1. Materials and methods

Text S1. Description of the wastewater treatment plant under investigation.

The wastewater treatment plant (WWTP) under study treats the effluent produced in the local large hospital and the urban wastewater of the surrounding area (Figure 1 in the manuscript). The hospital includes 900 beds and several departments (anesthetics, dermatology, endocrinology, forensics, gastroenterology, genetics, geriatrics, gynecology, hematology, infectious disease, neurology, nuclear medicine, oncology, pediatrics, traumatology and surgery) and a large set of medical services (clinical analysis, dialysis, pharmacology and radiology). It opened in 2012 when it was relocated from the center of the city (Ferrara) to the outskirts. The hospital wastewater (HWW) is directly discharged into a separate sewer pipe, and once it reaches the WWTP, it is cotreated with the wastewater coming from the catchment area, which includes households and small businesses. The sewer also collects rainwater that can strongly increase the influent flow rate to the plant. This second contribution is called urban wastewater (UWW).

The core treatment of the WWTP is an MBR equipped with submerged hollow fiber UF membranes (Koch Separation Solution, 8 modules, 500 m²/module, nominal pore size of 0.05 µm, maximum permeate flux of 25 L/(m²·h⁻¹), leading to a maximum hourly flow rate of 100 m³/h according to the nominal surface flow rate of the installed membranes (Figure 1). In particular, the WWTP consists of a pre-treatment (screening and degritting), the MBR, which includes P removal (100 m³), denitrification (250 m³), nitrification (350 m³) and membrane filtration (72 m³), followed by a tertiary treatment. The average hydraulic retention time (HRT) is 24 hours. The sludge recycled in the MBR (denitrification tank) is approximately 2100 m³/d. The excess sludge, which is withdrawn from the denitrification tank, accounts for between 0 – 43.6 m³/d (average of 16.3 m³/d) depending on the food/microorganism ratio and the bioreactor performance. The mixed liquor concentration in the nitrification tank is on average 6.7 ± 1.3 g/L with an organic loading rate of 0.039 gBOD₅/(gVSS·d), which is characteristic of an extended aeration plant. The sludge retention time (SRT) is between 24 and 40 days (on average 27 days). The average operating temperature is 23 °C and the pH of the final effluent is 7.1. Oxygen concentration in the nitrification tank is maintained at 1.5 ± 0.3 mg/L. Further details of the plant are available in Verlicchi et al., (2010).

The tertiary treatment consists of UV disinfection (irradiation of 100 mJ/cm², exposure time of about 4 – 7 s) of the permeate before its release into a canal belonging to the local surface water network which is used for irrigation: The final WWTP effluent (average flow of 0.011 m³/s) is therefore indirectly reused for irrigation, and is diluted by approximately 50% once it is discharged into the water body (average flow of 0.01 m³/s).

The WWTP also includes an accumulation tank (180 m³) that dampens the variations in the influent flow rate due to rain events and guarantees a correct and safe working of the treatment train, in particular the membranes. The accumulation tank is installed before the pre-treatments and stores any excess wastewater arriving at the WWTP. Then, the collected wastewater is gradually sent back to the UWW line. In this way, the effect of intense rain events is controlled and mitigated, and a very stable influent flow rate is guaranteed. However, the climatic conditions during the monitoring and experimental periods of this study were predominantly stable, with very few, light rain events.

Text S2. Experimental procedure to maintain the PAC concentration stable inside the MBR.

The PAC concentration was maintained stable IN THE BIOREACTOR by periodical and controlled additions of fresh PAC following this procedure. On the first day of the second (0.1PAC) and the third (0.2PAC) campaigns, a fixed amount of PAC (70 and 150 kg, respectively) was dispersed into the MBR tanks by means of 10 kg-water soluble bags until the desired PAC concentration was reached. Then, PAC additions were made to counterbalance PAC losses associated with the excess sludge withdrawn from the regularly-monitored MBR. By doing so, the PAC concentration varied by less than 10% from the nominal concentration. Average PAC concentrations were therefore 0.10 ± 0.01 g/L for 0.1PAC campaign and 0.20 ± 0.02 g/L for 0.2PAC campaign. The daily amount of PAC lost (wasted) from the system (PAC_w , kg/d) was estimated according to eq. 1:

$$PAC_w = PAC_{MBR} \cdot WAS \quad \text{eq. 1}$$

where PAC_{MBR} is the PAC concentration inside the MBR (kg/m³) and WAS the daily volume flow rate of the excess sludge removed from the system (m³/d). A mass balance of the PAC was carried out every day in order to calculate the residual concentration of PAC inside the MBR (PAC_{MBR}) after the withdrawal of excess sludge containing the PAC. This updated value of PAC_{MBR} was compared with the lower limit of acceptability of the specific campaign (0.09 g/L or 0.018 g/L) thus monitoring its decrement. In this way, it was clear in which day fresh PAC had to be added in order to maintain its concentration within the desired interval. The amount added corresponds to the PAC quantity necessary to increase its concentration inside the MBR up to the maximum value (upper limit of acceptability) of 0.11 g/L or 0.22 g/L depending on the campaign. In order to guarantee a rapid mixing and a homogenous PAC concentration in the MBR, the aeration was stopped in the nitrification before PAC addition and immediately switched on soon afterwards. Moreover, samples of the permeate were taken at least one day later. Due to technical reasons and time restrictions, it was not possible to prepare a solution (slurry) with the fresh PAC to be fed to the MBR when necessary.

2. Analyzed contaminants

Table S1. Main physicochemical properties and Predicted No-Effect Concentration (PNEC) in freshwater of the target OMPs analyzed. The compound classes were attributed according to the Anatomic Therapeutic Chemical (ATC) classification. The transformation products are written in *italics*. Data on (predicted) physicochemical properties were obtained from CAS SciFinderⁿ (<https://scifinder.cas.org>) and the PNEC values from the NORMAN database (<https://www.norman-network.com/nds/ecotox/>). The charge was obtained from pK_a values by calculating the molecular/ionic species at pH 7 (see **text S1**).

Table S2. Main physicochemical properties and Predicted No-Effect Concentration (PNEC) in freshwater of the non-target OMPs analyzed. The compound classes were attributed according to the Anatomic Therapeutic Chemical (ATC) classification. The transformation products are written in *italics*. Data on (predicted) physicochemical properties were obtained from CAS Scifinder (<https://scifinder.cas.org>) and the PNEC values from the NORMAN database (<https://www.norman-network.com/nds/ecotox/>). The charge was obtained from pKa values by calculating the molecular/ionic species at pH 7 (see **Text S1**).

Class	Name	CAS#	ATC code	Formula	PNEC freshwater (µg/L)	Molecular weight	Strongest acidic pKa at 25°C	Strongest basic pKa at 25°C	logDow pH = 6	logDow pH = 7	logDow pH = 8	logKow	Charge at pH 7

Text S3. Calculation of the OMP charge (ionic form).

The charge of the OMPs can be estimated by calculating the proportion of ionic species as a function of the acid dissociation constant (K_a) of the compound and the pH value of the wastewater (Sukul et al., 2008). The (predicted) pK_a values of the most acidic and/or basic groups of the molecule (strongest acidic/basic pK_a at 25 °C in **Table S1** and **S2**) were obtained from CAS SciFinderⁿ, which allowed the calculation of the speciation of the analyzed OMPs at pH values ranging from 1 to 14 (in this study, the pH was set as pH = 7) (Kovalova et al., 2013; Schwarzenbach et al., 2003). Depending on whether the compound has one or two pK_a values, the speciation goes as follows:

One pK_a value If the compound has only the strongest acidic pK_a , it is defined as the pK_a of an acidic pharmaceutical (HA), $HA \xrightleftharpoons{K_a} H^+ + A^-$

If the compound has only the strongest basic pK_a , it is defined as the pK_a of the conjugate acid (BH^+) of a basic compound (Schwarzenbach et al., 2003), $BH^+ \xrightleftharpoons{K_a} B + H^+$

The

$$x_0 = \frac{[HA]}{[HA] + [A^-]} = \frac{[BH^+]}{[BH^+] + [B]} = \frac{[H^+]}{[H^+] + K_a} \quad x_1 = \frac{[A^-]}{[HA] + [A^-]} = \frac{[B]}{[BH^+] + [B]} = \frac{[B]}{[H^+] + K_a} \quad \text{where, } x_0 + x_1$$

$$x_1 = \frac{[A^-]}{[HA] + [A^-]} = \frac{[B]}{[BH^+] + [B]} = \frac{K_a}{[H^+] + K_a} \quad \text{where, } x_0 + x_1 = 1 \text{ being}$$

$x_0 + x_1 = 1 \text{ being}$

$$x_0 = \frac{[H^+]^2}{[H^+]^2 + K_1 \cdot [H^+] + K_1 \cdot K_2} \quad x_1 = \frac{K_1 \cdot [H^+]}{[H^+]^2 + K_1 \cdot [H^+] + K_1 \cdot K_2} \quad x_2$$

$$x_1 = \frac{K_1 \cdot [H^+]}{[H^+]^2 + K_1 \cdot [H^+] + K_1 \cdot K_2} \quad x_2 = \frac{K_1 \cdot K_2}{[H^+]^2 + K_1 \cdot [H^+] + K_1 \cdot K_2} \quad \text{where, } x_0 + x_1 + x_2 = 1 \text{ Being}$$

$$x_2 = \frac{K_1 \cdot K_2}{[H^+]^2 + K_1 \cdot [H^+] + K_1 \cdot K_2} \quad \text{where, } x_0 + x_1 + x_2 = 1 \text{ Being}$$

$x_0 + x_1 + x_2 = 1 \text{ Being}$

Text S4. Analysis of the average loads, the frequency of detection, the range of variability and the average concentrations of the target OMPs in the HWW and the INF.

During the sampling periods, the WWTP treated on average 855 m³/d, from which 221 m³/d are from UWW and 634 m³/d from HWW, representing approximately 25% and 75% of the total flow rate, respectively. HWW varied between 393 m³/d and 1,131 m³/d (standard deviation, SD = 170), the UWW between 73 m³/d and 940 m³/d (SD = 184) and the INF between 538 m³/d and 1,963 m³/d (SD = 317) (Figure S1). Since the hospital has a capacity of 900 beds, the corresponding specific consumption is 705 L/bed/day, in agreement with the literature (Verlicchi et al., 2010).

Overall, the OMP load of the HWW represents 78.6% of the total load arriving at the WWTP. Seven out of the twenty OMP classes are the main contributors to the OMP load in the INF. As reported in Table S9: analgesics/anti-inflammatories (27%), antibiotics (20%), X-ray contrast media (18%), psychiatric drugs (11%), plastic additives (10%), stimulants (6%) and illicit drugs (3%), whereas the remaining 13 classes represent less than 4% of the total load.

During the noPAC (March – August 2021) and 0.1PAC (September – November 2021) campaigns, the average load of OMPs in both HWW and INF was significantly higher compared to the 0.2PAC campaign (April – May 2022) (Figure S2A). The first two campaigns were conducted during the Covid-19 pandemic which, in the face of the trend of infection steadily decreasing by 2022, led to the end of the state of emergency in Italy before the beginning of the 0.2PAC treatment. The analgesics/anti-inflammatories average load decreased from 23.3 g/d during noPAC to 12.1 g/d in 0.1PAC and 6.1 g/d in 0.2PAC, whereas antibiotics were on average 11.7 g/d and 11.4 g/d during the noPAC and 0.1PAC campaigns, respectively, and decreased to 3.8 g/d during 0.2PAC campaign (Table S9). Antibiotics were frequently prescribed to patients with Covid-19 and related post-structural lung damage due to their increased vulnerability to microbial infections (Knight et al., 2021). Furthermore, the use of scanning tools to determine the degree of infection is one of the main techniques used in the diagnosis and aftercare of Covid-19 patients (Abuzaid et al., 2023), which can be outlined by the high average load of X-ray contrast media during the 0.1PAC campaign (12 g/d) (Table S9).

Water sampling was not carried out during rainy events, as the precipitation collected in the combined urban sewer may alter OMP and macroparameter quantification. Yet on two occasions during the 0.1PAC treatment (September 21, 2021 and October 5, 2021), the rain collected in the accumulation tank (see Figure 1) increased the flow rate of the UWW arriving at the WWTP (Figure S1), which considerably increased the total load of OMPs in the INF compared to the HWW (Figure S2B). Higher HWW loads observed on August 3, 2021 and April 26, 2022 (Figure S2B) and average loads per OMP class (Table S9) may be due to uncertainties related to the sampling mode (i.e., 24-h time proportional instead of flow proportional composite sampling), OMP quantification (i.e., influence of the water matrix) and most significantly the presence of the accumulation tank (Figure 1). Most of these issues are described in detail in section 4.3.

Table S10 shows the frequency of detection, range of variability and average concentration of the 232 target OMPs analyzed and grouped according to their class in both HWW and INF, considering the whole experimental period. Regarding the frequency of detection in the INF, it emerges that target OMPs may be categorized into four main groups, with each group accounting for roughly one-quarter of the total number of compounds: 63 highly detected ($Freq > 75\%$), 44 moderately detected ($25\% < Freq \leq 75\%$), 59 slightly detected ($0\% < Freq \leq 25\%$) and 66 non-detected ($Freq = 0\%$). A similar distribution of frequencies was found in HWW. In both HWW and INF, 28% of the target compounds were not detected.

Regarding OMP concentrations (Table S10), it emerges that in the INF 11 compounds show an average concentration higher than 1 µg/L, namely iopromide (7.14 µg/L), acetaminophen (4.99 µg/L), benzotriazole (4.64 µg/L), gabapentin (3.38 µg/L), azithromycin (3.08 µg/L), caffeine (2.64 µg/L), naproxen (2.09 µg/L), ketoprofen (1.68 µg/L), ciprofloxacin (1.27 µg/L), ofloxacin (1.21 µg/L) and diclofenac (1.04 µg/L), with all of them having a frequency of detection of 100% except naproxen ($Freq = 11\%$). Among them, four OMPs reached maximum concentrations above 10 µg/L, i.e., iopromide (44.48 µg/L), naproxen (19.62 µg/L), diclofenac (15.49 µg/L) and benzotriazole (10.50 µg/L). On the other hand, 85 OMPs were found, on average, below the < LOD.

Comparing INF and HWW, it emerges that for 85 out of 232 target compounds, HWW have higher average concentrations than INF (corresponding to the 60% of the detected OMPs). The highest differences were found for iopromide (11.9 µg/L in HWW and 7.14 µg/L in INF) and albendazole (0.13 µg/L in HWW and 0.003 µg/L in INF). However, on some occasions, the concentration was higher in the INF compared to the HWW, which was the case for diclofenac (1.04 µg/L versus 0.08 µg/L, respectively) and the psychiatric drug amisulpride (0.12 µg/L versus 0.01 µg/L).

Table S11 reports the range of variability and the average load of all the target compounds. A total of 10 OMPs stood out due to their high average loads (> 1 g/d) in the INF: three analgesics/anti-inflammatories, namely acetaminophen (4.4 g/d), naproxen (2.2 g/d) and ketoprofen (1.4 g/d); three antibiotics, azithromycin (2.4 g/d), ciprofloxacin (1.1 g/d) and ofloxacin (1 g/d); one plastic additive, benzotriazole (4.2 g/d); one psychiatric drug, gabapentin (3 g/d); one stimulant, caffeine (2.3 g/d), and the contrast media, iopromide (6.4 g/d). In some cases, discrepancies between the OMP loads, in particular concerning HWW and INF, are found. An effort to interpret these results is made in section 4.1.

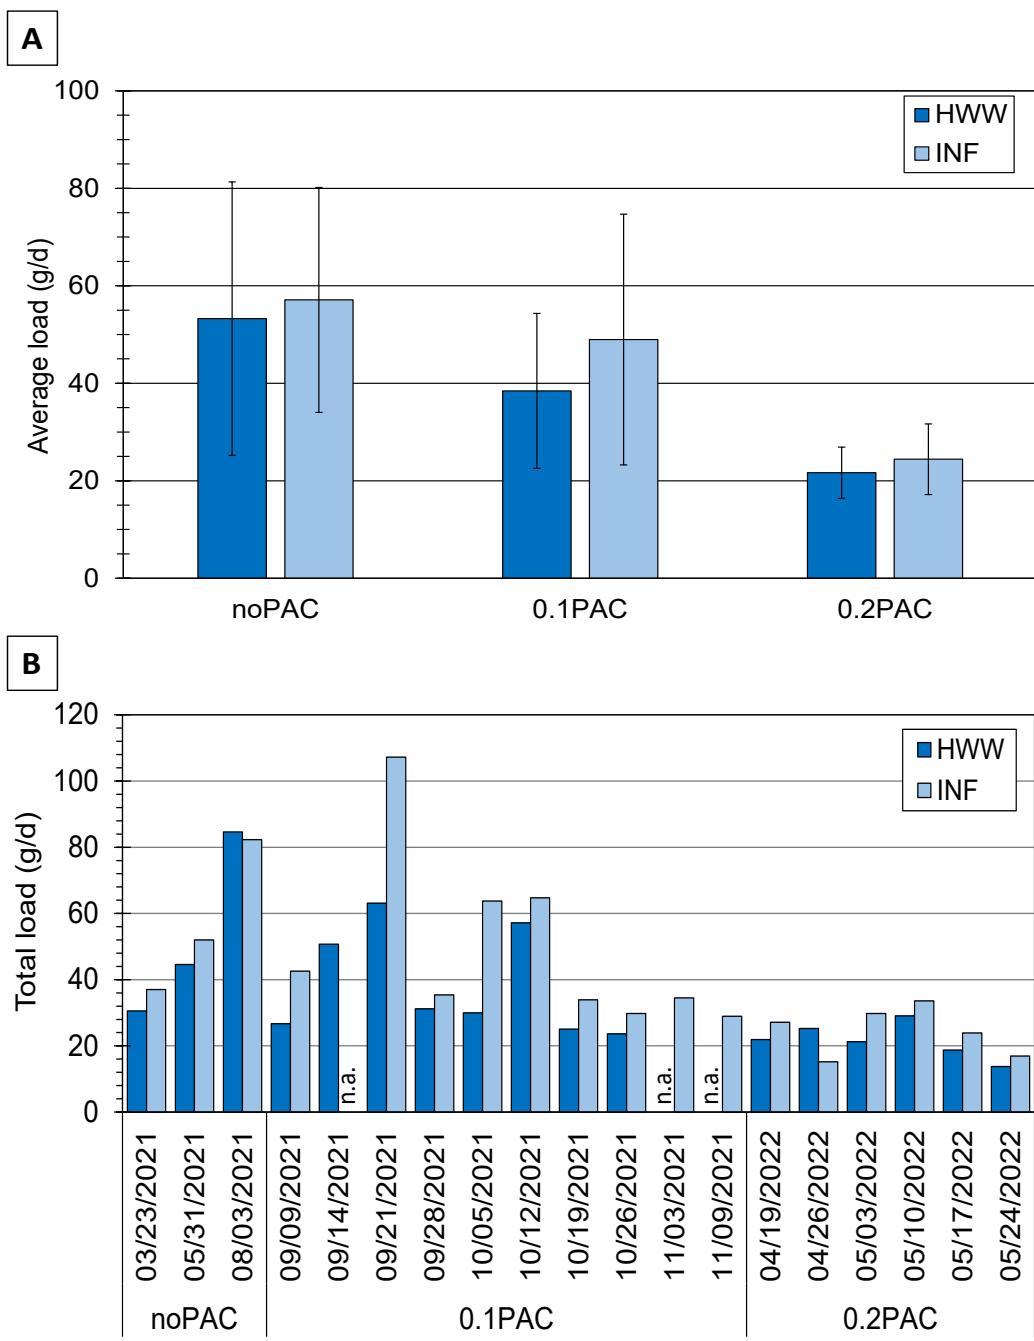

Figure S2. OMP load distribution in HWW and INF during three experimental campaigns (i.e., noPAC, 0.1PAC and 0.2PAC). A) Average load (g/d) and SD of all the target OMPs; B) total load (g/d) (sum of the individual OMP loads) per sampling day and campaign. n.a. = data not available.

Table S9. Average load and contribution to the load (%) of each class of target OMPs in HWW and INF during the three experimental campaigns and referring to the whole period. In between brackets, the number of OMPs pertaining to each class.

OMP class	noPAC		0.1PAC		0.2PAC		Whole period	
	HWW (n=3)	INF (n = 3)	HWW (n=8)	INF (n = 9)	HWW (n=6)	INF (n = 6)	HWW (n=17)	INF (n = 18)

Table S10. Frequency of detection, range of variability and average occurrence of the 232 target OMPs analyzed in HWW and INF considering the three experimental campaigns together: noPAC, March – August 2021 ($n = 3$); 0.1PAC September – November 2021 ($n = 8$, HWW and $n = 9$, INF); 0.2PAC April – May 2022 ($n = 6$). Transformation products are written in italics. SD: standard deviation. LOD: Limit of detection. n: number of samples.

Table S11. Ranges of variability and average load of the 232 target OMPs analyzed in HWW and INF considering the three experimental campaigns together: noPAC, March – August 2021 (*n* = 3); 0.1PAC September – November 2021 (*n* = 8, HWW and *n* = 9, INF); 0.2PAC April – May 2022 (*n* = 6). The compounds in italics correspond to the transformation products. SD: Standard deviation. *n*: number of samples.

Compound	HWW (<i>n</i> = 17)		INF (<i>n</i> = 18)

Table S12. Scores attributed to each OMP for frequency (F), average occurrence (O_{av}), maximum occurrence (O_{max}) and load (L) criteria in HWW and INF as well as bioaccumulation (B) and toxicity (T). The final score S of $FO_{av}BT$, $FO_{max}BT$ and FLBT approaches for HWW and INF are displayed. The final scores $S \geq 14$ are in bold. The transformation products are in italics.

Text S5. Analysis of the contribution of the different criteria to the $\text{FO}_{\text{av}}\text{BT}$ final score S in the selection of the key OMPs.

The following analysis refers to Figure 2 in the manuscript.

The eight analgesics/anti-inflammatories selected as key OMPs were: buprenorphine, diclofenac, hydrocodone, hydromorphone, ibuprofen, ketoprofen, lidocaine and tramadol. They present a high frequency of detection in the HWW (82% – 100%) and a high bioaccumulation potential ($\log K_{\text{ow}} \geq 2.127$). Among them ibuprofen, which has an average concentration of 0.579 µg/L, is the compound with the highest score in the OMP class (18 out of 20). Diclofenac obtained a final score of 17 since it had a maximum score (5) in three criteria: $\text{Freq} = 100\%$; $\log K_{\text{ow}} = 4.55$; $\text{PNEC} = 0.05 \mu\text{g}/\text{L}$ and a score of 2 for O_{av} , with an average HWW concentration of 0.082 µg/L. It is worth noting that the INF average concentration of 1.04 µg/L leads to the maximum score of 20 when applying the $\text{FO}_{\text{av}}\text{BT}$ to INF. Diclofenac and ibuprofen are compounds that have been included in prioritization lists in previous studies (Daouk et al., 2015).

Amoxicillin, azithromycin, ciprofloxacin, clarithromycin, erythromycin, minocycline, ofloxacin, oleandomycin, roxithromycin, spiramycin and sulfamethoxazole are the compounds among the antibiotics to be ranked in the $\text{FO}_{\text{av}}\text{BT}$ analysis. They are characterized by high toxicity (PNEC in the range 0.019 – 0.87 µg/L), and many of them are found at concentrations higher than 1 µg/L in HWW: azithromycin (4.005 µg/L), ciprofloxacin (1.639 µg/L), ofloxacin (1.304 µg/L) and spiramycin (1.240 µg/L), with the latter being the only compound in the antibiotics with a significantly lower frequency of detection (47%).

Among the psychiatric drugs, nine OMPs (carbamazepine, fluoxetine, gabapentin, lorazepam, maprotiline, memantine, quetiapine, trazodone and venlafaxine) and two transformation products, EDDP (major metabolite of methadone) and α -hydroxymidazolam (linked to midazolam), are selected. As for antibiotics, the psychiatric drugs selected present quite low PNEC values (in the range of 0.016 – 0.3 µg/L) except for memantine (1.84 µg/L) and gabapentin (10 µg/L). These compounds show high frequencies of detection in HWW ($\geq 76\%$), although their average occurrence could be considered low ($\leq 0.129 \mu\text{g}/\text{L}$) except for gabapentin (2.611 µg/L), a pharmaceutical primarily used to treat seizures and neuropathic pain.

Among the 4 illicit drugs selected, only amphetamine obtained a score of 5 in both the F ($\text{Freq} = 94\%$) and O_{av} ($c = 1.27 \mu\text{g}/\text{L}$) criteria. Cannabinol and THC are selected due to their high potential for bioaccumulation ($\log K_{\text{ow}} \geq 6.8$) and their toxicity (PNEC of 0.072 and 0.08 µg/L for THC and cannabinol, respectively). Benzoylecgonine, a metabolite of cocaine (which was not among the key OMPs) is selected due to 100% frequency of detection and the lack of a PNEC value which, according to a precautionary principle, implies a score of 5 for the toxicity criterion.

Only one compound was selected for the rest of the OMP classes, propafenone (antiarrhythmic agent), albendazole (antiparasitic), verapamil (calcium channel blocker), benzotriazole (plastic additive), caffeine (stimulant), octinoxate (UV filter) and iopromide (X-ray contrast medium). Among them, three compounds are selected due to their high frequency of detection (100%) and average concentration in HWW, namely

benzotriazole (4.847 µg/L), caffeine (2.301 µg/L) and iopromide (11.896 µg/L). Caffeine and iopromide are the most hydrophilic substances selected ($\log K_{ow}$ = -0.628 and -2.658, respectively).

Verapamil is the only compound that is included in the selection with a final score S lower than 14 in HWW ($S = 13$) since its frequency of detection is higher in the INF ($Freq = 89\%$) compared to the HWW ($Freq = 71\%$).

For this reason, it was not primarily included in the final list of key OMPs. Octinoxate is the compound with the highest score (17) among the latter group, due to its particularly high bioaccumulation potential ($\log K_{ow} = 5.921$) and high toxicity (PNEC = 0.026 µg/L). It is worth noting that these last two compounds are more frequently detected in the INF than in HWW, which implies that they are used in the households of the catchment area around the hospital. UV filters are used on a daily basis as a personal care product, and the calcium channel blocker may be prescribed for daily consumption to the inhabitants of the urban settlement.

4. Removal in the hybrid MBR

Text S6. Removal of macropollutants.

During the experimental campaigns, the removal of the macropollutants was assessed in order to evaluate whether the addition of PAC to the bioreactor may improve the overall quality of the effluent. Table S8 reports their concentration in the EFF, together with the average removal achieved during the noPAC and 0.1PAC campaigns. When adding a concentration of 0.1 g/L PAC to the MBR, the removal efficiencies of all the measured parameters increase (between 3% and 15%) except for N-NH₄⁺, the average removal efficiency of which slightly reduces from 97% to 93%. Previous studies (Alvarino et al., 2018; Cho et al., 2011; Gao et al., 2016) found that the addition of PAC has little to no effect on the removal of organic matter and nutrients, since MBRs already provide very good quality effluent, however, at times the presence of PAC may slightly improve the removal of organic matter (Johir et al., 2016; Remy et al., 2012) and nutrients, especially total nitrogen (Serrano et al., 2011). PAC has been shown to increase biological denitrification in the bioreactor since it provides anoxic zones in the microbial biofilm attached to the PAC surface (Alvarino et al., 2016, 2018). In this way, denitrification occurs not only in the denitrification tank, but also within the granules of sludge that incorporate the PAC. In our study, the average removal of total nitrogen increases from 64% to 73%, which improves the quality of the effluent (from 9.9 mg/L to 7.1 mg/L). Regarding total phosphorous (P_{tot}), its removal efficiency increases by 15% during the 0.1PAC campaign. In activated sludge systems, phosphorous is usually removed from wastewater by (co)precipitation and/or adsorption, with very poor amounts used for cell metabolism and growth (Radjenović et al., 2009). The WWTP under study possesses a tank for the removal of phosphorous, and therefore its effluent concentration was maintained at approximately around 3.2 mg/L, fulfilling the legal limit (10 mg/L, according to Italian Legislative Decree 152/2006 (Decreto Legislativo 152/06, 2006).

Table S13. Minimum, maximum and average removal efficiencies of the 232 target OMPs analyzed during the three experimental campaigns (i.e., noPAC, 0.1PAC and 0.2PAC), classified according to their therapeutic class. *m* indicates the number of values taken into consideration to calculate the removal efficiency. The compounds in italics correspond to the transformation products. SD: Standard deviation.

Legend

“n.d.” indicates that the OMP was not detected in both INF and MBRperm, hence the removal efficiency was not calculated.

“--” indicates that negative removal efficiencies were obtained on all sampling days of that experimental campaign.

“*” indicates that negative removal efficiencies were obtained on certain sampling days of the corresponding experimental campaign which were then discarded for the calculation of the minimum, maximum and average removal efficiencies. To check the negative values discarded, refer to **Table S14**.

Notes

The term “removal” refers to the change in the load of a given OMP in the MBRperm compared to the load in the INF, as described in **Section 2.5** of the manuscript, regardless of whether it is mineralized, transformed or adsorbed in the system. Samples in which the OMP was not detected (n.d.) in both INF and MBRperm were not taken into consideration for removal efficiency calculation. Instead, the term “negative removal” refers to a higher load in the MBRperm with respect to the INF.

The term “transformation product” refers to compounds that are formed by sub-sequential reactions of the parent compound. These reactions include biodegradation/metabolization in living organisms (i.e., formation of metabolites), and chemical transformations that take place during the transport in the sewage or during the wastewater treatment. Transformation products can be the result of any reaction which does not completely mineralize the parent compound to water and dioxide.

Table S14. Values of negative removal efficiencies of target OMPs obtained during the three experimental campaigns (i.e., noPAC, 0.1PAC and 0.2PAC), classified according to their therapeutic class. Negative values were discarded for the calculation of the minimum, maximum and average removal efficiencies of the corresponding OMPs during each campaign (see **Table S13**). The compounds in italics correspond to the transformation products.

Compound	noPAC		0.1PAC		0.2PAC

Table S15. Range of variability and average occurrence of the 232 target OMPs analyzed in HWW, INF, MBRperm and EFF during the noPAC experimental campaign (only MBR) (March – August 2021). For MBRperm, the frequency of detection (*Freq*) is displayed and the hydraulic retention time was considered for the sampling. The transformation products are written in italics. SD: Standard deviation.

Table S16. Range of variability and average occurrence of the 232 target OMPs analyzed in HWW, INF, MBRperm and EFF during the 0.1PAC experimental campaign (September – November 2021). For MBRperm, the frequency of detection (*Freq*) is displayed and the hydraulic retention time was considered for the sampling. The transformation products are written in italics. SD: standard deviation.

Table S17. Range of variability and average occurrence of the 232 target OMPs analyzed in HWW, INF and MBRperm during the 0.2PAC experimental campaign (April – May 2022). For MBRperm, the frequency of detection (*Freq*) is displayed and the hydraulic retention time was considered for the sampling. The transformation products are written in italics. SD: standard deviation.

Table S18. Range of variability and average load of target OMPs in HWW, INF, MBRperm and EFF during the noPAC experimental campaign (only MBR), classified by OMP class. For MBRperm, the hydraulic retention time was taken into consideration when sampling. The transformation products are written in italics. SD: Standard deviation.

Table S19. Range of variability and average load of target OMPs in HWW, INF, MBRperm and EFF during the 0.1PAC sampling campaign, classified by OMP class. For MBRperm, the hydraulic retention time was taken into consideration in the sampling. The transformation products are written in italics. SD: Standard deviation.

Table S20. Range of variability and average load of target OMPs in HWW, INF and MBRperm during the 0.2PAC sampling campaign, classified by OMP class. For MBRperm, the hydraulic retention time was taken into consideration in the sampling. The transformation products are written in italics. SD: Standard deviation.

Table S20. Range of variability and average load of target OMPs in HWW, INF and MBRperm during the 0.2PAC sampling campaign, classified by OMP class. Text S7. Removal of key OMPs according to their properties.

The removal of OMPs found in wastewater greatly depends on the treatment configuration, operational conditions adopted in the bioreactor as well as the OMP physicochemical properties. Limiting the attention to the latter, it is well known the parameters involved in the removal are manyfold, and that the OMP charge and lipophilicity play an important role in hybrid systems such as a MBR coupled to PAC (Gutiérrez et al., 2022). At the range of pH in which the wastewater is commonly found, most of the OMPs of the current study are found to be in their ionic form (Table S3 and S4), which, to a certain degree, determines the interaction with the mixed liquor and the activated carbon. Besides, the octanol-water dissociation constant (D_{ow}), that is considered the effective hydrophobicity, is also fundamental in determining the predisposition of a substance to be sorbed into the activated carbon or in the sludge (Martínez-Alcalá et al., 2021).

In Figure S3, the average removal efficiencies of the key OMPs obtained in the 0.2PAC campaign are depicted with respect to their prevalent charge and $\log D_{ow}$ at pH = 7. Roughly speaking, cationic compounds containing aromatic rings exhibited better overall removal efficiencies and, in particular, the range of variability was reduced for those with $\log D_{ow} > 1$. In a previous study, the charge was found to be positively correlated with the removal of OMPs in hybrid MBRs coupled to PAC inside the bioreactor (Gutiérrez et al., 2022). As explained in many studies, among them Sipma et al., (2010) and Maillet et al., (2015), the PAC covered by organic matter from the mixed liquor acquires an overall negative surface charge that promotes positive

electrostatic interactions between the cationic compounds and surface of the adsorbent. However, other OMP properties may also influence the removal. For instance, the functional groups responsible for the electrostatic interaction between the OMPs and the surface of the activated carbon are not completely understood and are still under investigation, which may explain the unexpected behavior of certain charged compounds (Kovalova et al., 2013; Reif et al., 2023).

In the absence of adsorption mechanisms, the lipophilicity of the compounds may take the leading role in determining the tendency of an OMP to be sorbed to the activated carbon (with attached DOM) (de Ridder et al., 2011; Kovalova et al., 2013; Mailler et al., 2015). For the key OMPs, this fact did not occur. Uncharged compounds (among them, caffeine and iopromide) showed good overall removal efficiencies, whereas anionic compounds (e.g., ibuprofen and sulfamethoxazole) presented high variability. Since many other OMP parameters (e.g., molecular weight, presence of H-bonds and structure, etc.) as well as real wastewater characteristics, such as OMP load, seasonality and deconjugation of the metabolites, may influence the removal, the expected results may be shifted to a certain extent. Overall, the observed trends are in accordance with previous trends in the literature. However, it must be noted that the prediction of the removal in such a complex water matrix is not as accurate as it is in the case of PAC is used as a post-treatment (Kovalova et al., 2013).

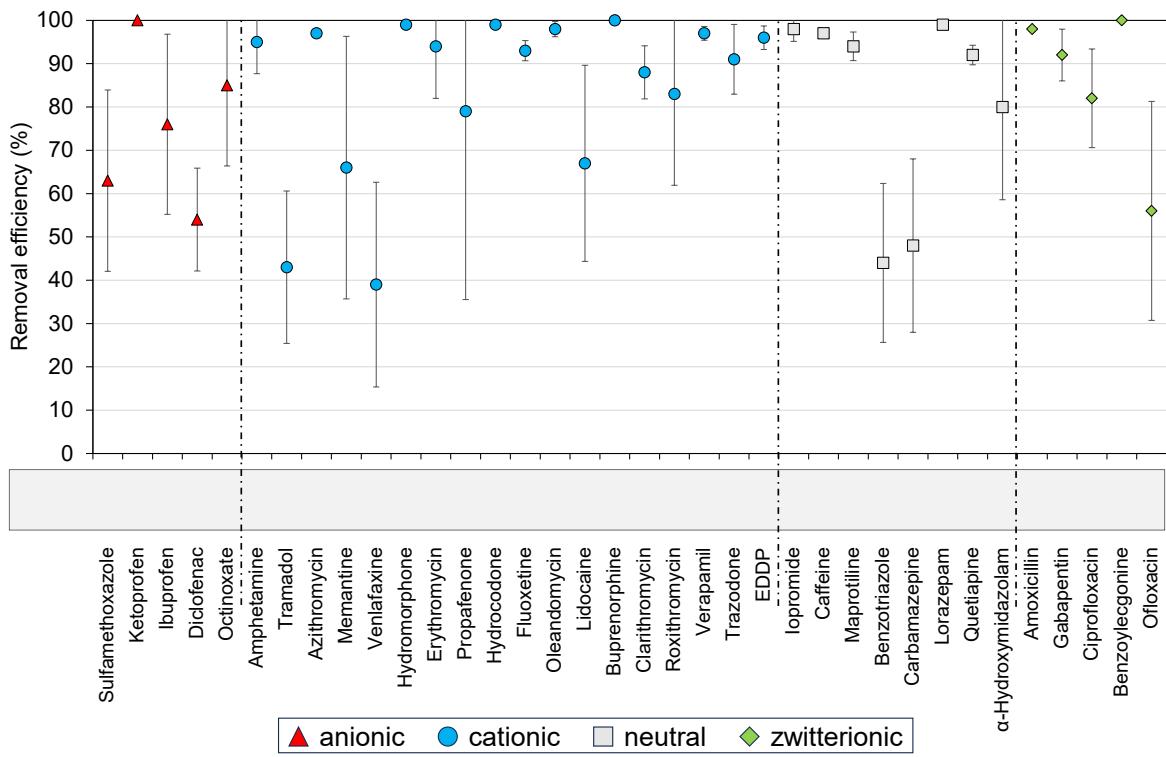

Figure S3. Average removal efficiencies and standard deviation during the 0.2PAC campaign of key OMPs, grouped by their prevalent charge and in increasing order according to their $\log D_{ow}$ at pH = 7.

Text S8. Removal of OMP classes.

The following analysis refers to the OMP classes, and the considerations regard set of compounds belonging to each of the classes, irrespective of the behavior of the single OMP which may differ from the class behavior. Bearing this in mind, the average removal efficiencies of the 20 OMP classes are displayed in Table S21, which refers to the whole list of target OMPs, with four exceptions. This is the case of nitrofural (antiseptic), hydrocortisone (hormone), triamcinolone acetonide (hormone) and metoprolol (beta-blocker). They were discarded since they presented persistent negative and/or highly variably removals and significantly shifted the average removal of the class they pertain to (corresponding to those with a star in Table S21). In addition to these, three additional classes, i.e., antifungals, antihistamines and diuretics, did not have any compound over the LOD during the three campaigns, and thus the corresponding removal could not be calculated. Compounds pertaining to antihypertensives and receptor antagonist classes were only detected during the 0.1PAC campaign, and thus no comparison between the campaigns could be made.

No clear effect of the removal of analgesics/anti-inflammatories, beta-blockers, calcium channel blockers, UV filters and X-ray contrast media was shown due to the PAC addition into the MBR. They all presented very high removal efficiencies in MBR (> 90%), and thus the potential increase in their removal due to PAC addition is not significant. Furthermore, the effect of PAC on analgesics/anti-inflammatories depends on the compound analyzed, which is not the case for the other classes mentioned, including only one or two compounds. Benzotriazole was the compound that mainly influenced the significant decrease in the removal efficiencies obtained in the plastic additives class, since the other compound, *p*-toluenesulfonamide, had a low frequency of detection.

Except for the above-mentioned classes, the eight remaining ones (antiarrhythmic agents, antibiotics, antiparasitics, hormones, illicit drugs, psychiatric drugs, stimulants and veterinary drugs) increased their removal efficiencies during PAC campaigns and, in most cases, a positive correlation with the PAC dosage was observed. Four of these OMP classes contribute the most to the OMP load in the WWTP (Table S9, Figure S4A), and their removals increased between 10% and 35% during the PAC treatment. On the other hand, although the analgesics/anti-inflammatories class had the highest loads in the INF, the high removal efficiencies obtained in the three experimental campaigns significantly reduced their contribution to the load in the MBRperm (Figure S4B) compared to other classes. The same applies for X-ray contrast media, for which the contribution to the MBRperm load accounts for only between 0.4% and 3%. Apart from analgesics/anti-inflammatories, the MBRperm load therefore constituted of mainly antibiotics, psychiatric drugs and plastic additives, due to the high load of certain OMPs which presented low removals (e.g., ofloxacin and benzotriazole) despite the addition of activated carbon.

Table S21. Average removal efficiencies of the main classes of target OMPs analyzed in this study per experimental campaign. *m* represents the number of values (i.e., daily removal efficiencies) used to calculate the average. In brackets, the number of OMPs pertaining to each class. Classes with an * symbol do not consider all the OMPs pertaining to that class when calculating the removal. SD: standard deviation.

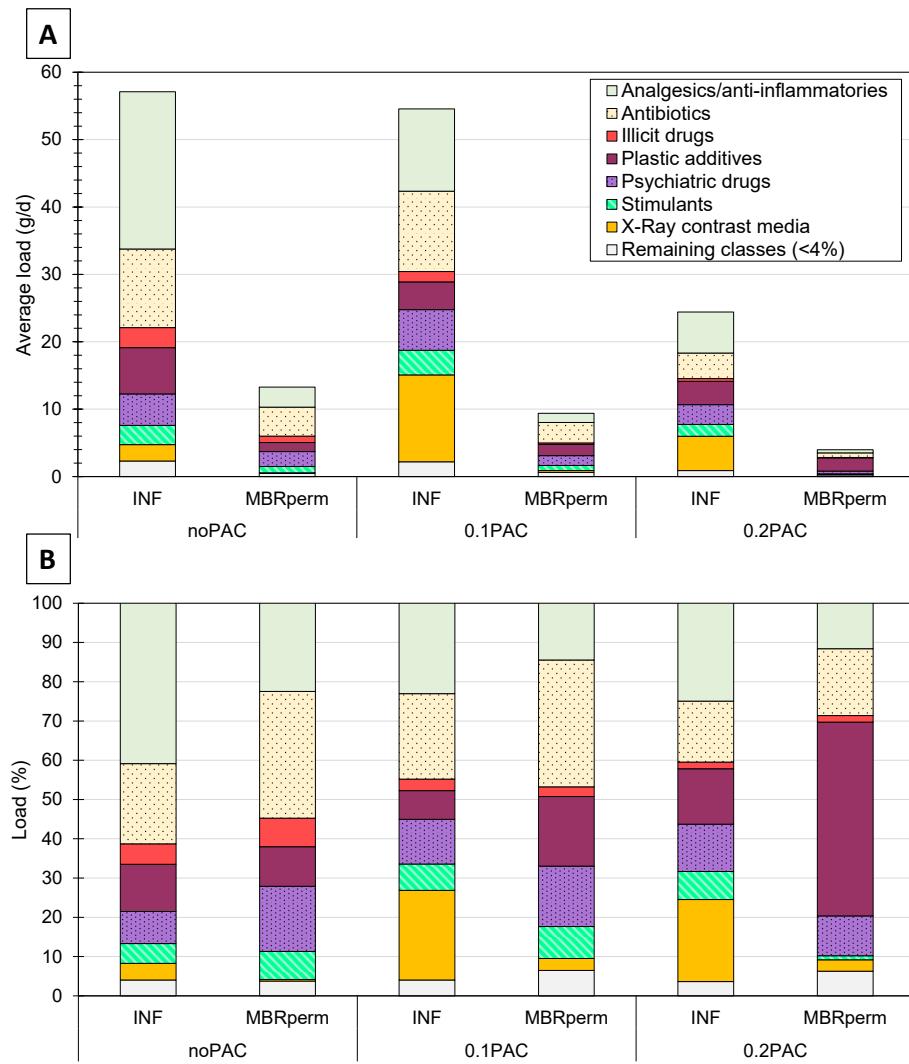

Figure S4. Average load of the main OMP classes (A) and contribution (%) of their loads (B) to the total one in the INF and MBRperm during the noPAC, 0.1PAC and 0.2PAC campaigns.

Text S9. Overall OMP load reduction.

As shown in Figure S5, the average load of OMPs reduced from 171 g/d in the INF to 27 g/d in the MBRperm during the noPAC campaign, from 441 g/d to 85 g/d during 0.1PAC and from 147 g/d to 24 g/d during 0.2PAC, which correspond to 80%, 81% and 84% of the average removal, respectively. Although the average removal was only increased by 4% with the highest dosage of PAC tested, a significant reduction for certain OMPs and OMP classes was described in the above sections, which may have a positive effect on the reduction of the environmental risk which will be discussed in section 3.5.

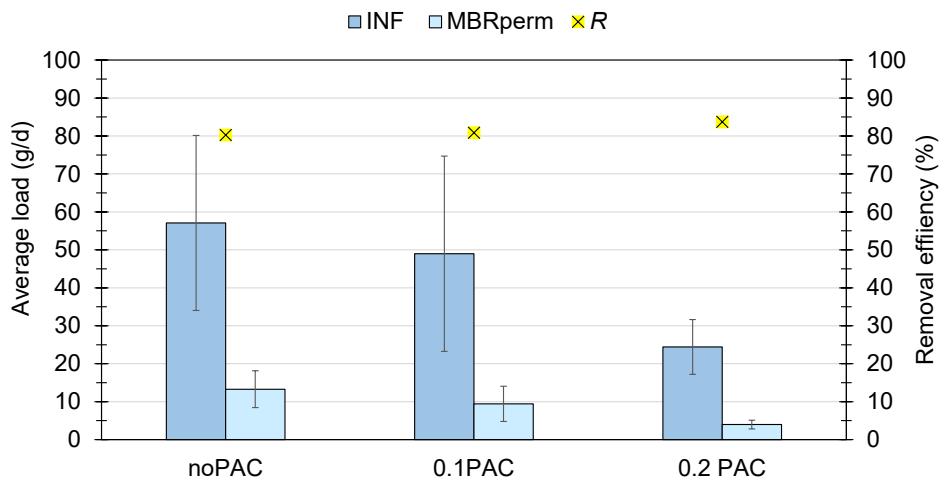

Figure S5. Average load of all target OMPs in the INF and MBRperm in each experimental campaign and corresponding removal efficiencies R (%).

Table S22. Frequency of detection and removal efficiencies in the MBRperm of the 90 non-target OMPs in the three experimental periods (i.e., noPAC, 0.1PAC and 0.2PAC), classified by class. Frequency of detection in HWW and INF consider the three experimental periods together. m is the number of values of removal efficiency taken into consideration to calculate the average. The transformation products are written in italics. SD: Standard deviation.

Table S24. Range of variability and average concentration of target OMPs in the EFF during the noPAC and 0.1PAC campaigns, together with their \overline{RQ} values. At the end of the table, values of RQ_{mix} for the 232 target OMPs and 40 key OMPs¹ during noPAC and 0.1PAC campaigns. In red, $\overline{RQ} > 1$ (high risk). The transformation products are written in italics. SD: standard deviation.

noPAC				0.1PAC		
$RQ_{\text{mix}, 232}$				47		
$RQ_{\text{mix}, 40}$				1.0		

Legend

n.a.: PNEC value was not available in the NORMAN database, and thus the RQ calculation.

¹ 40 key OMPs refer to the 41 key OMPs selected in section 3.1.1 of the manuscript, with the exception of benzoylecgonine, for which the calculation of the RQ value was not possible.
