/100g) of Benomyl and Tecto-40 EC treated and non-treated cocoyam samples.

Samples	Nitrogen (N)	Phosphorous (P)	Potasium (K)	Calcium (Ca)	Magnesium (Mg)	Sodium (Na)	Tannin	Phytate	Oxalate
Control - O 8 WAP	1.96	9.60	9.20	5.01	1.23	0.88	0.48	56.35	49.66
Control - O 16 WAP	1.19	7.50	7.03	8.02	1.23	1.03	0.43	56.71	48.87

Sample + Benomyl 16 WAP	1.82	9.00	8.55	7.02	1.23	0.63	0.45	50.11	50.19
Sample + Tecto - 40 8 WAP	1.82	8.70	9.13	4.01	1.84	1.34	0.53	56.99	45.34
Sample + Tecto 40 16 WAP	2.17	10.20	5.15	7.02	1.23	1.35	0.50	56.47	45.55

DISCUSSION

The relative low moisture content determined in this study can be helpful for the storage of cocoyam tubers at ambient temperatures. The high crude protein content of the cocoyam samples as revealed in the study can be considered as a good attribute since it is mainly consumed by resource poor farmers. The results of crude fibre content showed that the cocoyam tubers could be a good source of dietary fibre. The low crude fat content observed in the study indicates that cocoyam is a low fat crop, and thus would contribute less to the health problems related with excess fat intake. The high total ash content is an indication that the food crop is rich in minerals. Both the carbohydrate and gross energy content of the food crop were high, and thus can be regarded as rich foods with high energy value.

The study showed that both the Benomyl and Tecto-40EC treated cocoyam were rich in both the minerals and phytochemicals. Consumption of nutrient rich foods such as cocoyam would help the body to utilize protein, carbohydrate and other nutrients.

The anti-nutritional factors (tannin, phytate and oxalate) were significantly lower than those reported from other regions. The environment could be a contributing factor. However, various studies have shown that the processing methods such as boiling, fermentation roasting, etc, can significantly reduce anti-nutritional factors to low levels.

CONCLUSION

This study has shown that the use of some selected fungicides can help in controlling the diseases of cocoyam that lead to yield loses, and that cocoyam would play a significant role in alleviating the household food insecurity and periodic food shortages existing in some families inhabiting cocoyam growing areas.

RECOMMENDATION

More detailed analysis including processing, sensory testing and determining the antioxidants from extract of this food crop are suggested for further investigation in order to obtain healthful and comfortable cocoyam products.

Agricultural Society of Nigeria
24 - 28 Oct., 2022

ABSTRACT
The experiment was conducted between the months of June to September 2021 in Igboora to evaluate the effectiveness of selected herbicides for weed control in zero tilled plots for the cultivation of maize. The experiment was arranged in a randomized complete block design consisting of five treatments and three replicates. The treatments were three herbicides (Glyphosate, Gramoxone and United force) and two tillage methods (Minimum and Conventional tillage). Data were collected on the growth, yield parameters of maize and on the effectiveness of these herbicides on weeds. All growth, yield parameters of maize and weed parameters measured were significantly influenced at 5% level of probability using DMRT. The highest yield was observed on the conventional tilled plots (6853.3kg/plot) similarly weed biomass was significantly high in conventional tilled plots (23.3g), however it can be observed that, given increasing dearth of cheap labor for conventional tillage, the use of glyphosate should be encourage for zero tillage production of maize since it is less labour intensive and has high yield return when compared to other herbicides.
Key words: Glyphosate, Gramoxone, United force, Minimum tillage, Convectional tillage

INTRODUCTION
Cereal is the most widely cultivated and consumed crops globally (Enyisi et al 2014), of all these cereals, maize remains the most popularly grown and consumed in all ecological zones of the country (Iken et al 2002). In Nigeria, specifically in the Northern part of the country, maize provides a major food resource for both man and animal and as major source of energy and protein in their diet. Maize is the most important cereal crop in Nigeria ranking second behind sorghum in the number of people that feeds on it (Enyisi et al 2014). Maize is a multipurpose crop, provides food and fuel for human being and feed for animals (poultry and livestock) (Enyisi et al 2014).
The production of maize (zea mays) is increasing globally and this trend is evident throughout central Europe and Africa, we may expect this trend to continue in the future (Tatsumi *et al* 2011). Maize is the third most important staple food in the world today and a staple food of great socio – economic importance in sub- Sahara Africa (Pamodh Sharma et al 2018). At the present time, maize is the most significant crop in the world next to wheat and rice. Weed management has major effect on the

success of maize productivity because the competition ability of maize is relatively low. Weeds are a constant source of concern for the successful growth and development of this crop. They compete with crops for light, moisture, space and nutrients and consequently interfere with normal growth of the crop.

Weed control is important in maize cultivation; the critical period of weed interference is influenced by the competing weed species, the cultivars, plant density and environmental factors such as light, water, nutrient and allelopathy (Shrestha *et al* 2018)). Weed interference not only results in crop losses but also increases insect pest damage, harvesting difficulties and crop contamination. It is generally conceded that the recurrent economic damage to agriculture from weeds surpasses the more incidental damage inflicted by insect pest rodents and diseases (James, et al 2000). The nature of weed interference influence strongly the choice of weed control measures to be adopted which could either be chemical, cultural or biological weed management. Chemical weed controls are increasingly being used in Nigeria and other developing countries because it offers an effective and relatively inexpensive means for managing weed problems.

MATERIALS AND METHODS

Experimental site.

The experimental plot was located at the Teaching and Research farm of Oyo state college of Agriculture and Technology, Igboora (Latitude $7^0$40N and Longitude $3^0$30E).

Land preparation and plot layout

The land was slashed manually and debris packed. There were 15 plots each measuring 3m by 3m and 1m between plots.

Sowing of seed was done at a spacing of 75cm by 50cm.Three (3) seeds were planted per hole and later thinned to two (2) plants per stand to make a total plant population of 53.333 plant/ha

Experimental design.

The experiment was laid out in a Randomized Complete Block Design (RCBD) with three replicates. The treatments include: (i). Glyphosate applied at 4.1 liters/ha (ii). Gramoxone applied at 4.1 liters/ha (iii). United force applied at 4.1 liters/ha which was done one week after the slashing and clearing the plot. The minimum tillage and conventional tilled plots were weeded manually at 3rd and 5th weeks after planting. N.P.K 15:15:15 fertilizer was applied at 5g per stand at 3rd and 5th week after sowing. At flowering stage of the crop the plots rouged after the data for weed population and biomass had been taken. This was to allow for complete harvesting.

Data collection

The agronomic parameter taken on the plants include Germination % at 5days after planting by visual counting which was calculated as $\frac{\text{number of seeds germinated per bed}}{\text{Total number of seed sown per bed}} \times \frac{100}{1}$.

Plant height was measured using a meter rule at four weeks after sowing (4WAS) and at flowering stage. Leaf area was measured at (4WAS) and at flowering stage using the formula (Lx B) 0.75. Weed population biomass was also taken at (4WAS) and at flowering stage using 0.25/ 0.25 quadrant for measurement, Number of days to flowering was done by counting, Number of days to 50% flowering was done by counting, Weight of seeds per cob was measured on a sensitive scale and Stem diameter was measured using Vanier caliper at flowering stage.

Data analysis

All the data collected were subjected to analysis of variance (ANOVA) and significant means separated using Duncan multiple range tests (DMRT).

RESULTS AND DISCUSSION

Table 1: Effects of herbicides on the germination and growth performance of maize

		Plant height (cm)		Leave area (cm)		Stem diameter
Herbicides	Germination (%)	4WAP	At Flowering	4WAP	At Flowering	At flowering
Glyphosate	92.3a	57.0a	181.2b	34.2ab	712.1a	2.1ab
Gramoxone	88.6a	56.5a	162.3b	19.3b	481.5a	1.9bc
United force	82.9a	41.3b	158.4b	29.0ab	467.4a	2.0bc
Minimum tillage	88.6a	53.5a	159.6b	32.1ab	552.4a	1.8c
Convectional tillage	90.5a	64.7a	231.3a	39.2a	772.1a	2.3a

Means followed by the same letter are not significantly different from others at 5% level of probability using Duncan's Multiple Range Test (DMRT)

Effects of herbicides on the germination and growth performance of maize

It was observed in table 1, that there was no significant difference in maize germination percentage across the treatments though the plant height was significantly affected by the treatments. At the flowering stage, significant difference was observed between the conventional tillage and other treatments. It was also observed that the conventional tillage significantly affected the plant leaves area (39.2cm) similarly the conventional tillage had significant effect on the stem diameter of the plant.

Table 2: Effects of herbicides on the yield parameters and yield of maize

Herbicides	**Numbers of days to flowering**	**Numbers of days to 50% flowering**	**Numbers of seeds per cob**	**Weight of seeds per cob (g)**	**weight of 100 seeds (g)**	**Seed yield (kg/ha)**
Glyphosate	53.0c	57.7c	419.1b	98.7a	23.6a	5264.0ab
Gramoxone	55.3b	60.3b	365.9b	89.1b	23.0a	4752.0b
United force	58.3a	63.0a	368.6b	71.6b	21.0a	3818.6b
Minimum tillage	55.3b	59.7b	412.3b	97.5b	23.6a	5200.0ab
Convectional tillage	52.0c	56.0c	531.6a	128.5a	24.2a	6853.3a

Means followed by the same letter are not significantly different from others at 5% level of probability using Duncan's Multiple Range Test (DMRT)

Effects of herbicides on the yield parameters and yield of maize

The result in Table 2 shows that there is significant difference in the number of days to flowering among all the five treatments. Conventional tillage and glyphosate were the first to flower (52days) which is significantly faster than gramoxone and minimum tillage (55days). The highest number of seeds per cob (531.6 seeds) was produced from conventional tillage which was superior to other treatments. The least number was produced from gramoxone treated plot (365.9 seeds). There was significant difference between the treatments in respect to the weight of 100 seeds, conventional tillage produced the heaviest seeds (24.2g) as against united force (21.0g). Conventional tillage produced also had the highest maize seed yield (6853.3kg/ha) while plot treated with united force had least seed yield.

Table 3: Effects of herbicides on weed population and biomass

	weed density ($N_0/0.25m^2$)		**weed fresh weight ($g/0.25m^2$)**		**Weed biomass at flowering ($g/0.25m^2$)**
Herbicides	4WAP	At Flowering	4WAP	At Flowering	
Glyphosate	2.0ab	2.3ab	12.0b	118.5a	20.0a
Gramoxone	2.3a	3.0a	12.3b	92.3a	18.3a

United force	1.3b	2.7ab	20.0a	124.5a	21.7a
Minimum tillage	1.3b	2.7ab	9.7b	101.6a	21.7a
Convectional tillage	1.3b	2.0b	10.3b	105.5a	23.3a

Means followed by the same letter are not significantly different from others at 5% level of probability using Duncan's Multiple Range Test (DMRT).

Effects of herbicides on weed population and biomass

The result in table 3 shows the effect of herbicides on weed population and biomass, it can be observed that at 4WAS the weed density of plots treated gramoxone (2.3/0.25m^2) were significantly high while the least value (1.3/0.25 m^2) was observed on plots treated with united force, minimum tillage and conventional tillage. After flowering conventional tillage had the least weed density (2.0/0.25m^2) which is however similar to other treatments except gramoxone (3.0/0.25m^2) which had high weed density after flowering. The value of weed fresh weight at (4WAS) were similar among the treatments except united force (20.0g) however at flowering stage there was significant difference among all the treatments which significantly had higher value. It was also observed that weed biomass at flowering stage was similarly not affected by the treatments.

CONCLUSION

It can be concluded from the study that conventional tillage and glyphosate had the best effect on growth and yield performance of maize, it was also observed that united force caused delay in growth and reduced the yield performance of maize in the study area, thus glyphosate herbicide is recommended for zero tillage of maize production since it is less laborious when compared to conventional tillage system.

PROCEEDINGS
56th Annual Conference
Agricultural Society of Nigeria
24 - 28 Oct., 2022

ABSTRACT
A screen house experiment was conducted to evaluate growth and fresh pod weight of *Corchorus olitorius* using moringa leaf extracts and NPK 15:15:15 fertilizer. Moringa leaf extracts were extracted from moringa leaves using standard procedures. Corchorus seeds were sown into 20 experimental pots containing 8 kg of topsoil each. The seedlings were thinned to one seedling per pot after a week. Treatments were applied at 2 weeks of sowing in five replicates arranged in a complete randomized design (CRD). The seedlings were treated separately with 20ml foliar application of moringa leaf extracts (ethanol and water extractions) at 2 and 4 weeks after sowing; NPK 15:15:15 side-dressed at 100 kg/ha and control (untreated). Data were collected on plant height, number of leaves, stem diameter, leaf area and fresh pod weight on weekly basis from the 4th week after sowing to the 9th week. Data were analysed using Analysis of Variance and significant means were separated using Duncan Multiple Range Test at $p \leq 0.05$. Both NPK 15:15:15 and moringa leaf extracts enhanced the growth of corchorus. However, NPK 15:15:15 at the rate of 100 kg/ha gave the highest significant results in all the growth and yield parameters considered in this study. NPK 15:15:15 gave the highest significant plant height, number of leaves, stem diameter, leaf area and pod weight of 34.20cm, 33.20, 3.76mm, 35.80cm^2 and 15tonnes/ha respectively compared to other treatments and the control. Since, moringa is readily available and cheaper to obtain by the farmers in the study area, the extracts can be used by corchorus farmers when NPK15:15:15 is unavailable and the cost becomes uneconomical to boost the growth and yield of corchorus.
Keywords: Corchorus; Moringa; NPK; Growth and Yield

INTRODUCTION
Jute Mallow (*Corchorus olitorius*) is a popular leafy vegetable (Dansi *et al.*, 2008). It is an erect annual herb that varies from 60 cm to approximately 150 cm in height depending on the cultivar. The leaves and young fruits are used as a vegetable (Plants for a future, 2012). However, the crop yield is in serious decline due to low fertility soil, poor yield, pest and diseases. In traditional farming systems, low quantity of fertilizer is applied, but, Jute mallow responds well to fertilization, particularly

nitrogen (Ogunrinde and Fasinmirin, 2011). However, excessive and indiscriminate use of chemical fertilizers leads to soil degradation and imposes a serious threat to human health (Fujimoto, 1998). In the study area, jute mallow is cultivated on a small scale, so that the production cannot pay back the cost of purchase and transportation of mineral fertilizers, hence the need of alternative sources of fertilizer is important for sustainable production.

However, organic waste could be viable alternative to chemical fertilizers. Organic farming has enough positive impacts: the long-term productivity in soil conservation and improvement of soil fertility involves the sustainability of production for future generations and environmental impact. Moringa is suitable for intense production of many crops due to its growth hormone activity (Foidl *et al*., 2001). Moringa leaf extract can be used as foliar spray to increase plant growth (Rady *et al*., 2015). Moringa contains zeatin, a plant hormone derived from the purine adenine. It is a member of the plant growth hormone family known as cytokinins (Howladar, 2014). These plant hormones help cell division, differentiation, growth, protect against oxidation and help in nutrient assimilation. However, there are limited reports on the frequency of application of the moringa leaf extract and its impact on crop productivity in the study area.

The major constraint to increased corchorus production in the study area are low soil nitrogen and the non-availability of mineral fertilizer at the right time of farming to augment the soil nutrient deficiency and even when available most peasant farmers cannot afford it. Therefore the objective of this study was to evaluate the effects of moringa leaf extract and NPK 15:15:15 fertilizer on growth and yield of jute mallow.

MATERIALS AND METHODS

The experiment was carried out at the Screen house of Department Crop Production Technology, Oyo State College of Agriculture and Technology, Igboora, Oyo State. Igboora is in a derived savanna zone located (Latitude 7^0 26'1"N and Longitude $3^0$17'16"E) in Ibarapa Central Local Government Area of Oyo State. The region has two distinct seasons. The dry season is usually from November to March and wet season is from April to October. Also, the average high temperature of the region is 33 °C, while the average low temperature is 22 °C (weatherspark.com).

Composite soil samples were taken from the topsoil collection site at 0-20cm depth, air dried and passed through 2mm sieve and were sent to the laboratory to determine the physical and chemical properties of the soil. The pH was determined with pH meter and available phosphorus was estimated using Bray and Kurtz, 1945 method. Macro-Kjeldahl method was used to assess the total nitrogen of the soil (Jackson, 1958) and exchangeable Ca, Mg, K, Na and effective cation exchange capacity C.E.C in soil by use of atomic absorption spectrophotometer (Tel and Hargerty, 1984).

Fresh moringa leaves were collected from a moringa farm in Igboora town, thoroughly washed and air dried at room temperature. The dried leaves were pounded using pestle and mortar, kept in a well labeled sampling bag and taken to the laboratory for nutrients extraction. The ethanol extraction was done using the method of Makkar and Becker (1996). Moringa leaf powder (20g) was weighed and added to 675ml of ethanol in a 2.5 L Winchester bottle for 24 hours. Also, aqueous extraction was carried out using the method of Bashir *et al*. (2014). Fresh leaves (1kg) was weighed and added to 200ml of distilled water for 24 hours. The extracts were taken to the laboratory to analyze the chemical compositions of the solutes.

Corchorus seeds used for the study were collected from National Horticultural Research Institute (NIHORT) Ibadan. The seeds were sown directly into 20 experimental pots containing 8kg soil each at three seeds per pot before they were thinned down to one seedling per pot a week after sowing. The pot experiment was arranged in a completely randomized design (CRD), containing four treatments viz: - ethanol moringa leaf extract (EMLE), aqueous moringa leaf extract (AQMLE), NPK 15:15:15 fertilizer and the control in five replicates. Foliar application of EMLE and AQMLE was also done at the rate of 20ml 2 and 4 weeks after sowing.The application of NPK 15:15:15 fertilizer was done at the standard rate of 100kg/ha according to (Aluko, 2014) at 2 weeks after sowing (WAS) using side-dressing method. The control had no application of fertilizer or moringa extract. Data were collected from 4th to 9th WAS on weekly basis on the following growth parameters. The plant height was collected using measuring tape, leaf area (the length and breadth of the widest leaf) using measuring tape, number of leaves through visual counting, stem diameter using vernier caliper and fresh pod weight using measuring scale. The data collected were subjected to Analysis of Variance (ANOVA) and significant means were separated by Duncan Multiple Range Test at 5% level of probability using STAR, 2.0.1 (2014) version software package.

RESULTS AND DISCUSSION

Pre cropping soil analysis

The chemical and physical properties of the soil used for the experiment shows a pH value of 6.47 (Table 1) indicating that the experimental soil was slightly acidic. The soil is low in essential plant nutrients like nitrogen, phosphorus and potassium with values of 0.17%, 5.97mg/kg and 0.36cmol/kg respectively. These values were below the critical values of soils in the derived savanna ecological zone (Adeoye and Agboola, 1985).

Table 1: Physico-chemical composition of experimental soil

Element	pH (H_20)	Ca^{2+} (cmol/kg)	Mg^{2+} (cmol/kg)	K^+ (cmol/kg)	Na^+ (cmol/kg)	ECEC (cmol/kg)	Total N (%)	Av. P (mg/kg)
Value	6.47	3.65	0.76	0.36	0.54	5.34	0.17	5.97

Chemical composition of ethanol and aqueous moringa leaf extracts

Essential nutrients nitrogen, phosphorus and potassium were present in the EMLE and AQMLE. The composition of nitrogen, phosphorus and potassium in the EMLE were 11.68mg/100g, 5.24mgkg^{-1} and 4.20Cmolkg^{-1} respectively, while that of AQMLE were 4.10mg/100g, 1.20mgkg^{-1} and 1.83Cmolkg^{-1} respectively. Also, Zeatin and Giberrellin are present as natural growth enhancer with 4.94mg/100g and 2.80mg/100g respectively in EMLE and 2.83mg/100g and 1.90mg/100g respectively in AQMLE (Table 2).

Table 2: Chemical compositions of moringa leaf extracts

Elements	N	P	K	Zeatin	Giberellin
Ethanol moringa leaf extract (mg/100g)	11.68	5.24	4.20	4.94	2.80
Aqueous moringa leaf extract (mg/100g)	4.10	1.20	1.83	2.83	1.90

Growth responses of corchorus to moringa leaf extracts and NPK 15:15:15

The plant height of *Corchorus olitorius* responded differently to the treatments. There were significant differences P≤0.05 in the plant height of corchorus from fourth to ninth, weeks after sowing (WAS). Also at 9 WAS, corchorus treated with NPK 15:15:15 gave highest significant P≤0.05 plant height (34.20cm) than other treatments and the control with 22cm (Table 3). Also, different responses in the number of leaves of corchorus were observed amongst the treatments. There were significant differences P≤0.05 in the number of leaves of Corchorus from the fifth to ninth weeks, after sowing. At 7 WAS, Corchorus treated with NPK 15:15:15 gave highest significant P≤0.05 number of leaves of 33.20 than other treatments and the control with 18.40 (Table 3).

Moreover, the treatments showed significant P≤0.05 variations in corchorus stem diameter all through the experimental duration. At 9 WAS, corchorus plants treated with NPK 15:15:15 gave highest significant P≤0.05 stem diameter of 3.76mm than aqueous moringa leaf extract and the control of 1.51mm (Table 3), but was not significantly different from ethanol moringa leaf extract. There were significant differences P≤0.05 in leaf area of Corchorus from the fourth to ninth weeks, after sowing. At 9 WAS, corchorus plants treated with NPK 15:15:15 gave highest significant P≤0.05 leaf area of

35.80cm^2 than aqueous moringa leaf extract and the control with 19.80cm^2 (Table 3), but was not significantly different from ethanol moringa leaf extract.

CONTROL	8.20c	11.60c	12.60b	14.60d	17.20c	19.80a

Means with the same letter are not significantly different.

EMLE- Ethanol Moringa Leaf Extract at the rate of 20ml 2 and 4 WAS, AQMLE - Aqueous Moringa Leaf Extract (AQMLE) at the rate of 20ml 2 and 4 WAS, NPK- NPK 15:15:15 at the standard rate of 100kg/ha at 2 WAS, CONTROL- No application. WAS= Weeks after sowing.

Effects of moringa leaf extracts and NPK 15:15:15 on fresh pod weight (tons/ha) of corchorus

There was significant difference P≤0.05 in the fresh pod weight of *Corchorus olitorius* at ninth WAS. All the fruits collected were weighed weekly and the summed up. *Corchorus olitorius* treated with NPK 15:15:15 gave highest fresh pod weight of 15 tonnes/ha and was significantly higher (P≤0.05) than other treatments and the control of 2.01 tonnes/ha (Table 4).

Table 4: Effects of moringa leaf extracts and NPK 15:15:15 on fresh pod weight (tons/ha) of corchorus

TREATMENTS	9 WAS
NPK	15.00a
EMLE	9.28b
AQMLE	5.11c
CONTROL	2.01d

Means with the same letter are not significantly different at (P≤0.05)

The application of moringa leaf extracts and NPK 15:15:15 influenced the growth and fresh pod weight of corchorus. The significant increase in growth and fresh pod weight of corchorus treated with NPK 15:15:15 was due to the high levels of essential macro nutrients (nitrogen, phosphorus and potassium) present in the inorganic fertilizer than the moringa leaf extracts. This is because nitrogen, phosphorus and potassium are required for optimum growth and yield of crop. However, moringa leaf extracts increased the growth and fresh pod weight of corchorus than the control. This is because of the presence of Zeatin and Gibberellins which are growth enhancers present in the moringa leaf extracts. This is in line with Hala and Nabila (2017) who reported that Zeatin increased the yield of crop by 25 to 30% and Palada (1996) reported that foliar application of moringa leaf extracts increased the yield of peanut, soybean, sorghum and tomato.

CONCLUSION

It can be concluded that NPK 15:15:15 and moringa leaf extracts enhanced the growth and fresh pod weight of corchorus. Therefore the use of inorganic and organic fertilizers to boost growth and yield of the crop is of high importance. However, the application of NPK15:15:15 at the rate of 100 kg/ha gave the highest results in the growth parameters considered in this study. The high levels of nitrogen, phosphorus, potassium, Zeatin and Gibberellin present in the ethanol moringa leaf extract gave significant effects on the growth of the crop compared to the aqueous moringa leaf extract and the control. The results also indicated that Zeatin and Giberellin are the growth enhancers present in moringa leaf extract. However, moringa is readily available and cheaper to obtain by the farmers in the study area, and the extracts can be used by corchorus farmers when NPK15:15:15 is unavailable and the cost becomes uneconomical.

ABSTRACT

Cashew (*Anacardium occidentale* L.) seedlings are most times raised in the nursery and propagated by seed. Cashew seedlings are attacked by fungi diseases such as damping off and seedling blight caused by fungi such as *Fusarium spp*. and *Rhizoctonia spp*. which can amount to about 60-65% loss in the nursery. Cashew nut seeds are majorly sown by farmers untreated with fungicide-based seed dressings. Fungicides have also been observed to delay seedling emergence and negatively influence morphological traits. This experiment aims at observing the effect of using fungicide seed dressings on cashew seedling emergence and early morphological traits. Medium cashew nut biotype and three commonly used fungicide-based seed dressing's trade names which are; Seed Care, Dress Force and Apron Star were used using the recommended rate of 10g of fungicide/4kg of nuts on the label of each fungicide. The four weeks experiment was set up in a nursery using a Completely Randomized Design CRD. The treatments are; Control + Medium (CT+M); Apron Star + Medium (AS+M), Dress Force + Medium (DF+M) and Seed Care + Medium (SC+M). 2mm sieved topsoil using 25 cm by 12.5 cm nursery bags were used. The experiment was replicated thrice. Data were collected on the emergence and morphological traits which were analyzed using Analysis of Variance (ANOVA) by using GenStat statistical software while treatment means were separated using Least Significant Difference (LSD) at ($P \leq 0.05$). A significant difference was only observed at 28 DAS with AS+M (100%) and DF+M (100%) emerging as the best. A significant difference in stem girth was only observed between the control treatment CT+M ($0.63 cm^2$) and AS+M ($0.77 cm^2$). It could be deduced that the use of selected common fungicide-based seed dressing treatments can be used in preventing prevalent nursery fungi diseases without causing a delay in the emergence and negative impact on the morphology of young cashew seedlings

Key: Cashew; Seedling; Nursery; Seed dressing; Fungicide; Emergence.

INTRODUCTION

In Nigeria and other tropical nations around the world, cashew (*Anacardium occidentale* L.) is a tree crop of significant commercial importance (Ezeagu, 2002). It is a tough and drought resistant tree crop cultivated for its apple and most importantly the nut in Nigeria and other growing countries (Adeigbe *et al*., 2015). Commercial cashew plantations are established in various agro-ecologies of

Nigeria for cash earnings and sustainable income generation (Umeh, 2007) which has brought about an expansion in the land area cultivated in Nigeria.

Cashew is mostly propagated by seed (Yeboah *et al*., 2020) which is usually raised in the nursery for a recommended period of 2 to 3 months before transplanting to the field (Hammed *et al*., 2012). An encouraging and successful establishment of crops in the field has a direct effect on seedling performance in the nursery (Brown, 1984). Fungi which is a common pathogen of cashew in the nursery must be controlled as well as the use of dry, clean and insect free seeds to enhance vigourous and healthy cashew seedlings (Akos *et al*., 2017).

The health of cashew plants, including growth and nut yield in terms of quality and quantity, are severely compromised by diseases, which constitute a huge biological constraint to the plant (Kolawole *et al*., 2021). More than 10 common diseases of cashew are caused by fungi (Cardoso *et al*., 2013). Common fungi diseases of cashew at the seedling stage include damping-off, seedling blight, root rot, dieback and seedling wilt which constitute as high as 60-65% loss in the nursery as damping-off is the most prevalent constituting 15-20% of the losses (Hammed, 2015). Some important fungi disease causing pathogens includes *Phytophthora spp*., *Pythium spp*., *Rhizoctonia spp*., *Fusarium spp*. and *Cylindrocladium scoparium* (Dar *et al*., 2011).

Some seed dressing fungicide trade names commonly used in the nursery or on the field in Nigeria include Apron Star, Apron Plus, Forte Plus and Dress Force. Seed dressing treatments are not only known to control fungi diseases and pathogens but could also stimulate good plant performance and vigour (Yakubu *et al*., 2011).

Cashew seedling loss in two commercial nurseries caused by fungi diseases in the south-western part of Nigeria with a loss of about 80% to 85% facilitated the need to incorporate the use of fungicide-based seed treatments to prevent fungi diseases and also raise healthy seedlings. Most cashew farmers in Nigeria do not utilize agrochemicals to grow their cashew but are often used by researchers for experimental purposes (Aminu *et al*., 2021). Investigation of cashew farmers revealed that dressing cashew seeds with fungicide-based treatments are not a common practice in Nigeria as farmers believe cashew seed is a hardy seed and does not need dressing before planting. Seed dressing has been observed to be responsible for delay in germination, affects early morphological traits, interferes with yield in some arable crops and could however enhance their performance (Yakubu *et al*., 2011). It is therefore important to study the effect of the selected fungicide-based seed treatments on cashew seedling emergence and early morphological traits. Therefore, the objective of this study is to identify differences in using fungicide seed dressing on cashew seedlings' emergence and early morphological traits.

METHODOLOGY

The four weeks experiment was set up in July 2022 to August 2022 in a commercial nursery at Akinyele local government area of Ibadan, Oyo State. The experiment was laid in a Completely Randomized Design (CRD) with four treatments replicated thrice using the medium (4g-8g) cashew nut biotype and three commonly used fungicide-based seed dressings which are; Seed Care (Imidacloprid 10% + Thiram 10% WS), Dress Force (Imidacloprid 20% + Metalaxyl-M 20% + Tebuconazole 2% WS) and Apron Star (200g/kg Mefenoxam + 20g/kg Difenoconazole + 200g/kg Thiamethoxam WS) applied using the recommended rate of 10g of fungicide/4kg of nuts on the label of each fungicide. A control treatment was established where no fungicide was applied along with the other fungicide applied treatments. The treatments are; Control + Medium (CT+M); Apron Star + Medium (AS+M), Dress Force + Medium (DF+M) and Seed Care + Medium (SC+M). Sieved topsoil with a 2mm sieve was used in raising the cashew nuts planted using one nut per 25cm by 12.5cm perforated nursery polythene bag. The perforation of the nursery bags is to allow the drain of excess water that could promote fungi development and seed rot. The seeds were sown at 4cm depth and watering was done every 48 hours. Data on daily emergence % from the onset of the first noticeable emergence for four weeks were collected and morphological data on plant height (cm), stem girth (mm), leaf area (cm^2) and the number of leaves and seedling vigour (5-Excellent, 4-Good, 3-Fair, 2-Poor and 1-Bad) were recorded at four weeks after sowing. Data collected were subjected to Analysis of Variance (ANOVA) and analyzed using SAS 2010 Package while means were separated using DMRT at (0.05%) probability level.

RESULTS AND DISCUSSION

The emergence of cashew seedlings was first observed 13 days after sowing (DAS) but records were only taken between 14 to 28 DAS when emergence seems to have stopped according to Mog *et al*., (2017) as shown in Table 1. This emergence data agrees with Mog *et al*., (2017) who also observed that cashew seedling emergence starts as early as 12 DAS while emergence stops around 28 DAS. Percentage emergence was only comparable among the treatments at 28 DAS as shown in Table 1. Uniform % emergence of 25% was observed at 14 DAS. Emergence increased across the treatments at 16 DAS with AS+M and DF+M having the highest emergence of 66.70% each while both the control treatment CT+M and SC+M had 50% emergence each. At 18 DAS increase in emergence was also observed across the treatments when compared with 16^{th} DAS. AS+M (83.30%) had the highest emergence followed by DF+M (75%), SC+M (66.70%) and the control treatment CT+M (58.30%). No increase in emergence was observed at 20 DAS when compared with 18 DAS while only DF+M increased at 22 DAS to 100% from the previous 75%. This implies that DF+M was the first among the treatments to reach 100% emergence. This observation contradicts Yakubu *et al*., (2011) report that generally, seed dressing can cause a delay in emergence. CT+M (66.70%) and AS+M (91.70%) only increased in emergence at 24 DAS while CT+M (75%) only increased in emergence at 26 DAS. At the end of the emergence data reading at 28 DAS, AS+M and DF+M both had 100% emergence while the control treatments CT+M and SC+M both had 75% emergence. This result indicates that the application of the selected fungicide-based treatments on cashew nuts before sowing did not influence emergence negatively. A significant difference was observed between CT+M (75%) and AS+M (100%) and also between CT+M (75%) and DF+M (100%).

Table 2 shows the report of the early morphological parameters of the treatments 28 DAS. No significant difference was observed in plant height, the number of leaves, leaf area and seedling vigour though the control treatment CT+M (17.10cm) had the shortest plant height while SC+M (19.30cm) had the tallest plant height. AS+M (6.7) had the least number of leaves followed by CT+M (7), DF+M (7.2) and SC+M (8.3) which had the highest. The control treatment CT+M (56.60 cm^2) recorded the smallest leaf area while DF+M (62.60cm^2) had the largest leaf area. The treatments all had a relatively above good seedling vigour score. A significant difference in stem girth was only observed between the control treatment CT+M (0.63 cm) and AS+M (0.77 cm). However, CT+M had the smallest stem girth when compared with the other treatments. The result of these early morphological parameters indicates that the application of seed dressing fungicides on sown cashew nuts did not affect cashew seedlings negatively. This result also contradicts the general observation of Yakubu *et al*., (2011) that the application of fungicide-based seed dressings can negatively affect early morphological traits.

CONCLUSION

The application of the seed dressing fungicides did not delay cashew seedling emergence. Emergence was the same when comparing sown untreated nuts with nuts treated with Seed Care fungicide. Apron Star and Dress Force fungicides both gave improved emergence than untreated sown nuts and Seed Care fungicide treated nuts. The fungicide treated seedlings had taller plant height, stem girth and leaf area than the untreated cashew seedling though the overall seedling vigour showed no notable variation among the treated and the untreated seedlings. From this experiment, it could be said that the use of the selected common fungicide-based seed dressing treatments can be used in preventing common nursery fungi diseases without any negative impact on the emergence and plant morphology. However, a repeat of this experiment is encouraged in validating this result and also, the effect of these selected fungicide-based seed treatments should be checked on other cashew nut biotypes and when sown in situ.

ABSTRACT

Yam is one of the preferred staple foods in West Africa. The annual vegetative cycle of yam necessitates a long period of storage to make it available all year round. The major problems of yam tuber storage are dormancy which triggers sprouting, respiration and transpiration, which cause weight and quality losses and, expose the yam tubers to pathological issues. This work reviewed the effects of yam dormancy and respiration on yam tubers in storage, and how they affect the nutritional and other qualities of stored yam tubers thereby exposing them to pathological issues. Results of this review work on stored yam tubers showed that the methods which can help in controlling yam dormancy to reduce sprouting in storage, minimize respiration in stored yams to reduce weight loss and rot development will go a long way to increase the storability of yams tubers in storage.

Key words: Respiration, Dormancy, vegetative, sprout, transpiration

INTRODUCTION

Yam (Dioscorea spp.) are monocotyledonous plants belonging to the family *Dioscoreaceae* and genus Dioscorea. Over 600 species are identified but only six are important in Africa, Southeast Asia, and South America. The economically important species are *D. rotundata, D. alata, D. cayenensis, D. bulbifera, D. dumetorum, and D. esculenta* (Hahn 1995).

Yams produce edible subterranean or aerial tubers that form the organ of economic importance. The tuber is important chiefly as a staple food, providing nourishment to people in the tropics and subtropics. Depending on the specie, it is particularly rich in carbohydrate, containing 50–80% starch/dry weight. Other constituents of high nutritional values are vitamins C and B6, potassium, iron, manganese, and amino acids; contents of sodium and saturated fats are low. More than the daily adult requirement of vitamin C can be obtained from yam even after losses from cooking have been subtracted (Bell 1983). Also, the combination of high potassium and low sodium makes yam potentially important in protecting people against osteoporosis and heart-related diseases. Worldwide, as many as 5 million hectares of land are put to yam cultivation and about 49 million tonnes of the crop are produced with 94% of this value being grown in West and Central Africa (FAO 2005). In West Africa, consumption/capita/day ranges from 258 kcal (in Nigeria) to 364 kcal (in

Bénin Republic). Indeed, yam is so important that it has a place in festive occasions, rites, and taboos of the people. Agriculturally, the tuber is important as it is the source of planting material.

Planting materials

Cultivation is mainly by vegetative propagation using the whole tuber or pieces of it (setts). Planting is done between late January and April in West Africa coinciding with the start of the rains, although early plantings in November–December are known in areas where there are swamp land areas. Irrespective of when planting is done, vine emergence occurs about the month of February and beyond,. Tubers are initiated from 30 days after vine emergence and these are formed underground in most species including *D. rotundata*. However, some species, such as *D. alata*, produce aerial tubers. Flowering occurs 40 to 90 days after vine emergence (Ile *et al*., 2006) depending on the planting date. In yam, therefore, growth is dependent on yam dormancy as the farmer must wait for yams to break dormancy before planting them but tuber development commences during early growth.

Harvesting of yam

Tubers become mature for harvest as early as 6 months after vine emergence, corresponding to about the month of August. Early harvested tubers have very high moisture content and so are prone to deterioration from diseases. Also, they have a bland taste after being cooked. The main harvesting season falls between the months of November and January of the following year, coinciding with the onset of shoot senescence and the start of the dry season. These tubers are larger, morphologically more mature, have a higher dry matter content and lower moisture, a lower susceptibility to deterioration, and better cooking and nutritive qualities than those from an early harvest. After harvest and during storage, sprouting begins. Sprouting tends to occur at a definite period of the year, coinciding with the onset of the rains. Hence, the duration to sprouting varies from 30 to 150 days, depending on harvest date, species, and storage conditions. Tubers harvested early in the season spend a longer time in storage before sprouting occurs. Though the onset of sprouting is welcomed by the farmer who desires to commence planting, it marks the start of physiologically and pathologically induced deterioration and eventually the loss of food quality. The period during which yam tubers will not grow, even if put under ideal conditions for growth, is referred to as the dormant period and such tubers are said to be dormant.

Preservation as relates to white yam

Preservation refers to the process of treating foods to preserve them much longer in storage. It is the act of applying a physical or chemical treatment to food items to protect and maintain their nutritional contents and avoid food deterioration or spoilage over time. The shelf-life and shelf-stability of food are extended by food preservation. It also protects the food from dangerous bacteria and enzymes that might affect human health, promotes longer shelf life, and encourages availability of convenience foods, such as ready-to-serve beverages and instant mixes (Olaoye and Oyewole, 2012). It is important to understand how yam tubers change during storage. In the context of this presentation, it is important to give some background insight of the pathological events that take place in storage during yam preservation and we infer that yam preservation commences from the point of harvest and dormancy.

The concept of dormancy, tuber respiration and implication for storage

According to Lang *et al* (1987) dormancy is a temporary growth arrest of any plant part containing a meristem. It is the period during which yam tubers will not grow, even if put under ideal conditions for growth. . It is an inherent plant physiological mechanism that regulates the timing of sprouting of affected plant part. The dormancy period can also be defined as the period of reduced endogenous metabolic activity during which the tuber shows no intrinsic bud growth, although it retains the potential for future growth. It is highly influenced by genetic and evolutionary constituents and also affected by environmental factors such as; temperature, moisture, oxygen, and CO_2 content of the storage atmosphere (Ile 2004). Dormancy has been classified into three categories based on the factors that influenced growth arrest (Lang *et al* .,1987). These include: Endodormancy (this is a deep dormancy during which growth arrest is influenced by internal physiological and genetic factors within the meristem), Para-dormancy (this occurs due to growth arrest by physiological factors external to the meristem), and Eco-dormancy (growth is stopped by unfavorable external or environmental factors). The consequence of dormancy is severe for yam preservation system because the duration of dormancy is very long; as many as 270 days, depending on the time of tuber harvest and the definition of the start of dormancy (Hamadina 2011). Another perspective to this phenomenon buttresses that dormancy in yam tubers occurs in the following phases: the long phase I of dormancy (the period from tuber physiological maturity to the formation of tuber germinating meristem(TGM), which is up to 200 days). Phase II is the period from TGM to the initiation of foliar primordium-IFP, which is about 40 days long. Thirdly, a short phase the period from IFP to the physical appearance of shoot bud (ASB) on the surface of the tuber, which is only about 10 days (Ile 2004). In principle, increasing the period under Phase I (TGM) as highlighted above would be useful in developing yam genotypes with an increased period of dormancy. Though the onset of sprouting is welcomed by the farmer who desires to commence planting, dormancy breakage marks the start of physiologically and pathologically induced deterioration and eventually the loss of food quality (Hamadina 2011). Dormancy helps to maintain organoleptic quality during storage (Ovono *et al.*, 2010).

Yam tubers are living. It takes or breathes in oxygen from the air and uses it inside its body, in this case the fleshy interior. Breathing process involves that the tuber must give off air that is used. Secondly, to stay alive the tuber must “eat” or nourish itself by consuming a tiny part of its stored food. In this process the yam gives off heat and moisture as wastes. The entire process of breathing in air and consuming its stored food and then giving off used air carbon dioxide, heat and moisture is called respiration (Panneerselvam *et al.*, 2007). Good and safe storage of yam tuber requires that the tuber should respire slowly.

The aforementioned dormancy and respiratory dynamics is manipulated to confer storage elongation and pathological through the following protocols. These protocols evolved from rich indigenous knowledge of farmers. A practice that time has perfected but currently under threat with climate change scenarios.

Knowledge gained from different works in the past has made it much easier to relate the effects of treatments on dormancy to specific physiological states, the phases of dormancy. In the past, conclusions on the control of yam tuber dormancy were difficult because of the inability to relate the effects of plant growth regulators (PGRs), and other effects, to any physiological state. The findings of Hamadina (2011) has stimulated the establishment of more in-depth explanations of the mechanism controlling tuber dormancy, such as the effects of PGRs on subcellular activities relating to the progress towards appearance of shoot bud. The work also forms a base for effective studying and analyzing dormancy in yam species and other root and tuber crops exhibiting dormancy.

Pathological issues emanating from dormancy and respiration in yam

Causes of storage losses of yam tubers include dormancy (time length of sprouting), respiration, transpiration, rot due to fungi and bacteriosis, insects, nematodes and mammals (Passam *et. al*., 1978). Sprouting, transpiration and respiration are physiological activities which depend on the storage environment mainly temperature and relative humidity. These physiological changes affect the internal composition of the tuber and result in destruction of edible material, which under normal storage conditions can often reach 10% after 3 months, and up to 25% after 5 months of storage (Passam et. al., 1978). The dry matter portion of yam tubers is mostly composed of carbohydrates, which exist primarily in the form of starch and sugars (Ikediobi and Oti 1983). A study conducted on the chemical composition of yam tuber stored under ambient and cold room condition showed no significant differences between the means obtained for carbohydrate, fat and fiber after 72 hours of storage (Afoakwa and Sefa-Dedeh, 2001). Onyeme and Idowu (1988) studied physical and chemical changes that occur on yams stored in traditional barns. Their result shows losses in moisture, dry matter, crude protein and ascorbic acid after 120 days of storage. Consequently they recommended that farmers should not store yam tubers for a period longer than 120 days as this exposes the yams to pathological issues, loss in qualities and market value.

CONCLUSION

Generally, it can be concluded that all the methods that can help in managing dormancy and respiration on yams in storage such as good ventilation, high relative humidity and reduced light can help in reducing weight loss, drying, rotting and other pathological issues. This study shows unmanaged dormancy and high rate of respiration can cause reduction in quality of yams and expose them to attacks by pests and diseases during the storage period.

ABSTRACT

A research study was carried out in June 2021 to investigate the productivity index of Turmeric using poultry manure (PM) and NPK 15.15.15 in Kogi State University Anyingba. Treatments consisted of poultry manure, NPK 15:15:15 fertilizer and the combination of poultry manure and NPK with two varieties of turmeric (*Curcuma xanthorhiza* and *Curcuma longa*). There were eight treatments combination laid out in a complete randomized design block (RCBD). NPK fertilizer and poultry manure were applied at 400 kg/ha and 6 tonnes/ha respectively after weeding at 4 WAP. The result showed that the plots that received either poultry manure or its combination with NPK had significantly higher values of number and weight of rhizome than the control check. X+0 gave 19.0 and 0.89 kg on number and weight of rhizome respectively in *Xanthorhiza* variety, the same trend also occurred in *longa*. Harvest index was remarkably low on the zero application of X+0 (45.27%) and L+0 (45.27%) than other treatments. PM produced the highest leaf dry weight of *Xanthorhiza* species (0.30 kg), while its combination with NPK gave the highest value (0.30 kg) in *longa*. Higher yield was obtain in a single application of PM than single application of NPK15:15:15 but considerable high yield was achieved in the combination of both PM +NPK than the single application. Poultry manure + NPK produced highest yield of 15.6 t/ha in *C xanthorhiza* and 12.05t/ha in *C longa* resulting to 43 and 62% increase in yield over the control respectively. Therefore, to avert the high cost of NPK organic fertilizer and achieve a superior effect in terms of balanced plant nutrient in Anyingba, It is recommended that combination of Poultry manure and NPK fertilizer is required for optimum production of turmeric.

INTRODUCTION

Turmeric (*Curcuma longa* L Lam*)* is one of the underutilized crop species, it is an herbaceous perennial belonging to the family *Zingiberaceae* and a native of south Asia particularly India (Ouma and Jeruto, 2010). The plant is propagated from rhizomes, the leaves are long, broad, lanceolate and bright green. The flowers are pale yellow and borne on dense spikes. The pseudo stems are shorter than leaves and require a warm and humid climate (Ouma and Jeruto, 2010). Turmeric thrives in different types of soils ranging from light black loam, red soils to clayey loams. The production and nutritional values of these turmeric are limited due to the low fertility of native soils in most parts of Nigeria (Law-Ogbomo *et al*., 2012).The potentials of organic manure for improving crop yields in agriculture are widely recognized (Nwaogu *et al.*,2005).

However, differences exist in the quality of organic amendment materials which can considerably influence the levels of some organic compounds formed in plants thereby impacting on the biochemical and physiological process of the plant product. The use of inorganic fertilizer to increase the yield has been found to be effective only within few years, demanding consistent use on long-term basis (Ojeniyi *et al.*, 2009). The hazardous environmental consequences and high cost of inorganic fertilizers make them not only undesirable but also uneconomical and out of reach of the rural farmers who still dominate the Nigerian agricultural sector (Shiyam *et al*., 2011). Poultry manure has been reported to contain more plant nutrients than all other organic manures (Ali, 2005).The use of chemical fertilizers and organic manure has both positive and negative effects on plant growth and the soil. Chemical fertilizers are relatively expensive, have high nutrient contents, and are rapidly taken up by plants. There is a need to determine the independent influence of poultry manure and inorganic fertilizer such as NPK on the growth, yield, and nutritional quality of fast-growing turmeric as to justify the continuous mixture of both or otherwise. There is a dearth information on the use of chemical fertilizers and poultry manure on turmeric production in Anyingba Kogi state. The objective of the work is to determine the effect of poultry manure and NPK on yield and performance of turmeric.

MATERIALS AND METHODS

This study was carried out between June and November 2021 at the botanical garden of the department of Plant Science and Biotechnology, Faculty of Natural sciences, Kogi State University, Anyingba which lies between longitude 7.5˚N and latitude 6.9˚E with an altitude of 420 meters above sea level. The site is known with a suitable atmospheric condition, having an annual mean rainfall and temperature of 1250 mm and 25˚C respectively. The vegetation is typical of derived savannah with a sandy soil (Ifatimehin, 2009). The experimental site was cleared of the existing vegetation, cleared and bed were made manually with hoe.

Each bed represented a plot of 2 m × 2 m. The plots were marked out into three (3) replicates with eight treatments combinations laid out in a complete randomized block design (RCBD). Plant spacing was 50 cm x 30 cm. The treatments were as follow; two varieties of Turmeric (*Curcuma xanthorhiza* and *Curcuma longa*), NPK fertilizer 15-15-15 and poultry manure. The treatments combination were; *C. xanthorhiza* + Control (no fertilizer); *C. xanthohriza* + Poultry manure; *C. xanthorhiza* + NPK *C. xanthorhiza* + NPK + Poultry manure; *C. longa* + Control (no fertilizer); *C. longa* + Poultry manure; *C. longa* + NPK + Poultry manure and *C. longa* + NPK. NPK 15-15-15 fertilizer was weighed out as recommended rate of 400 kg/ha (Olojede *et al*,2007) while poultry manure was applied at 6 tonnes/ha (Nwokocha *et al*,2005) the treatments were applied at 4 weeks after planting (4WAP).Weeding and other cultural practices were done as at when due. Growth and yield data were collected and subjected to analysis of variance (ANOVA) (SPSS Program, version 20 SPSS Inc., Chicago, IL, USA for computer package). The differences between the treatments were compared using Duncan Multiple Range Test (DMRT). Values of P less than 0.05 ($P \leq 0.05$) were taken as significant.

RESULTS AND DISCUSSION

The result showed that the plots that received either poultry manure or its combination with NPK had significantly higher values of number and weight of rhizome than the control check (Table1). X+0 gave 19.0 and 0.89 kg on number and weight of rhizome respectively in *Xanthorhiza* variety, the same trend also occurred in *longa*. Harvest index was remarkably low on the zero application of X+0 (45.27%) and L+0 (45.27%) than other treatments.

In table 2, PM produced the highest leaf dry weight of *Xanthorhiza* variety (0.30 kg), while its combination with NPK gave the highest value (0.30 kg) in *longa*. Tiller dry weight responded more to organic manure and combination with NPK in both varieties. The treatments have no effect on the dry matter.

The highest yield in t/ha was obtained in combination of PM +NPK, this occurred in both varieties. The *C. xanthohriza* variety produced 15.6 t/ha while the *C. longa* gave 12.05 t/ha resulting to 43 and 62% increase in yield over the control respectively. This also reflected in harvest index where the lowest value was obtain in zero application (control) of X+0 (45.27) and L+0 (48.60). The yield components responded more on the combination of PM and NPK, although single application of PM produced more values than single application of NPK. This resulted due to excellent soil amendment performance of PM that provides nutrients for growing crops and also improves soil quality when applied wisely, because it has high organic matter content combined with available nutrients for plant growth (Van Ryssen *et al*., 1993).The harvest index showed optimal yield efficiency in all the treatments except the control, this revealed that poultry manure in combination with NPK is an indicator to yield efficiency and productivity. This agrees with the work done by Kour *et al*. (2014) and Obasi *et al.* (2021) that reported that yield and harvest index could be influenced by organic and inorganic soil amendment.

CONCLUSION /RECOMMENDATION

The application of organic and inorganic fertilizer to turmeric has significant effect on the yield components which also lead to a high yield in t/ha obtained during the study. Harvest index was significantly higher in all the treatments than the control. The experiment showed that high yield was obtained in a single application of PM than single application of NPK 15:15:15 but considerable higher yield could be achieved in the combination of PM +NPK than their single application. In conclusion, to avert the high cost of NPK fertilizer, it is recommended that combination of Poultry manure and NPK fertilizer is used to achieve a superior effect in terms of balanced plant nutrient and for optimum production of turmeric in Anyimgba Kogi .

ABSTRACT
Sweetpotato is cultivated in all the States in Nigeria including the Federal Capital Territory. However, there are traits preferred by Users., evaluation of advanced orange fleshed sweetpotato genotypes was carried out at the Western Experimental field of National Root Crops Research Institute (NRCRI), Umudike in Southeastern Nigeria in 2021 cropping season with the objectives to: select sweetpotato genotypes for high storage root yield, response to biotic reaction and high dry matter content attributes necessary for sweetpotato cultivation and consumption. Data collected were on: total fresh storage root yield in t/ha, total number of storage roots per genotype per plot, mean storage roots per plant and storage flesh colour and dry matter content. Data collected were analyzed using analysis of variance. The storage flesh colour was compared using sweetpotato colour chart while data on biotic stresses were rated on a Scale of 1 to 9. Results indicated that 60% of the sweetpotato lines had mean storage root weight of above 8.0t/ha and mean number of roots between 1.5 to 9.2 per plant. This indicated that the OFSP genotypes are high yielding. Their dry matter content ranged from 28 to 30.0% which is acceptable to sweetpotato consumers as high dry matter content gives good taste. It is therefore recommended that although some genotypes seem to be immune/resistant to sweetpotato virus infection, more work is required to better classify these genotypes with respect to their reaction to virus as some symptomless genotypes in the trial may have escaped infection. Also more work is required for the high yielding sweetpotato genotypes for immediate multi-location testing for selection of superior genotypes with high dry matter that will be acceptable to the end-users.

Key words: orange fleshed, sweetpotato, dry matter, high root yield, biotic response and attributes

INTRODUCTION
Sweetpotato is an important food crop for Nigerians. The crop is cultivated in all the States in the country including the FCT (Federal Capital Territory, Abuja). It plays important role in the diets of Nigerians where it is used as fast food by Super Markets and Road side food vendors in Nigerian cities, University campuses. In food industries it is used for making flour, cakes, chips, doughnuts and bread. Starch for textile industries, the leaves are used for dying clothes, fodder for animals and leafy vegetables for human consumption. The flour can be stirred in hot water into thick paste for use as swallow or in other food supplements like in cooking beans.

About 84,000 hectares is devoted to sweetpotato cultivation annually in Nigeria with 65% production from the northern part of the country, 25% production from the eastern part of the country particularly Ebonyi, Anambra and Enugu States while 10% production could be from Western part of the country especially Kwara State (FAOSTAT, 2022). Most of the sweetpotato storage roots produced from the country is consumed within the country with less than 1.0% for export to surrounding western African countries. The consumption rate of sweetpotato in the country is steadily increasing as a result of much pressure on cassava (Okpara, 2008). The crop is a short duration crop with only 4 months duration in the field. Its rate of cultivation turnover is faster when compared with other root and tuber crops. (Yam 7 to 12 months duration in the field, cassava 7 to 12 months duration in the field, cocoyam 12 months in the field (Okpara, 2008).

The average yield of storage roots of the crop in farmers field is only 6t/ha. This low yield is attributed to low yielding of varieties and late maturing of local landraces that farmers are cultivating (Gurmu et al., 2017). Other constraints in sweetpotato cultivation are sweetpotato virus disease complex, sweetpotato storage root weevils (Cylas Spp) and the inability of the sweetpotato to tap nutrients from the low soil fertility (Gasura, et al., 2008).

Nigerian farmers grow a wide range of sweetpotato landraces which have been selected by farmers over time Haris et al., 2020). These landraces came from sources such as chance seedlings and introductions from neighbouring countries. These varieties have accumulated high loads of viral diseases in their system which has led to low yields in both storage roots and in foliage (Arituaet al 1993). These landraces have low dry matter which is associated with culinary qualities acceptable by consumers, however, these landraces are also susceptible to sweetpotato virus diseases (SPVD) caused mainly by sweetpotato feathery mottle virus (SPFMV). SPVD complex is an important sweetpotato production constraint in Nigeria especially for the orange fleshed variety (Wambugu, 1991). The objective of this study is to screen sweetpotato genotypes at the Advanced Yield Trial for high storage root yield, response to biotic reaction (sweetpotato storage root weevil, leafspot, virus diseases) and dry matter content attributes necessary for sweetpotato cultivation and consumption**.**

A total of 30 genotypes were evaluated in a randomized complete block design with three replications at the Western experimental field of NRCRI, Umudike. Each genotype was planted on a $9m^2$ plot at a spacing of 100cm between ridges and 30cm between plants and planted on the crest of the ridges. A virus susceptible variety (UMUSPO/3) and a national variety (TIS87/0087) were included in the trial as Check varieties**.**. The planting materials from all the clones were healthy four node seed vine cut from the terminal portion of healthy sweetpotato mother plants and were planted on the ridges with at least two nodes of the seed vine inserted into the soil.

The sweetpotato crop was weeded at 4 WAP (Week After Planting). Other subsequent weeding were hand pulling of tall weeds that would otherwise block the sweetpotato plants from receiving maximum sunlight necessary for photosynthesis for storage root bulking. Harvesting took place 150 days after planting. At harvest the following data were collected: mean total fresh storage root yield in t/ha, mean total number of storage roots per genotype per plot, mean storage roots per plant and storage flesh colour. Also noted were storage dry matter content which was determined by oven drying of 100g of fresh sample at 80^0C for 48 hours. Data were also collected on virus severity, leafspot and storage weevil infestation. Data on storage components were subjected to analysis of variance and the storage flesh colour was compared using sweetpotato colour chart while data on biotic stresses were rated according to Toker et al (1999). Virus symptoms were scored at 2 and 3 MAP (Months After Planting), on a Scale of 1 to 9. Where 1.0 means no symptom and 9.0 means plant almost dead with disease. Disease assessment was carried out using 1-9 disease severity (DS) rating scale as suggested by Toker *et al*. (1999).

Where:
1 = Immune , 2 = Highly Resistant, 3 = Resistant, 4 = Moderately Resistant, 5 = Tolerant, 6 = Moderately susceptible, 7 = Susceptible, 8 = highly susceptible, 9 = highly susceptible.

RESULTS AND DISCUSSION

The result of 30 sweetpotato genotypes on mean number of storage roots, total weight of fresh roots, storage root dry matter content and size of storage roots of sweetpotato genotypes and their reactions to biotic stresses are presented in Table 1.

Table 1: Mean number, fresh, dry matter and size of storage roots of sweet potato genotypes and their reactions to biotic stresses

The number of storage roots produced by each of the genotypes varied significantly (p<0.01) and ranged from 0 to 9.2 plant per 1000/ha with the Check varieties producing less number of storage root of 1.5 (Tis87/0087) and 3.2 roots (UMUSPO/3) respectively less than the improved genotypes as per yield with mean of 3.8 per plant/1000plants/ha. This number of storage roots per genotypes indicated the potential yield per plant of each of the sweet potato genotypes. The number of storage roots produced by the genotypes is used by the farmers to assess high yielding genotypes. The number of storage roots enable the farmer to estimate the number of piece meal harvests the subsistent farmer may intend to do. The higher the number of storage roots, the higher the fresh weight yield of the sweet potato genotypes. High storage yielding sweet potato has a role to play in food security, creation of employment opportunities and poverty alleviation as well as export crop (Ogundele et al. 2008).

The mean performance of the sweetpotato genotypes with fresh storage root yield above 8.0t/ha is presented in Table 1. The total fresh storage root weight varied significantly (p<0.01) and ranged from 10.7 to 40.4t/ha. According to Henderson et al (1997) sweetpotato yield over the years are not stable as they are subjected to environmental effect. These genotypes yielded more fresh root weight than the two Check varieties UMUSPO/3 (with yield of 9.6t/ha and TIS87/0087 with yield of 8.7t/ha. About 40% of the genotypes were low yielding since genotypes yielding less than 10t/ha is regarded as low yielding variety, while up to 60% yielded above 10.0t/ha which indicated that many of the F1 sweetpotato generation at the Advanced Yield Trial were high yielding. (Ajiboye et al., 2008). Sweet potato genotypes suitable for cultivation must have high fresh matter yield across all agro-ecologies. Large scale production of these genotypes could further enhance food sufficiency in the country, and trigger economic revitalization and alleviation of poverty as the benefit trickle down from the farmer to middlemen to large scale or small sale business owners down to consumers.

The dry matter content of 60.0% of the genotypes was above 28.0%, which indicated that these genotypes would possess acceptable taste. This is because good sweetpotato taste is associated with high dry matter content. Also sweetpotato genotypes with high dry matter content would yield high starch and flour for industrial uses such as making of baby foods (Caetano, 2017).

Pathological reactions: Of the high yielding F1 advanced sweetpotato genotypes, only PO3/6 with virus score of 2.2 and PO3/36 with virus score rating of 2.3 presented mild virus symptoms while the rest of the genotypes in the field appeared immune. The susceptible Check variety (UMUSPO/3) was severely infected which indicated that virus infection did occur during the trial and that some of the high yielding genotypes may be immune to virus infection. All the genotypes showed no symptom of leafpot (Alternaria) attack. This indicated that the genotypes may be immune to fungus infection. However, more work is required to better classify these genotypes as immune, resistant or susceptible (Gruneberg et al., 2005; Kiyuva et al., 2020).

Entomological reactions: The following genotypes were mildly attacked by the sweetpotato storage root weevil; PO3/139 with score of 1.3, PO3/119 with score of 1.2, PO3/116 with score of 1.5, 87/OP/65 with score of 2.1 and NSPO/2012/068 with score of 1.2 while the rest escaped attack by the weevil. The harvest took place when the soil was still moist. The mild attack indicated that at the heart of dry period these genotypes would not survive. This is because research showed that sweetpotato storage root weevil is a dry season pest and attack more during dry spell.

CONCLUSION

This study revealed that 60% of the sweetpotato lines had storage root weight of above 8.0t/ha and number of roots between 1.5 to 9.2 per plant. This indicated that the OFSP genotypes are high yielding. Their dry matter content ranged from 28 to 30.0% which is acceptable to sweetpotato consumers as high dry matter content gives good taste. It is therefore recommended that although some genotypes seem to be immune/resistant to sweetpotato virus infection, more work is required to better classify these genotypes with respect to their reaction to virus as some symptomless genotypes in the trial may have escaped infection. Low yielding sweetpotato genotypes are a major constraint to high sweetpotato production and therefore the low yielding genotypes should be discarded. More work is required for the high yielding sweetpotato genotypes for immediate multi-location testing for selection of superior genotypes with high dry matter that will be acceptable to the end-users.

Agricultural Society of Nigeria
24 - 28 Oct., 2022

ABSTRACT

Not all sweetpotato genotypes perform better under all agro-ecologies. Based on this, one year trial was conducted in 2021 for multi-location trial of sweetpotato genonotypes across different agro- ecologies for high storage root yield and response to biotic stresses in Nigeria. Twenty five clones were planted in three replications at each site at spacing of 100cm between ridges and 30cm within plants in a plot size of 9m^2 (3m x 3m) in randomized complete block design across ten locations in Nigeria. Data collected include total weight of storage roots in t/ha (TWOSR) weight of commercial in t/ha (CRW), weight of non- commercial roots in t/ha (NCRW) and weight of vines in t/ha (VW). Statistical analysis was carried out using STAT computer package version 9. Analysis of variance was conducted for all the traits to detect significant differences among the clones with the model for a randomized complete block design. The Harvest index was used to select high yielding genotypes per unit area for on-farm trial. Results indicated that the following varieties were selected: 87/OP/195 (34.1t/ha), Cemsa 74-228 (31.0t/ha), PGN16021-39 (26.6T/ha), PGA14011-43 (26.6t/ha), Cri- Okumkom (25.4t/ha), Cri-Apomuden (25.0t/ha), PGA14442-1 (24.2t/ha), PGN17362-N1 (24.0t/ha), PGA14398-4 (24.0t/ha). PGA17265-N1 (23.4t/ha), Cri-Dadanyuie (23.1t/ha) and PGA14351-4 (23.0t/ha). The above genotypes were selected as a result of high harvest index and large storage root weight above their grand mean. The varieties selected could be used as parents in the breeding programme to utilize their good qualities as resistance to biotic stresses for progeny development in Nigeria. These genotypes should be tested further for farmers to make their final selection.

Keywords: multi-location, storage roots, harvest index, progenies and biotic stresses

INTRODUCTION

Sweetpotato is a light demanding crop grown primarily on well drained soils across the country Nigeria (Agbo, 2013). The crop adapt to a wide range of climatic and soil conditions, from the hot windy agro-ecological zone of the north to the colder rainy conditions of the South of the country. In the rain fed Nigeria agriculture, sweetpotato plants are used to provide fodder, control soil erosion on hilly regions, and to supply raw material in form of starch and dye for food and textile industries. Although, having good irrigation facilities, the sweetpotato crop could be cultivated during dry season In southern zones of Nigeria where high rainfall and soil acidity are problems, sweetpotato crop thrive well to earn some income (Nwodo, 2008). Sweetpotato a multipurpose and fast growing crop which provide a wide range of food products and non-food products. The crop is well suited for special purpose such as the establishment of biological control of soil erosion in erosion prone areas of the country and nutrient cycling when the crop dies and decay in low soil fertility areas. The crop is able to grow under erosion prone sites, compacted acidic and saline soils provided the roots have sufficient moisture content. Sweetpotato provide lots of potential in household foods, industry, biomass production for animal fodder (Woolfe, 2002). sweetpotato can be introduced as food crop under diverse climatic and edaphic conditions of Nigeria (Eneji et al., 1995). Sweetpotato food products are high in carbohydrate. The crop is rich in vitamins and minerals in comparison with other roots and tuber crops However, majority of sweetpotato genotypes and their landraces are low yielding. High storage root yielding varieties has high harvest index. According to Nwankwo, I.I.M and O. D. Onyegbula (2021), harvest index refers to the storage root yield per unit area and is defined as the ratio of storage root yield and above ground biomass. Harvest index could be used to select high yielding varieties (Nwankwo, I.I.M and O. D. Onyegbula (2021). One of the limiting factors of sweetpotato landraces are low yield in terms of number of storage roots per stand or in terms of fresh matter accumulation per unit area. The harvest index could be used to select high yielding varieties among the varieties evaluated. Therefore the objectives of this trial were to select superior high yielding storage root genotypes across diverse agro-ecologies in Nigeria for on-farm evaluation to replace old varieties in target environments using harvest index.

MATERIALS AND METHODS

The study was carried out in 10 experimental locations in order to estimate genotype by environment interaction in diverse environments. The locations and their soil description are presented in Table 1:

Table 1: Locations, Environments and Soil types

s/no.	Name of location	Location	Type of environment	Soil type
1	Abia State	Southeast	Rainforest belt	fine- coarse sandy loam
2	Benue State,	North Central	Derived Savanna	Hydromorphic soil
3.	Kwara State	North West	Savanna	
4.	Nasarawa State	North Central	Savanna	Sandy loam
5.	Akwa-Ibom State	South south	Humid Rainforest	Clay soil
6	Anambra State	South east	Derived savanna	Sandy soil
7	Osun State	South west	Rain forest	Clay soil
8	Plateau State	North Central.	savanna	Sandy loam
9	Kano State	North Central	Savanna	Clayey soil
10	FCT, Abuja	North Central	Savanna	Sandy clay loam

The fields were disc- ploughed, harrowed and ridged before planting to achieve a minimum tillage. No application of herbicides. The sweetpotato genotypes from CIP platform in Ghana were raised and multiplied in nursery. The genotypes comprised of 16 clones from CIP, 6 from NRCRI Umudike and 2 national Checks and one from the location where the evaluation was to be carried out. The twenty-five genotypes were planted at ten diverse agro-ecological locations across the country. The twenty five clones were planted in three replications at each site at spacing of 100cm between ridges and 30cm within plants in a plot size of 9m^2 (3m x 3m) in randomize complete block design. Planting was done on the crest of the ridge. Supply of dead seed vine was carried out two weeks after planting in each location. Application of N P K 15:15:15 fertilizer was done 4 weeks after planting as basal fertilizer. Weeding by hoe was done 4 weeks before fertilizer application. Later hand pulling of weeds were carried out in all locations to control post- emergence weeds and to maintain weed- free fields.

Data were collected on: Total weight of storage roots in t/ha (TWOSR) weight of commercial in t/ha (CRW), weight of non- commercial roots in t/ha (NCRW) and weight of vines in t/ha (VW)

Statistical analysis was done with Gen STAT computer package version 2003. Analysis of variance was conducted for all the traits to detect significant differences among the clones with the model for a randomized complete block design. The analysis of variance (ANOVA) was performed on collected data separately for each environment and later combined across locations. The Harvest index was used to select high yielding genotypes per unit area for on-farm trial.

RESULTS AND DISCUSSION

Weight of storage root yield: High significant ($p<0.01$) variation in the storage root yield of the genotypes were observed among the genotypes within the locations and across the locations. However, the performances of The 25 genotypes in the key environment for yield related measurements were compared with their performances over all the 10 locations by ranking. The mean weight of total storage roots, weight of large/commercial roots and weight of small/non-commercial roots are presented in Table 2.

Table 2: Mean total weights of Storage roots and weights of commercial roots and weight of small roots (in parenthesis) of sweetpotato genotypes evaluated in ten diverse Agro-ecologies of Nigeria

Total storage root weight: The combined analysis of the total storage root weight across locations indicated that the yield of the sweetpotato genotypes varied significantly (p<0.01) from 13.0.t/ha (Tu-purple) to 34.1t/ha (87/0p/195) with mean of 22.0t/ha. The genotype 87/OP/195, was ranked as a top yielder of total storage root yield and was ranked first in 8 out of 10 locations. This was followed by Cemsa 74-228 which came 2nd position with total storage root yield at first position in one out of 10 locations, while Tu-Purple was least with total storage root yield of 13.0t/ha and was ranked 25th as the poorest yielding genotypes. Based on yield selection differential, 12 genotypes with storage root yield potential above the general mean and with storage root yield more than the two Check varieties were selected for on-farm farmer' participatory varietal selection that will be conducted this year 2022. The following genotypes were selected for "On-farm farmers' participatory varietal selection: 87/OP/195 (34.1t/ha), Cemsa 74-228 (31.0t/ha), PGN16021-39 (26.6T/ha), PGA14011-43 (26.6t/ha), Cri-Okumkom (25.4t/ha), Cri-Apomuden (25.0t/ha), PGA14442-1 (24.2t/ha), PGN17362-N1 (24.0t/ha), PGA14398-4 (24.0t/ha). PGA17265-N1 (23.4t/ha), Cri-Dadanyuie (23.1t/ha) and PGA14351-4 (23.0t/ha). The on-farm evaluation is a stage where the farmers would be involved in the final varietal selection. The genotypes so selected by the farmers, if it were released by the varietal release committee will be adopted for cultivation by the farmers since it were selected by them. However, according to Nwankwo et al (2020) Sweetpotato genotypes with high yielding number of storage root potential per plant should be selected for further advancement and evaluation. Genotypes with large storage root number may be selected as having high storage root yield potential.

Commercial/large root weight: Storage root weighing 100g and above is regarded as large/commercial roots. The weight of the commercial roots differed significantly ($p<0.01$) among the various sweetpotato genotypes evaluated across the diverse agro-ecologies. Analysis across locations indicated that the weight of commercial roots ranged from 7.5t/ha (Tu-Purple) to as heavy as 26.5t/ha (87/OP/195) with grand mean of 22.0t/ha.

The location with the heaviest commercial root weight was Abia with mean weight of 17.7t/ha which ranged from 5.4 to 39.8t/ha. This was followed by Plateau location with mean commercial root weight of 17.0t/ha which ranged from 8.8t/ha to 29.4t/ha. The location with the least weight of commercial roots was Benue which had mean weight of 10.7t/ha and ranged from 0.8t/ha to 18.9t/ha. Commercial root weight is the storage root for commerce with heavy weight of fresh matter accumulation. Genotypes with heavy commercial root weight is an index of high photosynthetic efficiency and should be selected for on-farm farmers' participatory variety selection (Table 5). The major aim of breeding programmer is to breed and select varieties with commercial traits. Commercial trait in this context was to breed for large storage root yield with weights that generate income for the farmers. Varieties with large fresh storage weight root yield less than the check varieties should not be selected.

Non-commercial/Small root weight: This is a storage root with weight less than 100g. Non-commercial root weight varied significantly ($p<0.05$) across the locations with weight which ranged from 5.0 t/ha (PO3/116) to 8.7t/ha (PGA14351-4). However, the location with the heaviest non-commercial root was Kwara with mean weight of 7.8t/ha and which ranged from 2.9t/ha to 13.6t/ha followed by Akwa-Ibom with mean weight of 6.9t/ha which ranged from 4.0t/ha to 11.0t/ha. The location with the lowest weight was Osun with mean weight of 5.9t/ha and ranged from 3.1 to 8.0t/ha. Weight of non-commercial roots is an indication that fresh matter accumulation of the genotypes is very low in the high number of roots and that the genotype genetic constitution is not adaptable to the local environment. Genotypes with high weight of non-commercial root as a result of low photosynthetic efficiency will be discarded except if they are location specific in terms of storage root production. Nwankwo et al (2021) in their work on sweetpotato storage roots also reported that heavy weight of small roots is not a good index for selection. Heavy weight or high number of small storage roots is an indication of poor soil due to very low soil nutrient, poor genetic expression of the crop which may result due to poor agronomic management such as lack of weed control and climatic factors due to little or limited rainfall.

4.1: Vine weight at harvest: The mean vine weight (kg) of sweetpotato genotypes evaluated across ten diverse agro-ecologies of Nigeria is presented in Table 3.

Vine weight at harvest is the above ground biomass. It was observed from the result in Table 3 high significant (p<0.01) variation in vine weights among the genotypes within each location which resulted in variation in ranking. The mean vine weight (above ground biomass) of the sweetpotato genotypes across the locations ranged from 7.9 to 21.0t/ha The genotypes with the highest mean vine weight across location was TIS87/0087 with mean vine weight of 19.6t/ha and was given the first rank, followed by PO3/116 with 18.0t/ha and was given 2nd rank while the genotype with the least vine weight at harvest was NAN which had vine weight of 7.9t/ha and was given the last rank of 25th with grand mean of 11.9t/ha.

The vine weight of different genotypes showed large variation of above ground biomass at different environments/locations. The location with the highest vine weight was Nasarawa. The mean vine weights ranged from 4.8 to 23.2t/ha with grand mean vine weight of 15.2t/ha and was assigned the first rank. The second rank was assigned to Plateau location which had vine weights that ranged from 7, 2 to 22.0t/ha with grand mean of 13.8t/ha. The least vine weight was obtained from Abuja location. The vine weight ranged from 5.7 to 22.1t/ha with grand mean of 9.8t/ha.

Sweetpotato genotypes with heavy vine weight after harvest is of great importance in areas of livestock production. The above ground biomass is used as fodder for feeding cattle, sheep, goats, rabbits, pigs and even dried and included into poultry feed. However, the vine weight and total fresh weight of storage roots yield of the sweetpotato genotypes evaluated were used to calculate the harvest index.

5.1: Harvest index: The Harvest index of sweetpotato genotypes evaluated in ten diverse Agro-ecologies of Nigeria is presented in Table 3

Harvest index refers to the ratio of economic yield to biological yield of the crop. In this context, it is the storage root yield per unit area. Genotypes with high storage root yield have high harvest index. Harvest index could be used to select high storage root yielding varieties.

One of the limiting factors of Nigerian sweetpotato landraces are low yield in terms of number of storage roots per stand and fresh matter accumulation (storage root weight) per unit area (Degrass, 2000). The harvest index of the local best landrace was 0.4 while the genotype 87/OP/195 was 0.8. The harvest index could be used to select high yielding varieties among the genotypes evaluated. Significant (P<0.01) variation in the harvest index was observed among the genotypes tested and these ranged from 0.4 to 0.8 with mean of 0.6 (Table 8). High index genotypes accumulate large amount of fresh matter within short period of the growing season of four months. Based on this result, it indicated that 68% of the sweetpotato genotypes evaluated across the locations were high yielding per unit area with harvest index ranging from 0.7 to 0.8. The genotypes with harvest index above the grand mean 0.6 were selected for on -farm evaluation and for registration and release as high yielding storage root per unit area. (Table 3). Based on this, the following genotypes were selected:87/OP/105 (34.1t/ha), Cemsa 74-228 (31.0t/ha), PGN16021-39 (26.6t/ha), PGA14011-43 (26.6t/ha), Cri-Okumkom (25.4t.ha), Cri- Apomuden (25.0t/ha), PGA14442-1 (24.2t/ha), PGN17362-N1 (24.0t/ha), PGA14398-4 (24.0t/ha), PGA17265 (23.4t/ha), Cri-Dadanyuie (23.1t/ha) and PGA14351-4 (23.0t/ha).

CONCLUSION

Landraces have contributed much to the food menu of the people, economy of the country, and the farming system of the farmers. However, the good characteristics of the genotypes evaluated such as high storage root yield per unit area and adaptation to wide environments could be employed in breeding programme in the development of progenies that are adaptable to the biotic and abiotic stresses. The genotypes were selected as a result of their high harvest index and large storage root weight above their grand mean across the ten diverse agro-ecologies. The genotypes selected could be used as parents in the breeding programme to utilize their good qualities for progeny development and release for Nigerian farmers for domestic and industrial utilization. These genotypes should be tested On-farm for farmers to make their final selection.

24 - 28 Oct., 2022

ABSTRACT

The pot experiment was conducted at the Teaching and Research farm of Oyo State College of Agriculture and Technology (OYSCATECH), Igboora to evaluate the growth response of Soybean (*Glycine max*). The experiment was laid out in Complete Randomized Design (CRD) with four treatments and replicated four times. The treatments were applied at the rate of 5 tonnes / ha, 10 tonnes / ha, 15 tonnes / ha and 20 tonnes / ha which were incorporated into the soil two weeks before sowing and wet daily for proper decomposition and rapid growth of bacteria, Rhizobia. Growth parameters taken were plant height (cm), number of leaves, leaf area (cm^2) and stem diameter (cm^2). Data collected were subjected to Analysis of Variance (ANOVA) and the means separated with Duncan Multiple Range Test (DMRT) at 5% probability level. Maximum growth was recorded with application of orange peels at the rate of 20 tonnes / ha. The above rate is therefore recommended for subsistence farming of soybeans.

KEYWORDS: Soybeans, Bacteria, Rhizobia, Orange peels.

INTRODUCTION

Glycine max is one of the most important crops cultivated around the world and it is the principal grain legume growth in the United States. Soybean is valued because it has high protein content which 38%. And the high protein content makes soybean important for both human and animal nutrition. Soybean are a valuable crop because they belong to the legume family and they also partner with a type of bacteria called Rhizobacteria. Soybean seeds inoculated with rhizobacteria before planting grow better than non-inoculated seeds. Orange peels have a high content of pectin. Because the peels are a by-product of orange juice production and they are in expensive.

The orange peel treatment could also increase the size of plants root, size and number of nodules(Pers.com) And this can have a positive influence in the amount of nitrogen that soybean can fix from the atmosphere thereby increasing plant growth and yield without the need of nitrogen fertilizers. The orange peel treatment helps to boost the activities of rhizome in soybean(Pers.com) Soybean is one of the most important crops cultivated around the world and it is the principal grain legume grown in the United States. It is valued because it has a high protein content – around 38%. And that high-protein content makes soybeans important for both human and animal nutrition. Besides having high protein content, soybeans are a valuable crop because they are in the legume family. The plants can pull nitrogen from the air into the soils and use it in the process of growing and producing the soybeans. But they don't do this alone, they do it through a partnership with particular bacteria.

Soybeans partner with a type of bacteria called rhizobacteria to turn airborne nitrogen into a usable nutrient for the plant. The roots of the soybeans have nodules, providing a home to rhizobacteria. The bacteria metabolizes nitrogen into a form the soybeans can use and in return the soybean plant provides that home, and some sugars that help the bacteria growth. Other types of rhizobacteria can help plants absorb some nutrients and others can protect the plant against pathogens that cause diseases.Past research showed that soybean seeds inoculated with rhizobacteria before planting grow better than non-inoculated seeds. Greenhouse studies have better results than field studies. This may be because the rhizobacteria are not able to survive very well in agricultural soils and gets outcompeted by the very numerous and diverse bacteria that are already present in that soil. The rhizobacteria need "food" to grow and colonize the soybean roots in order to stimulate plant growth. One type of food source for some strains of rhizobacteria is a carbohydrate called pectin. Pectin is found in fruits and vegetables, and you may recognize it as an ingredient in jams and jellies. Soybean is one of the most important crops cultivated around the world, and it is the principal grain legume grown in the United States. It is valued because it has a high-protein content about 38 percent. And that high-protein content makes soybeans important for both human and animal nutrition. The world population is growing fast and is expected to reach 9.7 billion people by 2050. To feed all those people, crop production needs to be increased worldwide. The most feasible way to do that is to increase yield, in other words, boost the quantity of grain produced by area cultivated. That also needs to be done in a sustainable way that allows for food production while protecting the environment.Besides having high-protein content, soybeans are a valuable crop because they are in the legume family. The plants can pull nitrogen from the air into the soils and use it in the process of growing and producing the soybeans. But they don't do that alone, they do it through a partnership with particular bacteria.Soybeans partner with a type of bacteria called rhizobacteria to turn airborne nitrogen into a usable nutrient for the plant. The roots of the soybeans have nodules, providing a home to rhizobacteria. The bacteria metabolizes nitrogen into a form the soybeans can use, and in return the soybean plant provides that home, and some sugars that help the bacteria growth. Other types of rhizobacteria can help plants absorb some nutrients and others can protect the plant against pathogens that cause diseases.

Objectives of the study

The objectives of this study are to determine the effect of orange peels on growth performance of soybeans and to determine the effect of orange peels on yield of soybeans.

MATERIALS AND METHOD

The experiment was conducted at the Teaching and Research Farm of Oyo State College of Agriculture and Technology Igboora. OYSCATECH is located along latitude 3018. 089E to 30 17.752'E and latitude 7024.875' N. Igboora is situated at 180m above sea level. The soil was collected on arable farm land of the research farm with the use of auger at 0-15cm depth which was air dried and sieve with 2mm sieve before weighing and filling into twenty 5kg pot. The composite sample was sent to the laboratory for evaluation of it's physico-chemical properties. The experiment was laid out in a Complete Randomized Design (CRD) with five (5) treatments replicated four (4) times. The orange peels were buried into the soil 2 weeks before sowing soybeans seeds and wet everyday. The treatments was applied at 50g, 100g, 150g and 200g and was replicated four times. Soybeans seed was sowed at 4 seeds per hole and thinned to one stand per pot at 2weeks after sowing. Weeds was uprooted by hand and wetting was carried out every morning. Yield parameters to be taken number of pods per plant by counting, weight of pods per plant by measuring scale (g), number of seeds per plant, weight of seeds per plant (g). Data collected was subjected to analysis of variance (ANOVA) and means separated with Duncan Multiple Range Test (DMRT) at 5% significant level.

RESULT AND DISCUSSION

Table 1: Physical and Chemical properties of soil

The chemical and physical properties of the soil used for the experiment shows a pH value of 5.70 (Table 1) indicating that the experimental soil was slightly acidic. The soil is low in essential plant nutrients like Nitrogen, Phosphorus and potassium with values of 1.12%, 7.25mg/kg and 0.27cmol/kg respectively.

Table 1: Physical and Chemical properties of soil

Soil properties	Value
pH	5.70
Total N	1.12%
Organic Carbon	1.30
Available Phosphorus	7.25 mg/kg
K	0.29 cmol/kg
Ca	5.22 cmol/kg
Mg	1.48 cmol/kg

Effect of Orange Peel on plant height of Soybean (*Glycine max*)

There was increase in plant height and development. There was no significant difference on P≤ 0.05 means at 1, 2, 3, 4, 5, 6 and 7 weeks after planting. However at 7 weeks after planting, orange peels (200g) has the highest number of plant height (83.62cm). While the control has the lowest number of plant height (46.55cm).

Table 2: Effect of Orange Peels on plant height of Soybean

Treatment	1WAP	2WAP	3WAP	4WAP	5WAP	6WAP	7WAP
CONTROL	13.12a	22.95a	26.60a	33.27a	35.00a	38.88a	46.55a

Means with the same letter are not significantly different number of leaves P ≤ 0.05 means WAP – Weeks after planting.

Effect of Orange Peel on number of leaves of Soybean (*Glycine max*)

There was increase in number of leaves at 1, 2, 3, 4, 5, 6 and 7 weeks after planting. There was no significant differences on P≤0.05 means in number of leaves among the treatment at 1, 2 and 3 weeks after planting. However, there was significant difference among the treatment P≤0.05 means at 4, 5, 6, and 7 weeks after planting. At 7 weeks after planting, orange peels (200g) has the highest number of leaves (51.25). While the control has the lowest number of number of leaves (22.00cm).

CONCLUSION AND RECOMMENDATION

In the results presented above, it was evident that the growth parameters of soybeans performed best with the use of orange peels in plant height, number of leaves, stem diameter and leaf area to enhance the growth of soybean. This is may be due to the high nutrient contents in 200g than the other treatments. *Glycine max* is one of the most important crops cultivated around the world and it is the principal grain legume growth in the United States. Soybean is valued because it has high protein content which 38%. And the high protein content makes soybean important for both human and animal nutrition. Soybean are a valuable crop because they belong to the legume family and they also partner with a type of bacteria called Rhizobacteria In the results presented above, it was evident that the growth parameters of soybeans performed best with the use of orange peels in plant height, number of leaves, stem diameter and leaf area to enhance the growth of soybean. In the results presented above, it was evident that the growth parameters of soybeans performed best with the use of orange peels in plant height, number of leaves, stem diameter and leaf area to enhance the growth of soybean. 200g of orange peel as proved to have the best results and thereby recommended to soybeans farmers in the study area.

ABSTRACT

A farming system study to investigate the effect of three nitrogen levels on maize production under rainfed condition was carried out at the experimental farm of the Department of Horticulture and Landscape Technology, AkanuIbiam Federal Polytechnic, Unwana during the 2021 farming season. **A** Randomized Complete Block Design (RCBD) with four blocks. *Mucuna (Mucuna utilis)* plant was planted five months to the maize planting at a spacing of 45cm x 60cm. This was allowed to flower and then ploughed into the fields before maize planting.The maize seeds were sown at a spacing of 25cm x 75cm. Three levels of nitogen (100, 130 and 160kg N ha^{1}) from ammonium sulphate were randomly applied to the experimental units in split doses, one- third at planting (broadcasted), two- third at tasselling (By side dressing), while blanket application of single superphosphate and muriate of potash by broadcasting at planting at the rates of 50kg P_2O_5 ha^{1} and 40kg K_20 ha^{1} was done.The growth and yield parameters collected were days to 50% tasseling, days to 50% silking, plant height, mean number of leaves, number of cobs harvested per row, field weight of fresh cobs and dry grain weight per plant. Also, nutrient composition of the harvested grains including N, P, K, Ca, Mg, Cu and Na were determined in the laboratory. All data were subjected to analysis of variance (ANOVA) and means separated using $LSD_{0.05.}$ Results showed variabilties in both growth and yield attributes,but none was statistically significant. However,yield of maize increased with nitrogen levels. Inclusion of mucuna in the cropping system improved soil fertility condition and yield of maize.

Keywords: Farming system, Rainfed, Maize and Nitrogen

INTRODUCTION

Farming system has been holistically defined as a complex interrelated matrix of soil, plant, animal, implements, power, labour, capital and other inputs by farming families and influenced to varying degrees by political, economic, institutional and social forces that operate at many levels (Dixon *etal*., 2001). Proper farming system ensures efficient resource use that translates into maximum crop yield.

Maize is the world's third most important cereal after wheat and rice. It is grown primarily for grain and secondarily for fodder and raw material for industrial processes. Maize production in the recent years has declined drastically due poor soil conditions in southeastern Nigeria.(Ahalawart *et al.*, 1981) Therefore, to enhance maize productivity in the face of declining soil fertility, external fertilizer input is necessary.Inclusion of legumes into cropping systems has been traditionally used to improve soil fertility especially nitrogen nutrition (Brady and Weil, 2008). Legumes through their association with rhizobia bacteria promote nitrogen fixation which profits not only the immediate crop, but the successive crops (Azu *et al.*, 2020).

The introduction of mineral fertilizers especially nitrogen fertilizer into cropping system to improve soil fertility and crop nitrogen nutrition is a radical intervention that has over the years led to increased crop yield (Azu*et al.*, 2018). However, the use of mineral nitrogen fertilizer in recent times has not yielded the expected gain in terms of crop yield due to variable soil conditions, climate change, and improper use of nitrogen fertilizers in terms of quantity and application method.Also, poor organic matter content of most tropical soils predisposes these soils to leaching of soil nutrients especially mobile elements like nitrogen.

Thus, proper understanding of a sound farming system that integrates legumes and nitrogen fertilizer at optimum quantity and varying time of application in relation to rainfall pattern of a given region is very much fundamental to crop yield maximization. This information is still lacking in the hydromorphic soils of Unwana, southeastern Nigeria. This forms the basis of this paper.

MATERIALS AND METHODS

This study was carried out in the Research Fram of Department of Horticulture and Landscape Technology, AkanuIbiam Federal Polytechnic Unwana, (coordinates: latitude $5^{0}48$'N and longitude $7^{0}55$'E). The air temperature is generally high all year round and the current temperature range is 32^{o}C -21^{o}C with total annual rainfall exceeding 3,500 mm (Njoku, 2006). The soil of the experimental area is a TypicHapludult(Federal Department of Agriculture and Land Resources, 1985). The land area was earlier used for cassava cultivationThe maize variety used was a composite Downy Mildew, Resistant (DMR), Early maturing (E), Streak Resistance (SR), Yellow (Y), (DMRESR-Y) from the International Institute of Tropical Agriculture (IITA), Ibadan. Velvet bean (Mucunautillis) collected from IITA was used as green manure, while the fertilizers used were ammonium sulphate for nitrogen, single superphosphate and muriate of potash as sources of phosphorus and potassium respectively.

A Randomized Complete Block Design (RCBD) with four blocks was used for the study. The experiment covered a total land area of 0.366ha. Each block consisted of three plots measured 16m x 18.3min area with 21 plant rows in each plot and spacing of 75cm between rows, 1.0m between plots and 2.0m between blocks. The mucuna was planted five months prior maize planting at a spacing of 45cm x 60cm. This was allowed to flower before being ploughed in and harrowed, ready for maize planting.Two maize seeds were sown per hole at a spacing of 25cm x 75cm and thinned down two weeks after germination. There were 72 plants per row, giving a theoritical population of 53,333 plants per hectare. Three levels of nitogen (100, 130 and 160kg N ha^1) from ammonium sulphate were randomly applied to the experimental units in split doses, one- third at planting (broadcasted), two- third at tasselling (By side dressing). Blanket application of single superphosphate and muriate of potash by broadcasting at planting at the rates of 50kg P_2O_5 ha^1 and 40kg K_20 ha^1 was done. Weeding, pest control and other agronomic practice were observed throughout the growth period.

The growth and yield parameters collected were days to 50% tasseling, days to 50% silking, plant height, mean number of leaves, number of cobs harvested per row, field weight of fresh cobs and dry grain weight per plant. Also, nutrient composition of the harvested grains including N, P, K, Ca, Mg, Cu and Na were determined in the Laboratory according to standard methods. Simlarly, pre-planting and post-harvest soil samples picked randomly from the site were also analyzed for nutrient compositions according to standard methods. Data obtained from plant and soil parameters were subjected to statistical analysis using analysis of variance (ANOVA) and means separated using $Lsd_{0.05}$ as outlined by Steel and Torie (1980).

RESULTS AND DISCUSSION

Pre-planting and post-harvest soil chemical analysis of the experimental site showed that the soil was acidic, high in nitrogen and other nutrient elements(Table 1). However, the organic matter content were low in both the pre-planting and post-harvest soil samples. This indicates the potential for leaching of even the cations (Brady and Weil, 2008). The observed increase in organic matter after harvest may be attributed to more leaf fall due to moringa intercropping system.

The mean effect of different levels of nitrogen on Days to 50% tasseling,Days to 50% silking, plant height, plant ear height and number of leaves is presented in table 2. Results showed that there were differences on these properties due to levels of nitrogen application. However, these differences were not statistically significant. This result is contrary to the reports of Fox *et al*., (1974) who reported significant different on growth parameters of maize due the applation of different levels of nitrogen.

Table 1. Pre-planting and Post-harvest Chemical properties of the soil from the experimental site

Properties	Before planting	After harvest
pH in 1:2.5 soil/water	4.72	5.07
pH in 1:2.5 soil/KCL	4.06	4.23
Total N (g/kg)	33.00	24.00
Available P (mg/kg)	8.90	7.20
Exchangeable Ca (cmol/kg)	189.60	206.60
Exchangeable K (cmol/kg)	58.00	52.60
Exchangeable Mg (cmol/kg)	44.00	34.80
Copper Cu (cmol/kg)	Trace	Trace
Iron, Fe (cmol/kg)	20.80	20.10
Zinc, Zn (cmol/kg)	1.27	1.27
Organic matter (%)	1.89	2.18

Table 2 Mean effects of nitrogen levels on growth of maize

Parameters	Nitrogen Levels (KgN/ha) 100	130	160
Days to 50% Tasselling	66.50	66.25	66.25
Days to 50% Silking	71.50	69.25	70.50
Plant Height (cm)	121.25	115.0	123.99
Plant ear Height (cm)	46.04	43.83	49.46
Number of leaves	8.94	8.49	3.37

The mean effects of different levels of nitrogen on yield attributes of maize, including number of cobs per row, field freshweight,dehusked oven-dried weight per cob, oven-dried grain weight per cob and maize yield is shown in table 3. The yield parameters increased with rate of nitrogn application. Howver,these increaseas were not statistically significant. Nitrogen has been reported by several scholars as an essential element necessary for incrased plant growth and yield (Brady and Weil, 2008).

Table 3 Mean effects of nitrogen levels on yield of maize

Parameters	Nitrogen Levels (KgN/ha) 100	130	160	Significance
Number of cobs per row	25.38	27.28	27.32	Not
Field weigth of per plant (g)	217.77	199.37	225.71	Not
Dehusked oven-dry weight per cob(g)	153.05	161.66	152.76	Not
Oven-dry grain weight per cob (g)	55.59	59.03	54.54	Not
Maize grain yield (kg/ha)	2733.49	2888.44	2881.50	Not

The nutrient composition of the harvested maize from plots of different levels of nitrogen application is shown in table 4. The effect of different levels of nitrogen on the ntrient composition of maize was not significant. However, the were variability on the concentration of different nutrients contianed in the maize grains as a result of nitrogen application at different levels. Apart from potassium which showed clear increase in amount due to increase in nitrogen level, the variability in other nutrients compositions of maize due to levels of nitrogen application did not follow particular trend (Eneje and Azu, 2009). However, the incorpoation of the mucuna and addition of nitrogen generally increased the nutrient composition of the maize grain. Onwuka *et al.*, (2007) has previously reported inceased nutrient composotion of maize grain as a result of addition of organic manure and mineral fertilizers in the cropping system.

Table 4. Mean effects of nitrogen levels on nutrient composition of maize grain

Parameters	Nitrogen Levels (KgN/ha) 100	130	160	Significance
Nitrogen (%)	10.03	9.10	9.48	Not
Phosphorus (mg/kg)	6.03	6.08	6.25	Not
Potassium (cmol/kg)	148.13	165.08	157.23	Not
Magnesium (cmol/kg)	40.53	40.18	41.41	Not
Calcium (cmol/kg)	0.48	0.54	0.46	Not
Copper(cmol/kg)	0.19	0.13	0.15	sigificant
Sodium(cmol/kg)	2.48	1.53	2.05	Not

CONCLUSION

The inclusion of mucuna and different levels of nitrogen fertilizer in the farming system improved the soil fertility properties, growth, yield and nutrient compositions of maize grain. Incorporation of mucuna and 160kgN/ha gave the most appreciabe improvement of soil fertility indices, growth and yield of maize and the nutrient composition of maize and therefore recommeded for acid soils of Unwana, southeastern Nigeria.

24 - 28 Oct., 2022

ABSTRACT
Diseases constitute a major challenge to watermelon production in Nigeria through fruit yield and quality reduction. The diseases render the fruits unmarketable and inedible. Hence, this study identified the fungal pathogens associated with the leaves and fruits of watermelon using molecular characterization. The study also evaluated the potential antimicrobial activities of ethanol extracts of three selected plants: (leaves of *Vernonia- amygdalina*, *Piliostigma-reticulatum and Spondias- mombin*) against the fungal species.
The statistical analysis of the study was done using analysis of variance (ANOVA) and means were compared by using Duncan's Multiple Range test (DMRT).
The results showed that all the plants materials have antifungal potentials on the fungal species with *P. reticulatum* extracts having the highest antifungal activity (100%) at 50mg/ml, 100mg/ml and 200mg/ml. The diameters of inhibition zone varied according to leaf extract and concentration *Vernonia- amygdalina* and *Spondias- mombin* also showed significant zone of inhibition (100%) at 100mg/ml and 200mg/ml.
The study concluded that the plant extracts used have varying anti-fungal reactions on the three fungal pathogens detected and as such can be used as natural antibiotic and antimicrobial agents against plant diseases.

Keywords: plant extracts, fungal, antimicrobial, zone of inhibition.

INTRODUCTION
Watermelon (*Citrullus lanatus)* belongs to the family Cucurbitaceae (Koocheki *et al*., 2007) is a tropical fruit that grows in most parts of Africa and South East Asia. Besides its high nutritional value, it is gaining a high level of economic importance in income generation. Watermelon flesh is an excellent source of vitamins, minerals and anti-oxidants that help in preventing human diseases by acting as oxygen radical scavenger (Reetu et al., 2017). The

sweetness of watermelon is due to the presence of sucrose, glucose and fructose. Sucrose and glucose account for 20-40% and fructose for 30-50% of total sugars in a ripe watermelon (Bianchi et al., 2018).
Diseases such as blossom-end rot, bursting and rind necrosis reduce the yield and quality of watermelon fruit thereby making it unmarketable and inedible which in turn causes loss to the farmers (Donald et al., 2015).

The use of plants extracts is gaining momentum in the last few years in managing plant diseases. Many plants have been used because of their antibiotic and antimicrobial traits, which are due to compounds synthesized during secondary metabolism in the plants. These natural plant products are cheap, readily available, has little or no toxicity to humans (eco-friendly) and are easy to prepare.
Therefore, the objectives of this study are to:

- identify some fungal pathogens associated with *C. lanatus* leaves and fruits.
- assess the efficacy of three plant extracts in the management of these fungal pathogens.

MATERIALS AND METHODS

Collection of plants materials

Fresh leaves of *Vernonia- amygdalina, Piliostigma- reticulatum and Spondias- mombin* were collected from Ago Iwoye, Ijebu North Local Government Area, Ogun State in Nigeria. The leaves were collected in polyethylene bags and transported to the Postgraduate Plant Science Laboratory of the Department of Plant Science, Olabisi Onabanjo University, Ago-Iwoye, Ogun State.

Botanical identification

Botanical identifications were carried out at the Elikaf Herbarium, Department of Plant Science, Olabisi Onabanjo University, Ago-Iwoye, Nigeria.

Collection of infected fruits and leaves of *C. lanatus.*

Eighteen infected fruit samples and forty-two infected leaf samples were collected from eleven field in Ijebu North Local Government Area of Ogun State. They were packed into sterilized transparent bags, labeled and transported to Post Graduate Plant Science Laboratory of the Department of Plant Science Olabisi Onabanjo University, Ago-Iwoye, Ogun State, Nigeria.

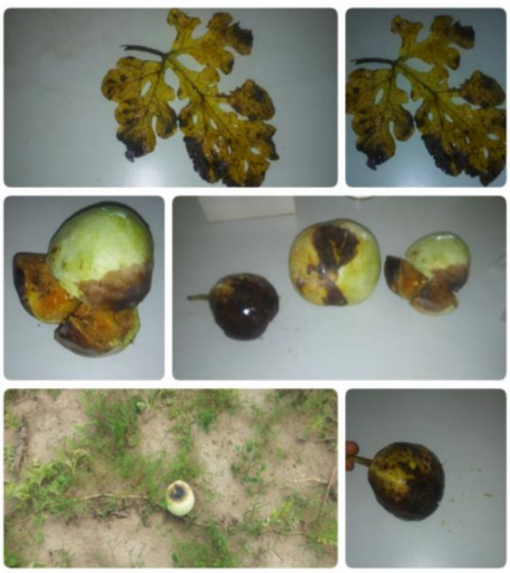

Figure 1: Infected watermelon fruits and leaf samples

Preparation of Culture Media

Potato dextrose agar (PDA) was used as the medium for the growth and maintenance of the fungi isolates.Nineteen and half gram (19.5g) of PDA powder was weighed and dispensed into 500millilitres of distilled water in a conical flask. The mixture was stirred vigorously to dissolve. The conical flask was covered with a foil paper and sealed with a masking tape. The content was sterilized in an autoclave at 121°c for 15 minutes and allowed to cool at room temperature.

The medium was poured into sterile Petri-dishes and allowed to solidify before inoculation was performed.

Isolation of Pathogens from Infected leaves and fruits of *C. lanatus*.

The infected fruits and leaf samples of *C. lanatus* were rinsed in sterile distilled water and small pieces of the rotten parts were picked using a sterile scalpel and placed directly on sterile PDA. The plates were incubated for 3 days at room temperature and sub-culturing was done to obtain pure cultures of the isolate. After incubation, different growths of mycelia colony were sub-cultured with the aid of sterilized inoculating loop into newly prepared PDA plates. The plates were incubated at room temperature for 3-5 days. Several sub-culturing was done, thus purifying the mixed culture plates. The purified fungi were transferred into McCartney bottles of broth agar and stored for characterization.

Identification of Fungi Isolates

The fungal strains were identified using molecular sequencing analysis. The genes (DNA extraction) of the fungal isolates were sequenced with universal primer of (ITS4TCCTCCGCTTATTGACATGS and ITS5GGAACTAAAAGTCGTAACAAGG) and the results are *Fusarium equiseti, Lasiodiplodia theobromae* and*Choanephora cucurbitarum.*

Preparation of Plants Materials

Five hundred grams each of mature fresh leaves of *V. amygdalina*, *P. reticulatum* and *S. mombin* were thoroughly rinsed in running tap water and air dried at room temperature. The samples were oven dried at a temperature of 55˚C for 30 minutes before grinding into powder with pestle and mortar to facilitate extraction. The samples were ground separately. The leaves were macerated (soaked) in an air-tight plastic container containing 1000ml of 99.9/100% ethanol at room temperature and was stirred using a sterile aluminum rod of 50cm length for 5days to allow for maximum extraction of the plants components and to encourage homogeneity of the plants extract and the solvent used. This was followed by filtration with what-man filter paper and the filtrate was concentrated using steam-water bath. The residue was put into sample bottles as the crude extracts of the test plants and stored.

Concentrations of Crude Extracts

Serial dilutions of the crude extracts were prepared using 0.2g in 1ml of 99.9/100% ethanol and concentrations of 25mg/ml, 50mg/ml, 100mg/ml and 200mg/ml were prepared.

Preparation of Biological Assay

Potato dextrose agar was prepared according to manufacturers' instruction and allowed to cool. The different concentrations of the extracts (25mg/ml, 50mg/ml, 100mg/ml and 200mg/ml) were dispensed into the Petri dishes. The prepared PDA was dispensed into the extracts of the different concentrations, the plates were gently mixed to dissolve the contents using agar dilution method. Four-millimeter diameter of mycelia incubated from old culture of each test fungi was inoculated centrally into the medium using cock borer(4mm) and was incubated for 48 hours to 120hours. The inhibition rate of the plant extracts was observed and measured. The control consists of Petri plates with the organisms but with no plant extract. The inhibition rate was recorded starting from day 2 to day 5. The rate of mycelia growth inhibition (MGI) was calculated using the formula (Jeum *et al*., 2015):

GI% = dc-dt/dc×100

where dc is mean colony diameter of control sets and dt is mean colony diameter of treatment sets.

Statistical Analysis

Test for significance in the zone of inhibition was done using analysis of variance (ANOVA) and means were compared using Duncan's Multiple Range test (DMRT).

RESULTS

Antifungal effects of the plants extracts on *F. equiseti* at different concentrations

Table 1 shows the percentage inhibition of the plant extracts concentration. On *Fusarium equiseti*, *S. mombin* extracts had percentage mycelia inhibition of 52.80%, 70.30%, 100% and 100% for concentrations of 25mg/ml, 50mg/ml, 100mg/ml and 200mg/ml respectively while the control was 0.00%. For *P. reticulatum*, the percentage mycelia inhibition was 70.53%, 100%, 100% and 100%, while *V. amygdalina* showed the percentage mycelia inhibition of 35.70%, 100%, 100% and 100% respectively.

Ethanol extracts of *P. reticulatum* and *V. amygdalina* at 50mg/ml, 100mg/m and 200mg/ml completely inhibited the growth of *F. equiseti* (100%) while *S. mombin* showed complete inhibition at 100mg/m and 200mg/ml on *F. equiseti.* Thus, the test plants extracts showed no significant difference ($P \geq 0.05$) on *F. equiseti* at 100mg/ml and 200mg/ml while at 25mg/ml and 50mg/ml showed significant difference ($P \leq 0.05$).

Analysis of variance on percentage of *F. equiseti* of the three plants extracts showed significant difference ($P \leq 0.05$) between plant extracts and concentrations of the extracts on *F. equiseti.* The table also shows that the inhibitory effects of the test plants increased with concentrations of the extracts. In comparison, the inhibitory effect of *P. reticulatum* extracts is higher than other extracts at all concentrations.

Antifungal effects of plants extracts on *L. theobromae* at different concentrations

Table 2 shows the percentage inhibition of the plant extracts. The percentage inhibition of the plant extracts was concentration dependent on *Lasiodiplodia theobromae*. *S. mombin* extracts had percentage mycelia inhibition of 23.72%, 84.21%, 100% and 100% for concentrations of 25mg/ml, 50mg/ml, 100mg/ml and 200mg/ml respectively while the control was 0.00%. For *P. reticulatum*, the percentage mycelia inhibition was 54.27%, 100%, 100% and 100%, while *V. amygdalina* showed percentage mycelia inhibition of 23.63%, 44.67%, 74.83% and 100%.

Ethanol extracts of *P. reticulatum* and *S. mombin* at 100mg/m and 200mg/ml completely inhibited the growth of *L. theobromae* (100%) while *V. amygdalina* showed complete inhibition at 200mg/ml on *L. theobromae.* Thus, the test plants extracts showed no significant difference ($P \geq 0.05$) on *L. theobromae* at 100mg/ml and 200mg/ml of *P. reticulatum* and *S. mombin* while at 25mg/ml and 50mg/ml showed significant difference ($P \leq 0.05$) on the extracts.

The inhibitory effects of the test plants increased with concentrations of the extracts. In comparison, the inhibitory effect of *P. reticulatum* extracts is higher than other extracts at all concentrations. Analysis of variance showed significant difference ($P \leq 0.05$) between plant extracts and concentrations of the extracts on *L. theobromae.*

Antifungal effects of plants extracts on *C. cucurbitarum* at different concentrations

The percentage inhibition of the plant extracts was concentration dependent on *Chaonephora cucurbitarum*. *S. mombin* extracts had percentage mycelia inhibition of 22.40%, 32.73%, 42.53% and 100% for concentrations of 25mg/ml, 50mg/ml, 100mg/ml and 200mg/ml respectively while the control was 0.00%. For *P. reticulatum*, the percentage mycelia inhibition

was 83.70%, 100%, 100% and 100%, while on *V. amygdalina* showed the percentage mycelia inhibition of 21.33%, 27.10%, 58.83% and 89.46% (Table 3).
Ethanol extracts of *P. reticulatum* and *S. mombin* at 200mg/ml showed a complete inhibition on *C. cucurbitarum* (100%), while *V. amygdalina* showed no complete inhibition at all the concentrations on *C. cucurbitarum*. Thus, the test plants extracts showed no significant difference ($P \geq 0.05$) on *C. cucurbitarum* at 200mg/ml of *P. reticulatum* and *S. mombin* while at 25mg/ml, 50mg/ml and on *V. amygdalina* showed significant difference ($P \leq 0.05$) on the plant extracts.
The inhibitory effects of the test plants increased with concentrations of the extracts. In comparison, the inhibitory effect of *P. reticulatum* extracts is higher than other extracts at all concentrations. Analysis of variance showed significant difference ($P \leq 0.05$) between plant extracts and concentrations of the extracts on *C. cucurbitarum* (Table 3).

DISCUSSION

This study shows three different fungal isolates associated with infected fruits and leaves of watermelon distributed among the seven locations within Ijebu North Local Government Area, Ogun State. *Lasiodiplodia theobromae* appeared in more locations than other fungal isolates on infected fruits and *Fusarium equiseti* appeared in more locations than other fungal isolates on infected leaves of watermelon.

The antifungal effects of *V. amygdalina, P. reticulatum and S. mombin* leaves extracts against; *F. equiseti, L. theobromae and C. cucurbitarum* at different concentrations obtained in this study drastically reduced the mycelia growth of the three fungi strains over a period of 4-5days at (96-120hours) of incubation.

This study revealed the fungal pathogens affecting *C. lanatus* in Ijebu North Local Government Area of Ogun State. In a similar study, Garba *et al*., (2014) reported isolation and identification of bacteria and fungi associated with rots of *Citrullus lanatus* and *Capsicum frutescens* in Sokoto market in Nigeria. List the pathogens detected in Sokoto market. Ratul *et al*. (2010) reported molecular detection and identification of *Fusarium oxysporum* as the fungal species as identified in this study.

Vernonia- amygdalina have been reported to have antifungal activities against some fungal pathogens (Bazie *et al*., 2014; Aondo *et al*., 2016). Stangarlin *et al*. (2011) reported that control of plant diseases using some plant extracts and at different concentrations of *P. reticulatum* on the fungal strains showed a great result of inhibition against the tested pathogen and this could be attributed to the antibiotic properties of the plant. It is therefore a botanical with potential antifungal property (Aderogba *et al.*, 2006). The plant contains very active biological agents that could be used to control fungal diseases of plants.

According to Ngoci *et al*., (2015), *P. reticulatum* extracts show significant antimicrobial activities against some fungi. *Pilostigma reticulatum* had higher antifungal potential compared to other plant extracts used which justified the report of Akomolafe *et al.* (2013), which showed that ethanol and aqueous extracts of *P. reticulatum* have been widely used as herb and also as antibiotic owning to several bioactive constituents it contains. The findings showed that ethanol and aqueous extracts of this plant had strong antioxidant properties.

Garuba *et al.* (2014) reported the ethanolic extracts of *V. amygdalina* showed antifungal potential against *Aspergillus. niger, A. clavatus, A. oryzae, Paecilomyces varioti and Saccharomyces cerevisae*. It was also reported that water extract of *V. amygdalina* leaves have inhibition effect on the growth of *Fusarium moniliforme* and mycelial and conidial growth of *Collectotrichum gloeosporioides* (Owolade *et al.*, 2000; Ogbebor *et al*., 2007; Suleiman *et al.*, 2008). Nkaa *et al*. (2016) also reported that leaf extract of *S. mombin* reduced the radial mycelial growth of *Proteus- mirabilis* and *Staphylococcus aureus*. Report also showed that ethanol leaf extract of *S. mombin* plant has antifungal activities against some fungal pathogens (Osuntokun *et al.*, 2018) as observed in this study.

CONCLUSION

Findings from this study, showed that the plant extracts used have varying anti-fungal activities on the three fungal pathogens detected.

The observed inhibition zone of *F. equiseti*, *L. theobromae* and *C. cucurbitarum* suggests that *P. reticulatum* possesses compounds containing antifungal properties that can effectively suppress the growth when extracted with ethanol. Therefore, *P. reticulatum* leaves exhibit the potential of being a good natural antibiotic agent against plant diseases caused by *F. equiseti, L. theobromae and C. cucurbitarum.*

24 - 28 Oct., 2022

ABSTRACT

The microbiological content of Banana (a fruit), commonly vended in the Benin metropolis of Edo state were evaluated. Five vending locations were chosen for the study. Whole and soft rot samples were purchased and analysed for microbiological composition. Results showed high counts in soft rot samples in banana. Nutrient Agar plated banana samples had bacterial counts in the range of 1.0×10^2 to 6.3×10^5. *Pseudomonas* species was the dominant species found in banana samples. Mac Conkey agar plated banana samples ranged from 0.0×10^2 to 7.2×10^5. *Enterobacter* species, *E. coli*, and *Klebsiella* species were the dominant species isolated. The study observes that soft rot samples are usually cheaper in the market and have higher microbial counts which when consumed could pose a risk of introducing pathogens to the consumer which could be detrimental to the health of the consumer.

INTRODUCTION

Generally, the trend in the world today is towards healthy eating more than ever. People are more conscious of what they eat, associating same with health conditions presently or in later years of life (Oriakpono *et al*., 2011; Odu and Akano, 2012). Fresh fruits are commonly found vended on the streets and in shops under both hygienic and unhygienic conditions. While many are less concerned with the processing and hygiene of these fruits for consumption, they pose a direct risk of causing microbial food borne illness particularly when highly contaminated with microorganisms. Fruits help to strengthen the immune system, fight disease, and boost the overall body health. Fruits are loaded with most of the essential antioxidants (Vitamins A, C, E and Lycopene) which the body may not produce on its own. Antioxidant nutrients help the body prevent disease, fight illness, and stave off the signs of aging. Fruits are an important source of nourishment, providing a ready source for the metabolism of some vital vitamins and nutrients required in healthy and balanced diets. Well balanced diets, rich in fruits and vegetables, are especially valuable for their ability to prevent vitamin C and vitamin A deficiencies and are also reported to reduce the risk of several diseases (Kalia and Gupta, 2006). Fruits products are usually exposed to potential microbial contaminants during the periods of cultivation, harvesting, transporting, packaging, storage and sale to the final consumers who may be purchasing on the streets, fruit shops or local market (Oranusi and Olorunfemi, 2011; Ibeyessie, 2007; Lelieveld *et al*.,2003). Apart from the great beneficial aspects of fresh fruits, they may serve as a source of food poisoning when contaminated with pathogenic microorganism during harvesting, human handling, transport containers and display in street markets or when in contact with fecal materials (Artes *et al*., 2007). Enteric pathogens such as *Escherichia coli* and *Salmonella* are among the greatest concerns during food-related outbreaks (Helen *et al*., 2018; Buck *et al*., 2003). Organic fertilizer or contaminated irrigated water may bring about contamination of fruits and vegetables. The lack of effective antimicrobial treatments at any step from planting to consumption means that pathogens introduced at any point may be present on the final food product even when available antimicrobials are applied, they may bring about a change in the final product. Such changes may include a change in the taste, colour, or the quality of the product (Patricia *et al*., 2002). Fresh vegetables and fruits may be washed or treated specifically to minimize microbial load (FDA, 2000). Food safety is of growing concern for consumer and professionals in the food industry worldwide (Schuele and Snead, 2001). Food safety in ready to eat produce especially raw foods live fruits and vegetables has long been an object of study with many assessing the microbiological condition of raw fresh fruits and vegetables available in street markets as well as in self-service and fast food restaurants (Angela *et al*., 2010). Consumers need to recognize the importance of food safety particularly for fresh fruits and vegetables which are commonly consumed. The objectives of this study therefore were to evaluate the bacteriologic assessment of fresh banana from street vended locations in Benin City Edo State and to identify the bacteria genus present on locally obtained banana.

MATERIALS AND METHODS

One hundred (100) banana fruit samples (50 whole and 50 soft rot banana) were purchased from 5 different vending locations in Benin metropolis in Edo State, Nigeria. The fruit from each sampling location were transported to the laboratory in a cool box at $\pm\ 4^0$C.

Preparation of Samples for Microbiological Analysis

Ten grams (10g) of banana were cut from each sample using a sterile scapel. These were separately added to 90ml of 0.1% peptone water and homogenized separately in a blender. One millilitre of each homogenate was transferred to separate test tubes containing 9ml peptone water to obtain a dilution of 10^{-1}. In a similar manner, 1ml each was transferred from this dilution to separate test tubes containing 9ml diluents and the process was repeated until a dilution of 10^{-9} was obtained for the banana samples (ISO 4832: 2006).

Enumeration of Microorganisms

0.1ml from each dilution of samples was transferred to plates of nutrient agar using the spread plate technique. Plates containing nutrient agar were incubated at 37^0C for 18-24hrs. Counts were made after incubation from plates having 30-300 colonies.

Identification of Bacterial Isolates

Bacterial colonies with characteristic edges, colours and sizes were isolated and purified by subculturing on nutrient agar plates and examined with a hand lens. Each isolate was subjected to biochemical test using the Bergey's Manual of Systematic Bacteriology. The different tests carried out were used in identifying the isolates to their genus level.

RESULTS

Microbiological analyses of the banana samples carried out on both whole and soft rot samples revealed some variation in bacterial count and diversity. For the nutrient agar plates, *Pseudomonas* species was the predominant organism in both whole and soft rot samples in locations 1 to 5. It was observed that whole samples had lower bacterial counts than soft rot samples.

No organism was isolated from the whole banana samples obtained from the five (5) locations. The soft rot samples showed varying microbial counts in samples from the different locations. *Klebsiella* species was the predominant organism isolated from soft rot banana samples obtained from the five (5) locations. *Enterobacter* species and *Escherichia coli* were isolated from samples from location 2 only. *Escherichia coli* and *Klebsiella* species were the predominant organisms isolated from whole samples in the five locations. Soft rot samples from the five (5) locations revealed the presence of *Escherichia coli, Klebsiella* species and *Enterobacter species*. *Proteus* species was isolated from soft rot samples from location 5 only.

Morphological characteristics of the test organisms revealed that the diameter of the colonies were in the range of 0.2- 3.0mm.

Table 1: Morphological Characteristics of the Isolate

Sample code	Organism	Colony Characteristics
BL1.	*Pseudomonas* species	Greenish colonies of 0.4mm in diameter, circular, raised, opaque, with entire edges.
B 2.	*Escherichia coli*	Pink, convex, opaque, smooth surface, entire edge, circular, 1-2mm in diameter

DISCUSSION

Fruits play a vital role to strengthen the immune system by providing some required essential antioxidants which may be difficult for the body to synthesize on its own. This study evaluated the quality of some fruits sold in Benin metropolis based on their bacteriological contents, which were tagged locations 1,2,3,4 and 5. This study observed that high microbial contaminants were found in sampled banana particularly in the soft rot samples obtained from the five market locations in Benin City. The microbial content of the soft rot sample is alarming and calls for concern because after consumption they may become pathogenic causing ailment in the consumer of such products. Microorganisms most commonly found in fruits are *Pseudomonas* species (Jay, 2003). Result from this study are comparable with those of Riordan *et al.* (2001), who reported that consumption of soft rot banana fruits is commonly viewed as a potential risk factor for infections with enteropathogens such as *Escherichia coli.*

Pseudomonas species is known to be an opportunistic pathogen of clinical relevance demonstrating a great deal of metabolic diversity, thus their ability to colonize a wide range of niches. *Pseudomonas* species have been found to be endosymbionts and operate a synergistic interaction to enhance plant growth. In this study, the *Pseudomonas* species were found in the tissues of banana fruit. *Klebsiella* species is also considered an opportunistic pathogen that produce significant endotoxin that can mediate fatal infection. The presence of *Escherichia coli* in banana calls for proper care and hygienic practice (Jay, 2003; Baiyewu *et al*., 2007). This is because travelers are known to patronize vendors and subsequently find themselves with the challenges of consuming fruits that may be contaminated with bacteria that may predispose them to health issues such as diarrhea or gastroenteritis.

CONCLUSION

The bacteriological assessment of fruits ready for public consumption shows contamination by various organism (*Pseudomonas*, *Enterobacter*, *Klebsiella* species and E. coli), which poses a risk for the consumer. This contamination problem can be caused by various factors such as environmental problems (pollution of water resources) and the use of animal fertilizers for treatments. Therefore, this research calls for hygienic practices in handling these vended products and strongly dissuades consumers from purchasing fresh fruits with signs of soft rot as their microbiological quality have been compromised, though in the market the price of fruits in their early state of soft rot are usually cheaper than whole samples. Consumers who purchase these cheap products face a risk of ingesting microbial pathogens that may be highly detrimental to their health. It is therefore recommended that optimal conditions of hygiene; transportation and storage should be observed, so that the product gets to the consumer at the best quality and safe from microbial induced spoilage. Also consumers are advice not to purchase fresh fruits and vegetables with signs of soft rot as their microbiological quality have been compromised. Lastly, there should be awareness on the health implication of pathogens introduced during cross contamination.

24 - 28 Oct., 2022

ABSTRACT

This study was conducted to assess the genetic variability, correlation of some mineral composition and other agronomic traits of 14 maize genotypes. The field study was conducted during the 2017 cropping season at the Department of Plant Science and Biotechnology Research Garden, Nasarawa State University, Keffi. These maize genotypes were evaluated in Randomized Complete Block Design (RCBD) with three (3) replicates. The results obtained from the analysis of variance for the agronomic traits studied showed significance differences ($p < 0.005$) for leaf length, leaf width, leaf area, boron and zinc. The significant differences observed among the genotypes indicated the presence of genetic variability among them. The total variation of phenotypic coefficients of variations (PCV) showed that the PCV were higher than the genotypic coefficients of variations (GCV) for all the traits measured except for molybdenum and zinc which GCV was higher than PCV, indicating the influence of environment in the expression of these characters. Heritability estimates were recorded for plant height, number of leaves, leaf length, leaf width, leaf area, ears per plant, anthesis-silking interval, days to maturity, boron, and zinc, moderate broad sense heritability was recorded for grain yield, and molybdenum. The genetic gain as a percentage mean in this study was high for leaf width, leaf area, EPP and ASI, indicating that these traits were under the control of additive genes. Genetic advance expressed as percentage of mean was observed for ear length, and number of kernels per row. Low estimates of genetic advances expressed as percentage of mean, were observed on plant height, leaf length, days to maturity, grain yield, boron and zinc indicating the presence of low genetic variability for these traits which are also reflected in their respective low genotypic and phenotypic variations. Positive correlation was observed between ears per plant and grain yield. This shows the importance of genetic variability for the improvement of the studied traits through selection.

Key words: Genetic variability, mineral composition, maize, Nasarawa State.

INTRODUCTION

Maize (Zea mays L, 2n=2x=20), a member of the grass family Gramineae (Poaceae), is one of the oldest cultivated crops. Maize generally called corn (Hausa name-Masara) is an annual cross-pollinating plant with the female (silk) and male (tassel) flowers bound on two separate positions (Abate *et al.*, 2015). Maize otherwise kwon as corn is one of the most widely grown and commonly cultivated all over the world (Abate *et al.*, 2015).

Maize is a preferred staple food for about 900 million poor consumers and about one third of all malnourished children (Laurence & Peters, 2012). Maize is used in many ways than any other cereal. It is considered as a multi-purpose crop and has been put to a wider range of uses such as human food, animal and poultry feed and for hundreds of industrial purposes. (Yusuf, 2010). It is palatable and nutritious, higher in fats (4%) than rice and wheat and also contains about 10% protein (Iqbal *et al*., 2015). Maize can be cooked in a variety of ways to make very palatable and popular foods. Every part of the plant has economic value. (Taya, 2014). The grain, leaves, stalks, and even the cob, are used to produce hundreds of food and nonfood products (Nzuve *et al.*, 2014).

Information on the nature and magnitude of variability and heritability in a population is one of the prerequisites for successful breeding program in selecting genotypes with desirable characters. Genetic improvement in traits of economic importance along with maintaining sufficient amount of variability is always the desired objective in maize breeding programs. In order to improve the genetic diversity of local germplasm, it is important to know the extent of already existing genetic variations in the material.

In Nigeria, maize improvement started half a century ago (Mosisa *et al.*, 2002). During the late 1960s and early 1970s, several promising genotypes of east African origin were introduced and evaluated at different locations. Different studies were conducted to elucidate the nature and magnitude of genetic variability among maize inbred lines which identified traits like ear length, ear diameter, kernel number per row, ears per plant, 100 seed weight and rows per ear as potential selection criteria in a breeding program.

MATERIALS AND METHODS

Study area

The research was carried out in the Department of Plant Science and Biotechnology Research Garden of the Nasarawa State University Keffi, which lies between Latitude 8.847^{o}N and longitude 7.905^{o}E about 68KMfrom Abuja, the federal capital (Awka *et al*., 2007).

Experimental materials

The experimental materials consist of fourteen (14) lines obtained from local farmer. The maze lines used for this research include, H1, H2, L1, L2, L3, Y1, Y2, Y3, Y4, Y5, W2, W3, W4, and W5.

Experimental design/field layout

The genotypes obtained were planted in a randomized complete block design (RCBD) with three replications. The plot size was 2m x 2m with plant spacing of 75 cm by 25 cm. Observations on the agronomic traits were recorded on 5 individual plants, randomly selected from each plot.

Data collection

Ears per plant, anthesis-silking interval (ASI), plant height (cm), leaf length (cm), days to pollen, days to silking, days to maturity, number of cubs per plant and grain yield (t/ha)

Statistical analysis

Data collected were all subjected to analysis of variance using General Linear Model procedure of Statistical Analysis System (SAS) package (SAS, 2002). Principal Component Analysis (PCA) using the correlation matrix to test the different mineral elements in each of the samples.

RESULTS AND DISCUSSIONS

The result on Table 1, indicated highly significant differences ($P \leq 0.05$) for leaf length, leaf width, leaf area, boron and zinc. The significant differences observed among the genotypes indicated the presence of genetic variability in them, while the non-significant ones indicate that they may be conditioned by the same genes and are genetically related for these characters. It might be possible that the genotypes are related through some remote ancestors. These results indicated that there is significant genetic variability for the traits, thus genetic improvement can be achieved for these traits (leaf length, leaf width and leaf area). Hence, suitable hybrids could be developed. This is in agreement with the findings of Showemimo *et al.* (2000a & 2000b) and Aghaei *et al*. (2012) who reported performance or expression of genes controlling maize characters to be strongly influenced by environmental variation.

The mean performance of fourteen maize genotypes evaluated for yield and other agronomic traits is presented in table2, Indicated a wide range of variability for traits such as number of rows per ear, kernels per row, kernels per ear, ear length, ear diameter, 100-kernels weight and plant height. Yoseph (2005) also reported that grain yield, plant height, ear height and days to maturity showed wide range of variation, while number of leaves, leaf width and ear diameter showed a narrower range of phenotypic variation of maize in Ethiopia. In general, range and mean values in this study suggested the existence of sufficient variability among the tested genotypes for the majority of the traits studied and their considerable potential in the improvement of maize crop.

PH= Plant Height (cm), NL= Number of Leaves, LL=Leaf Length (cm), LW=Leaf width (kg), LA= Leaf Area (cm^2), EPP= Ears Per Plant, ASI= AnthesisSilking Interval, DM= Days to Maturity, GY=Grain Yield (kg/ha), Mo= Molybdenum, B=Boron and Zn= Zinc

The estimates of coefficient of variation for the 14 maize genotypes evaluated at the botanical garden are presented in Table 3. The total variation of PCV and GCV showed that, Phenotypic Coefficients of variations (PCV) were higher than the Genotypic Coefficients of variations (GCV) for all the traits measured except molybdenum and zinc which GCV were higher than PCV. The phenotypic variances (σ^2_{ph}) and PCVs were slightly higher than their respective genetic variances (σ^2_{g}) and GCVs for all the traits suggesting some influence of environment in the expression of these characters. Similar results have been reported by Bello *et al*. (2012). Genotypic and phenotypic coefficients of variation (PCV and GCV) showed that all the traits recorded higher values of phenotypic coefficient of variation than genotypic coefficient of variation. This might be due to the fact that there is high environmental effect on the studied genotypes. This observation was in line with that of Mansir (2010) who reported high phenotypic coefficient of variation than genotypic variation in his study on maize. According to Majid (2011), traits having high GCV indicate high potential for effective selection. This indicates the presence of high variability for these traits and provides ample scope for selection of superior genotypes which is in conformity with the findings of Abhirami *et al.* (2005) and Pradeepa (2007). High broad sense heritability estimates were recorded for plant height (0.91), number of leaves (0.78), leaf length (0.95), leaf width (0.95), leaf area (0.95), ears per plant (0.64), anthesis-silking interval (0.88), days to maturity (0.66), boron (0.93) and zinc (0.90), moderate broad sense heritability was recorded for grain yield (0.33), and molybdenum (0.36).

The estimate of Pearson correlation coefficient yield and other agronomic traits for 14 maize genotypes are presented in Table 4. Plant height exhibited significant positive correlation with leaf length (r=0.53), leaf width (r=0.42) and leaf area (r=0.56), and this study contradicts the findings of Jadhav *et al.* (1991) reported that grain yield was significantly and positively correlated with plant height. Number of leaves showed significant positive correlation with leaf length (r=0.64), leaf width (r=0.72) and leaf area (r=0.78). Leaf length exhibited a significant positive correlation on leaf width (r=0.58), leaf area (r=0.82) and boron (r=0.34). Leaf width showed a significant positive correlation on leaf area (r=0.86), leaf area exhibited a significant positive correlation on days to maturity (r=0.36) and ears per plant exhibited a significant positive correlation on grain yield (r=0.50), this contradicts the findings of Biasutti and Peiretti, (1992). Dash *et al.* (1992) reported that yield was significantly but negatively correlated with maturity traits. Molybdenum exhibited positive correlation with boron (r=0.34). The positive correlations between micronutrient concentrations in maize grain suggest that it is possible to improve various micronutrients in maize grain simultaneously.

The variation among the fourteen maize collections assessed through principal component analysis evaluated for nine agronomic traits and three mineral compositions. Four of the twelve principal components extracted, had Eigenvalue greater than 1 and accounted for 0.70% of the total variation among the fourteen genotypes (Table 5 and 6). The first principal component accounted for 0.30% of the total variation. The variation in the principal component 1 was mainly attributed to leaf area (0.47), leaf length, leaf width and number of leaves (0.42), plant height (0.36), days to maturity (0.21, boron (0.17), anthesis-silking interval (0.13), zinc (0.00), grain yield (-0.03), ears per plant (-0.06) and molybdenum (-0.16). The principal component 2 contributed 0.19% of the total divergence and depicted the pattern of variation mainly ingrain yield (0.59), ears per plant (0.43), boron (0.24), leaf length (0.15), leaf area (0.05), leaf width and zinc (0.01), days to maturity (-0.01),plant height and molybdenum (-0.05),number of leaves (-0.09) and anther silking interval (-0.14). The principal components 3 constitute 0.11% of the total variation and was mainly attributed to molybdenum (0.55), anthesis-silking interval (0.27), grain yield (0.13), days to maturity (0.12), number of leaves (0.10), leaf length (0.08), leaf width (0.05), leaf area and ears per plant (0.04), plant height (0.00), boron (-0.45) and zinc (-0.61). The principal components 4 described an additional 0.09% of the total variation and was dominated by anthesis-silking interval (0.62), days to maturity (0.34), plant height (0.22), grain yield (0.16), boron (0.15), zinc (-0.12), leaf length (-0.13), leaf area (-0.18), leaf width (-0.21), number of leaves (-0.23), ears per plant (-0.29) and molybdenum (-0.36).

CONCLUSION

The study revealed ample genetic variability for the agronomic traits in the materials used for the study. PCV greater than GCV in the study gave an ample opportunity for selection to take place. High broad sense heritability estimates were high (> 60%) for leaf length and leaf width among the traits studied heritability coupled with low genetic advance as percent of mean, due to relatively small population used in the study. However, the amount of variation and magnitude of gene effects depended on the genetic backgrounds of the materials used in the study. Significant and positive correlation was observed between ears per plant and grain yield and no significant correlation was observed between other traits and grain yield. Generally positive correlations between micronutrient concentrations in maize grain suggest that it is possible to improve various micronutrients in maize grain simultaneously. Further work should be done to elucidate underlying physiological mechanisms of the relation among the micronutrients, particularly in cases when the relations are not obscured by deficiency of any element as an additional complicating factor.

24 - 28 Oct., 2022

ABSTRACT

Sweet potato is an important carbohydrate root crop grown annually as food security crop. However, many developed sweet potato genotypes vary greatly in their maturity periods. Therefore the objectives of this experiment were to select potential early storage root bulking and maturing genotypes for early sweet potato cultivation genotypes, to have information on precise time for harvesting each genotype and to nominate sweet potato genotypes for extra-early, early, medium and late maturing for various users. Based on this, an experiment was conducted in 2021, laid out in a randomized complete block design with three replications. The 25 plots containing each genotype were replicated 3 times which gave a total of 75 plots. Each plot measured 4 x 3 m and comprised 4 ridges. Ten sweet potato plants from each plot were randomly selected and tagged for harvesting and data collection. Ten sweet potato plants per plot were harvested at the interval of 4 weeks after planting (WAP). Plant attributes studied were number of marketable roots at the proposed harvesting dates of 8, 12, 16 and 20 weeks after planting. The yield data were subjected to analysis of variance and their means and harvest dates were separated with standard error of difference at the probability level of 0.05. The sweet potato genotypes were grouped into four harvest dates proposed as: Very early maturing, early maturing, Intermediate/medium. and Late maturing. Results indicated that sweet potato genotypes vary remarkably in their marketable root bulking and maturity dates. It was evident that bulking was interrupted at 8WAP in all test genotypes and some sweet potato genotypes require more than 16WAP to reach maturity. Therefore it was recommended that harvesting should be at 16 WAP since most sweet potato genotypes possessed marketable root size. Sweet potato genotypes that fall into this group were regarded as medium/intermediate maturing genotypes.

Keywords: marketable roots, harvest time, root number, standard error of difference and sweetpotato genotypes.

INTRODUCTION

The current research effort is geared towards developing not only high yielders but also rapid storage root bulking and early type high starch content sweet potato genotypes. The early maturing types produce yields of high tonnage. The number of storage roots as well as earliness of root bulking and maturity may depend on the genotype, assimilate supply, photoperiod, and temperature (Maini, *et al*., 1977). The process of tuberous root formation and maturity may also depend on soil water supply, soil fertility and soil temperature (Ikpi *et al*., 1986).

Storage root maturity is characterized by leaf area decline and a slow rate of storage root bulking/growth. This phase may not occur in the field when a medium or late maturing genotypes is grown in a short season. Early season storage root initiation and bulking or growth are acceptable for production in areas where sweet potatoes are harvested prior to physiological maturity.

Environmental factors influence storage root bulking. For example, storage root bulking is best promoted by short photoperiods, high light intensity and cool climates, the meteorological factors influencing this process at a given location are basically air and soil temperatures, solar radiation, photoperiod, soil moisture, and crop water use (Githunguri, 2004). According to Nnodu *et al.*, (2006) sensitivity to environmental conditions varies between genotypes. The most limiting environmental factors for sweet potato production are heat and water stresses. Higher temperatures favor above ground biomass development and delay storage root initiation. Leaf senescence is also shortened by high temperatures, especially greater than 30°C as Maini *et al* (1977) reported. Heat stress leads to a higher number of smaller storage roots per plant and reduced dry matter content.

Drought stress limits vine growth and reduces the number of storage roots in larger size categories. Breeding genotypes must be suited to the cropping systems and growing season of a particular region within their agro-ecological area of adaptation. Base on this, storage root bulking information of genotypes at an advanced stage of selection is of great interest for recommendation for testing toward final adoption. Farmers prefer sweet potato varieties which have high yielding and early maturing capacity. The desired attributes of a good early sweet potato types are early storage rooting, rapid storage root bulking and short maturity period coupled with high starch accumulation within a short period before the onset of dry season, good in-ground storability, and good cooking qualities (Nnodu *et al*., 2006). Early storage root bulking keeps pace with crop growth rate. Too early harvest of the sweet potato crop often leads to reduction in storage root yield, while delayed harvest causes development of fibrous, weevil infested storage roots, reduction in starch content and deterioration of root quality (Ntawuruhunga *et al*., 1998). Many factors influence the maturity period of sweet potato however, these factors varied as per each genotype. The optimum stage of harvest, depends on varieties and ecological factors. It was considered desirable to determine the influence of different stages of growth, storage root yield and yield related traits with a view to defining the optimum harvest time for some genotypes. This study aims at selection of potential early storage root bulking and maturing genotypes for early cultivation genotypes and to have information on precise time for harvesting each genotype and to select genotypes for extra-early, early, medium and late maturing for various end users.

MATERIALS AND METHODS

Study site and experiment details: The experiment was conducted in 2021 cropping seasons at Umudike Umuahia Abia State, Nigeria. Umudike is located within latitude 05°17' and 05°27'

North and longitude 05°29' and 07°32' East of the Greenwich Meridian at altitude 122 m above sea level (NRCRI metrology Unit, 2021). It lies in high rainfall forest area of over 2500 mm per annum, with mean photoperiod of 5 hours per day. The temperature is generally high, ranging from 27 to 34°C throughout the year. The average relative humidity is about 76%, with the lowest and highest values in January/December and July, respectively. The soil is typical Ultisol of acid sandy loam soil. The trial was conducted at the Western experimental field of NRCRI, Umudike for assessing storage root bulking maturity of 25 sweet potato genotypes. The site for the experiment was cleared and ridges constructed and spaced 1 m apart. The experiment was laid out in a randomized complete block design with three replications. The 25 plots were replicated 3 times which gave a total of 75 plots, each plot measured 4 x 3 m and comprised 4 ridges. Twenty-five sweet potato genotypes were used for the experiment. Ten genotypes were used as samples per plot per genotype. The sweet potato seed vines were cut 25 cm long, with at least 4 nodes. The seed vines were inserted two nodes° on the crest of the ridges in a slanting position and placed 1 m between ridges and 0.3m apart along the row on the ridges. Thirty plants per plot, equivalent to 33,333 plants per hectare. The seed vines were treated with Decis EC 12 against soil inhabiting pests, especially termites and weevils which attack sweet potato seed vines in the field by dipping and spread under shade for one hour before planting. Weeding was manually done three times, using the West African hoe and hand pulling. Cross bars were constructed to control erosion and conserve soil moisture.

Data collection and analysis

Ten sweet potato plants from each plot were randomly selected and tagged for harvesting and data collection. Ten sweet potato plants per plot were harvested at the interval of 4 weeks after planting (WAP). Plant attributes studied were number of storage roots, length and diameter of storage roots (cm) at 8, 12, 16 and 20 weeks after planting. The yield data were subjected to analysis of variance and their means separated with standard error of difference at the probability level of 0.05. Four harvest dates for the sweet potato genotypes were proposed: Very Early maturing (8WAP), Early maturing (12WAP), Intermediate/medium (16WAP) and late maturing (20WAP).

Evaluation parameters: Marketable root size

Data collected at harvest:

Size of marketable roots: Separate marketable roots i.e., those ≥ 4cm in diameter (>100g). The percentage of marketable roots and number of unmarketable roots were calculated as those less than 4cm or less than 100g

Each harvest date 10 plants from each plot were harvested.

Data Analysis

Marketable root number were analyzed using analysis of variance (ANOVA). Means between harvest dates within test genotypes, and means between test genotypes at each harvest date are compared using standard error of difference. Procedures for performing these comparisons in ANOVA

Data Interpretation

The Storage root bulking stage is a key determinant of the marketable component of total yield, characterized by a constant rate of increase in storage root size. Hence, performance of marketable storage root size across harvest date is of great importance in determining bulking maturity. To assign a test genotype to a given storage root bulking maturity grade, The genotype that did not perform statistically different for marketable storage root number across harvest date in the first harvest date can be regarded as early maturing. The genotypes that perform statistically better in the second harvest date though not significantly different to the third harvest date can be regarded as medium maturing. The genotypes that perform statistically better in the third harvest date can be regarded as late maturing. Genotypes that show no statistical difference in marketable storage root weight in two consecutive harvest dates may show a statistically significant increase in their marketable storage root yield. Since marketable storage root yield is a function of marketable storage root weight and number, a significant increase in marketable storage root yield can be attributed only to a greater number of marketable storage roots. This would be the case of sweet potato genotypes that were able to produce additional storage roots during later stages of plant development or genotypes with more than one storage root setting cycle.

RESULTS AND DISCUSSION

The results from the Table 1 showed a positive significant difference (P = 0.05) for all the four characters: number of storage root, length of storage root, diameter of storage roots and weight of storage root. The highest number of storage root from 8 to 20 WAP for 2020 cropping season was given in Table 1.

Table 1: Number of storage roots of the sweet potato genotypes at 8, 12, 16 and 20 weeks of harvesting in 2020 cropping season

Table 1 shows that very few storage roots of each clone reached marketable size at 8WAP. And therefore low marketable storage root yield were recorded. High standard errors for marketable storage roots at 8WAP led to the lack of statistical differences among the sweet potato genotypes for this trait despite the wide range of yield values of 0 to 3.0 with mean number of marketable root of 0.5. The standard error of difference indicated that all the genotypes were still in the same group of immaturity and bulking. The mean number of small roots at 8WAP was high compared to other harvest dates given up to 96.1% of unmarketable root size and 3.9% of unmarketable root size out of the total number of storage root yield. This indicated that the earlier harvest interrupted the bulking rate of the roots reducing the storage root size and render the storage roots unmarketable in all the test sweet potato genotypes. It is likely that most of the genotypes might require more number of weeks to reach maturity. It is not recommended to harvest any of the test genotypes at 8WAP. Table 1 shows that most of the sweet potato genotypes had at 12 WAP produced significantly greater number of storage roots of marketable size. The standard error difference in the number of marketable root potential in the bulking maturity may account for the statistical differences among the genotypes at 12WAP. Although almost all the genotypes showed good number of marketable root size when harvested at 12WAP. The number of marketable root size ranged from 0 to 16 number of storage roots per genotype with mean marketable root number of 7.4 which accounted for 90.2% of marketable root size. If harvesting was to be carried out, the sweet potato genotypes that yielded more than the mean number of marketable roots of 7.4 and were grouped together by the standard error of difference. These should be harvested at 12WAP and these genotypes should be regarded based on the proposed four harvest dates as early maturing. These genotypes included: NWA/OP/242, 87/OP/194, PO3/95, PO3/40, 87/OP/208. These sweet potato genotypes should be of particular importance for areas of short growing seasons, where early harvesting is required.

At 16WAP the genotypes yielded significantly better even though a few marketable roots were harvested, they were not significantly different from those harvested at 12WAP. However, a significant greater number of marketable roots at 16WAP indicated that bulking was still in progress while at 12WAP for most of the genotypes and as such those genotypes could be regarded as intermediate/medium maturing genotypes. The marketable root size ranged from 0 to 13 with mean of 5.7 which accounted for 68.7% of marketable root size while unmarketable root size number accounted for 31.3% of total number of storage roots harvested. This should be expected because some creeping sweet potato genotypes continue to produce storage at the nodes that made contact with the soil.

In contrast, no significant differences was observed for marketable number of roots across harvest dates which indicated that these genotypes could as well be regarded as both early and medium maturing under Umudike conditions. The genotypes grouped by their standard error of difference as belonging to this group were: PO3/145, PO3/93, 87/OP/194, PO3/95, PO3/8, 87/OP/210. Their marketable root yield were above the mean yield of 5.7 number of marketable root yield which accounted for 68.7% of the total number of storage roots harvested.

At 20WAP, few genotypes produced mean marketable roots higher than the mean marketable root of 2.8 which accounted for 31.3% of the total marketable roots yield. This indicated that some of the genotypes could be late maturing. These genotypes were: 87/OP/194, PO3/93, PO3/95, PO3/119 and 87/OP/210. The standard error of difference placed them in late maturing group. The late maturing genotypes have an advantage over the early maturing ones as significantly higher marketable roots can be expected in a late harvest. This is important when farmers need to decide their harvest date according to the markets' demands and supply of sweet potato roots.

The medium/intermediate maturing sweet potato genotypes such as NWA/OP/231 and PO3/01/14 had long senescence and died and could not survive up to 20WAP. The sweet potato genotypes that gave the lowest mean storage roots were NWA/OP/28 of 2.0 numbers of marketable roots while the genotypes with the highest mean number of marketable roots was 87/OP/194 followed by 87/OP/210 and they did well across all the 4 proposed harvest dates by producing significantly high number of marketable roots.

The highest number of storage root from 8 to 20 WAP for the year 2021 cropping season was given in Table 2.

%	2.8	97.2	=	33.8	66.2	=	75.2	24.8	=	70.1	29.9	=	=

The result in Table 2 also showed very few mean number of marketable of root of 0.4 in 8 weeks after planting which accounted for 2.8%. The mean number of unmarketable root represented 97.2% of the total roots produced. This suggested that the storage roots of most of the clone genotypes were still bulking and were not yet mature. The number of marketable roots ranged from 0 to 2. The high standard error of difference of 0.64 for marketable root at 8 weeks after planting indicated no statistical difference among the genotypes which showed that they are still in the same group of storage root immaturity and still bulking and therefore cannot be harvested at this stage.

At 12 WAP, the mean number of marketable roots was 5.4 which represented 33.8% while the mean number of unmarketable roots was 11.4 or 66.4% of the total number of storage roots produced. This result indicated that major part of the storage roots were still bulking and immature. The marketable root number ranged from 0 to 14. The standard of error of difference in the number of marketable root potential in the bulking account for statistical difference among the genotypes at 12 WAP. Some genotypes showed marketable root size when harvested at 12 WAP. However, 52% of the genotypes evaluated may be harvested at 12WAP as a result of producing 33.8% of marketable root yield.

At 16 WAP, mean marketable yield number was 11.3 which accounted for 75.2% of the total root yield while mean yield of unmarketable root was 3.9 which represented 24.8%. The marketable root yield ranged from 0 to 18. At this stage, the genotypes yielded significantly better marketable roots potential. The statistical error of difference of 3.46 indicated significant difference means among the test genotypes. However, no significant differences was observed for number of marketable roots across harvest dates as shown by the standard error of difference. This group of genotypes could be assigned as medium maturing genotypes under Umudike agro-ecological condition. Forty-eight percent which yielded more than the grand mean fall under this group.

At 20 WAP yield of marketable roots ranged from 2 to 10 with mean of 6.0 which accounted for 70.1% of total number of storage roots produced that period. This showed that some genotypes were late maturing. The standard of error of difference of 2.52 grouped these genotypes under late maturing genotypes. Thirty-nine percent of the genotypes were under this group.

The duration and rate of storage root bulking in the sweet potato plant determines the yield of the crop. The rate of storage root bulking describe the increase in storage root weight with time, while storage root bulking duration is the time between storage root initiation and persistence of the sweet potato leaves. The decline in leaf area by senescence is as a result of the ceiling in storage root bulking. Although some sweet potato genotypes does not senescence their leaves throughout their growing period. This factor account for yield differences between genotypes. However,

storage root bulking duration is of greater importance as it seems to determine the final yield of sweet potato crop.
Storage root bulking results from two basic processes which include storage root initiation and storage root growth. These two factors is also affected by timing, duration, location, environmental factors, and genotypes.

However, genotypes of medium or late bulking maturity can be recommended for an earlier harvest date provided that the genotype is among those with best marketable storage root weight and yield at the referred date. Therefore, a comparison test between genotypes at a given harvest date is of paramount importance for a final recommendation of the genotype's harvest date. This is of particular importance for areas of short growing seasons, where early harvesting is required.

CONCLUSION

Sweet potato genotypes vary remarkably in their marketable root bulking and maturity. This indicates that earlier harvests would render immature unmarketable size. It is evident that bulking was interrupted at 8WAP in all test clones and it is likely that some of them might require more than 16WAP to reach maturity. Nevertheless, almost all clones showed good marketable tuber weight and number when harvested at 16 WAP. It is therefore recommended that harvesting should be at 16 WAP.

ABSTRACT

Studies on cocoyam have shown that it is a very important food crop especially in the tropics and subtropics,but little studies have been considered when it comes to its nutritional composition due to the difficulty in accessing its recombinants. This study was carried out to determine and document the nutritional composition of the available accessionsin the cocoyam germplasm of National Root Crops Research Institute, Umudike. Six accessions of cocoyam both (*Colocasia esculenta)* Nce001, Nce012, Nce011 and (*Xanthosoma maffafa*) (Nxs001, Nx002, Nxs003) were harvested,samples were cleaned and oven dried at 50^{0}C and processed into flour.From the findings, NCe001 has the highest significant value of 8.47% and 9.01% for moisture and protein contents respectively. Nx$_s$001 had the highest significant value of 6.33% for fibre content while NX$_s$002 had the least significant value of 2.48% for fibre content.The highest carbohydrate value of 81.28% was recorded for Nx$_s$003. From the findings, these accessions should be recommended to both children and adult as a cheap dietary nutrients source for the promotion of good health. This study also provided important information from the institute's cocoyam germplasm, which can help to develop cocoyam food products and to promote production and utilization of cocoyam by encouraging its sustainability.

Keywords:Cocoyam, proximate composition, accessions and sustainability.

INTRODUCTION

Cocoyams (*Colocasiaesculenta (L.) Schott and Xanthosomasagittifolium (L.) Schott*) are the important species of edible aroids, grown in tropical and sub-tropical countries. Cocoyams are grown mainly for their edible starchy corms, cormels, and their leaves that could serve as vegetables (Aregheore and Perera, 2003). Nigeria is the largest producer of cocoyam in the world, producing 40% of the world output. Cocoyam is eaten in various ways as yam. It can be eaten boiled, fried, pounded into fufu. studies has shown taro flours are rich in starch, total dietary fibre and low in fat, protein and ash contents respectively. Moisture contents are 9.17%; fat contents 3.37% ash contents 2.27% (Apotiola and Fashakin 2013). A high protein contents than most other tropical root crops. Cocoyam appears to be in stiff competition with yam and cassava, which are the preferred tubers for consumption, it is still regarded as an underutilized and insufficiently studied crop (Watanabe, 2002). There is a dearth in information on the nutritional composition of these accessions, it is necessary to analyse each of these accessions and document them This study was carried out to determine and document the nutritional composition of the available accessions in the cocoyam germplasm of National Root Crops Research Institute, Umudike.

MATERIALS AND METHODS

Six accessions of cocoyam both (*Colocasia esculenta)* Nce00*1*, Nce012, Nce011 and (*xanthosoma maffafa*) (Nxs001, Nx002, Nxs003) were harvested from the multiplication field of cocoyam, the Accessions were cleaned(sorted, washed, peeled and chopped into particle sizes) and oven dried at 50^0C and processed into flour and stored in an air tight containers. Proximate analysis was carried out on the different flour samples.

RESULT AND DISCUSSION

Table 1 shows the moisture content ranged from 4.40 to 8.47.There was significant differences among the accessions. Moisture content gives an idea of the storability of the food material, high moisture content depicts high susceptibility to microbial attack and deterioration within a short storage period (Oladebeye*et al.,* 2009). The moisture content of all accessions reported were generally low and corresponds with the report of Oladebeye*et al.*, 2006. Ash content measures the total amount of minerals content in a food crop. The ash content of all the cocoyams used in this study was high suggesting that their flour are rich sources of mineral element of nutritional importance. Crude fibre plays a very important role in nutrition (Olaleye*et al.,* 2013). Evidence has shown that a diet low in fibre is undesirable and could cause constipation, hence many diet are associated with diseases of the colon (pile, appendicitis) the highest crude fibre value was on NX_s001 had the highest significant value of 6.33% while NX_s002 had the least significant value of 2.48%. The values were significantly different from each other and higher than the values reported by Nwanekezi *et al*., (2010). The highest carbohydrate value of 81.28% was recorded for Nx_s003.Fat supplies most of the energies required by man, it is broken down in the body to release glycerol and free fatty acids. The glycerol can be converted to glucose by the liver and used as a source of energy. High amount of lipid present in these accession could be the reason for the fast and high satiety observed when they are consumed. The fat content of the six accessions studied were low when compared to the report of Amandikwa, (2012) but higher than values reported by (Nwanekezi et al., 2010). protein is necessary for good nutrition. Value ranged from 6.03% to

9.01%; there was significant differences ($p<0.05$) among the accessions The crude protein content was high for all the accessions studied. The value compares to the report of Amanze (2009). Carbohydrate supplies energy to body cells, it contributes to fat metabolism and spares protein as an energy source. (Gordon 2000)The highest carbohydrate value of 81.28% was recorded for Nx_s003.The high carbohydrate content is an indication of the high energy reserve inherent in these accessions.The good nutritional value inherent in these accessions, it is good to be recommended to both children and adult as a cheap dietary nutrients source for the promotion of good health.This study also provided important information from the institute's cocoyam germplasm, which can help to develop cocoyam food products and to promote production and utilization of cocoyam by encouraging its sustainability.

24 - 28 Oct., 2022

ABSTRACT

This experiment evaluated the effect of different plant manure sources on the growth and yield of three local varieties of groundnut (*Arachis hypogaea* L.) conducted at the Research and Teaching Farm of Federal College of Agriculture Ishiagu, Southeast Nigeria during 2020 and 2021 cropping seasons. Three local varieties of groundnut used were; *Nwafum*, *Gwonkworo* and *Oso'obo*, and plant manure sources (*Gmelina*, *Jatropha* and *Neem* leaves) were used as soil amendments at 10 t/ha each in the experiment. A 4 x 3 factorial fitted into randomized complete block design was used in the experiments. The plant manure sources and control were used as Factor A while the varieties served as Factor B. Data were obtained from plant height (cm) and number of leaves at 3, 6, 9 and 12 weeks after planting, number and weight (kg) of pods and number of galled roots at harvest. Data obtained were averaged over the two years and subjected to analysis of variance (ANOVA) using GENSTAT 3 Edition 7.2. Significant treatment means were separated using Least Significant Difference (LSD) at 5% level of probability. Results indicated that the plant manure sources significantly ($P<0.05$) increased the plant height, number of leaves at 3 and 6 weeks after planting, number and weight (kg) of pods at harvest over the control. The plots amended with *Jatropha* leaves gave the highest plant height, number of leaves, number and weight of pods. It is therefore recommended that the plant manure sources used in this experiment could be employed in the production of groundnut with more emphasis on *Jatropha* leaves.

Key words: plant manure; local; groundnut; yield

INTRODUCTION

Groundnut (*Arachis hypogaea* L.) is an important food and forage crop because of its high protein and oil contents. Its seed is used as a source of cooking oil and in confectionary products for human consumption. Groundnut hay (vine) is a nutritious animal feed, particularly for the subsequent dry season when green forage is not available. In addition, groundnut seed and hay are often sold in local markets, providing income to the resource-poor farmers (Alabi *et al.*, 2003).

Groundnuts usually grow well in light sandy to sandy-loam, well-drained, aerated soil but heavy soils or soils with a tendency to form crust are unsuitable because they hamper the penetration of the pegs during flowering and impact negatively on harvesting (Waele and Swanevelder, 2001). Hack (1997) observed that heavy clay soils make harvesting difficult, reduce yield through fracture and pod may be strained by adhering clay. Interestingly, groundnuts will grow in heavier soils according to Tweneboah (2000) if there is no water logging and if the surface soil is loose enough to allow penetration of the ovary. Farmers have general preference for well drained, light sandy loams because of ease of cultivation and harvest.

Groundnut is grown either as a sole crop or intercropped with maize or sorghum. The cultivation of the crop started in irrigated agriculture, but later spread to the dry land cropping system. Groundnut germinate in 3 to 6 days. It grows rapidly on fertile soils with leaf development proceeding rapidly. Soil conditions in dry land farming are considered more favorable for groundnut production. The seed contains 50 to 52% oil and 24 to 25% protein. Though the seed is generally roasted and eaten as a snack, there is great potential for oil extraction (Abbiw, 1990).

Nutrient management is always an important consideration for groundnut production because it requires large quantities of nutrient, especially potassium is one of the most limiting factors for groundnut production (Basiron, *et al.*, 2000).

Therefore, continuous cultivation of a crop like groundnut on the same land will lead to soil mining, degradation of soil quality and consequent low yield. For optimum target yield, there is the need for fertility enhancing technologies including the integrated application of organic manure/amendments that will ensure immediate nutrient release for the present crops as well as the long term build up of soil nutrients.

High cost of fertilizer and increasing concern for ecological stability and sustainable soil productivity have led to renewed interest in plant manure (Jibrin 2002, Fageria, 2007). In many parts of West Africa, *Mucuna* has been adopted as a low input strategy for addressing the problem of declining soil fertility arising from population pressure, intensive cultivation and shortening fallow periods (Mahmoud, *et al.*; 1992). Some leguminous Plant manure crops have the ability to accumulate high amount of N within a short time.

The objective of this study was to determine the effects of different plant manure sources on the growth and yield of three local varieties of groundnut produced in Ebonyi state, Nigeria.

MATERIALS AND METHODS

Description/Location of Experiment Allocation

The experiment was conducted at the Research and Teaching Farm of Federal College of Agriculture, Ishiagu, Ebonyi State, during the 2020 and 2021 cropping seasons. The study area lies within latitude 05^0 56'N and longitude 07^0 41'E in the derived savannah zone of the Southeastern Nigeria. The area has a mean annual temperature of about 30 ^{0}C and rainfall of 130mm (Federal College of Agriculture Ishiagu, 2013). Geologically, the area is underlain by sedimentary rock and lies within Asu River Group (Nwite *et al*., 2014).

Experimental Design/Treatment Allocation

The experimental design was a 4 x 3 factorial fitted into randomized complete block design replicated three times. The plant manure sources constituted factor A while varieties were factor B. The treatments used were; older leaves Neem, *Gmelina* and *Jatropha* at10 t/ha each. The plots without amendment served as control. The three local groundnut varieties used were; *Nwafum, Gwonkworo,* and *Oso'obo*.

Factor A were plant manure sources (Control, *Gmelina, Jatropha* and Neem leaves) formed the main plot while Factor B were local groundnut varieties (*Nwafum, Gwonkworo,* and *Oso'obo*) constituted the sub-plots. These local groundnut varieties used for the research were the local best obtained from farmers in Ishiagu, Ivo Local Government Area of Ebonyi State.

Field Preparation

The experimental sites were cleared, ploughed, harrowed and later made into beds using native hoe. The net plot size was 2 m X 2 m. The different plant manure sources were randomly allocated to the main plots and were incorporated into the soil and left for two weeks before planting. The un-amended plots served as the control. The local groundnut varieties were randomly allocated to the sub-plots and were planted at the spacing of 30 cm X 40 cm with two (2) seeds per hole giving a projected plant population of 83,333 stands per hectare. Two weeding operations were carried out manually with weeding hoe and hand pulling at two and five weeks after planting. At six (6) weeks after planting, the plants were earthened up in each year.

Data Collection

Ten plants were randomly selected from each variety and tagged for data collection each year. Data were collected on the following parameters:.

a. Plant height at 3 weeks, 6weeks, 9 weeks and 12 weeks after planting (WAP).
b. Number of leaves at 3, 6, 9 and 12 weeks after planting
c. Number of pods at harvest
d. Weight (kg) of pods at harvest.

Statistical Analysis

Data collected were averaged over the two years and subjected to the analysis of variance (ANOVA) according to the procedure for the factorial in a randomized complete block design (RCBD) using GENSTAT 3 Edition 7.2. Significant treatment means were separated and compared using least significant different (LSD) at 5% probability level as outlined in Obi(2002).

RESULTS

The physical and chemical properties of the soil before application of amendments are shown on Table 1. The soil is sandy clay loam with a total percentage of sand as 60.9%, 17.9% silt and 21.2% clay. The soil is slightly acidic with a pH of 4.8. The organic carbon and total nitrogen of the soil were 0.98% and 0.41% respectively. The analysis indicated that the studied soil was moderate in exchangeable bases. In addition, the cation exchange capacity was low, also with the amendable phosphorus (23.1 mg/kg) in the studied soil. Some of the chemical components of the soil before used for planting showed that N, P, K, Ca, Mg, Na and OC were of low values which revealed that the soil is low in fertility.

Table 1: Physical and chemical properties of the studied Soil (0-20cm).

Properties	Values
Sand (%)	60.90
Silt (%)	17.90
Clay (%)	21.20
Textural class	Sandy clay loam
pH (H_2O)	4.8
Organic Carbon (%)	0.98
Total nitrogen (%)	0.41
Exchangeable bases (cmol/kg)	-
Sodium	0.4
Potassium	0.19
Calcium	3.20
Magnesium	0.80
Available phosphorus (Mg/kg)	23.1
Base saturation (%)	66.43
Exchangeable acidity (cmol/kg)	2.32
Organic matter (%)	1.68
ECEC (cmol/kg)	6.91

The results in Table 2 show that the plant heights were significantly ($P<0.05$) affected by the plant manure sources and varieties at 3 and 6 weeks after planting (WAP). The interaction of the Plant manure sources and varieties had significant ($P<0.05$) effect on the plant height at 3 WAP only. The highest plant heights were obtained from plots amended with *Gmelina* leaves (46.79 cm), Gwonkworo (43.31 cm) and the interaction of Plant manure sources by varieties (48.97 cm). The lowest plant heights were obtained at the control plots.

The results in Table 3 show that the plant manure sources significantly (P<0.05) affected the number of leaves produced by the plants at three (3) weeks after planting. The number of leaves produced significantly (P<0.05) varied amongst the varieties at 3, 6, 9 and 12 WAP. The interactions between plant manure sources and varieties have significant (P<0.05) effects on the number of leaves produced by the plants.

DISCUSSION

The experimental soil was sandy clay loam with a total percentage of sand as 60.9%, 17.9% silt and 21.2% clay. The soil was slightly acidic with a pH of 4.8. The organic carbon and total nitrogen of the soil were 0.98% and 0.41% respectively. The analysis indicated that the studied soil was moderate in exchangeable bases. In addition, the cation exchange capacity was low, also with the amendable phosphorus (23.1 mg/kg) in the studied soil. Some of the chemical components of the soil before used for planting showed that N, P, K, Ca, Mg, Na and OC were of low values which revealed that the soil is low in fertility.

The increase in plant height across the weeks was attributed to the relative decay periods of the plant manures and the absorption rates of the nutrients released by the varieties. This is in line with the works of Mukhtar *et al*. (2014) who stated that organic manures as valuable by-products of farming and agro-allied industries, contribute to plant growth through their favourable effects on the physical, chemical and biological properties of soil and nutrient availability.

The increase in the number of leaves shows that the nutrients contained in the leaves used as soil amendment were released on decomposition to the plants for vegetative growth which led to increase in the number of leaves produced by the plants on the treated plots.

The increase in the number and weight of pods from the treated plots showed marked effects of the plant manures sources when compared with that obtained from the control plots. These indicated that plants utilized the products from the decomposition of the various plant manures which increased their matter content. Ajari *et al*. (2000) reported that nutrient absorption by plants facilitates normal physiological function and photosynthetic processes, which made the plants to posses the ability to increase yield. Sonbeer *et al.* (2017) and Falodun and Egharevbra (2018) also reported enhanced growth and yield of onion and carrot in soil amended with *Jatropha* leaves.

CONCLUSION

The results of the experiment revealed that the Plant manures sources used could be employed in enhancing the growth and yield parameters of the three groundnut varieties. *Jatropha* and *Gmelina* leaves showed better effects than neem leaves though not statistically different. They could be employed as veritable alternatives to organic fertilizers in the production of groundnut.

ABSTRACT
Insect pest infestation affects crops during production and storage, thereby leading to food insecurity. The study was conducted to examine the farmers' awareness of insect pest infestation during production and storage of three neglected food crops (bambaragroundnut, breadfruit and bush mango) in Southern Nigeria. A purposive technique was used to sample 120 farmers of the selected neglected crops in Akwa-Ibom, Ebonyi and Rivers states.. A well-structured questionnaire was used to obtain information from the respondents and analyzed using descriptive statistics. The result revealed that the mean age of neglected food crops farmers in the study area was 41 years, with 65% of them being females. Their averagefarming experience was 11.4 years and the mean farm size was less than 1 hectare. The results revealed that 41.7% of the respondents are aware of insect pests as a major production constraint while 65% of the respondents stored their crops in bags/sacks. Findings revealed that 33.3% of the farmers encountered insect pest infestation as a major storage constraint. The insect pests encountered in storage are weevils (25.8%) and beetles (13.3%) and the coping strategy to reduce the spoilage during storage in the area were early sales (70.8%) and consumption (69.2%). The common pests identified were *Callosobruchus maculatus* and *Oryzaephilus mercator*. This study recommends that more researches into post-harvest technology related to the selected food crops be carried out

INTRODUCTION
In Nigeria, peasant farmers constitute a high proportion of farming population with the output still insufficient to feed the population of about 217 million people (Ojeka*et al.*, 2016; Worldometer, 2022). Post-harvest loss in Nigeria is estimated to be 20-30% of the total production (World Bank, 2011). Jaspareet and Anita (2013) reported that the food consumed is lesser than the food lost or

wasted. Food insecurity, poor nutritional value, reduction in farmers' income, and lack of input for the next production are some of consequences of post-harvest losses (Olayemi*et al.*, 2011).
Insect pest infestation is one of the major causes of food insecurity in Sub-Saharan Africa (Nwaubani*et al.*, 2014). Insect pests are responsible for deterioration and destruction of food products (Silva-Aguayo *et al.*, 2004). Insect damage causes serious losses to grain famers during storage (Nwaubani *et al.*, 2014) through reduction in quality and quantity of food available for human consumption (Okonkwo *et al.*,2017). Peasant farmers and grain aggregators in Sub-Saharan African are frequently forced to sell their crops at giveaway prices due to lack of effective ways to control insect pests during storage (Stathers*et al.*, 2008; Nwaubani *et al.*, 2014).
Most of important crops in South-South and South-East regions of Nigeria have been neglected and underutilized due to oil discovery in area and this has reduced most of the resources to be used in agriculture (Matemilola and Elegbede, 2017). In Nigeria, neglected crops receive little research attention, poor communication, marketing, lack of effective policy frame works for harnessing their potentials (Idowu, 2009). Hence, there is need for more reliable data that can explore some of the potentials of these neglected crops. The objectives of this study are to;ascertain the socio-economic characteristics of farmers;identify the insect pestchallenges encountered during the production andstorage of some neglected food crops; identify the storage methods used by the farmers and identify ways of solving challenges during storage ofthese neglected food crops in the study area.

METHODOLOGY

The study was carried out in three States in Southern Nigeria; Akwa-Ibom (4.9057^{0}N, and 785370E), Ebonyi (6.2649^{0}N, 8.0137^{0}E)and Rivers (4.8396^{0}N, 6.9112^{0}E), between May and June 2021. The study population consists of farmers cultivating the selected neglected crops (bambara groundnut, breadfruit and bushmango).A multistage purposive sampling procedure was used for this study. The first stage involved purposive selection of three states, two from the South-South (Akwa-Ibom and Rivers States) and one from the South-East (Ebonyi) where the three selected cropsweregrown. The second stage involved liaising with Agricultural Development Programme (ADP) in each state through their extension agents for the selection of 4 local governments in each state where the selected crops are grown to make 12 Local Government Areas(LGAs) consisting of Abak, Ibiono-Ibom, Itu, Oruk-Anam, Ezza-South, Ikwo, Ishielu, Ohankwu, Degema, Abua-Odual, Ahoda-East, and Asari-Toru.Afarming community was selected from each L.G.A. to make 4 communities in a state and a total of 12 communities in the three selected states. In each community, 10 farmers that grow any of the crops were selected, giving, a total of 40 respondents in a state and 120 respondents in the 3 states selected. Data were collected from the respondents through the use of structured questionnaires and were analyzed using frequency and percentages.

RESULTS AND DISCUSSION

Table I: Distribution of farmers of neglected food crops according to socio-economic characteristics (N= 120)

Socio-Economic Characteristics	Frequency (Percentage)Mean

Age (Years)	F (%)	Mean
20-29	18 (15)	
30-39	43(35.8)	
40-49	35 (29.2)	41
50-59	15 (12.5)	
60-69	5 (4.2)	
70-79	4 (3.3)	
Sex		
Female	78 (65)	
Male	42 (35)	
Years of Business Experience		
1-5	15(12.5)	
6-10	45 (37.5)	11.4
11-15	38 (31.7)	
16-20	7 (5.8)	
21-25	15 (12.5)	
Farm Size		0.3812 hect.

Source: NSPRI Field Survey, 2021

Table 1 shows that the mean age of the neglected food crop farmers in the study area was 41 years, with 65% of them being females. Their average farming experience was 11.4 years while their average farm size was 0.3812 hectare, a figure considered too low for commercial crop production. The finding also implies that the farmers of the neglected crops in the study area are in their active ages, more energetic and productive, and they are conversant with the crops limitations and benefits because the respondents are less than 50 years of age and have business experiences of more than 10 years. This supports the findings of Elemasho *et. al.* (2017) who reported that, young farmers are more willing to adopt new innovation than elders because the young farmers are more open to innovations, willing to adopt new technology and are not afraid of taking risks.This is tandem with the findings of Ojeka*et al.*, (2016) who reported that Nigerian farmers'output is not enough to feed her population because each farmer on the average cultivates less than 5 hectares using simple tools and traditional methods for production.

Table 2: Distribution of farmers according to the kind of neglected food crops produced (N= 120)

Neglected food crops	Frequency (F)	Percentage (%)
Bambaragroundnut	25	20.8
Breadfruit	30	25
Bushmango	65	54.2
Total	**120**	**100**

Source: NSPRI Field Survey, 2021.

Table 2 indicates that 20.8% of the neglected food crop farmers in the study area produced bambara groundnut, while 25% were breadfruit farmers and 54.2% were bush mango farmers. The majority of the farmers in the study area engaged in Bushmango farming and this supports the findings of Chah *et al*. (2014) who reported that Bushmango as important non-timber forest product in Southern Nigeria.

Table 3: Distribution of farmers according to insect pestchallenges during production (N= 120)

Selected neglected crops	Yes F (%)	No F (%)
Bambara groundnut	20 (16.7)	5 (4.2)
Breadfruit	1 (0.8)	29 (24.2)
Bush mango	29 (24.2)	36 (30)
Total	**50 (41.7)**	**70 (58.3)**

Source: NSPRI Field Survey, 2021. % = Percentage, (F) = Frequency

Table 3reveals that 41.7% of the farmers acknowledged that insect pests attack these neglected crops on the field. This supports the findings of Uddin II *et al.* (2017) and Baudoin & Mergeai (2001), who reported insect pest attack on bambaragroundnut on the farm at different developmental stages. In a similar study, Germain *et al.* (2010) reported insect pest infestation on bush mango.

Table 4: Distribution of farmers according to the method of storage of the selected neglected food crops (N= 120)

Method of storage	Crops	Yes F (%)	No F (%)
Bag/Sack	Bambara groundnut	25 (20.8)	0 (0)
	Breadfruit	10 (8.3)	20 (16.7)
	Bushmango	58 (48.3)	7 (5.8)
	Total	**93 (77.5)**	**27 (22.5)**
Container	Bambara groundnut	25 (20.8)	0 (0)
	Breadfruit	10 (8.3)	20 (16.7)
	Bushmango	42(35)	23 (19.2)
	Total	**77 (64.2)**	**43 (35.8)**

Source: NSPRI Field Survey, 2021. % = Percentage, (F) = Frequency

Table 4indicates that 77.5% of the respondents stored their crops in bags/sack while64.2% of the respondents indicated container (drum, gallon, etc). This study supports Babarinde *et al.*, (2016), who found out that majority of crop stakeholders stored their produce in sacks.

Table 5: Distribution of farmers according to the insect pests responsible for the storage challenges of the selected neglected food crops (N= 120)

Causes of storage challenges	Crops	Yes F (%)	No F (%)
Insect	Bambara groundnut	24 (20)	1 (0.8)
	Breadfruit	2(1.7)	28 (23.3)
	Bushmango	14 (11.7)	51 (42.5)
	Total	**40 (33.3)**	**80 (66.7)**

Source: NSPRI Field Survey, 2021. F = Frequency, % = Percentage

Table 5shows that 33.3% of the farmers are aware of losses due to insect pest infestation on their produce during storage, out of which 20% were for bambara groundnut farmers 16.7% from bushmango farmers and 1.7% from breadfruit farmers. This supports Hodges *et al.* (2014) who stated that biological agents such as insects cause post-harvest losses.

Table 6: Distribution of farmers according to the type of insect pest encountered during storage of selected neglected food crops (N= 120)

Types of insect	Crops	F	%
Weevil	Bambara groundnut	25	20.8
	Breadfruit	1	0.8
	Bush mango	5	4.2
	Total	**31**	**25.8**
Beetle	Bambara nut	0	0
	Bread-fruit	1	0.8
	Bush mango	15	12.5
	Total	**16**	**13.3**

Source: NSPRI Field Survey2021. F = Frequency, % = Percentage

Table 6reveals that 25.8% of the neglected crop farmers encountered weevils during storage while 13.3% encountered beetles. The insects reported in bambaragroundnut and bush mango by e farmers are cowpea weevil (*Callosobruchus maculatus*) and merchant grain beetle(*Oryzaephilus mercator*). This supports the findings of Mbah-Omeje *et al.*(2019) who reported that weevil is the primary pest of bambaragroundnut while Mbah *et al.* (2015) reported beetle as the primary pest of bush mango.

Table 7: Distribution of farmers according to the method of minimizing losses from insect pests during storage of selected neglected food crops (N= 120)

Solution to challenges	Crops	Yes F (%)	No F (%)
Early sales	Bambara groundnut	18 (15)	7 (5.8)
	Bread fruit	22 (18.3)	8 (6.7)
	Bush-mango	45 (37.5)	20 (16.7)
	Total	**85 (70.8)**	**35 (29.2)**
Consumption	Bambara groundnut	20 (16.7)	5 (4.2)
	Breadfruit	15 (12.5)	5 (4.2)
	Bush-mango	48 (40)	17 (14.2)
	Total	**83 (69.2)**	**27 (22.5)**

Source: NSPRI Field Survey, 2021. F = Frequency, % = Percentage

Table 7 shows that 70.8% of the farmers used early sales technique to minimize losses from insect pest infestation during storage while 69.2% of the farmers adopted consumption of the produce. This supports Olayemi*et al.* (2011) who reported that farmers adopted early sales to reduce storage problems from insect pests.

CONCLUSION

Findings from this study showed that farmers of selected neglected food crops in the study area were experiencing production and storage limitations due to insect pest infestation, and the methods used in minimizing the losses by the farmers will reduce the their income. Findings from the study recommend that more researches into post-harvest technology related to the selected food crops be carried out.

ACKNOWLEDGEMENTS

We thank Dr (Mrs.) P. O. Pessu (Executive Director/Chief Executive Officer) and the entire management staff of Nigerian Stored Products Research Institute (NSPRI) for funding this work.

ABSTRACT

Climate variability has resulted to soil depletion and low yield of turmeric. There is need for soil amendment with organic waste which is reported to improve soil nutrient use efficiency in crops. This study evaluated the potentials of different compost manure in enhancing the yield, curcumin, and total carotenoid content of turmeric species, *curcumin longa*. Composts evaluated were poultry manure, cow dung, pig waste and cocoa pod, applied at the rate of 6 t/ha one week before planting. NPK fertilizer applied at the rate of 200 kg/ha was used as the standard to compare the organic waste and absolute control (no fertilization). The experimental design was RCBD with 4 replications. Harvested turmeric rhizomes were analyzed for yield, total curcuminoids and total carotenoids. The result of the yield showed poultry manure (22.28 t/ha) > cow dung (20.66 t/ha) > cocoa husk (20.39 t/ha) > swine waste (16.17 t/ha) > NPK (10.61 t/ha) > zero application (3.11 t/ha). Curcumin content was not enhanced by any of the manure, whereas total carotenoid content was enhanced by NPK (3192 µg/g) > cocoa husk (3189 µg/g) > cow dung (3087 µg/g) > poultry manure (2724.5 µg/g) > swine waste (2630.0 µg/g) > zero fertilizer (2542.0 µg/g). Therefore, for sustainable turmeric seed production, compost manure is highly recommended.

Keywords: Turmeric, compost manure, yield, curcumin, carotenoids

INTRODUCTION

Two species of turmeric (*curcuma longa Linn* and *Curcuma xanthorriza*) are perennial crops cultivated in the tropical countries. They are used as spices to add flavour and colour to food, *longa* specie is a major constituent of curry powder giving it the reach golden yellow colour. Both species of turmeric are of great medicinal values (Ortega, and Campos, 2019). Curcumin, a polyphenolic compound found in turmeric is responsible for the numerous health benefits associated with it.

Turmeric consumption is mainly because of the associated health benefits therefore, it is imperative that any interventions mitigated towards increasing turmeric yield should also increase the bioactive compounds in turmeric which is high curcumin and carotene content.

Turmeric crop requires fertilization to improve yield and globally there is a shift from inorganic to organic fertilizers. Organic fertilizers and manures have been reported by several authors to improve soil health and nutrient use efficiency in root and tuber crops, enhance improving the yield. In addition to being cheaper and very readily available to farmers (Olojede *et al.*, 2022; Senobi, 2010; Njoku *et al.*, 2014). This study seeks to find out which of the organic liquid fertilizers and compost manures has the best potential to enhance turmeric yield as well as curcumin and total carotenoid content.

MATERIALS AND METHODS

Two turmeric species (*Curcuma longa and Curcuma xanthorrhiza*) grown with different organic fertilizers were evaluated for yield, curcumin, and total carotenoids content. The fertilizers consisted of four organic waste manure (poultry manure, cow dung, pig waste and cocoa pod) applied at the rate of 6 t/ha one week before planting and two foliar liquid fertilizers (black diamond and boost extra) applied at 100mls in 15 liters of water one month after planting. NPK fertilizer applied at the rate of 200 kg/ha was used as the standard to compare the organic waste and absolute control. The experimental design used was RCBD with 4 replications. The roots of harvested turmeric were analyzed for total curcuminoids using the methods described by Anindya *et al.* (2015), total carotenoids using the method described by Mieko and Delia (2003) and yield. Data were subjected to ANOVA and significant means separated at 5% level.

RESULTS AND DISCUSSION

Table 1 reveals the result of the effect of fertilization on curcumin accumulation in *longa* specie. From the result it is seen that highest curcumin was found in longa with zero fertilizer application, and this was not significantly different from what was obtained in the groups treated with swine waste and poultry manure. NPK, cocoa husk, boost extra and black diamond reduced the amount of curcumin accumulated compared to the negative control which is the zero-application group. However, in *xanthorrhiza* specie (Table 2), treatment with black diamond, boost extra and NPK enhanced curcumin accumulation compared to the negative control without treatment. Comparative analysis of curcumin content in both species (Table 3) reveals that more curcumin is domiciled in *longa* specie than *xanthorrihza* specie.

For total carotenoid content, we observed that of the two species, *xanthorrihza* contains higher carotenoid than *longa* expecially in *xanthorrihza* with no treatment, while *longa* treated with boost extra, black diamond and NPK gave an appreciable amount of carotenoids content (Table 4).

Table 5 reveals that fertilization significantly increased yield of turmeric. However, the yield of *longa* was much higher than that of *xanthorrihza,* it was observed that poultry manure and cow dung was responsible for this high yield (Table 5).

CONCLUSION

Longa specie contains higher curcumin and there is no need for fertilizer application if the interest is to cultivate longa for high curcumin. *Xanthorrihza* requires no treatment for high carotenoid, but longa does, and organic liquid fertilizers (boost extract and black diamond) are advised. To obtain a combination of high yield with high carotenoid we propose longa variety with poultry manure or longa with cow dung. Finally, if interest is on vitamin A intervention in addition to high yield, we propose *xanthorrihza* produced with boost extract.

Table 1 Effect of treatments on curcumin content of Curcuma longa

Treatment	Curcumin (%)	Groups
Longa + zero application	3.190	a

ABSTRACT

Response of soybean varieties to osmo- priming duration were investigated under field condition at the Research Farm of the Faculty of Agriculture, Kano University of Science and Technology, Wudil, Gaya station in 2018 rainy season. The treatment consisted of four improved soybean varieties (TGX-1835, TGX-1904, TGX-1951 and TGX-1955) and four priming duration 0hour (dry seed or control), 4hours, 6hours and 8hours. These were combined and laid out in a randomized complete block design (RCBD) and replicated three times. The varieties tested differed significantly in the parameters investigated. The result showed that Soybean varieties TGX-1904 and TGX-1955 proved superior in terms of number of pods and seeds per plant, total grain yield and stover yield compared to the other varieties. In addition, priming duration has significant effect on both crop growth and yield parameters investigated. The highest value was obtained at 8 hour priming duration, where TGX-1904 and TGX-1951 recorded superior growth and yield parameters compared to TGX-1835 and TGX-1955. Therefore, from the foregoing, priming duration of 8 hours with varieties TGX-1904 and TGX-1955 is recommended for farmers in the area for good crop yield.

Keywords: Agro-ecology; Osmo-priming;**;** TGX-1955; Stover; Yield;

INTRODUCTION

Soybean (*Glycine max* [L.] Merr.) is one of the major legume crops in sub-Saharan Africa. The crop is beneficial in cereal cropping system because it contributes substantially to soil fertility. It is used to supplement cereals food stuff in many instances because cereals have low protein contents and are imbalanced in essential amino acid composition. Soybean protein has been the subject of intense investigation and has played an increasing role in human nutrition over the last few decades (Riaz, 2001). Nigeria is the largest producer of soybean in sub-Saharan Africa (SSA) but yield per unit area is usually low. According to FAO (2013), about six million tonnes of soybeans were produced in Nigeria in 2013, from 6 million hectares of land. Low productivity of the crop has been partly attributed to seed viability, poor germination and varietal differences. The use of high quality seed with appropriate seed rate is essential to establish a suitable plant population in a soybean field for better returns. Vigorous seeds germinate rapidly, uniformly and are able to withstand environmental adversity after sowing (Ajouri *et al*.,2015).

Osmo-priming or seed priming is a water based process that is carried out on seeds to increase uniformity of germination and emergence, and enhance plant establishment. Rapid germination and emergence of seed is an important factor of successful establishment. It is reported that seed priming is one of the most important developments to help rapid and uniform germination and emergence of seeds and to increase seed tolerance to adverse environmental conditions (Lewandowska *et al*., 2020). New varieties of soybean have been developed and released for cultivation NCRI, (2018). It is of interest to determine appropriate priming duration for these varieties with the aim of obtaining maximum yield of the crop and also increased economic value for the farmers in the study area. Therefore, this study determined the yield and yield components of soybean [*Glycine max* (L.) merrill] varieties as influenced by osmo-priming at Gaya, Kano State, Sudan Savanna Agro-ecological zone of Nigeria.

MATERIALS AND METHODS

Description of the experimental site

Field experiments was conducted during the 2018 rainy season at the Research Farm of the Faculty of Agriculture, Kano University of Science and Technology, Wudil, Gaya station (11^0. 14 and 738. 8038' with an altitude of 475 m above mean sea level. The average annual rainfall is about 700 mm. The pattern of rainfall in the area is highly variable. This can result in severe and widespread droughts that can impose serious socio-economic constraints (Tukur *et al*., 2013). The mean annual temperature ranges from 29 °C – 31 °C. The highest air temperature normally occurs in April/May and the lowest in December through February. Evapo-transpiration is generally high throughout the year. The vegetation of the area is the Sudan Savanna type which combines the characteristics and species of both the Guinea and Sahel Savanna (Tukur *et al*., 2013).

Treatments, Experimental Design

The treatments consists of four improved soybean varieties (TGX-1835, TGX-1904, TGX-1951 and TGX-1955) and 4 priming duration 0hour (dry seed or control), 4hours, 6hours and 8hours, these were combined in a 4 × 4 factorial experiment and laid out in a randomized complete block design (RCBD) and replicated three times. Samples of 5kg each of the soybean variety was placed in a container and soaked in tap water of pH 6.5 according to treatment specifications i.e (2hour intervals for 8 hours). The seeds were dried superficially afterwards.

Cultural Practices

The land was cleared and harrowed thoroughly to obtain fine tilth soil when the rain was fully established. Ridges were made at 0.75m apart using tractor mounted ridger. Each plot consisted of 6 ridges with 0.75cm apart, the size of each of the plot were 6 by 3m. Two seeds were initially sown per hole at 3cm soil depth and 5cm intra-row spacing and latter thinned to one plant per stand at two weeks after sowing. Single super phosphate (18% P_2O_5) was applied at the rate of 40kg P_2O_5 per hectare. The weeds were controlled manually using hoes 6 weeks after sowing (WAS). Careful observation of disease was considered although, no any serious threat was observed. When pods reached physiological maturity, harvesting was conducted immediately to avoid losses through shattering using cutlass. Threshing was conducted after sundrying for one week. The net plots were harvested as net plot for both grain and stover yield. Crop data such as plant stand count, number of plant stand, number of seeds per plant, grain and stover yield were collected from the plants within net plot (five plants were selected at random). Data collected on all measured parameters were subjected to Analysis of Variance (ANOVA) as described by Snedecor and Cohran (1967). Means were separated using Duncan Multiple Range Test (DMRT) at 5% level of probability (Duncan, 1955).

RESULTS

The effect of variety and priming duration on stand count of Soybean is shown in Table 1. At full emergence (7 days after sowing) result obtained showed significant impacts ($P < 0.05$) among the varieties tested with soybean variety TGX-1904 having significantly ($P < 0.05$) highest mean stand count TGX1904 (267) followed by TGX-1955 (214), whereas the least was obtained from TGX 1835 and TGX-1951 (101 and 84) which were similar. Priming duration at 0hour (control) gave significantly ($P < 0.05$) highest stand count of 249, this was followed by and 8hours (178). There was no significant interaction between the varieties and priming duration on stand count. Seed numbers per pod is a very important yield attribute to researchers, the performance of the varieties differed significantly among one another with TGX1904 significantly produced approximately 73 pods per plant. TGX-1955 and TGX1951 had 67 and 63 seeds respectively which were similar statistically. Among the priming duration evaluated on pod numbers per plant, their performance was the same. There were no significant effects among the varieties evaluated. The interaction between variety and priming duration on pod numbers per plant was not significant. Soybean grain yield ranged significantly ($p \leq 0.05$) from136.0 to 147.5 kg/ha. Significantly ($p \leq 0.05$) highest grain yield of 147.5 and 145.3 kg/ha was found in TGX-1955 and TG-X1904 respectively while the lowest grain yield (6136.0 kg/ha) was observed on TGX1951 among others. Among the priming duration evaluated, their performance was the same. There were no significant effects among the varieties evaluated. The interaction between variety and priming duration was not significant on grain yield. There were no significant impacts among the varieties investigated with respect to the stover yield; likewise the performance of the priming duration was the same. The interaction between variety and priming duration was not significant on the stover yield (Table 1).

Table 1: Effect of variety and seed priming duration on yield components of Soybean at Gaya during the 2018 rainy season

Treatment	Plant stand count	pods/ Plant	Grain yield (kg/ha)	Stover yield (kg/ha)

DISCUSSION

Plant stand, number of pod per plant, grain and stover yield (t/ha) of the soybean varieties tested were significantly influenced by priming duration, however, priming duration with 8 hours exhibited more stand count and canopy height compared to others while the least priming duration of four hour was observe. This result agrees with the findings of Meseret (2020) which reports the speed of germination to increased as the priming duration increased from 0 hour to 14 hour and afterwards decreased rapidly with increasing priming duration with the least recorded in 24 hours. The relative increase in yield at 8 hours priming duration although not significant could be attributed to higher level of precipitation and better soil condition (moisture and soil nutrient) as earlier suggested by Zlatica *et al*. (2018). Significant increase in stand count was observed on variety TGX-1955 and TGX-1904 as compared to others, this may be attributed to the genetic factor which determined their growth habit. This result agreed with the findings of Shahram (2015) who reported that, higher number of stand count and plant height could be attained from the indeterminate varieties than the determinate types. Furthermore, soybean varieties TGX-1904 and TGX-1955 produced higher number of seeds per pod, grain and stover yield (t/ha). However, the interaction between the priming duration and the variety was not significant throughout the growth stages. These results confirm the findings of Michalak *et al*. (2018) who reported highest germination, improved emergence and good stand establishment in the field trials of pigeon pea primed seed, however, without any interaction found among the factors tested. Likewise Arif *et al*., (2005) reported improved and early germination as well as enhanced emergence in hydro primed seed but without any interaction amongst factors. There was no any significant interaction between the variety and priming duration for all the yield parameters.

Conclusion and Recommendations

The results of this study indicated significant effect of variety in some of the parameters on growth and yield measured. Also, it can be concluded that different hydro priming duration influenced the growth and yield on soybean varieties. These differences were also attributed to genetic variation among soybean varieties. From the foregoing, for good crop yield and food security, soybean varieties TGX-1904 and TGX-1951 with priming duration of 8 hours could be recommended for soybean farmers in the study area.

ABSTRACT

Screen house experiment was conducted at the Landmark University Teaching and Research Farm Omu-aran Kwara State. The experiment was carried out to determine the influence of Organic and inorganic sources of N on the photosynthetic pigment concentration, and performance of Cucumber. Different rates of Urea at (0,60 and 120 t/ha) and Cow dung at (0,60 and 120 t/ha) were applied sole and combined. The experimental layout in the screen house was a completely randomized design (CRD) with three replicates respectively. Parameters were collected on the plant height, number of leaves, and number of branches, stem diameter, yield and photosynthetic pigments concentration. Data collected were subjected to Analysis of Variance (ANOVA) using GENSTAT Discovery Software, Edition 4. Comparison of the treatment means was carried out using the Duncan multiple rang test (DMRT) at 0.05 level of probability. The result of this study indicated that there was an increase in the vegetative parameters (vine length, stem girth, number of leaves and number of branches) of cucumber when applied with combined urea and cow dung as compared with sole application of the two amendments. The effect of application of $U_{60}CD_{60}$ was more pronounced on the performance, chlorophyll a, b, a+b and carotenoids of Cucumber. It can therefore be concluded that the combined application of urea and cow dung at $U_{60}CD_{60}$ is economical and suitable for the growth and increased photosynthetic pigments of cucumber.

Keywords: Cucmber, performance, pigments, organic and inorganic amendments

INTRODUCTION

Cucumber (*Cucumis sativus* var. sativus L.) is a member of the economically important family Cucurbitaceae which includes squash (Cucurbita ssp.), watermelon (*Citrullus lanatus)*, and melon (*Cucumis melo* L.). Cucumber and melon are grown more widely than any other vegetable species, next only to tomato (Solanum lycopersicum L) and watermelon (Pitrat *et al.* 1999).

Nitrogen is a very important element needed for plant growth as it gives plants the energy to grow and produce fruit or vegetables. Nitrogen is actually considered the most important component for supporting plant growth. Nitrogen is part of the chlorophyll molecule, which gives plants their green colour and is involved in creating food for the plant through photosynthesis (Home Guides, 2018). Lack of nitrogen shows up as general yellowing (chlorosis) of the plant. Because nitrogen is a highly mobile nutrient and as such moves around in the plant.

Some physiological parameters of plants include Chlorophyll a & b, Leaf Chlorophyll, Carotenoid, Xanthophyll amongst others**.** Chlorophyll and Carotenoid both make up to form photosynthetic pigment found in land plant (Kahn Academy, 2022)**.** A pigment is a generic term for a molecule that absorbs light and has a color**.** Chlorophyll and Carotenoid, are able to absorb the energy of light and use it effectively as a result of their molecular structure and organization within the cell of plant. Nitrogen is a major constituent of chlorophyll.

Light and nitrogen are two important factors that affect crop growth. Light is a prerequisite for photosynthesis and growth of plants. Nitrogen nutrition directly affects the photosynthetic rate and growth, and ultimately affects yield and light energy utilization. The objective of this study was to determine the performance, and photosynthetic pigments concentration of cucumber under the application of organic and inorganic sources of N fertilizer.

MATERIALS AND METHODS

Experimental Site:- Screen house experiment was conducted at the Teaching and Research Farm of Landmark University, Omu-Aran, Kwara State (Lat 8^o 9'N and Long 5^o 61'E) with an altitude of 495 meters' elevation above the sea level in the derived savannah zone of Nigeria with a predominant annual rainfall of about 600 mm – 1200 mm extending between April and September. The temperature of the study area varies between 33°C and 34°C during the year, with a distinct dry season from November to March.

Top soil was collected from the field around the screen house where no agricultural activities had been carried out for five years, the soil was thoroughly mixed using a hand trowel. Twenty (20) kg of the top soil was put inside the pot of size 30 x 17 cm, perforated at the bottom to allow for air and water movement.

Pre-cropping soil samples for the experiment was randomly taken and bulked to obtain composite samples for laboratory analysis. Organic manure (cow dung) was collected from the ranch of Landmark University farms located at the University Teaching and Research Farms. Urea fertilizer (46%) and cucumber seeds were purchased from a reputable agro-allied store in Omu-aran, Kwara state.

The cow dung used for the study was analyzed for its nutrient composition after being air-dried using warm air (18 – 21^oC) for 7 days. The dried cow dung was crushed and passed through a 2-

mm sieve. Analysis was done for Organic Carbon (OC), and the total concentration of N, P, K, Ca, Mg, Cu, Mn, Zn, and Na (AOAC, 2006). The variety of cucumber that was used for the experiment was the pionsett variety of Cucumber.

Treatments consisted of two sources of N fertilizer viz- Urea at 46% N (0, 60 and 120 kg N ha^{-1}) and cow dung (0, 60 and 120 t ha^{-1}). Treatments were combined and tested as follows: -U_0CD_0, U_0CD_{60}, U_0CD_{120}, $U_{60}CD_0$, $U_{60}CD_{60}$, $U_{60}CD_{120}$, $U_{120}CD_0$, $U_{120}CD_{60}$, and $U_{120}CD_{120}$. The treatments were arranged in the screen house according to a completely randomized design (CRD) using 30 cm by 60 cm inter- and intra-row spacing and was replicated three times.

Cow dung was applied two weeks before sowing for mineralization and nutrient release to take place while, urea fertilizer was applied two weeks after sowing. The equivalent of application of 0, 60 and 120 kg N ha^{-1} of urea to 20 kg of soil were 0 g, 1.3 g, and 2.6 g while the equivalent of the application 0, 60, and 120 kg N cow dung to 20 kg of soil were 0 g, 33.33 g, and 66.67 g.
Two cucumber seeds were sown per pot at a depth of about 5 cm. At two weeks after sowing, thinning operation was carried out leaving one vigorous and healthy seedling per pot. Regular irrigation with a small quantity of water was applied during the first one week after sowing using the drip irrigation system, subsequent deep irrigation and one to two days' water stress was adopted to encourage deep rooting.
Training and trellising were carried out on a weekly basis and as the need arises. Training helps the plants to grow vertically while trellising supports the plant to grow horizontally.
Mature fruits were harvested at intervals of five days for four weeks before the experiment was terminated. Harvested fruits were weighed with the aid of automated weighing balance of maximum capacity of 2100 g, readable at 0.01 g, and a model by OHAUS Corporation, USA. Fruit sample of each treatment was thereafter taken to the laboratory for chlorophyll and carotenoid determination.
The following parameters were monitored during the experiment- Vine length (cm), number of leaves, number of primary branches, stem diameter (cm), number of days to first flowering, number of days to 50% flowering, Fruit weight and determination of leaf photosynthetic pigments (chlorophyll a, b, a+b, and β-Carotenoid).

Statistical Analysis
Data obtained from the study were subjected to statistical analysis of variance (ANOVA) using GENSTAT discovery (2014). A Comparison of the treatment means for significance was carried out using the Duncan multiple range test (DMRT) at 5% level of probability.

RESULTS

Initial Soil Properties: - The pre-planting soil analysis is as shown in Table 1. The pH of the soil was strongly acidic, the Nitrogen content of the soil was very low, the available phosphorus was high, and the exchangeable K was also low while the exchangeable Na, Ca and Mg were all suitable. The organic matter was low. The soil is high in sand with relatively low values in both silt and clay; hence the textural class is Sandy Loam.

Table 1: Pre-cropping soil physicochemical analysis

Property	Value
Sand (%)	69.2
Silt (%)	14.5
Clay (%)	16.3
Soil texture	Sandy loam
PH (water)	5.62
Organic matter (%)	1.88
Total N (%)	0.15
Available P (mg kg-1)	9.71
Exchangeable K (cmol kg-1)	0.14
Exchangeable Ca (cmol kg-1)	2.45
Exchangeable Mg (cmol kg-1)	0.34

Chemical Composition of the cow dung used for the study

The results of the laboratory analyses of the cow dung used for the study is shown in Table 2. The results showed that cow dung contained varying values of macro and micro-nutrients required for improved soil fertility and plant growth.

Table 2. Chemical composition of the organic amendments (Cow Dung) used for the study

Parameters	O.C%	N%	P%	K%	Ca%	Mg%	Zn%	C:N
Values	25.70	1.84	0.82	1.98	0.99	0.54	0.10	14.78

Effects of the application of urea and cow dung on vine length and number of leaves of cucumber

The sole and different combinations of the application of cow dung and urea showed a significant effect on the vine length and stem girth of cucumber. The vine length of cucumber significantly increased with the application of sole cow dung, urea and their combinations (Table 3). Though the difference in vine length with the application of amendments was not significant at 2 WAS and at 4 WAS when $U_{60}CD_{60}$, $U_{60}CD_{120}$, $U_{120}CD_{0}$, $U_{120}CD_{60}$ and $U_{120}CD_{120}$ were applied. At 6 and 8 WAS all treatments with combined cow dung and urea significantly increased the vine length. The control gave the least value for vine length.

The data revealed a non-significant effect of amendments on number of leaves at 4 and 6 WAS. Compared with the control which gave the least number of leaves, a significant maximum number of leaves was observed in plots applied with $U_{120}CD_{60}$ at 6 and 8 WAS, though the value was statistically similar to the values obtained when $U_{60}CD_{60}$, $U_{60}CD_{120}$, $U_{120}CD_{0}$, and $U_{120}CD_{120}$ were applied.

Table 3: Effect of the application of urea and cow dung on vine length and stem diameter of cucumber.

Means followed by the same letter(s) are not significantly different from each other at 5% level of probability.

Effects of the application of urea and cow dung on the number of days to first flowering, the number of days to maturity and fruit weight of cucumber.

Table 4 presents the effects of urea and cow dung on the phenology, number of days to maturity, and fruit weight. Data presented showed that pots applied with $U_{120}CD_{120}$ produced first flower earlier than the other treatments and were statistically similar to pots applied with $U_{60}CD_{60}$, $U_{60}CD_{120}$, $U_{120}CD_{0}$, $U_{120}CD_{60}$, and $U_{120}CD_{120}$. In a similar vein, control pots had a delayed number of days to 50% flowering followed by pots amended with U_0CD_{60}, U_0CD_{120}, and $U_{60}CD_0$. Pots amended with $U_{120}CD_{120}$ had a delayed number of days to 50% flowering though statistically similar to the application of $U_{60}CD_{60}$, $U_{60}CD_{120}$, $U_{120}CD_{0}$, and $U_{120}CD_{60}$.

The effect of treatments on the number of days to maturity shows that cucumber fruits matured earlier with the application of $U_{60}CD_{60}$, and $U_{60}CD_{120}$. Other treatments produced a significant and similar number of days to fruit maturity. Non-significant heavier fruit weight was observed with pots treated with combined application of urea and cow dung..

Table 4: Effect of the application of urea and cow dung on flower pattern, fruit maturity and fruit weight of cucumber of cucumber.

Treatment	Days to First Flowering	Days to 50% Flowering	Days to Fruit Maturity	Fruit Weight
U_0CD_0	44.67a	53.33a	0.00c	0.000c

Means followed by the same letter(s) are not significantly different from each other at 5% level of probability.

Effects of the application of urea and cow dung on leaf chlorophyll a, b, a+b, and β-carotenoids of cucumber

The leaf photosynthetic parameters are as shown in Table 5. Treated cucumber with combined application of urea and cow dung significantly increased all the photosynthetic pigments. The leaf chlorophyll a, b, a+b, and β-carotenoids were higher with the application of $U_{60}CD_{120}$ and $U_{120}CD_{60}$ though the values were not significantly different from the values obtained $U_{60}CD_{60}$, $U_{120}CD_{60}$, and $U_{120}CD_{120}$. The control treatment significantly reduced values for all the photosynthetic pigments except chlorophyll b where the value was statistically similar with the values obtained when U_0CD_{60}, U_0CD_{120}, and $U_{60}CD_0$ were applied.

Table 5: Effect of the application of urea and cow dung on leaf chlorophyll a, b, a+b, and β-carotenoids of cucumber

DISCUSSION

Nitrogen (N) is one of the most important nutrients affecting the growth, development, yield and fruit quality of plants (Gerenda´ s *et al.*, 1997). Adequate supply of N to crops is fundamental to optimize crop yields, but an excessive N application can result in contamination of groundwater (Jaynes *et al*., 2001). The result of this study indicated that there was an increase in the vegetative parameters of cucumber when applied with combined urea and cow dung as compared with sole application of the two amendments. The difference in the vegetative parameters could be as a result of the combined effect of urea and cow dung.

The combined application of the two sources of N used for the study had greater effect on the yield of cucumber. The significant increase in yield and its attributes could be adduced to the continuous supply of nutrients to the crop as a result of the use of organic source of N which assisted the crop in the uptake and utilization of nutrients. Organic manure has been reported to improve plant nutrient uptake by acting as a buffering agent against undesirable pH fluctuations and by improving soil water availability through retention and aeration which ultimately contributes to better nutrients utilization by the crop (Adediran *et al.* 2015).

Photosynthetic pigment content plays a critical role in photosynthesis. Chlorophyll is important for energy capture during the photosynthesis process. Differences in chlorophyll activity could be considered as a current symptom of inappropriate fertilization, or due to a nutritional imbalance, however other environmental factors, such as temperature, salinity, or drought can also decrease chlorophyll activity (Zekri, 1991).

The study revealed that there were significant effects of different sources of N on the photosynthetic pigments of cucumber. Increased N supply stimulates plant growth and productivity, as well as photosynthetic capacity of leaves through increased amounts of stromal and thylakoid proteins in leaves (Teixeira Filho et al., 2011)

Application of urea and cow dung had significant effect on leaf chlorophyll a, chlorophyll b, total (a+b) and carotenoides. The higher values of chlorophyll a, b (a+b) and carotenides were obtained on plots fertilized with combined application of the two amendments and high rate of sole application of urea ($U_{120}CD_0$). Increased in these pigments as a result of the application of the two sources of N could be because nitrogen is a constituent molecule of chlorophyll. It could also be as a result of nitrogen being the main constituent of all amino acids and hence of proteins and lipids as glactolipids, acting as a structural components of chloroplast. The result of this study is in agreement with those obtained by El-Robae (2002) who found that concentration of chlorophyll a, b, total (a+b) and carotenoids in leaf tissues of tomato increased with increasing N. Increase in chlorophyll a, b and a+b of the leaves and fruit of cucumber as a result of application of combined organic and inorganic sources of N could also be as a result of the effects of the organic N which releases its nutrients gradually. This is in agreement with the works of Abd Alla et al. (2009) who found that, cucumber treated with a biofertilizer produced higher chlorophyll content in its leaves.

CONCLUSION

The combined application of urea and cow dung at varying levels significantly increased all the parameters measured. This study clearly showed that increased photosynthetic pigments are related to the increasing levels of N amendments. The effect of application of $U_{60}CD_{60}$ was more pronounced on the performance of cucumber chlorophyll a, b, a+b concentration and carotenoids. Based on these findings, it is recommended that the combined application of urea and cow dung at the rate of $U_{60}CD_{60}$ is economical and suitable for the growth and increased photosynthetic pigments of cucumber.

ABSTRACT

It is important to select appropriate cultivars that are well adapted and suited to specific ecological zones and also transform agricultural waste into useful and rich sources of organic nutrient. Hence, study was conducted to determine the effect of different types of organic fertilizer on the growth, yield and quality of five genotypes of tomato grown under screen house condition. The experiment was a two-factor experiment comprising of five tomato genotypes (NGBOO722, NGB00724, NGB00692, NGB00714 and OMU-ARAN LOCAL), two organic fertilizers treatment (cocoa pod and fluted pumpkin pod) and a control (no fertilizer of any kind). The experiment was laid out in Completely Randomized Design (CRD) and each treatment was replicated three times. The results of this study revealed that organic fertilizers produced from Cocoa and fluted pumpkin pods increased the growth, yield and mineral contents of tomato relative to the control and fluted pumpkin pod fertilizer increased these parameters relative to cocoa pod fertilizer due to its high nutrient contents. Among tomato genotypes, NGB00714 produced the highest plant height, stem girth and number of branches, the value was statistically similar to NGB00722, NGB00724 and NGB00692, whereas OMU-ARAN LOCAL had the least value. The order of fruit yield were: NGB00714 > NGB00722 > NGB00724 > NGB00629 > Omu-Aran Local. The yield of tomato genotype NGB00714 amongst the tested cultivars was significantly higher than that of other cultivars and are therefore recommended to farmers wishing to key into tomato production in the area.

Keywords: Tomato genotype; cocoa pod fertilizer; fluted pumpkin pods fertilizer;

INTRODUCTION

Tomato *(Solanum lycopersicum*) is one of the most important edible and highly nutritious vegetable crops, it is a very important vegetable in the world. Tomatoes are also high in minerals, vitamins, essential amino acids, sugars, and dietary fibers, which contribute to a stable, well-balanced diet. Tomatoes are high in vitamin B and C, as well as iron and phosphorus. Tomatoes can be eaten raw in salads or baked in sauces, soups, and meat and fish dishes. Purées, juices, and ketchup can all be made from them. Tomatoes, both canned and dry, are environmentally friendly.

The fertilization system is one of the most important factors that influence crop quality in food production especially in crop like tomato (Ogbonna, 2008). Since soil fertility is one of the most important factors, it is therefore of necessity to add fertilizer to the soil to boost its fertility. Lack of sufficient amounts of nutrients result in poor performance of the crop with growth been affected resulting to low yield (Adekiya et al., 2020) .Organic fertilizers, in this case used (cocoa pod and fluted pumpkin pod) are agricultural wastes which were converted to fertilizers. They play a critical role in both short-term nutrient availability and longer-term maintenance of soil organic matter in smaller holder farming systems in the tropics. The use of organic fertilizer now become important and necessary due to recent trend toward consumption of organically produced vegetables in contracts to in-organic grown vegetables which is said to be detrimental to human health.

Also there is need to transform agricultural waste into useful and rich sources of organic nutrient with respect to the SDGs 12 this is to ensure the culture of recycling and reusing agricultural waste products, the nutrient content of cocoa pod is high. There is need to keep up with the trend that explains the consumption of organically produce vegetables which do not have health implications compared to the consumption of vegetables cultivated with organic fertilizers which is in line with the SDG 3 (good health and wellbeing). Hence there is need to reduce the use of inorganic fertilizers which causes environmental degradation, pollution, emission of greenhouse gas etc. and increase the use of organic fertilizers.

Furthermore, the various varieties of tomato could respond to organic fertilizer differently. It is important to select appropriate cultivars that are well adapted and suited to specific ecological zones in order to ensure optimum growth and efficient performance. The choice of varieties needs to be selected based on the combination of yield, flavor, texture, appearance of fruits. Therefore main objectives of the study were to determine the effect of different types of organic fertilizer on the growth, yield and quality of five genotypes of tomato grown under screen house condition

MATERIALS AND METHODS

Description of the experimental site, soil collection and source of planting materials

The experiment was conducted at the Screen House of the Teaching and Research Farms of Landmark University Omu-Aran, Kwara state (Latitude 8° 9′N and Longitude 5° 61′E) located at the derived savannah zone of Nigeria. The experiment was carried out in a screen house that had a galvanized iron as a frame, a UV covering on top, side net for screening insect pests with the floor fairly covered with granite. Temperature and relative humidity within the screen house during the period of the experiment was monitored using a Thermograph and a Barograph and they were at an average of 31°C and 75%, respectively. The soil at Omu-Aran is an Oxic Haplustalf from the USDA soil order Alfisol or Luvisol from the FAO soil classification. Soil samples were taken from an area that has been exposed to maize cultivation for two years. Top soil was collected from the Farm field through excavation using shovel and digger which was then transported to the weighing and bagging site using a wheel barrow, soil was thoroughly mixed, sieved and bagged at 13 kg in a polythene bag of 30cm × 17cm which was also perforated to allow aeration and water drainage.

Five genotypes of tomato seed were collected from NACGRAB in Ibadan Nigeria where were (NGBOO722, NGB00724, NGB00692, NGB00714 and OMU-ARAN LOCAL sourced from Omu-Aran market.

Experimental design, treatment and tomato nursery and transplanting

The experiment was a two-factor experiment comprising of five tomato genotypes (NGBOO722, NGB00724, NGB00692, NGB00714 and OMU-ARAN LOCAL), two organic fertilizers treatment (cocoa pod and fluted pumpkin pod) and a control (no fertilizer of any kind). The experiment was laid out in Completely Randomized Design (CRD) and each treatment was replicated three times. Cocoa pod fertilizer was applied at 13 g per 13 kg of soil and fluted pumpkin pod fertilizer at 12g per 13 kg of soil. The application of organic fertilizer differ in weight due to the content of Nitrogen element present in the two organic fertilizer, the cocoa pod fertilizer has a lower Nitrogen element when compared to the fluted pumpkin pod fertilizer. Prior to filling of bags with soil, seeds of the five genotypes of tomato were sown into a rich loamy soil in some portion of the screen house and watered daily in the evening using a watering can to field capacity. After 3 weeks in the nursery the seedlings were transplanted to the already prepared and watered soil in the bag. Two tomato seedling were transplanted per bag which was later thinned to one per bag.

Laboratory Analysis of pre-planting soil and Tomato Fruit

Soil physical and chemical analyses were performed on the 2 mm sieved initial samples before transplanting of tomato using methods as described by Carter (1993).

Tomato fruits were collected from each treatment, oven dried for 24 h at 80^{o}C and these samples were analysed for N, P, K, Ca and Mg as described by Tel and Hagarty (1984) and vitamin C content was determined by using the indophenol dye method (Singh et al., 2007)

Growth and yield parameters

Plant height: - The height of each plant per pot was measured at 1, 2, 3 and 4 weeks after transplanting (WAT) using a meter rule, number of leaves by counting the number of fully expanded leaves. The stem girth was taken at 1, 2, 3 and 4 WAT. Tomato fruits was harvested at maturity and the number of harvested fruits were recorded per bag and per treatment. Harvested matured tomato fruits were weighed using a sensitive weighing balance and the value were recorded.

3.8 Data Analysis

Data collected was subjected to statistical analysis of variance (ANOVA) using Statistical Analysis Software (SAS, Institute Inc. 2000). The treatment means were compared using the Duncan Multiple Range Test (DMRT) at 0.05 level of probability.

RESULTS

Initial Soil Properties and Analysis of Organic fertilizer used

The pre-planting soil analysis contains 69.2%, 14.5%, and 16.3% of sand silt and clay respectively, and 5.62, 1.88%, 0.15mg kg^{-1}, 0.14 cmol kg^{-1}, 2.45cmolkg^{-1} and 0.34 cmol kg^{-1} respectively for pH, OM, N, P, K, Ca and Mg. The nutrient content of the soil was generally low. The chemical analysis of the organic fertilizers used for the experiment is presented in Table 1. The fertilizers are rich in macro (N (7.74% for cocoa pod and 8.46% for pumpkin pod), P (0.80% for cocoa pod and 0.44 for pumpkin pod), and K (1.19% for both cocoa and pumpkin pods)) and micro nutrients (Cu, Fe, Mn, Zn) that can add substantial nutrients to the degraded soil and hence improve the growth, yield and qualities of the tomatoes.

Table 1: Chemical composition of the organic fertilizers used for the cultivation of tomat0 genotypes

Property	Cocoa pod	Fluted pumpkin pod
pH (water)	7.35	7.35
Copper (%)	0.56	0.67
Calcium (%)	11.20	13.20
Iron (%)	0.16	0.18
Magnesium (%)	3.44	5.24
Manganese (%)	0.003	0.004
Potassium (%)	1.05	1.19
Nitrogen (%)	7.74	8.46
Phosphorus (%)	0.40	0.84
Zinc (%)	3.60	2.38

Effects of fertilizer and genotype on growth and yield of tomato

Table 2 shows the result of the effects of fertilizer and genotypes on the growth and yield of tomato Fertilizer and genotype significantly ($p = 0.05$) influenced the on growth and yield of tomato. Using fertilizer as a single factor, pumpkin pod increased the on growth (plant height, stem girth, number of branches and number of leaves) and yield (number of fruits and fruit weight) of tomato of tomato relative to cocoa pod and the control. The control had the least values. Using genotype as a single factor, NGB00714 produced the highest plant height, stem girth and number of branches, the value was statistically similar to NGB00722, NGB00724 and NGB00692, whereas

OMU-ARAN LOCAL had the least value. The order of fruit yield were: NGB00714 > NGB00722 > NGB00724 > NGB00629 > Omu-Aran Local. The interactive effect of fertilizer and Genotype (F × G) was not significant for any growth and yield parameters.

	Plant height (cm)	Stem girth (cm)	Number of branches	Number of leaves	Number of fruits	Fruit weight (g)
Fertilizer						
Control	34.19c	2.51b	4.49b	9.58c	4.13c	38.40c
Cocoa pod fertilizer	44.29b	3.16a	5.89a	11.48ab	8.46b	103.56b
Fluted pumpkin pod fertilizer	47.57a	3.18a	5.89a	12.05a	9.26a	133.56a
Genotype						
NGB00722	66.00a	4.11a	9.33a	16.22b	10.00ab	120.12b
NGB00724	62.44a	3.72a	8.33a	14.22b	4.66bc	85.66c
NGB00692	59.22a	3.88a	7.00ab	12.77bc	7.22abc	76.17d

F × G	0.309	0.198	0.538	0.135	0.255	0.104

Values followed by similar letters under the same column are not significantly different at p = 0.05 according to Duncan's multiple range test

Effects of fertilizer and genotype on Mineral composition of tomato

Table 8 shows the effect of fertilizer and genotype on mineral composition of tomato genotypes. Fertilizer and genotype significantly (p = 0.05) influence the magnesium, calcium, potassium and nitrogen composition of tomato. Pumpkin pod had highest magnesium, potassium, calcium and nitrogen composition. Using genotype as a single factor, NGB00722 recorded highest value for magnesium and potassium composition, NGB00692 recorded highest value for calcium composition while NGB00714 recorded highest value for nitrogen. The interactive effect of fertilizer and Genotype (F × G) was significant on mineral composition of tomato.

Table 8: Effects of fertilizer and genotype on Mineral composition of tomato

Treatments	Mg	Ca	K	N
Fertilizer				
Control	1.27c	1.34c	0.14c	0.12c
Cocoa pod fertilizer	1.65b	1.67b	0.16b	0.19b

Genotype (G)	0.000	0.000	0.000	0.000
F × G	0.000	0.000	0.000	0.000

Values followed by similar letters under the same column are not significantly different at p = 0.05 according to Duncan's multiple range test

DISCUSSION

Fertilizer treatments increasing the growth and yield of tomato relative to the control showed that the fertilizers are rich in nutrients and affirmed that these nutrients in the fertilizers are released into the soil for plant uptake. It also suggests that the soil used for the experiment was deficient in nutrients.

Pumpkin pod fertilizer enhanced higher vegetative growth and yield than the cocoa pod fertilizer as a result of higher nitrogen composition in the fluted pumpkin fertilizer treatment (Table 2).The pumpkin fertilizer applied would have increased N supply to the soil and consequently absorbed by the tomato plant and hence increased number of leaves and photosynthetic activity and enhancing physiological processes leading to the production of more assimilates which leads to increase in chemical composition of the tomato leaves hence higher yield (Adekiya et al., 2019).

Increasing the Nitrogen content of treatments will increase vegetative parameters of tomato genotypes due to this mechanism; increase in nitrogen uptake will result to increase in synthesis and accumulation of amino acids in the plant (Atanasova, 2008), increasing the chlorophyll content of green plant and promoting growth of cells and tissues (Atanasova, 2008).

The significant difference in plant growth and yield of tomato due to the different genotypes particularly with NGB00714 having the best values could be attributed to their distinct growth habit and genetic difference in the five genotypes which put NGB00714 to be the best and OMU-ARAN LOCAL the least as well as their adaptability to the soil under study as well as the soil nutrient content.

The fact that organic fertilizer treatments increased tomato mineral contents compared with the control was attributed to increased availability of the nutrients in soil as a result of the mineralization of the organic fertilizers leading to increased uptake by tomato plants. Fluted pumpkin pod fertilizer had the highest values of N, K, Ca and Mg in the tomato fruit compared with cocoa pod fertilizer, this was attributed to the superior nutrient contents of fluted pumpkin pod fertilizer relative with cocoa pod fertilizer

CONCLUSION

The results of this study revealed that organic fertilizers produced from Cocoa and fluted pumpkin pods increased the growth, yield and mineral contents of tomato relative to the control and fluted pumpkin pod fertilizer increased these parameters relative to cocoa pod fertilizer due to its high nutrient contents.

Among tomato genotypes, NGB00714 produced the highest plant height, stem girth and number of branches, the value was statistically similar to NGB00722, NGB00724 and NGB00692, whereas OMU-ARAN LOCAL had the least value. The order of fruit yield were: NGB00714 > NGB00722 > NGB00724 > NGB00629 > Omu-Aran Local. The yield of tomato genotype NGB00714 amongst the tested cultivars was significantly higher than that of other cultivars and are therefore recommended to farmers wishing to key into tomato production in the area.

ABSTRACT

A field experiment was carried out at the Teaching and Research Farm of the Federal College of Agriculture Ishiagu- Ebonyi state during the 2014 and 2015 planting seasons. Ishiagu is within the southern part of Ebonyi state and lies on Latitude 5^0 57^1N and on Longitude 7^0 34^1E with a mean annual rainfall of 1350mm with an average humidity of 88% and a mean annual temperature of 29^0C (FCAI, 2009). It has gentle slope topography. The main objective was to determine the effect of seedbed, cover crop species and densities on the weed control and yield of cassava in yam/cassava/maize intercrop. It was a split -split plot experiment fitted into randomized complete block design and replicated three times. The main plot was seedbed consisting of ridge and flat, the sub plots were cover crop species of egusi melon, pumpkin and sweet potato, the sub-sub plots were cover crops densities of 0, 10,000, 20,000 and 30,000 plants/ha. Data was collected on the fresh cassava root yield. Data were subjected to statistical analysis of variance.(ANOVA) using Genstat® version 3.0 (2003) software packages and significant means were separated using least significant difference (LSD) at 5% probability level. The yields of the fresh cassava roots were significantly improved by the seedbed type. The ridge had more root yield than the flat. The cover crop species significantly affected the root yield as the pumpkin plots had higher root yield than sweet potato and the egusi melon plots. Density reduced the yield of the roots though there was an increase at 30,000 stands /ha

Key words: Seedbed, Cover crop species, Density, Intercrop, Yield, Ishiagu

INTRODUCTION

Intercropping is the practice of growing two or more crops simultaneously in close proximity in a definite pattern, alternate rows or set of rows within the same plot (Reddy, 2012). Intercropping encourages intensification of crop production in both time and space dimensions. The most common goal of intercropping is to produce a greater yield on a given piece of land by making use of resources or ecological processes that would otherwise not be utilized by a single crop (Ouma, 2010). Yield advantage in intercropping occurs due to the component crops differences in the use of growth resources. When they are grown in combination, they are able to complement each other and do make better use of overall resources than when they are grown separately (Reddy,2012). In dry land agriculture intercropping is practiced mainly to minimize the risk of total crop failure due to rainfall vagaries rather than yield and economic advantage over sole cropping, as tropical weather is very unpredictable as rain fall and drought occur spontaneously (Bello *et al*, 2013). Rainfall is heavy and soil depletion and leaching are eminent, intercropping acts as an insurance against failure of crops in abnormal year (Agris info.in, 2005). The advantages of intercropping include greater system resilience by the interplay of different crops, greater crop production (Ghaffarzadeh *et al*, 1997), reduced disease transfer and environmental benefits such as greater soil and water conservation (Gilley *et al*, 2002). These advantages occur because the component crops differ in their use of growth resources (Reddy, 2012). Intercropping of compatible plants encourages biodiversity, by providing a habitat for different insects and soil organisms that would not be present in a single crop environment (Altieri and Nicholls, 2004).

Such concern has necessitated interest in finding systems that minimizes negative impact on the soil while maintaining sustainable crop production. This is true especially with cover crops or smother crops such as forage legumes inter seeded with a main crop such as cereals. This experiment therefore was designed to determine the effects of seedbed practices, cover crops and density on the yield of fresh cassava roots in a yam/cassava/maize intercrop

MATERIALS AND METHODS

This experiment was conducted at the Teaching and Research Farm of the Federal College of Agriculture, Ishiagu, Ebonyi State, Nigeria during the 2014/ 2015 planting seasons. Ishiagu is a tropical environment and lies on Latitude 5^0 57^1N and longitude 7^0 34^1E with an annual rainfall of 1350mm, it has an average humidity of 88% and a mean annual temperature of 29^0C (Nwite *et al*, 2008) and is situated on a gentle slope. The experiment was a split- split plot experiment, fitted into a Randomized Complete Block Design (RCBD) and replicated three times. Two seedbed practices were adopted, conventional seedbed (ridge) and harrowed seedbed (flat). In conventional seedbed, the bush was cleared by slashing and the plot ploughed, after two weeks it was harrowed and ridged. On harrowed seedbed the plot was cleared by slashing, ploughed and after two weeks it was harrowed and marked out. Three cover crop species were used Egusi-melon *Citrullus vulgaris*, pumpkin *Cucurbita moschata* and sweet potato *Ipomea batatas*. The cover crops were planted at different densities, ten thousand, twenty thousand, thirty thousand and control (zero) stands per hectare (10,000, 20,000, 30,000 and 0 stands/ha)

Planting of Test Crops, Yam. Setts of 100g of yam (*Dioscorea rotundata* L) cultivar 'agboghohu' were measured out using Ohaus sensitive scale. The yam setts were planted on the crest of the ridges and on the flats, according to the treatment schedule at a distance of 1m x 1m within row and 1m between rows at a population density of 10,000 plants /ha.

Cassava. Cassava (*Manihot esculenta*, Crantz) stem cuttings of 30 cm, variety TMS 0581 were planted on mid way down the ridge on the right side of the yam at a distance of 1m x 1m and also on flat by the right side of yam stands at a population density of 10,000 plants /ha.

Maize. The maize (*Zea mays* L) variety 'Oba super11' seeds were planted. Planting was at the foot of the ridges and flats, opposite the cassava stands, 1m within row and 1m between rows.

Three seeds were planted per hole at a depth of 4cm and thinned to one stand at two weeks after planting (2WAP) which gave a population of 10,000 plants / ha.

Cover crops. Melon: *Citrullus vulgaris* (Schrad), ('egusi' melon) and **Pumpkin:** *Cucurbita moschata* (L.) 'Anyu' seeds were planted, 4 seeds per hole and at a depth of 4cm. The seeds were planted on the mid way on the ridges and flats at the same side with maize and in holes opposite the cassava stands at a distance of 1m x 1m. The seedlings were thinned to respective densities of 10,000, 20,000 and 30,000 plants/ha after two weeks of planting (2 WAP), while there was none planted on the control. **Sweet potato**: *Ipomoea batatas* (L.) Lam. Vines of variety TIS 2498, spreading type obtained from National Root Crops Research Institute Umudike were planted on the mid way on ridges and flats. Sweet potato vine cuttings of 25cm length with four nodes were planted at angle of 45^0 on the same side with maize opposite the cassava stands. This was done at a spacing of 1m x 1m for 10,000 plants/ha (15 stands), 0.5m x1m for 20,000 plants/ha (30 stands) and 33.3cm x 1m for 30,000 plants /ha (45stands) while none was planted on the control. (0).

Yield. The cassava roots were harvested at 32WAP and the yield was measured in tonnes per hectare (t/ha). Yield = Average yield of the tagged plants multiplied by the crop planting density.

Analysis of Data. The data collected on fresh cassava roots yield and subjected to statistical analysis (ANOVA) using Gensat3 statistical software. Significant means were separated using LSD at P= 0.05 as described by Wahua (2010)

RESULTS AND DISCUSSIONS

Yield of fresh cassava roots

Seedbed type significantly increased the cassava root yield. Ridge produced significantly higher fresh cassava root yield than the flat (Table 3) Pumpkin cover crop produced the highest cassava roots followed by sweet potato while egusi melon produced the least. This may be due to its high leaf area which was used to cover the soil and maintained reduced soil moisture loss or the production of root exudates which had allelopathic effects on weeds and controlled soil diseases. This is in agreement with Kruidhof, *et al* (2008) who found out that some cover crops can prevent the development of weeds population, control soil diseases, increase organic matter and reduce soil losses. Density of cover crops decreased the yield of the cassava roots as the control had the highest cassava roots yield. The control (No cover crop plots) where plots were manually weeded benefited cassava roots yield over other cover crop densities.

CONCLUSION

The use of ridge in cassava production was more rewarding as the yield in tonnes / hectare of fresh cassava roots was more than on flat. Cassava planted in ridges increase the cassava root yield as the roots penetrate deep into the soil allowing roots growth and expansion. The cover crops ensured reduced effect of torrential rains on the soil avoiding erosion and runoffs. The results were obtained based on the prevailing situation at the time of the experiment.

ABSTRACT

The world is moving towards innovation in harnessing bioresources materials into wealth for self-reliance without affecting the natural environment. The reason to give it keen attention. The aim of this study was to produce organic amendment from waste and its effects on soil properties and plant germination index. The aim was achieved by producing the organic amendment through composting processes where 5 kg of the mixed wastes was charged into a biodigester. Temperature, pH and moisture content were monitored throughout the process, and subsequently been converted into organic amendment after subjecting the matured compost through fermentation process, and the product was analyzed. The moisture content of the compost stabilizes at 50 % in which the temperature dropped from $50^{O}C$ to $25^{O}C$ at the maturity stage. The active microorganism identified in the produced amendment consist of bacteria and fungi with cell counts of 4.3×10^7 and 1.7×10^7 cell/g respectively, which enhanced the soil properties by improving its water holding capacity by 91 %, organic carbon by 84.5 %, average root length and shoot length of 1.46 and 5.66 cm respectively (organic amendment plant) from 0.3 and 0.6 cm for control. It is therefore, concluded based on the investigation carried out that, bioresources wastes were successfully converted into useful organic amendment to improve soil properties.

Key words: Organic amendment, water holding capacity, plant germination index

INTRODUCTION

There is a growing alarm on soil degradation, as universal need for food, water, energy, and raw materials persists at unparallel amount (Liu *et al*., 2019). The shortage of feat to meet up with these needs can be without difficulty result in unpleasant wave influence in human race. According to Corato, (2020), the universal land outlook approximates that one third of the universal land surface is harshly degraded, which has harmful effect on the comfort of no less than 3.2 billion populace traversing all continents. This leads to death of biodiversity and ecology services resulting to a financial loss of roughly 10 % of the globe's yearly overall produce in 2020 (Mendonca *et al*., 2021; Ballardo *et al*., 2021). These effects harmfully influence soil quality as the water holding capacity is abridged due to the soil structural instability (Adebayo *et al*., 2021; Heshan and Latif, 2021; Malta and Anna, 2021).

As reported by Abdulkadir *et al*., (2021); Xianfang *et al*., (2021; Pane and Anubha, (2021), the integration of bioresources waste directly on soil without adequate treatment is unsafe. However, composting by biological degradation is one of the best approaches used to achieve soil amendment (Gai *et al*., 2019; Kranz *et al*., 2020; Ghulam *et al*., 2021). More so, considering an average 98 million tons of agricultural waste and 28 million tons of animal waste been generated annually in Nigeria as reported by Choudhary *et al*., (2018); Asses *et al*., 2019; Ghulam *et al*., 2021; Anar *et al*., (2019) and Jangir *et al*., (2019) without adequately harnessing them through the waste management system, thereby adding to the existing environmental pollution problem and also depriving country the economic value of these waste into wealth potential. The need to utilize the abundance availability of these raw materials to justify this study. This work was aimed to produce organic amendment and study its impact on soil properties and germination index of plant.

MATERIALS AND METHODS

Characterization of the compost.

Total organic carbon (TOC), total nitrogen (TN), carbon to nitrogen ratio (C/N), available potassium (K_2O) and phosphorous (P_2O_5) of the compost pile were analyzed before and after composting process. The methods used were adopted from the work of Adebayo *et al*., (2019); Aftab *et al*., (2019); Gai *et al*., (2019).

Development of the organic Amendment

5 kg of compost pile, consisting of dried cow dung and jatropha (carrier) cake were charged into bioreactor in ratio of 70 % to 30 % for composting processes. The composting process was monitored in terms of temperature, pH and moisture content of the system for two weeks, after which fermentation process was done by dissolving mixture of 0.5 kg of brown sugar and 2 liters of water into the reactor. The solution was mixed and sealed tightly for 5 days, to form active substrate for the microorganism to strive. Sample was taken from the liquid product formed from fermentation process for analysis to ascertain the active microorganisms present after culturing using standard method and Kjeldahl digestion methods for the nutrient contents.

Soil texture determination

The particle size distribution was determined following the Bouyoucos hydrometer method as described by Ozlu and Kumar, (2018); of which 50 ml of 6 % H_2O_2 was added to 500 g of sieved soil sample in a beaker. The classification values are 480 gkg^-1, 320 gkg^{-1} and 200 gkg^{-1}, which is equivalent to 89.8 wt.%, 7.9 wt.% and 2.3 wt.% compositions respectively. The percentage of sand, silt and clay were computed using the following relationships and guided by adopting texture classification triangle.

$$\text{Clay (\%)} = \frac{Wc}{W} \times 100 \quad (1)$$

$$WC = R_{2HR} - R_B \quad (2)$$

$$\text{Silt (\%)} = \frac{Wsi}{W} \times 100 \quad (3)$$

$$Wsi = R_{40s} - R_B) - (R_{2HR} - R_B) \quad (4)$$

$$\text{Sand (\%)} = 100 - (\%\text{silt} + \%\text{clay}) \quad (5)$$

Where: W = weight of sieved soil sample, WC = weight of clay), R_{2hr} = 2 hrs hydrometer reading, R_B = blank hydrometer reading, R_{40S} = corrected forty seconds reading, Wsi = weight of silt.

Characterization of the soil and application of the organic amendment

The soil used was analyzed before and after using standard method described by Dukuziyaturemye *et al*., (2020), where 10 g of the produced organic amendment was weighed in ten different sample bottles, mixed with 100 ml of distilled water and then enthused for 24 hrs in each case. Samaize-37seeds were the specie of maize used in which two seeds were slumped in 9-cm-diameter petri dishes lined with a filter paper. Germination of seeds and length of root and shoot size dimensions were carried out after 72 h of the investigation, where the average values were recorded. Equations 6 and 7 were used to compute germination index and viror index.

$$\text{Germination index (GI)} = (10 \times n1) + (9 \times n2) + \cdots + (1 \times n10) \quad (6)$$

Where n1, n2……n10 = numbers of germinated seed on day 1, 2 until the 10^{th} day

$$\text{Vigor Index (VI)} = \text{Germination \%} \times (\text{mean root length} + \text{mean shoot length}) \quad (7)$$

RESULTS AND DISCUSSION

Characterisation of the Initial Co-compost Pile

Table 1 shows result of the characteristic of composting mixture of cow dung and jatropha cake before the composting process and afterward.

Table 1: The main characteristics of initial and final co-composting

Parameters	Before co-composting	After co-composting
Moisture content (%)	43.40	58.71
Total carbon (%)	27.65	22.98
Organic matter (%)	47.67	39.62
Total nitrogen (%)	2.42	3.43
P_2O_5 (%)	4.68	6.16
K_2O (%)	1.36	1.97

C: N	11.45	9.56
pH	5.7	7.8

As shown in the table, the initial moisture content of the compost pile was 43.40 %, it was increased to 58.71 % at the completion of the processes, which is within the range as reported by Corato, (2020). Chemical reaction occurs at this optimum moisture content in which microorganism activities are enhanced. The availability of sufficient nitrogen which was improved subsequently from 2.42 % to 3.43 % was responsible for synthesis of amino acids within the system. As observed from the results presented in Table 1, the availability of carbon was reduced from 27.65 % to 22.98 % due to its consumption during the composting process. Also, the organic matter load within the system was reduced from 47.67 % to 39.62 % by the activities of microorganism as shown in the table, which further justified the C: N values deprecation from 11.4 % to 9.56 %. These agree with trends reported in the work of Marta and Anna, (2021).

pH profile of the composting process

The variation in pH values of the composting system over 30 days investigating period was presented in Figure 1. As shown in the figure, during the mesophilic period (the first two days), the pH value was 7.91 after which it raised to 9.85 during the thermophilic stage. The rise in the pH value is due to the liberation of ammonia gas as a result of rapid breakdown of waste by microbes as reported by Adebayo *et al.*, (2018); Ballardo *et al.*, (2021); Marta and Anna (2021). However, the pH value at day 14th was observed to have reduced to 8.08. This may be as a result of the organic acids released and elevated amount of CO_2 absorbed into the system from the extreme breakdown of carbohydrates

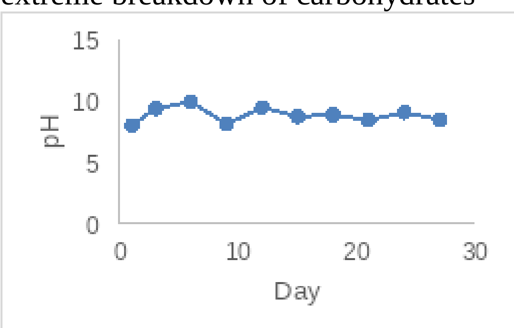

Figure 1: pH profile of the co-composing process

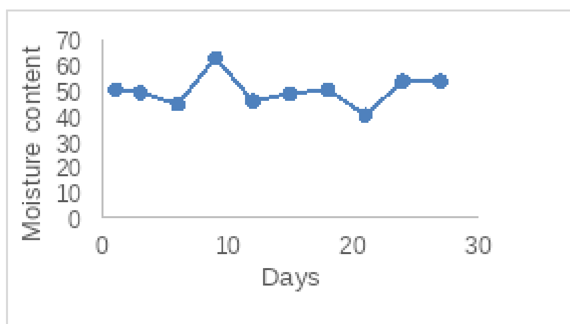

Figure 2: Moisture content profile of the co-composting process

Moisture content profile of the co-composting process

As shown in Figure 2, the initial moisture content of the compost system was 50 %, which is considered minimum as reported in the work of Liu *et al.*, (2019). As observed from the figure on the 3rd and 5th day of composting, the moisture content reduced to 45 % and 44 % respectively. The moisture content continued to reduce and increase during the observation as shown in Figure 2 until it stabilizes on 50 % from days 25th to 29th. These trends which is similar to Pane and Anubha, (2020) report is due to the activities of microbe to completely break down of the organic matter until maturity stage was achieved.

Temperature profile of the co-composting process

As shown in Figure 3, the initial temperature increased from 28^0C to 47.80^oC at the 7^{th} day of composting as a function of the microorganism activities within the system, which is in agreement to the report of Ghulam *et al.*, (2021). The temperature of the composting system rose to 50.20^oC on the 9^{th} day as a result of intense decomposition of the available organic matter, which is sufficient enough to eliminate any pathogen present in the system before it was reduced 25^0C from the 23^{rd} day until the process remain linear, signifying the maturity stage.

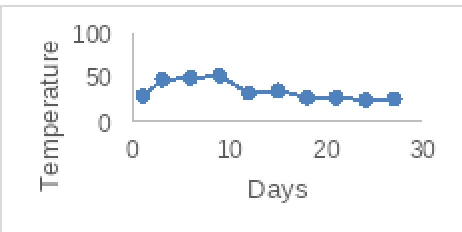

Figure 3: Temperature profile of the co-composting process

Biochemical analysis of the produced organic amendment

The microbial analysis of organic fertilizer is shown in Table 2. As shown in the table, the active microorganisms in the produced organic amendment are *Bacillus SP* (bacterial) with cell count of 4.3×10^7 cell/g which helps in maintaining mesophilic temperature. Also, the active fungi present are *Aspergillus Fumigatus, Aspergillus Versicolor and Penicillium SP* with the same cell count of 1.7×10^7 cell/g. These fungi present are the microorganism that continuously recycling carbon and nitrogen as reported in the work of Kranz *et al*., (2020).

Table 2: Biochemical analysis results of the produced organic amendment

Active microorganism	Microorganism type	Cell count (cell/g)	Function	Moisture content (%)
Bacillus SP	Bacteria	4.3×10^7	P-solubilizer	40
Penicillium SP	Fungi	1.7×10^7		
Aspergillus versicolor	Fungi	1.7×10^7		
Aspergillus fumigatus	Fungi	1.7×10^7		

Characteristics of the soil before and after application of organic fertilizer

As shown in Table 3, the amount of sand, silt and clay in the experimented soil sample classification were 480 gkg^{-1} 320 gkg^{-1} and 200 gkg^{-1} respectively. The relative proportions of sand silt and clay content indicated the loam texture of the soil as shown by the United State Division of Agricultural textural triangle.

Table 3: The main characteristics of the experimental soil

Soil characteristics	Value (Before application)	Value (After application)
Sand (gkg^{-1})	480	
Silt (gkg^{-1})	320	
Clay (gkg^{-1})	200	
Soil texture	Sandy loam	
pH	6.5	7.3
Carbon (gkg^{-1})	1.5	9.7
Water holding capacity (%)	0.49	5.3

As shown in Table 3, the organic carbon in the soil was 1.5 gkg^{-1} which is very low compared with the standard specification of >15 as reported by Xianfang *et al.*, (2021). The low organic carbon content observed may be attributed to the exhaustion of the organic matter in the soil as a result of soil degradation by continuous cropping without replenishing the used nutrients which were loss during soil leaching. The improvement of the organic carbon through the effect of incorporated amendment does not meet the required specification, however, the effect was shown as it was increased by 91 % which proved that, the soil amendment was good. Also, the low water holding capacity was improved from 0.49 % to 5.3 % due to the impact of the amendment as shown in Table 3.

Impact of the organic amendment on germination index of plant

Table 4 show the impact of organic amendment on plant roots and shoot lengths growth and that of control sample. As presented in the table, the root length for plant 1 in the organic amendment incorporated plant was 0.9 cm which is 33.3 % higher than the one in a control sample when compared based on the same experimental treatment condition. Also 1.9 cm root length was observed for plant 2 in organic amendment plant while 0.5 cm was recorded in the control sample as shown in Table 4. More so, the trends in shoot length of all the plants in organic amendment incorporated sample are better in terms of productivity and yield when compared to of control samples. The evidence was observed on the average shoot length of 5.66 cm as compared to 0.6 cm in a control sample. Therefore, the effect of organic amendment on the soil and plant roots can be justify with efficiency of the improved soil properties as observed in this investigation.

Table 0: Average root and shoot lengths in organic amendment and control plants experiment

	Organic amendment incorporated plants		Control plants	
Plant	Root length (cm)	Shoot length (cm)	Root length (cm)	Shoot length (cm)

1	0.9	2.6	0.6	1.0
2	1.9	7.7	0.5	1.1
3	1.5	8.6	0.5	1.0
4	1.9	2.9	0.3	0.7
5	1.1	6.0	0.0	0.2
6	1.8	7.5	0.2	0.5
7	2.3	9.5	0.0	0.1
8	0.7	3.0	0.4	1.5
9	1.1	4.1	0.1	0.5
10	1.4	4.7	0.4	0.5
Average	1.46	5.66	0.3	0.6

Plate I (a and b) show some of the plant roots investigated during the experimental process

Plate I: Plant roots of the (a). organic amendment sample and (b). Control sample

CONCLUSION

It can be concluded at the end of this investigation that, the produced organic amendment characterized with 40 % moisture content contained *bacillus SP*, *penicillium SP*, *aspergillus versicular* and *aspergillus fumigatus* as its active microorganism. More so, the produced organic amendment improved the water holding capacity of the soil by 91 % and the soil organic carbon by 84.5 % which are functions of the average root and shoot lengths of 1.46 cm and 5.66 cm respectively recorded for organic fertilizer amended soil compared to the 0.3 cm and 0.6 cm average lengths obtained for the control sample. Therefore, the produced amendment impacted the soil efficiently.

ABSTRACT

The study assessed the Decentralized Vine Multipliers (DVMs) model as pathway for sweet potato seed system development in Abia State. Multi stage random sampling technique was used to elicit responses from the farmers. Two blocks from each of the three zones and two circles from each block were randomly selected making it twelve (12) circles. Ten (10) Sweet potato DVMs were randomly selected from each circle, giving a total of 120 farmers for the study. Primary and secondary data were used for the study. Data were analyzed using descriptive statistics such as percentages, and means and were presented in tables and charts. Results revealed that DVMs were trained on good agronomic practices but no training on business management practices and lack of National Agricultural Seed council (NASC) certification leading to absence of guaranteed quality assurance. The DVMs were also trained on vine production using net tunnel for pre-basic vine production, maintenance operations on sweetpotato vines, cost effective net tunnel and vines in containers in the net tunnel. The DVMs produced improved sweetpotato varieties such as UMUSPO 3, UMUSPO 4, TIS 87/0087, Ex-Igbariam, UMUSPO 1 and TIS 8164. The study revealed that major constraint to sweet potato vine production faced by the DVMs were access to market, inadequate input, lack of capital and low market price of vines. It was recommended that DVMs should form clusters to enable them attend regular trainings on good agricultural practices and business management to ensure high yields and certification by the NASC in order to attract guaranteed market for sustainable sweet potato early Generation Seed (EGS) business.

Key words: Assessment, Sweet potato, Decentralized Vine Multipliers and Seed System.

INTRODUCTION

Sweet potato *(Ipomoea balatas*(L)) is a herbaceous, warm-weather creeping plant that belongs to the family of *Convolvulaceae* and genus of *Ipomoea* (Mbanasor, 2010). In 2018 Nigeria produces 3.9 metric tons of sweet potatoes and is the largest producer in sub-Saharan Africa (Shanhbanden, 2018). In recent times, the West Africa region has witnessed increase in crop output; sweet potato recorded a positive per capita annual rate of increase in production in sub-Saharan Africa (Ndaula *et al*., 2020). The Decentralized Vine Multipliers Model was introduced as a means of scaling out clean sweet potato vines through the relevant stakeholders to the farmers to ensure high yield and productivity by farmers. The DVMs are comprised of farmer associations, out-growers, Non-governmental organizations (NGOs), cooperative societies and other seed producers with strong interest in sweet potato vine production in many sweet potato growing ecologies of Nigeria. The collaboration between the International Potato Centre (CIP) and National Root Crops Research Institute (NRCRI) during the Sweet Potato Action for Security and Health in Africa (SASHA), a five-year initiative which had the objective to improve the food security and livelihoods of poor families in sub Saharan Africa by exploiting the untapped potential of sweet potato. The decentralized vine multipliers model has greatly improved in capacity and output since its introduction in sweet potato seed production in Nigeria. The DVMs were trained and equipped with net tunnels for the production and sale of clean vines. The net tunnel is specially designed to ward off pests and diseases at the pre- basic level of vine multiplication. There is need for the study to know how decentralized vine multipliers model has gone far in development of sweet potato seed system.

METHODOLOGY

The study was carried out in Abia State (Aba, Umuahia and Ohafia agricultural zones). Abia State lies between longitude 7^0 $00^0$and 8^010^1 East and latitude 4^0 45^1 and 60^0 10^1 North. It occupies a land mass of 5,833.77 square kilometers (ABSEEDS, 2006). Multi stage random technique was used to elicit data from the farmers. The three agricultural zones were involved. Two blocks from each zones were randomly selected; two circles were also randomly selected making it twelve (12) circles. Ten (10) Sweet potato DVMs were randomly selected from each circle, making a total of 120 farmers for the study. Primary and secondary data were used for the study. Data were analyzed using descriptive statistics such as percentages and mean.

Sweet Potato Seed Flow

In the sweet potato seed flow, the major flow is from the Research Institute (NRCRI Umudike) to the decentralized vine multipliers, sweet potato farmers' cooperatives, ADPs and sweet potato farmers. National Root Crops Research Institute produces and supplies clean Pre-Basic seeds at moderate price. Farmers also save some of their seeds which they utilize in planting the next year. Famers saved seeds are of low productivity and are not resistance to pest and diseases.

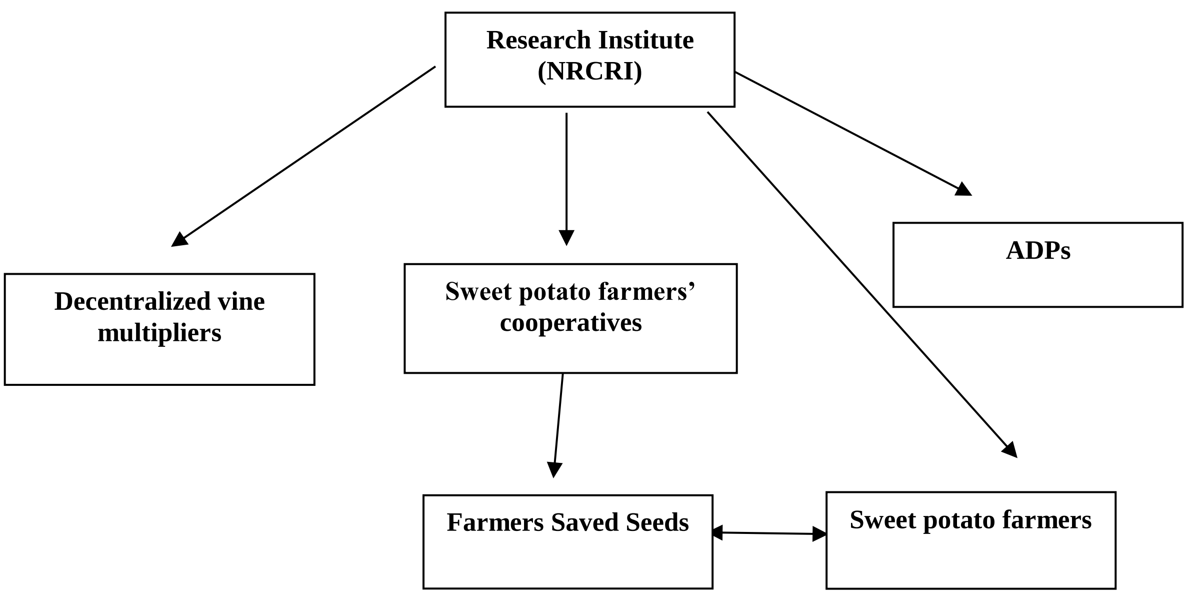

Fig. 5. Sweet Potato Seed Flow

Sweet Potato vine produced by the DVMs

From the chart below the major sweet potato vines produced by DVMs in Abia State was UMUSPO 3(33%), followed by UMUSPO 4 (19%), TIS 87/0087 (17%), Ex-Igbariam (12%), UMUSPO 1 (9%), UMUSPO 2 (6%) and TIS 8164 (4%). This result showed that the DVMs were producing improved sweet potato varieties in the study area.

These Are Improved Varieties of Sweet Potato, High Yielding and Resistant to Pest and Diseases.

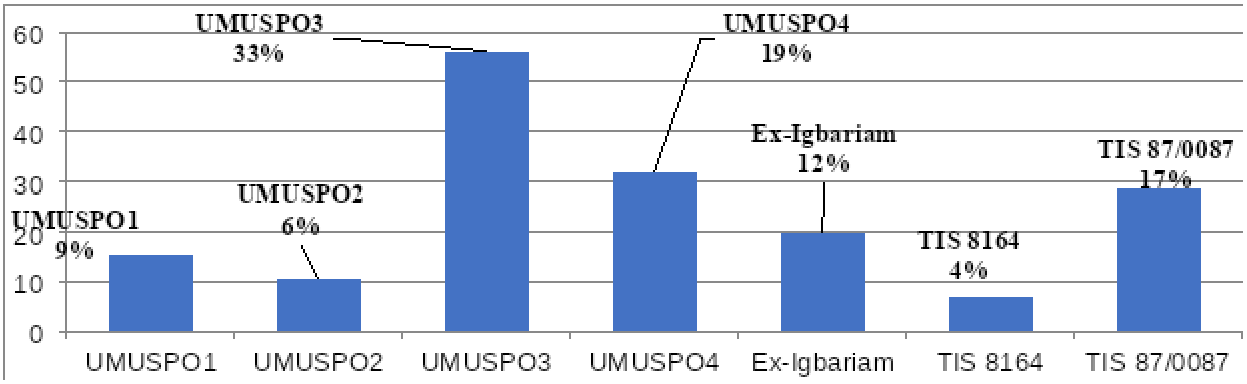

Figure 6
Source: Field survey, 2019.

Quality of Sweet Potato Vines Produced by Sweet Potato Vine Multipliers

- The sweet potato seeds produced by the Decentralized vine multipliers were not certified.
- The vines were healthy, free from pest and diseases.
- No NASC certification of vines yet.

Training on Improved Agronomic

The Decentralized vine multipliers have been trained on improved agronomic practices and the DVMs participated in the training. The result showed that all the DVMs 100% participated in harvesting of vines, followed by planting (80%), ridging/ bed making (76%), weeding (70%) land clearing (60%), site selection (58%) and fertilizer application (50%). There was no training on business management. This shows that the DVMs had training on good agronomic practices on sweet potato vine production. This finding agrees with the report of Ukoha *et al.* (2016) that farmers participate in trainings to equip and keep them abreast with major happenings in the field of agriculture.

Challenges to Sweet Potato Seed Production and Marketing

Table 1 revealed that the major challenges to sweet potato vine production and marketing in Abia State were lack of capital, inadequate inputs, lack of sweet potato seed market and low market price for sweet potato seed. These challenges have made it difficult for farmers to expand their scale of production in sweet potato seed business in the state. According to Oni (2013), identification of the constraints or challenges in the agricultural sector is a necessary step to unlock the factors inhibiting performance of the sector towards promotion and growth of the sector.

Table 1. Challenges to Sweet Potato Seed Production and Marketing

Challenges (three point rating scale of very serious, serious and not serious)	Mean Score
Availability of improved varieties of sweet potato seeds	1.2
Lack of capital	2.5
Access to credit facilities	2.0
Inadequate inputs	2.6
High cost of labour	2.0
Access to market	2.8
Low market price	2.5
Pests and diseases	1.0
High cost of improved planting materials	1.8
Soil fertility	1.5
