This systematic review and meta-analysis aimed to examine the effect of the antioxidant alpha-lipoic acid (ALA) on various cardiometabolic risk factors and hormonal parameters in patients with polycystic ovary syndrome (PCOS). We searched PubMed, EMBASE, SCOPUS, Cochrane Library, and Web of Science databases without language restrictions until May 2023 to find randomized controlled trials (RCTs) that assessed the impact of ALA supplementation on anthropometric, glycemic, lipid, oxidative stress, and hormonal parameters in women with PCOS. Outcomes were summarized using the standardized mean difference (SMD) and 95% confidence interval (CI) in a random-effects model. An I<sup>2</sup> statistic of >60% established significant between-study heterogeneity. The overall certainty of the evidence for each outcome was determined using the grading of recommendations, assessment, development, and evaluations system. Seven RCTs met the inclusion criteria. The ALA group had significant reductions in fasting blood sugar (fasting blood sugar (FBS), n=7 RCTs, SMD, -0.60; 95% CI, -1.10 to -0.10; I<sup>2</sup>=63.54%, moderate certainty of evidence) and homeostatic model assessment for insulin resistance (homeostatic model assessment of insulin resistance (HOMA-IR), n=4 RCTs, SMD, -2.03; 95% CI, -3.85 to -0.20; I<sup>2</sup>=96.32%, low certainty of evidence) compared with the control group. However, significant differences were observed between the groups in body mass index, insulin, estrogen, follicle-stimulating hormone, luteinizing hormone, testosterone, low-density lipoprotein, highdensity lipoprotein, triglyceride, total cholesterol, malondialdehyde, or total antioxidant capacity profiles. ALA supplementation improves FBS and HOMA-IR levels in women with PCOS. ALA consumption is an effective complementary therapy for the management of women with PCOS.

Keywords: Thioctic acid; Inositol; Polycystic ovary syndrome; Cardiometabolic risk factors

### Introduction

Polycystic ovary syndrome (PCOS) is a condition that affects the reproductive, metabolic, and hormonal systems. PCOS accounts for 50-70% of all infertility cases in women of childbearing age who are not ovulating [1-3] and affects approximately 10% of women of reproductive age worldwide, with annual medical expenses >\$4 billion in the United States alone [4,5].

PCOS is diagnosed when two of the three criteria listed below are met: irregular menstrual cycles, signs of hyperandrogenism, and polycystic ovaries, while ruling out other causes of hyperandrogenism [6]. In addition to these clinical criteria, the metabolic profile of women with PCOS is significant in the development of this syndrome. High levels of insulin and insulin resistance (IR) have been recognized as crucial factors in PCOS development [7,8]. Insulin sensitizers such as biguanides and glitazones have been proposed as potential therapeutic options for managing hyperinsulinemia in patients [9]. Furthermore, women with PCOS have a high prevalence of several comorbidities, including obesity, ovarian dysfunction, dyslipidemia, hypertension, type 2 diabetes mellitus, and cardiovascular disease [10].

Oxidative stress is characterized by an overabundance of reactive oxygen species (ROS) and an imbalance between oxidants and antioxidants in the body [11]. Women with PCOS have higher levels of oxidative stress indicators in their blood than healthy individuals [12]. Although the exact mechanism of PCOS remains unclear, numerous studies have demonstrated a correlation between oxidative stress and its onset [13].

Supplements containing antioxidants have demonstrated positive outcomes in enhancing insulin sensitivity and addressing health risks in women diagnosed with PCOS [14,15]. Alpha-lipoic acid (ALA), a powerful antioxidant known for reducing oxidative stress and IR, is a notable supplement [16]. Evidence suggests that the controlled release of ALA can improve glucose regulation in women diagnosed with type 2 diabetes mellitus [17]. ALA exhibits robust antioxidant properties, efficiently counteracts ROS, and replenishes additional antioxidant molecules [18]. Moreover, the amalgamation of ALA and myo-inositol has demonstrated advantageous outcomes in countering oxidative stress and IR [19]. These findings suggest that antioxidant supplements such as ALA have the potential to improve insulin sensitivity and effectively manage the negative health impacts of PCOS.

Hence, a comprehensive evaluation was undertaken through a systematic review and meta-analysis of randomized controlled trials (RCTs) to consolidate the existing evidence on the effect of ALA intake, either alone or in combination with inositol, on various anthropometric, glycemic, lipid, and oxidative stress parameters in women with PCOS.

### **Methods**

This investigation was conducted in accordance with the following recommendations outlined in the preferred reporting items for systematic reviews and meta-analyses statement, which serves as a guide for systematic reviews and meta-analyses [20], and was registered in the International prospective register of systematic reviews database (CRD42023422189).

#### 1. Search strategy

We searched PubMed, EMBASE, SCOPUS, Cochrane Library, and Web of Science databases without language restriction. The following search terms were used: ("Alpha-Lipoic Acid," "Lipoic Acid," "Thioctic Acid," "Inositol" "myo-inositol," or "D-chiro-inositol") AND ("Polycystic Ovary Syndrome," "Stein-Leventhal Syndrome," "Sclerocystic Ovarian Degeneration," "Sclerocystic Ovaries," "hyperandrogenism," "Hypertrichosis" "Hirsutism," "PCOS," or "PCO"). Grey literature was searched using OpenGrey. The reference lists of the articles and related reviews were manually evaluated to identify additional relevant papers. The electronic databases were searched from their inception until May 15, 2023. Supplementary Material 1 shows the detailed strategy and syntax used to search each database.

#### 2. Study selection and data extraction

Two researchers screened all titles and abstracts of the articles to remove any unrelated records. Full texts of the remaining records were obtained and evaluated to ensure they met the inclusion criteria. Data of interest were then extracted, and quality appraisals were performed. Any disagreements at each level were resolved through discussions with a third researcher. This systematic review included original papers that met the following criteria: (i) RCT studies, (ii) use of ALA supplementation alone or in combination with other treatments,

Ahmed Abu-Zaid, et al. ALA and PCOS

(iii) studies conducted on women with PCOS, and (iv) studies with a treatment duration of at least 2 weeks. The exclusion criteria were as follows: (i) observational studies, case series, reviews, and case reports; (ii) studies without an appropriate control group; (iii) studies that lacked sufficient data on the variables of interest; and (vi) experimental, in vitro, and laboratory studies. The following information was extracted from the included RCTs: (i) the first author's last name; (ii) the year of publication; (iii) the country of origin; (iv) the sample size: (v) the dose and duration of ALA supplementation; (vi) age of patients; and (vii) the main outcomes of the variables of interest, such as body mass index (BMI), fasting blood sugar (FBS), insulin, homeostatic model assessment of insulin resistance (HOMA-IR), total cholesterol (TC), triglyceride (TG), high-density lipoprotein (HDL), low-density lipoprotein (LDL), malondialdehyde (MDA), total antioxidant capacity (TAC), estrogen, follicle-stimulating hormone (FSH), luteinizing hormone (LH), and testosterone.

#### 3. Quality assessment and data synthesis

The Cochrane risk-of-bias assessment tool was used to evaluate systematically the risk of bias in the selected trials [21]. The following criteria were applied: adequacy of random sequence generation, allocation concealment, blinding, addressing dropouts (incomplete outcome data), selective outcome reporting, and other possible sources of bias. The overall certainty of evidence for the obtained effect size of each variable of interest was determined using the grading of recommendations, assessment, development, and evaluations (GRADE) system [22].

In anticipation of potentially high heterogeneity among the published articles, the significance of the net alteration between the ALA intake and control groups was evaluated using the standardized mean difference (SMD) and its 95% confidence interval (CI). Heterogeneity was assessed using the I<sup>2</sup> statistic (significant when I<sup>2</sup> was >60%) and Cochrane Q test (significant at *P*<0.1). The restricted maximum likelihood random effects model was used to calculate the pooled effect sizes of the variables of interest. The sensitivity of the effect size was assessed using the leave-one-out method. Statistical analysis was conducted using Stata/SE 17.0 for Windows (StataCorp, College Station, TX, USA).

### Results

#### 1. Results of database search

The electronic database search yielded 708 relevant records. After eliminating duplicate articles and excluding non-eligible records, 19 articles were evaluated in full-text format. Finally, seven articles [23-28] met the inclusion criteria for quantitative synthesis, and 12 articles were excluded. Of the 12 excluded articles, nine were excluded because they were not RCTs. Two articles were excluded because they provided insufficient information about their studies. One article with irretrievable data was excluded after careful consideration. Fig. 1 shows the flow diagram of the inclusion process.

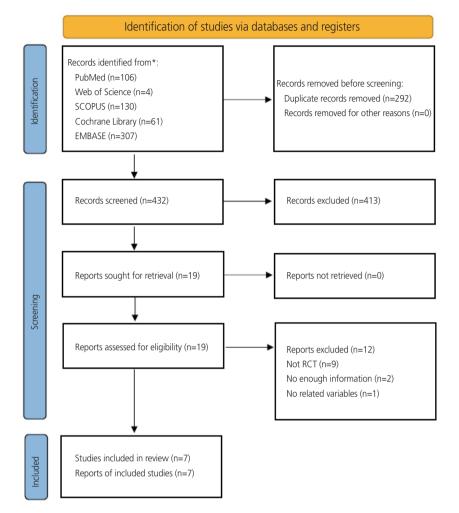

#### 2. Summary of RCT characteristics

Table 1 summarizes the main characteristics of the included studies. Three studies were conducted in Italy [24,25,28], two in Iran [23,27], one in Russia [26], and one in Egypt [29]. All the included studies were conducted between 2015 and 2023. The sample sizes of the included studies ranged from 38 to 71 women with PCOS. The participants in the included RCTs were generally young adults aged 21-37 years and were overweight, with a BMI range of 21-30 kg/m<sup>2</sup>. The ALA dose ranged from 600 to 1,800 mg/day, with a median supplementation duration of 15 weeks (6-25 weeks). Five of the included studies evaluated the effects of ALA supplementation alone [23,26-29]. However, two of the included trials investigated the effects of ALA supplementation in combination with D-chiro-inositol [24] and myo-inositol [25]. We performed a subgroup analysis of all variables to determine the effect of ALA alone or in combination with inositol on the variables of interest in women with PCOS. Supplementary Fig. 1 shows the risk of bias assessment report for the included studies. Supplementary Fig. 2 shows the sensitivity analysis results of the included studies. Supplementary Fig. 3 shows the certainty of evidence for each variable based on the GRADE approach.

#### 3. Summary of qualitative results

Two of the included studies evaluated the effect of ALA supplementation on lipid profiles in women with PCOS [24,28]. Their results indicated that ALA intake did not affect TC, TG, HDL, or LDL levels. Two additional studies were included in our systematic review that reported the effects of ALA supplementation on oxidative stress parameters in

Vol. 67, No. 1, 2024

**Fig. 1.** The preferred reporting items for systematic reviews and meta-analyses flow diagram. RCT, randomized controlled trial. \*The electronic databases were searched from their inception until May 15, 2023.

women with PCOS [23,27]. Both studies indicated that ALA intake in women with PCOS led to a significant decrease in MDA levels and a significant increase in TAC levels. However, the limited number of included studies prevented us from performing a meta-analysis to draw clear conclusions.

#### 4. Summary of meta-analysis

The overall findings of our meta-analysis of five trials showed no significant difference in BMI after ALA supplementation in women with PCOS (SMD, -0.06; 95% CI, -0.39 to 0.27;  $I^2$ =43.46%, low certainty of evidence) (Fig. 2). No significant difference was observed after stratifying the studies based on ALA dosage and its combination with inositol (whether in combination or not) (Table 2).

The effect of ALA supplementation on glycemic param-

eters in women with PCOS indicated that ALA intake significantly decreased FBS (SMD, -0.60; 95% CI, -1.10 to 0.10;  $l^2$ =63.54%, moderate certainty of evidence) and HOMA-IR (SMD, -2.03; 95% CI, -3.85 to -0.20;  $l^2$ =96.32%, low certainty of evidence), but did not affect insulin levels (SMD, -1.48; 95% CI, -3.04 to 0.07;  $l^2$ =97.66%, very low certainty of evidence) (Fig. 2). However, our sensitivity analysis indicated that the insulin levels significantly decreased after ALA supplementation when we excluded the Hamed et al. [29] study (SMD, -0.74; 95% CI, -1.40 to -0.08; Supplementary Fig. 2). The results of the subgroup analysis demonstrated that ALA supplementation alone significantly reduced FBS levels compared to ALA combined with inositol. HOMA-IR was significantly decreased with ALA supplementation of  $\leq$ 600 mg/day compared to >600 mg/day. Furthermore,

Random-effects REML model

**Fig. 2.** The effect of alpha-lipoic acid intake on body mass index (A), fasting blood sugar (B), insulin (C), homeostatic model assessment for insulin resistance (D), estrogen (E), follicle-stimulating hormone (F), luteinizing hormone (G), and testosterone (H) in women with polycystic ovary syndrome. SD, standard deviation; SMD, standardized mean difference; CI, confidence interval; REML, restricted maximum likelihood. (Continued)

insulin levels significantly decreased with combined ALA and inositol supplementation compared to ALA supplementation alone (Table 2).

The results of the meta-analysis indicated that ALA supplementation did not affect estrogen (SMD, -0.02; 95% CI, -0.29 to 0.25;  $l^2=0\%$ , low certainty of evidence), FSH (SMD, -2.16; 95% CI, -4.35 to 0.03;  $l^2=97.95\%$ , very low certainty of evidence), LH (SMD, -3.28; 95% CI, -6.70 to 0.15;  $l^2=99.10\%$ , very low certainty of evidence), and testosterone (SMD, 0.12; 95% CI, -0.20 to 0.44;  $l^2=0\%$ , low certainty of evidence) levels in women with PCOS than in the control group (Fig. 2). The subgroup analysis showed that FSH levels significantly decreased in individuals receiving  $\leq$ 600 mg/day of ALA compared to those receiving >600 mg/day. Additionally, FSH levels significantly decreased when ALA was supplemented alone. Subgroup analysis also indicated that LH levels significantly decreased when ALA was supplemented for  $\leq$ 12 weeks compared to >12 weeks. Additionally, LH levels decreased in the  $\leq$ 600 mg/day dose of ALA compared to >600 mg/day dose. Finally, LH levels decreased significantly after ALA supplementation alone than after combined ALA and inositol supplementation (Table 2).

### Conclusion

-0.5 0 0.5 1

This systematic review and meta-analysis of RCTs indicate that ALA supplementation effectively reduces FBS levels (moderate certainty of evidence) and may effectively decrease HOMA-IR levels (low certainty of evidence) in women with PCOS. However, no substantial impact was observed on BMI or insulin, estrogen, FSH, LH, and testosterone lev-

Table 2. Subgroup analysis of all outcomes based on ALA dosage, duration of supplementation, and combination with inositol (Continued)

ALA, alpha-lipoic acid; SMD, standardized mean difference; CI, confidence interval; BMI, body mass index; FBS, fasting blood sugar; HOMA-IR, homeostatic model assessment for insulin resistance; E2, estrogen; FSH, follicle-stimulating hormone; LH, luteinizing hormone. <sup>a)</sup>Statistically significant (*P*<0.05).

els in women with PCOS. However, the assessment using the GRADE framework suggests low and very low certainty of evidence for the above findings. Therefore, these results should be approached with caution. Furthermore, our systematic review showed no substantial influence of ALA intake on lipids (TC, TG, LDL, and HDL) or oxidative stress (MDA and TAC) parameters in women with PCOS. To our knowledge, this systematic review and meta-analysis is the first to examine the effect of ALA alone or in combination with inositol based on anthropometric, glycemic, lipid, oxidative stress, and hormonal parameters in women with PCOS.

Several studies have proposed that combining inositol with ALA may enhance its effects [30]. The influence of ALA on reproductive hormones seems minimal. However, its beneficial effects are probably restricted to metabolic aspects, specifically in women with PCOS and IR [30].

This systematic review and meta-analysis suggest that adding ALA to the diet does not affect the BMI of women with PCOS. Furthermore, no significant difference was observed in the BMI when inositol was combined with ALA at various dosages. These results contradict those of previous studies indicating a positive effect of ALA supplementation on BMI. Previous systematic reviews and meta-analyses demonstrated that ALA administration can significantly reduce BMI levels [31-33]. The limited number of included trials and different pathophysiologies of PCOS may have contributed to our inability to determine a significant effect of ALA on BMI.

Analysis of the collected data indicated that ALA supplementation did not significantly affect insulin levels. However, the effects of ALA on insulin levels were marginally insignificant, and ALA showed a non-significant trend toward decreasing insulin levels. Regarding the effect of ALA intake on insulin levels, our findings are consistent with those of Rahimlou et al. [17], who could not detect any significant effects of ALA supplementation on insulin levels. However, our results are inconsistent with those of Mahmoudi-Nezhad et al. [34], who reported a significant decrease in insulin levels following ALA administration. This inconsistency may be due to high heterogeneity among the included trials and the limited number of trials in our systematic review. Subgroup analysis of insulin indicated that combined ALA and inositol significantly decreased insulin levels compared to ALA alone. However, it is imperative to note that owing to the limited number of included studies in each subgroup, these results must be interpreted carefully, and larger studies are needed to further clarify and validate these findings.

The findings of the current systematic review on the effect of ALA on FBS are consistent with those of previous systematic reviews, demonstrating that ALA intake can lower FBS levels [17,35]. Regarding HOMA-IR, our results indicate a Vol. 67, No. 1, 2024

significant reduction after ALA supplementation in HOMA-IR compared to the control group, consistent with previous studies [34].

Several explanations have been proposed for the potentially favorable effects of ALA supplementation on high FBS levels and IR [36]. Research has indicated that ALA may affect FBS levels by promoting glucose absorption through improved transportation of the glucose transporter type 4 to the membranes of fat and muscle cells [37,38]. According to Jacob et al. [39], intravenous administration of 1,000 mg ALA improved insulin sensitivity and the rate at which the body cleared metabolized insulin in patients with type 2 diabetes mellitus. Additionally, the significant effect of ALA on FBS is because of increased glucose transport activity in skeletal muscles [40,41]. However, it is crucial to acknowledge that the influence of ALA extends beyond skeletal muscles, as it inhibits gluconeogenesis and glucose production in the liver [42,43]. Furthermore, ALA exerts a partially positive impact on insulin metabolic pathways [44]. Numerous studies have indicated that ALA boosts the efficiency of distinct proteins involved in the insulin signaling pathway, such as insulin receptor, phosphatidylinositide 3-kinase [45], insulin receptor substrate 1 [46,47], and protein kinase B [48]. Owing to these effects, ALA is often described as a substance that emulates the functions of insulin. Lee et al. [49] demonstrated that ALA stimulates AMP-activated protein kinase (AMPK) activation in skeletal muscles. These results suggest that the improvement in insulin sensitivity induced by ALA was mediated by AMPK activation [50].

This systematic review and meta-analysis results indicate that ALA supplementation does not significantly affect hormonal parameters, including estrogen, FSH, LH, and testosterone levels in women with PCOS. However, subgroup analysis suggested that ALA supplementation at a dosage of <600 mg/day significantly decreased FSH and LH levels compared to a dosage of >600 mg/day. Subgroup analysis demonstrated that ALA alone significantly decreased FSH and LH levels compared to ALA combined with inositol. The subgroup analysis indicated that compared to >12 weeks, ALA supplementation decreased LH levels in  $\leq$ 12 weeks. However, it is important to note that because of the limited number of included studies in each subgroup, these results must be interpreted carefully, and larger studies are needed to further clarify and validate these findings.

Our study had several limitations. First, the included RCTs

originated from four countries, which may have affected the generalizability of the results. Second, although ALA demonstrated the most notable variation in supplementation, other minor modifications could complicate the effect of ALA on the cardiometabolic and hormonal aspects of individuals with PCOS. Other potential factors influencing cardiometabolic markers also exist, such as vitamin D levels and alterations in gut microbiomes. Third, certain trials lacked sufficient information regarding the characteristics of the participants, including BMI and age, making it difficult to accurately categorize these studies into specific subgroups. Fourth, some variables were available in a few studies, which impedes the ability to draw definitive conclusions and conduct more detailed subgroup analyses. Their interpretation should be exercised with extreme caution. Finally, significant variability was observed among the studies, which should be considered when interpreting the conclusions and outcomes of this meta-analysis.

ALA will beneficially reduce FBS levels and may favorably improve IR (by decreasing HOMA-IR) in women with PCOS. However, further research is necessary to validate these findings, particularly when combined with inositol and hormone supplementation. Furthermore, studies focusing on the influence of ALA on other PCOS features, such as fertility and pregnancy rates, are needed. Nevertheless, regarding clinical application, ALA is an effective complementary therapy for managing PCOS. The favorable antioxidant and anti-inflammatory properties of ALA can help decrease cardiometabolic risk factors, including IR, in women with PCOS.
