**Abstract:** Herein, as an indispensable key reactant for the hydrolysis of organic sulfur, H<sub>2</sub>O was firstly introduced to optimize the NH<sub>3</sub>-SCR activity of CeO<sub>2</sub> by providing the adsorption and reaction spots of catalysis for organic CS<sub>2</sub>+COS during the low-temperature gas-phase sulfation. The results demonstrate that the introduction of 0.33 vol.% H<sub>2</sub>O is beneficial to enhance the interaction between organic CS<sub>2</sub>+COS and cube fluorite CeO<sub>2</sub>, which not only increases the concentrations of Ce<sup>3+</sup> ions, chemisorbed oxygen (O<sub>β</sub>) and oxygen vacancies on CeO<sub>2</sub>-CS<sub>2</sub>+COS surface, but also effectively enhances the redox cycle of Ce<sup>4+</sup>/Ce<sup>3+</sup> ion pairs and the medium-strong acid sites of catalyst. These all help enhance the promotional effect of organic sulfur low-temperature gas-phase sulfation on the NH<sub>3</sub>-SCR activity of CeO<sub>2</sub> and further improve NO<sub>x</sub> reduction over the CeO<sub>2</sub>-CS<sub>2</sub>+COS catalyst. However, the introduction of 5.0 vol.% H<sub>2</sub>O shows a certain inhibitory effect due to the competitive adsorption of excess water and COS+CS<sub>2</sub> on the cube fluorite CeO<sub>2</sub> surface, which weakens their interaction during the low-temperature gas-phase sulfation, thereby decreases the promotional effect of low concentration water introduction on the NH<sub>3</sub>-SCR activity of the CeO<sub>2</sub>-CS<sub>2</sub>+COS catalyst. Therefore, the results of this research provide a scientific reference for developing the NH<sub>3</sub>-SCR CeO<sub>2</sub>-based catalyst in practical applications.

**Keywords:** NH<sub>3</sub>-SCR, CeO<sub>2</sub>, Organic sulfur, Low-temperature gas-phase sulfation, H<sub>2</sub>O concentration

## 30 **1. Introduction**

31 The rapid development of global economy inevitably leads to an intense demand of energy  
32 or/and fuel, thus the traditional fossil fuels (coal, oil, and natural gas, etc.) have been extensively  
33 utilized in power generation, transportation and industry [1-3]. However, large fine particulate  
34 matter (PM 2.5) and greenhouse gases (CO<sub>2</sub>, CH<sub>4</sub>, etc.) are discharged during the utilization of  
35 fossil fuels and 3 million tons of CO<sub>2</sub> can be emitted for a 500MW coal-fired power plants per  
36 year, and the concentration of CO<sub>2</sub> in the atmosphere is expected to exceed 500 ppm by 2050  
37 [4,5]. In addition, the toxic and harmful gases such as nitrogen oxides (NO<sub>x</sub>, mainly NO and NO<sub>2</sub>)  
38 and sulfur-containing compounds (SO<sub>2</sub>, COS, CS<sub>2</sub>, etc.) are also produced during the combustion  
39 of fossil fuels, which brings many environmental problems [6,7]. For example, the emission of  
40 nitrogen oxides and sulfur compounds are prone to oxidation reactions, causing acid rain,  
41 photochemical smog, ozone holes and other environmental disasters [8-10]. Therefore, it is  
42 necessary to develop an effective method to reduce nitrogen oxide and sulfur compounds.

43 Compared to inorganic SO<sub>2</sub>, organic carbonyl sulfide (COS) and carbon disulfide (CS<sub>2</sub>) are  
44 linear triatomic molecules similar to carbon dioxide (CO<sub>2</sub>), which are less reactive and difficult  
45 to be removed [11,12]. At present, catalytic hydrolysis [13,14], hydrogenation [15,16],  
46 adsorption and absorption [17-19] have been developed to reduce the emission of organic sulfur.  
47 Among them, catalytic hydrolysis has the advantages of low energy consumption, less side  
48 reactions and high efficiency, especially when dealing with high levels of organic sulfur. Wang et  
49 al. found that the synthesized (Co+Ni)/Al catalyst derived from various hydrotalcite-like  
50 compounds presented a good catalytic hydrolysis activity of COS, and the introduction of Ce  
51 additive effectively improved its catalytic performance due to the alterations of the structural  
52 properties, oxidation properties and surface defect sites [20,21]. At present, the development of  
53 the low temperature hydrolysis catalyst to reduce organic sulfur has attracted widespread  
54 attention, especially the metal oxide catalysts with a rich pore structure, a good thermal stability,  
55 abundant basic sites and a strong anti-poisoning ability. For instance, the introduction of 3DOM  
56 structure via the colloidal crystal template method is beneficial to the extraction of the hydrolysis  
57 product H<sub>2</sub>S from the aluminum-based and titanium-based hydrolysis catalysts, inhibiting the

58 deposition of sulfate species on catalysts surface [22].

59 Generally, the hydrolysis of organic sulfur is an alkali-catalyzed reaction process: H<sub>2</sub>O  
60 firstly adsorbs and dissociates on metal oxides surface to form -OH groups, and then CS<sub>2</sub>  
61 preferentially adsorbs on the surface basic sites of catalyst and generates thiocarbonate (HSCO<sub>2</sub><sup>-</sup>)  
62 or COS intermediates via the interaction of -OH group and M-O pair (M: Ti, Al, Fe, Ce, etc.).  
63 Subsequently, the formed COS can further be converted into HSCO<sub>2</sub><sup>-</sup> through the above  
64 hydrolysis reaction pathway, and the intermediate of HSCO<sub>2</sub><sup>-</sup> finally decomposes into CO<sub>2</sub> and  
65 H<sub>2</sub>S under the action of -OH group and M-O pair to complete the catalytic hydrolysis of organic  
66 sulfur [23-27]. Therefore, the surface basic sites of catalyst play a dominant role on the  
67 hydrolysis activity of organic sulfur. It should be noted that the active -OH groups on the catalyst  
68 surface can serve as an alkaline site for the adsorption and activation of organic sulfur, thus  
69 promotes the hydrolysis reaction. A large number of literatures had also investigated the effect of  
70 H<sub>2</sub>O on the hydrolysis efficiency of organic sulfur. Gao et al. [28] pointed out that the absorbed  
71 H<sub>2</sub>O could dissociate into generate active -OH groups for the hydrolysis reaction of COS on  
72 catalyst surfaces, thus ensured the stable and efficient hydrolysis of organic sulfur. Wang et al.  
73 [29] found that the presence of H<sub>2</sub>O on the alumina catalyst surface slowed down the  
74 deactivation process of organic sulfur hydrolysis by promoting the deposition and adsorption of  
75 sulfur and sulfate species at different sites. It is worth noting that the presence of H<sub>2</sub>O also has a  
76 negative effect on the hydrolysis removal of COS/CS<sub>2</sub>. Gu et al. [25] reported that the excessive  
77 H<sub>2</sub>O on catalyst surface led to a competitive adsorption with COS, which inhibited the hydrolysis  
78 reaction and reduced the COS removal efficiency. This phenomenon had also been found in the  
79 hydrolysis process of CS<sub>2</sub> [30]. Furthermore, the presence of H<sub>2</sub>O could promote the formation  
80 of sulfur-containing species (sulfates), which had been considered to be the main reason for the  
81 deactivation of organic sulfur hydrolysis for catalysis [26]. Because the accumulation of  
82 sulfur-containing species on the catalyst surface led to the blockage of pore structure, and also  
83 reduced the basic sites of catalyst due to the formation of surface sulfates, resulting in the  
84 deactivation of organic sulfur hydrolysis [23,31]. Therefore, H<sub>2</sub>O plays an essential role in the  
85 formation of sulfur-containing species during the hydrolysis process of organic sulfur.

86 Owing to the unique 4f electronic structure, CeO<sub>2</sub> presents an excellent oxygen storage  
87 capacity (OSC) and redox ability [32], which has been used as the main active components or

88 doping additives in the selective catalytic reduction of  $\text{NO}_x$  with  $\text{NH}_3$  ( $\text{NH}_3$ -SCR). However, pure  
89  $\text{CeO}_2$  exhibits bad  $\text{NH}_3$ -SCR performance due to the poor surface acidity and  $\text{NH}_3$  peroxidation  
90 at high temperatures, which limits its application in engineering. Interestingly, the formed  
91 surface sulfates during the hydrolysis of organic sulfur might retain Lewis acid sites and enhance  
92 Brønsted acid sites of  $\text{CeO}_2$ , thus contributes to the adsorption and activation of  $\text{NH}_3$  on it  
93 surface [33,34]. Actually, the formed sulfate species can serve as the reducible species to  
94 promote redox reactions and improve the  $\text{NH}_3$ -SCR activity of cerium-based catalysts [35,36].  
95 Therefore, the sulfation treatment, including the gas-phase sulfation of the traditional  $\text{SO}_2$  and  
96 the liquid-phase sulfation of  $\text{H}_2\text{SO}_4/(\text{NH}_4)_2\text{SO}_4/\text{CS}(\text{NH}_2)_2$ , have been regarded as the effective  
97 strategy to improve the de-nitrification activity of cerium-based catalysts mainly via optimizing  
98 the surface acidity [37-42]. Our previous study [33] showed that the gas-phased sulfation of  
99 organic sulfur ( $\text{CS}_2$  or  $\text{COS}$ ) at  $300\text{ }^\circ\text{C}$  presented a better improvement on the  $\text{NH}_3$ -SCR activity  
100 of  $\text{CeO}_2$  than the traditional  $\text{SO}_2$ . Recently, we have found that the gas-phased sulfation of  $\text{CS}_2$   
101 or/and  $\text{COS}$  under the low-temperature hydrolysis conditions can further improve the catalytic  
102 performance of  $\text{NO}_x$  reduction over the  $\text{CeO}_2$  catalyst. The above references indicated that the  
103 presence of  $\text{H}_2\text{O}$  contributed to regulating the formation of sulfur-containing species on the  
104 catalyst surface during the low-temperature hydrolysis process, thus might affect the surface  
105 acidity of the used cerium-based catalyst, which had been widely proven to improve the  
106  $\text{NH}_3$ -SCR activity of  $\text{CeO}_2$ . However, the promotional effect of low-temperature hydrolysis of  
107 organic  $\text{CS}_2$  or/and  $\text{COS}$  on the  $\text{NH}_3$ -SCR activity of  $\text{CeO}_2$  catalyst has rarely been studied,  
108 especially under the presence of  $\text{H}_2\text{O}$ .

109 Furthermore,  $\text{H}_2\text{O}$  widely co-present with organic sulfur in blast furnace gas, which can  
110 affect the hydrolysis of  $\text{CS}_2$  or/and  $\text{COS}$  over catalysts. Meanwhile, cerium oxide had been  
111 verified to improve the anti-oxygen poisoning of catalyst for the hydrolysis of organic sulfur by  
112 avoiding the sulfation of active species due to its better adsorption of sulfates [21,24]. Therefore,  
113 as an indispensable key reactant for the hydrolysis of organic sulfur,  $\text{H}_2\text{O}$  is proposed for the first  
114 time to improve the  $\text{NH}_3$ -SCR catalytic activity of  $\text{CeO}_2$  during the low-temperature gas-phase  
115 sulfation of organic  $\text{CS}_2$  and  $\text{COS}$ , which is more conducive to the synthesis of catalysts with  
116 excellent performance in practical engineering. The results demonstrate that the introduction of  
117  $\text{H}_2\text{O}$  further enhances the promotional effect of  $\text{CS}_2+\text{COS}$  gas-phase sulfation on the  $\text{NH}_3$ -SCR

118 activity of CeO<sub>2</sub> catalyst at the simulated low-temperature for the hydrolysis of organic sulfur.  
119 Furthermore, a series of characterization techniques were employed to investigate the sulfuric  
120 acid optimized strategy of the "CS<sub>2</sub>+COS+H<sub>2</sub>O" gas-phase sulfation on the physicochemical  
121 properties, reduction properties, sulfate species, and NH<sub>3</sub>-SCR performance of CeO<sub>2</sub>.

## 122 2. Experimental

### 123 2.1. Catalyst preparation

124 Pure CeO<sub>2</sub> was synthesized via a one-pot hydrothermal method [33,43], and the used  
125 cerium nitrate (Ce(NO<sub>3</sub>)<sub>3</sub>·6H<sub>2</sub>O, AR), ammonium bicarbonate (NH<sub>4</sub>HCO<sub>3</sub>, AR) and hydrogen  
126 peroxide (H<sub>2</sub>O<sub>2</sub>, AR) were purchased from China Pharmaceutical Group Chemical Reagents Co.,  
127 Ltd. According to the preparation of CeO<sub>2</sub> in Scheme 1, 0.005 mol Ce(NO<sub>3</sub>)<sub>3</sub>·6H<sub>2</sub>O was firstly  
128 dissolved in deionized water and stirred violently for 2 hours until a clear and transparent  
129 solution was obtained. Next, a certain amount of ammonium bicarbonate was added into the  
130 mixed solution with a milky white suspension formed. After being stirred for 30 minutes, 9 mL  
131 of H<sub>2</sub>O<sub>2</sub> (10 mol/L) was dropped and the milky white solution quickly turned into orange. Finally,  
132 the mixed solution was poured into a 100 mL of polytetrafluoroethylene and transferred to  
133 stainless steel autoclave. After being hydrothermally heated at 200 °C for 24 hours, the resulting  
134 precipitate was washed with deionized water and anhydrous ethanol until the pH reached 7. The  
135 obtained precipitate was dried at 80 °C for 12 hours and calcined at 400 °C for 5 hours in a  
136 temperature-programmed muffle furnace to obtain pure CeO<sub>2</sub> catalyst.

137

138 **Scheme 1.** Schematic diagram for the preparation of pure CeO<sub>2</sub> by the one-pot hydrothermal method.

139 The gas phase sulfation of CeO<sub>2</sub> was carried out in a tube furnace according to the  
140 following sulfation conditions (Scheme 2): the total gas flow rate of the simulated COS and CS<sub>2</sub>  
141 (the molar ratio of 7:3) is 500 mL/min by ensuring the concentration of S element being 200 ppm  
142 [33]. A certain concentration of H<sub>2</sub>O was introduced into the vulcanization test bench via an  
143 injection pump and N<sub>2</sub> was used as the equilibrium gas. The gas-phase sulfation was carried out

144 at 50 °C for 3 hours. For convenience, the pretreated samples were labeled as CeO<sub>2</sub>-CS<sub>2</sub>+COS  
145 without water, CeO<sub>2</sub>-CS<sub>2</sub>+COS-H<sub>2</sub>O(*x*), where *x* represents the concentration of water (*x* =  
146 0.33%, 1.5%, 5.0%).  
147

148

149

**Scheme 2.** The low temperature gas-phase sulfation of CeO<sub>2</sub> catalyst by organic sulfur.

## 150 2.2. Catalytic activity test

151 The fixed bed reactor was used to test the NH<sub>3</sub>-SCR catalytic performance of catalysts. The  
152 dosage of sample and the total gas flow rate are 0.45 g (40~60 mesh) and 1500 mL/min with the  
153 gas hourly space velocity (GHSV) being 200,000 mL/(g·h). The flue gas reaction conditions are  
154 as follows: 600 ppm NH<sub>3</sub>, 600 ppm NO, 5 vol.% O<sub>2</sub> and 99.999 vol.% N<sub>2</sub> used as the equilibrium  
155 gases. The concentration of inlet and outlet flue gas (O<sub>2</sub>, NO<sub>x</sub>) was continuously monitored by  
156 T-350 flue gas analyzer (Testo, Germany). Then, the NO<sub>x</sub> conversion rate ( $\eta$ ) is calculated  
157 according to the following formula:  $\eta = (1 - [\text{NO}_x]_{\text{out}} / [\text{NO}_x]_{\text{in}}) \times 100\%$ , where  $[\text{NO}_x]_{\text{in}}$  and  $[\text{NO}_x]_{\text{out}}$   
158 represent the inlet and outlet concentrations of gaseous NO<sub>x</sub> (NO and NO<sub>2</sub>), respectively.

## 159 2.3. Catalyst characterizations

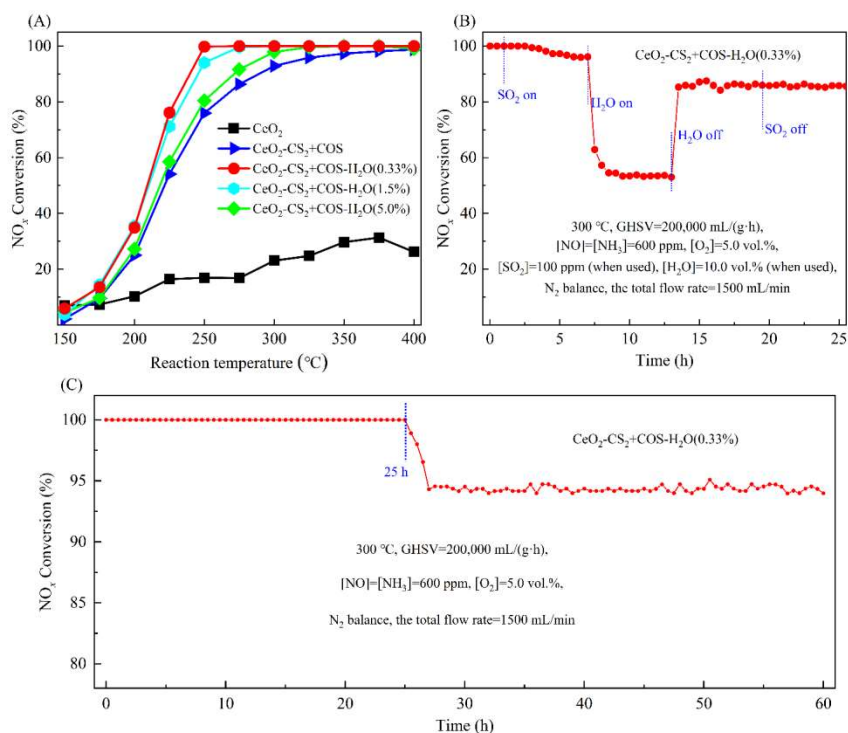

160 The surface morphology and structure of catalyst were observed through scanning electron  
161 microscopy (SEM) using the ZEISS SIGMA HD instrument. The N<sub>2</sub> adsorption-desorption  
162 curves were measured at -196 °C using a powder technology ASAP 2460 system instrument. The  
163 specific surface area was calculated through the Brunauer-Emmett-Teller (BET) method, while

164 the Barrett Joyner-Halenda (BJH) method was used to determine the pore volume and pore size  
165 distribution. X-ray diffraction (XRD) patterns were obtained using Cu K $\alpha$  radiation on a 6100  
166 X-ray diffractometer (Rigaku, Japan) at a scanning rate of 5 °/min from 2 $\theta$ =10 ° to 80 ° and the  
167 composition of the diffraction peaks was analyzed using MDI Jade 6.0. Raman spectra of  
168 samples were collected on a Raman spectrometer (InVia Reflex, Renishaw), where a laser with a  
169 wavelength of 532 nm was used as the excitation source. Fourier transform infrared (FTIR)  
170 spectra ranging from 400 to 4000 cm<sup>-1</sup> were recorded using a Nicolet iS5 FTIR spectrometer,  
171 with a resolution of approximately 4 cm<sup>-1</sup>.

172 The X-ray photoelectron spectrometer (XPS, Thermo Fisher Scientific Escalab 250 Xi)  
173 utilizes Al K $\alpha$  radiation with an excitation energy of 1486.7 eV. The photoelectron spectroscopy  
174 was calibrated with the C1s signal with a binding energy of 284.8 eV and the spectrum was fitted  
175 with the Gaussian-Lorentz function using XPSPEAK software. H<sub>2</sub>-temperature programmed  
176 reduction (H<sub>2</sub>-TPR) and NH<sub>3</sub>-temperature programmed desorption (NH<sub>3</sub>-TPD) analyses were  
177 performed using the AutoChem II 2920 instrument from Micromeritics, along with a thermal  
178 conductivity detector (TCD). In the H<sub>2</sub>-TPR detection process, 100 mg samples were pretreated  
179 in an Ar atmosphere at 300 °C for 30 minutes, and then cooled to room temperature. The TPR  
180 curves were obtained using a heating rate of 10 °C/min, ranging from 50 to 900 °C in a 10%  
181 H<sub>2</sub>/Ar flow. For NH<sub>3</sub>-TPD analysis, 100 mg samples were subjected to heating at 500°C for an  
182 hour in the presence of Ar flow and then cooled to 35°C. A continuous flow of 10% NH<sub>3</sub>/He (50  
183 mL/min) was directed through the sample tube for a purge time of 2 hours and the desorption of  
184 NH<sub>3</sub> species was carried out in a helium flow to obtain the data at temperatures ranging from  
185 35 to 900 °C. Thermogravimetric analysis (TGA) was conducted using PerkinElmer STA6000 in  
186 an  $\alpha$ -Al<sub>2</sub>O<sub>3</sub> crucible under a nitrogen atmosphere. Thermogravimetric curves in the temperature  
187 range of 30-900 °C were recorded with a heating rate of 10 °C/min to investigate the thermal  
188 properties and thermal decomposition of the sulfated samples.

### 189 **3. Results and discussion**

#### 190 **3.1. Evaluation of catalytic activity**

191

192 **Fig. 1.** (A) The effect of H<sub>2</sub>O concentration on the NH<sub>3</sub>-SCR activity of CeO<sub>2</sub> during the gas-phase sulfation  
 193 process. Sulfated conditions: COS:CS<sub>2</sub> = 7:3 with the total amount of S element being 200 ppm; the sulfation  
 194 temperature 50 °C; the sulfation time 3 h; H<sub>2</sub>O (water vapor) concentrations 0.33 vol.%, 1.5 vol.% and 5.0 vol.%.  
 195 (B) H<sub>2</sub>O and SO<sub>2</sub> resistance study of CeO<sub>2</sub>-CS<sub>2</sub>+CO<sub>2</sub>-H<sub>2</sub>O(0.33%) catalyst and (C) the long time stability test of  
 196 CeO<sub>2</sub>-CS<sub>2</sub>+CO<sub>2</sub>-H<sub>2</sub>O(0.33%) catalyst.

197 The influence of H<sub>2</sub>O introduction on the NH<sub>3</sub>-SCR activity of CeO<sub>2</sub>-CS<sub>2</sub>+COS catalyst was  
 198 investigated during the gas-phase sulfation at 50 °C, and the results are given in Fig. 1(A). It can  
 199 be found that the gas-phase sulfation of COS+CS<sub>2</sub> at 50 °C effectively enhances the NH<sub>3</sub>-SCR  
 200 activity of CeO<sub>2</sub>, and the highest NO<sub>x</sub> conversion of catalyst is increased from 31% to higher  
 201 than 90% at the GHSV of 200,000 mL/(g·h). The main reason for the poor catalytic performance  
 202 of CeO<sub>2</sub> might be attributed to the low concentrations of Ce<sup>3+</sup> ions, active oxygen and acid sites  
 203 on its surface [44,45]. And the low-temperature gas-phase sulfation of COS and CS<sub>2</sub> optimizes  
 204 these defects and improves the surface concentrations of Ce<sup>3+</sup> ions, active oxygen and acid sites  
 205 of CeO<sub>2</sub>, thereby increases its NH<sub>3</sub>-SCR activity effectively. This promotional effect of organic  
 206 sulfur gas-phase sulfation had also been verified by our previous research [33], and COS or CS<sub>2</sub>  
 207 presented a better enhancement on the NH<sub>3</sub>-SCR activity of CeO<sub>2</sub> than the traditional inorganic  
 208 SO<sub>2</sub> when the gas-phase sulfation was carried out at 300 °C. Interestingly, as depicted in Fig.  
 209 1(A), the introduction of H<sub>2</sub>O during the low-temperature gas-phase sulfation of COS and CS<sub>2</sub>

210 can further increase the  $\text{NH}_3$ -SCR activity of the  $\text{CeO}_2+\text{CS}_2+\text{COS}$  catalyst, and  
211  $\text{CeO}_2-\text{CS}_2+\text{COS}-\text{H}_2\text{O}(0.33\%)$  presents good catalytic performance with a 100%  $\text{NO}_x$  reduction  
212 obtained at the temperature range of 250 ~ 400 °C. However, the enhancement of water  
213 concentrations from 0.33 vol.% to 5.0 vol.% decreases this promotional effect. In order to  
214 validate the disadvantageous effect of high  $\text{H}_2\text{O}$  concentration during the low-temperature  
215 gas-phase sulfation, 1.5 vol.%  $\text{H}_2\text{O}$  had also been introduced and the  $\text{NH}_3$ -SCR activity of  
216  $\text{CeO}_2-\text{CS}_2+\text{COS}-\text{H}_2\text{O}(1.5\%)$  is between the values of  $\text{CeO}_2-\text{CS}_2+\text{COS}-\text{H}_2\text{O}(0.33\%)$  and  
217  $\text{CeO}_2-\text{CS}_2+\text{COS}-\text{H}_2\text{O}(5.0\%)$ . This implies that the introduction of  $\text{H}_2\text{O}$  during the  
218 low-temperature gas-phase sulfation can optimize the catalytic performance of  $\text{CeO}_2+\text{CS}_2+\text{COS}$   
219 catalyst, but large concentration of water decreases this promotional effect. The previous  
220 researches about the sulfated  $\text{CeO}_2$  and other metals catalyst for  $\text{NH}_3$ -SCR had been summarized  
221 in Table S1, and it can be found that compared to other sulfated catalysts in recent years,  
222  $\text{CeO}_2-\text{CS}_2+\text{COS}-\text{H}_2\text{O}(0.33\%)$  exhibits excellent low-temperature performance and a wide  
223 temperature window even at a high GHSV of 200,000  $\text{mL}/(\text{g}\cdot\text{h})$ . Meanwhile, the influence of  
224  $\text{CS}_2/\text{COS}$  molar ratio (7:3, 5:5, 3:7) on the  $\text{NH}_3$ -SCR activity of  $\text{CeO}_2-\text{CS}_2+\text{COS}-\text{H}_2\text{O}(0.33\%)$   
225 catalyst was also examined, as shown in Fig. S1. Under the  $\text{CS}_2/\text{COS}$  molar ratios of 7:3 and 3:7,  
226 the sulfated  $\text{CeO}_2-\text{CS}_2+\text{COS}-\text{H}_2\text{O}(0.33\%)$  catalysts present similar denitrification performance,  
227 which are better than that of the catalyst treated at the  $\text{CS}_2/\text{COS}$  molar ratio of 5:5. Meanwhile, it  
228 is generally believed that the organic sulfur in blast furnace gas is mainly composed of  $\text{COS}$  and  
229 the molar ratio of  $\text{COS}/(\text{COS}+\text{CS}_2)$  is about 70% [24]. Therefore, 7:3 of  $\text{COS}/\text{CS}_2$  molar ratios  
230 was chosen for the subsequent research and characterization.

231  $\text{H}_2\text{O}$  and  $\text{SO}_2$  that commonly present in the denitrification process and potentially influence  
232 the  $\text{NH}_3$ -SCR activity of catalyst, therefore it is necessary to study the anti-poisoning of  $\text{H}_2\text{O}$   
233 or/and  $\text{SO}_2$  for the  $\text{CeO}_2-\text{CS}_2+\text{COS}-\text{H}_2\text{O}(0.33\%)$  catalyst. As shown in Fig. 1(B), when 100 ppm  
234  $\text{SO}_2$  is introduced into the simulated flue gas, the  $\text{NO}_x$  reduction of catalyst slowly decreases to  
235 93% and then remains stable, and  $\text{CeO}_2-\text{CS}_2+\text{COS}-\text{H}_2\text{O}(0.33\%)$  exhibits excellent resistance to  
236  $\text{SO}_2$  poisoning. When further introducing 10.0 vol.%  $\text{H}_2\text{O}$ , the  $\text{NO}_x$  conversion rate of  
237  $\text{CeO}_2-\text{CS}_2+\text{COS}-\text{H}_2\text{O}(0.33\%)$  rapidly decreases to 53%, which might be due to the competitive  
238 adsorption of  $\text{H}_2\text{O}$  and the deposition of sulfate species [39,40]. After removing  $\text{H}_2\text{O}$ , the activity  
239 is promptly recovered to 85%, which indicates that the catalyst deactivation caused by  $\text{H}_2\text{O}$  is

240 reversible. After further stopping the introduction of SO<sub>2</sub>, the activity is not further recovered,  
241 indicating an irreversible deactivation of catalyst caused by the deposition of sulfate species. In  
242 the meantime, the long-term stability of the NH<sub>3</sub>-SCR activity over the  
243 CeO<sub>2</sub>-CS<sub>2</sub>+COS-H<sub>2</sub>O(0.33%) catalyst was also investigated and the results are given in Fig.  
244 1(C). It is found that CeO<sub>2</sub>-CS<sub>2</sub>+COS-H<sub>2</sub>O(0.33%) presents a good stability of the NH<sub>3</sub>-SCR  
245 activity, and more than 90% of NO<sub>x</sub> reduction can be maintained after a 60 h test, although its  
246 NO<sub>x</sub> reduction decreases from 100% to about 95% at 25~27 h.

247 Previous studies had shown that an appropriate amount of H<sub>2</sub>O could promote the  
248 hydrolysis and conversion of organic sulfur (CS<sub>2</sub> or/and COS) via optimizing the formation of  
249 active -OH groups on catalysts surface, but excessive H<sub>2</sub>O inhibited the catalytic hydrolysis due  
250 to the competitive adsorption and the introduced concentration of H<sub>2</sub>O could regulate the  
251 formation of sulfur-containing species on the catalyst surface during the low-temperature  
252 hydrolysis of CS<sub>2</sub> or/and COS [29,46]. Meanwhile, the formed sulfur-containing species, mainly  
253 sulfate, were proven to optimize the concentrations of Ce<sup>3+</sup> ions, active oxygen and acid sites on  
254 CeO<sub>2</sub> catalyst surface, which are closely related to its NH<sub>3</sub>-SCR activity. Therefore,  
255 CeO<sub>2</sub>-CS<sub>2</sub>+COS-H<sub>2</sub>O(0.33%) and CeO<sub>2</sub>-CS<sub>2</sub>+COS-H<sub>2</sub>O(5.0%) were chosen to be characterized  
256 to investigate the influence of H<sub>2</sub>O introduction on the physical-chemical properties of  
257 CeO<sub>2</sub>-CS<sub>2</sub>+COS catalyst in the following sections.

### 258 **3.2. Morphological analysis**

259 Scanning electron microscopy (SEM) was applied to investigate the influence of H<sub>2</sub>O  
260 introduction on the morphology of CeO<sub>2</sub> catalyst during the low-temperature gas-phase sulfation  
261 of organic CS<sub>2</sub> and COS, and the particle size distributions were also calculated. According to the  
262 results in Fig. 2 and 3. CeO<sub>2</sub> presents an irregular morphology composed of dispersed  
263 nanoparticles and exhibits a maximum particle size of 2.33 μm. Meanwhile, the low-temperature  
264 gas-phase sulfation of CS<sub>2</sub> and COS decreases the crystallinity of nanoparticles on CeO<sub>2</sub> surface  
265 and inhibits the occurrence of agglomeration, although CeO<sub>2</sub>-CS<sub>2</sub>+COS also exhibits a  
266 disordered granular morphology. Furthermore, the introduction of H<sub>2</sub>O seems to further reduce  
267 the agglomeration of surface nanoparticles and causes the particle size to shift towards smaller  
268 direction. In particular, the introduction of 5.0 vol.% H<sub>2</sub>O significantly enhances the dispersion  
269 of CeO<sub>2</sub> nanoparticles and reduces the average particle size to 0.281 μm. Therefore, the

270 gas-phase sulfation of organic sulfur at 50 °C decreases the crystallinity of nanoparticles on CeO<sub>2</sub>  
 271 surface due to the formation of surface sulfur-containing species, and the introduction of H<sub>2</sub>O  
 272 further improves the dispersion of nanoparticles on catalysts surface. Furthermore, the  
 273 nanoparticles on CeO<sub>2</sub>-CS<sub>2</sub>+COS-H<sub>2</sub>O(5.0%) surface are more evenly dispersed (Fig. 2(D), Fig.  
 274 3(D), Fig. S2(D)), which might be due to the inhibition of excess H<sub>2</sub>O on the aggregation of  
 275 sulfate species during the low-temperature gas-phase sulfation of CS<sub>2</sub> and COS.

276  
 277 **Fig. 2.** SEM images of (A) CeO<sub>2</sub>, (B) CeO<sub>2</sub>-CS<sub>2</sub>+COS, (C) CeO<sub>2</sub>-CS<sub>2</sub>+COS-H<sub>2</sub>O(0.33%) and (D)

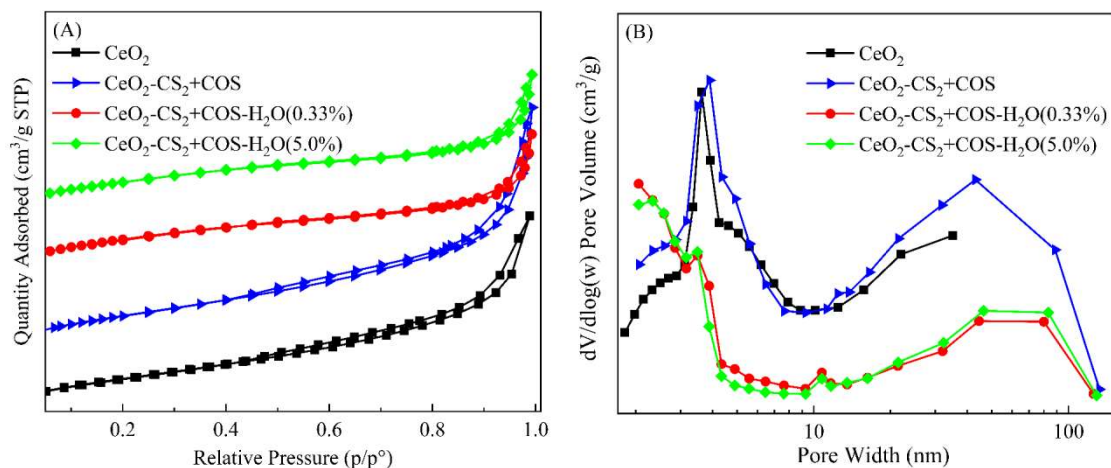

278 CeO<sub>2</sub>-CS<sub>2</sub>+COS-H<sub>2</sub>O(5.0%) catalysts.

305

Herein, N<sub>2</sub> adsorption-desorption, XRD and Raman were carried out to reveal the influence of H<sub>2</sub>O introduction on the texture and structural properties of the sulfated CeO<sub>2</sub> catalysts by CS<sub>2</sub> and COS at 50 °C. As shown in Fig. 4(A), the adsorption-desorption isotherms of CeO<sub>2</sub> and CeO<sub>2</sub>-CS<sub>2</sub>+COS catalysts belong to type IV with the hysteresis loop of H3 type in the relative pressure range of  $p/p^\circ = 0.05\sim 1.0$  according to the IUPAC classification, indicating the presence of mesoporous structures composed of non-rigid aggregates of nanoparticles [47,48]. In addition, the rapid increase in nitrogen adsorption capacity at the  $p/p^\circ$  of 0.8 demonstrates the presence of a macroporous structure [22,49]. Thus, both CeO<sub>2</sub> and CeO<sub>2</sub>-CS<sub>2</sub>+COS catalysts have mesoporous and macroporous hierarchical porous structures, which is confirmed by the BJH desorption pore size distribution calculated from the desorption isotherm of N<sub>2</sub>. From Fig. 4(B), it can be observed that CeO<sub>2</sub> has a narrow and sharp single peak in the range of 2-10 nm belonging to the typical mesoporous structure, and the gas-phase sulfation of CS<sub>2</sub> and COS at 50 °C widens the pore size distribution of CeO<sub>2</sub>. However, the introduction of H<sub>2</sub>O during the gas-phase sulfation makes the low-pressure closure point of nitrogen adsorption and desorption for CeO<sub>2</sub>-CS<sub>2</sub>+COS shift to the right, and both CeO<sub>2</sub>-CS<sub>2</sub>+COS-H<sub>2</sub>O(0.33%) and CeO<sub>2</sub>-CS<sub>2</sub>+COS-H<sub>2</sub>O(5.0%) present more concentrated pore size distribution than CeO<sub>2</sub> and CeO<sub>2</sub>-CS<sub>2</sub>+COS although they also exhibit the mesoporous and macroporous hierarchical porous structures. This indicates that the presence of water might affect the sulfation degree of nanoparticles and the formation of sulfur-containing species on CeO<sub>2</sub>-CS<sub>2</sub>+COS surface during the gas-phase sulfation of CS<sub>2</sub> and COS at 50 °C, which are in accordance with the results of the

306 morphology. Previous studies had pointed out that an abundance of mesopores could provide  
 307 more active sites and internal surface area for the NH<sub>3</sub>-SCR reaction over P-W/CeO<sub>2</sub>, and the  
 308 hierarchical porous structure helped to reduce the mass transfer resistance and facilitated the  
 309 contact between the reactant gas molecules and the active sites on the inner surface of catalyst  
 310 [50,51]. Therefore, CeO<sub>2</sub>-CS<sub>2</sub>+COS-H<sub>2</sub>O(0.33%) and CeO<sub>2</sub>-CS<sub>2</sub>+COS-H<sub>2</sub>O(5.0%) exhibit  
 311 slightly worse mesoporous and macroporous hierarchical porous structures than CeO<sub>2</sub> and  
 312 CeO<sub>2</sub>-CS<sub>2</sub>+COS. In addition, they have smaller specific surface areas (Table 1). These all  
 313 demonstrate that the introduction of H<sub>2</sub>O affect the sulfation degree of nanoparticles and the  
 314 accumulation of the formed sulfur-containing species during the gas-phase sulfation of CS<sub>2</sub> and  
 315 COS at 50 °C, but the pore structure and specific surface area might not be the determining factor  
 316 for the NH<sub>3</sub>-SCR activity of the sulfated CeO<sub>2</sub> catalysts by organic sulfur at low-temperatures.

317 **Table 1** The physical structural parameters of the as-prepared catalysts

Samples	BET surface area <sup>a</sup> (m <sup>2</sup> /g)	Pore volume <sup>b</sup> (cm <sup>3</sup> /g)	Pore diameter <sup>c</sup> (nm)
CeO <sub>2</sub>	119.62	0.199	6.44
CeO <sub>2</sub> -CS <sub>2</sub> +COS	127.86	0.280	8.34
CeO <sub>2</sub> -CS <sub>2</sub> +COS-H <sub>2</sub> O(0.33%)	113.31	0.155	6.43

319 <sup>b</sup> BJH desorption pore volume

320 <sup>c</sup> BJH desorption pore diameter

321 According to the X-ray diffraction (XRD) patterns in Fig. 5 and Fig. S3, pure CeO<sub>2</sub> presents  
 322 the typical lattice diffraction peaks attributed to cubic fluorite CeO<sub>2</sub> (PDF#34-0394) [40,52], and  
 323 the low-temperature gas-phase sulfation of CS<sub>2</sub> and COS effectively reduces the intensity of the  
 324 diffraction peaks ascribed to cubic fluorite CeO<sub>2</sub>. Furthermore, a broad peak at the low scanning  
 325 angle range of 15 ~ 26 ° appears over the CeO<sub>2</sub>-CS<sub>2</sub>+COS catalyst, which is attributed to the  
 326 sulfur elements or/and the sulfur compounds dominated by hydrated metal sulfates  
 327 (PDF#37-0762; PDF#24-1250; PDF#24-1216). Interestingly, the introduction of 0.33 vol.% H<sub>2</sub>O  
 328 might slightly suppress the sulfation of cubic fluorite CeO<sub>2</sub> by CS<sub>2</sub> and COS at 50 °C, but

329 CeO<sub>2</sub>-CS<sub>2</sub>+COS-H<sub>2</sub>O(0.33%) still presents a similar broad peak of sulfur elements or/and  
 330 compounds to CeO<sub>2</sub>-CS<sub>2</sub>+COS. However, the enhancement of H<sub>2</sub>O concentration from 0.33 vol.%  
 331 to 5.0 vol.% increases the intensity of this peak, indicating that higher crystallinity sulfur  
 332 elements or/and compounds are formed in CeO<sub>2</sub>-CS<sub>2</sub>+COS-H<sub>2</sub>O(5.0%). Mu et al. [53] pointed  
 333 out that the hydrolysis of COS led to a new XRD pattern peak emerging at 2θ = 24.2 ° in  
 334 10Cu-Co<sub>3</sub>O<sub>4</sub> catalyst, which was attributed to elemental sulfur. This phenomenon was also found  
 335 in the CeO<sub>2</sub>-R catalyst after the catalytic selective oxidation of H<sub>2</sub>S [54]. In addition, the  
 336 hydrated metal sulfates could gradually become amorphous during the slow heating process,  
 337 which further thermally decomposed into the anhydrous sulfate species such as Ce<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub> and  
 338 Ce(SO<sub>4</sub>)<sub>2</sub> [55]. Therefore, the low-temperature gas-phase sulfation of organic CS<sub>2</sub>+COS  
 339 contributes to the formation of sulfur element or/and compounds in the CeO<sub>2</sub> catalyst under the  
 340 condition of low concentration water, but the enhancement of H<sub>2</sub>O concentration from 0.33 vol.%  
 341 to 5.0 vol.% further improves the crystallinity of the formed sulfur-containing species.

342  
 343 **Fig. 5.** The XRD patterns (Left) and the locally enlarged XRD (14~27 °) (Right) of as-prepared sulfated  
 344 catalysts.

345 Fig. 6 gives the Raman spectra of CeO<sub>2</sub>, CeO<sub>2</sub>-CS<sub>2</sub>+COS, CeO<sub>2</sub>-CS<sub>2</sub>+COS-H<sub>2</sub>O(0.33%)  
 346 and CeO<sub>2</sub>-CS<sub>2</sub>+COS-H<sub>2</sub>O(5.0%) catalysts, and it can be found that three peaks are detected at  
 347 464 cm<sup>-1</sup>, 600 cm<sup>-1</sup> and 1180 cm<sup>-1</sup> for pure CeO<sub>2</sub> catalyst, respectively. The first prominent peak  
 348 is related to the symmetric stretching vibration of Ce-O-Ce, which is assigned to the F<sub>2g</sub>  
 349 characteristic vibration of cubic fluorite CeO<sub>2</sub>, while the last two vibration peaks are attributed to

350 the surface oxygen defects [56,57]. It is evident that the low-temperature gas-phase sulfation of  
351 CS<sub>2</sub>+COS makes the F<sub>2g</sub> characteristic peak of CeO<sub>2</sub> shift to a lower wave number via altering its  
352 Ce-O-Ce structure [58-60], and the introduction of H<sub>2</sub>O further improves the FWHM (full width  
353 at half-maximum) and peak intensity of F<sub>2g</sub> vibration peak significantly. This indicates that the  
354 introduction of H<sub>2</sub>O strengthens the influence of CS<sub>2</sub>+COS low-temperature gas-phase sulfation  
355 on refining the grain size of nanoparticles on CeO<sub>2</sub> surface, which is in accordance with the  
356 results of SEM and XRD. Jang et al. [61] found that the introduction of SiO<sub>2</sub> refined the particle  
357 size of CeO<sub>2</sub> with a wider FWHM of the F<sub>2g</sub> vibration peak detected for the core/shell CeO<sub>2</sub>-SiO<sub>2</sub>.  
358 Furthermore, the relative concentration of oxygen vacancies on the catalyst surfaces could be  
359 obtained by calculating the integral area ratio of the peaks at 600 cm<sup>-1</sup>+1180 cm<sup>-1</sup> and the peak of  
360 F<sub>2g</sub> characteristic vibration [62]. As shown in Fig. S4, the introduction of H<sub>2</sub>O improves the  
361 promotional effect of organic CS<sub>2</sub>+COS low-temperature gas-phase sulfation on the relative  
362 concentration of oxygen vacancies on CeO<sub>2</sub> surface, but high concentration H<sub>2</sub>O decreases this  
363 promotional effect. And the calculated relative concentrations of oxygen vacancies are as follow:  
364 CeO<sub>2</sub>-CS<sub>2</sub>+COS-H<sub>2</sub>O(0.33%) > CeO<sub>2</sub>-CS<sub>2</sub>+COS-H<sub>2</sub>O(5.0%) > CeO<sub>2</sub>-CS<sub>2</sub>+COS > CeO<sub>2</sub>, which  
365 is consistent with the NH<sub>3</sub>-SCR activity of catalysts. Therefore, the introduction of H<sub>2</sub>O further  
366 helps to the generation of oxygen vacancies during the gas-phase sulfation process of organic  
367 CS<sub>2</sub>+COS at 50 °C, thus accelerating the conversion frequency between the chemisorbed oxygen  
368 and lattice oxygen via the Ce<sup>3+</sup>/Ce<sup>4+</sup> ion pair, which might be beneficial to promote the oxidation  
369 of NO to NO<sub>2</sub> and improves the NO<sub>x</sub> conversion through the 'fast SCR' reaction [63-65].

Fig. 6. Raman spectra of the as-prepared CeO<sub>2</sub> catalysts.

370

371

372 The FTIR spectra of CeO<sub>2</sub>-CS<sub>2</sub>+COS, CeO<sub>2</sub>-CS<sub>2</sub>+COS-H<sub>2</sub>O(0.33%), and  
 373 CeO<sub>2</sub>-CS<sub>2</sub>+COS-H<sub>2</sub>O(5.0%) catalysts are given in Fig. 7. The vibration peaks located at 1627  
 374 cm<sup>-1</sup> and 3417 cm<sup>-1</sup> are attributed to the bending vibration and stretching vibration of -OH group,  
 375 respectively [66]. When the content H<sub>2</sub>O increases to 5.0% during the low-temperature gas-phase  
 376 sulfation process, a new weak vibration peak attributed to H<sub>2</sub>O appears at 847 cm<sup>-1</sup> in  
 377 CeO<sub>2</sub>-CS<sub>2</sub>+COS-H<sub>2</sub>O(5.0%) [67]. Meanwhile, the formation of sulfate species during the  
 378 low-temperature gas-phase sulfation results in the detection of multiple vibrational bands at  
 379 900~1300 cm<sup>-1</sup>. Among them, the vibration peaks at 979 cm<sup>-1</sup> and 1043 cm<sup>-1</sup> are attributed to the  
 380 characteristics of inorganic chelated bidentate sulfates, caused by the S-O and S=O bond  
 381 vibrations of surface sulfate species, while the bands at 1116 and 1190 cm<sup>-1</sup> are caused by the  
 382 formed bulk sulfates on catalysts surface [65,68]. However, the enhancement of H<sub>2</sub>O content  
 383 from 0.33 vol.% to 5.0 vol.% weakens the intensity of the vibrational band caused by sulfate  
 384 species, which is reasonable due to the enhanced interaction between the groups of -OH and  
 385 SO<sub>4</sub><sup>2-</sup> [69].

Fig. 7. FTIR spectra of the sulfated CeO<sub>2</sub> catalysts by COS+CS<sub>2</sub> at 50 °C.

### 3.4. Surface active components analysis

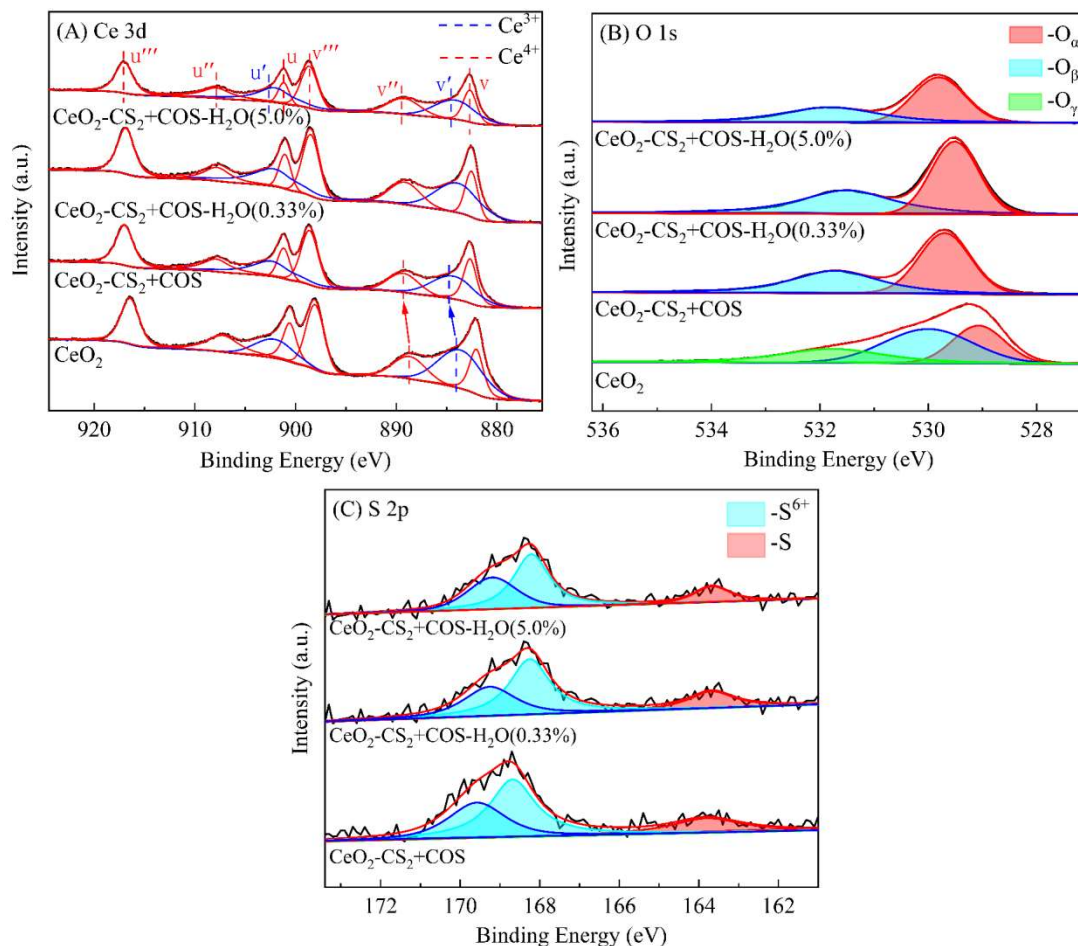

In this section, XPS (X-ray Photoelectron Spectroscopy) technique was employed to investigate the influence of H<sub>2</sub>O introduction on the dispersion of elements on catalysts surface. As shown in Fig. 8(A), the Ce 3d XPS spectra could be deconvoluted into eight peaks via the Lorentz/Gaussian method. Among them, u' and v' are attributed to Ce<sup>3+</sup> species (3d<sup>10</sup> 4f<sup>1</sup>), and the other peaks are ascribed to the Ce<sup>4+</sup> electronic state (3d<sup>10</sup> 4f<sup>0</sup>) [49]. In addition, the low-temperature gas-phase sulfation of organic CS<sub>2</sub>+COS increases the molar ratio of Ce<sup>3+</sup>/(Ce<sup>3+</sup>+Ce<sup>4+</sup>) on CeO<sub>2</sub> surface and makes the Ce 3d spectra of catalyst shift to a higher binding energy direction by approximately 0.6 eV, indicating the electron-induced effect between Ce, O and S species, which alters the electron cloud density around Ce [70,71]. Interestingly, the introduction of H<sub>2</sub>O improves this electron-induced effect and further increases the molar ratio of Ce<sup>3+</sup>/(Ce<sup>3+</sup>+Ce<sup>4+</sup>) on CeO<sub>2</sub>-CS<sub>2</sub>+COS surface. However, as shown in Table 2, the enhancement of H<sub>2</sub>O concentration from 0.33 vol.% to 5.0 vol.% reduces this promotional effect and makes the surface Ce<sup>3+</sup>/(Ce<sup>3+</sup>+Ce<sup>4+</sup>) molar ratio of CeO<sub>2</sub>-CS<sub>2</sub>+COS-H<sub>2</sub>O(0.33%) decrease from 36.42 % to 33.15%. Generally, the generation of oxygen vacancies is associated with the electron transfer of Ce<sup>4+</sup>/Ce<sup>3+</sup> ion pair, and the presence of Ce<sup>3+</sup> can aggravate the charge imbalance and promote the redox cycle of Ce<sup>4+</sup>/Ce<sup>3+</sup>, thus heightens the activation of oxygen on the catalysts surfaces and results in the generation of more oxygen vacancies [72,73]. Therefore, the further enhancement of H<sub>2</sub>O introduction on the surface Ce<sup>3+</sup>/(Ce<sup>3+</sup>+Ce<sup>4+</sup>) molar ratio of

407 CeO<sub>2</sub>-CS<sub>2</sub>+COS might be an important reason for increasing the NH<sub>3</sub>-SCR activity of catalyst.  
408 However, the introduction of higher concentration H<sub>2</sub>O (5.0 vol.%) results in a stronger  
409 competitive adsorption between H<sub>2</sub>O and organic CS<sub>2</sub>+COS, which might affect the conversion  
410 of the adsorbed CS<sub>2</sub>+COS on cubic fluorite CeO<sub>2</sub> surface, thus decreases the Ce<sup>3+</sup>/(Ce<sup>3+</sup>+Ce<sup>4+</sup>)  
411 molar ratio of CeO<sub>2</sub>-CS<sub>2</sub>+COS-H<sub>2</sub>O(0.33%).

412 As shown in Fig. 8(B), the O 1s spectrum of pure CeO<sub>2</sub> can be fitted into three peaks, which  
413 belongs to the lattice oxygen existing in cubic fluorite CeO<sub>2</sub> (O<sub>α</sub>, 529.1 eV), the chemisorbed  
414 oxygen (O<sub>β</sub>, 530.0 eV) and the lattice oxygen bonded with Ce<sub>2</sub>O<sub>3</sub> (O<sub>γ</sub>, 531.8 eV), respectively  
415 [74]. Meanwhile, the low-temperature gas-phase sulfation of CS<sub>2</sub>+COS leads the O 1s XPS  
416 binding energy of CeO<sub>2</sub> shifting to a higher value, while only O<sub>α</sub> and O<sub>β</sub> are detected for the  
417 sulfated CeO<sub>2</sub> catalysts due to the formation of Ce-O-S bonds [75]. Interestingly, the introduction  
418 of H<sub>2</sub>O further increases the binding energy of O 1s of CeO<sub>2</sub>-CS<sub>2</sub>+COS catalyst. Furthermore, as  
419 shown in Table 2, the presence of H<sub>2</sub>O during the low-temperature gas-phase sulfation of  
420 CS<sub>2</sub>+COS improves the concentration of chemical adsorption oxygen (O<sub>β</sub>) on catalyst surface,  
421 but excessive water leads to a decrease of this value. The regular pattern of H<sub>2</sub>O introduction on  
422 the surface O<sub>β</sub> concentration is in accordance with that of Ce<sup>3+</sup>/(Ce<sup>3+</sup>+Ce<sup>4+</sup>) molar ratio. A large  
423 number of studies had demonstrated that the surface chemisorbed oxygen had a higher mobility  
424 than the lattice oxygen, which was easy to be activated and played an important role in the  
425 oxidation reaction. Consequently, higher surface molar ratio of O<sub>β</sub>/(O<sub>α</sub>+O<sub>β</sub>+O<sub>γ</sub>) are generally  
426 regarded to be beneficial to improve the oxidization of NO to NO<sub>2</sub> and the 'fast SCR' process  
427 (NO + NO<sub>2</sub> + 2NH<sub>3</sub> = 2N<sub>2</sub> + 3H<sub>2</sub>O) [76,77].

428 From Fig. 8(C), it can be found that the S 2p spectra of the sulfated CeO<sub>2</sub> catalysts can be  
429 fitted into three peaks located at 163.8 eV, 168.3 eV and 169.3 eV (±0.3 eV), and the last two  
430 peaks belong to S<sup>6+</sup> species. Meanwhile, the peak located about 163.8 eV is attributed to sulfur,  
431 which is different from the formation of sulfate species (SO<sub>4</sub><sup>2-</sup>, etc.) in CeO<sub>2</sub> catalyst during the  
432 gas-phase sulfation of inorganic SO<sub>2</sub> [54,78]. However, the introduction of H<sub>2</sub>O decreases the  
433 intensity of S 2p spectra of CeO<sub>2</sub>-CS<sub>2</sub>+COS, thereby reduces the concentrations of the formed  
434 S<sup>6+</sup> and S species on catalyst surface. As shown in Table 2, the introduction of H<sub>2</sub>O during the  
435 low-temperature gas-phase sulfation of CS<sub>2</sub>+COS helps to increase the surface molar ratio  
436 S<sup>6+</sup>/(S<sup>6+</sup>+S), and the enhancement of H<sub>2</sub>O concentration from 0.33 vol.% to 5.0 vol.% not only

437 increases the formed surface total concentration of  $S^{6+}$  and S, but also further improves the molar  
 438 ratio  $S^{6+}/(S^{6+}+S)$  on  $CeO_2-CS_2+COS-H_2O(0.33\%)$  surface. Therefore, it can be included that  
 439 lower concentration of sulfur-containing species might be helpful to the  $NH_3$ -SCR activity of the  
 440 sulfated  $CeO_2$  catalyst.

441  
 442 **Fig. 8.** (A) Ce 3d, (B) O 1s, and (C) S 2p XPS spectra of the as-prepared catalyst.

443 **Table 2** Surface composition and atomic ratio of the as-prepared catalysts calculated from XPS

Catalysts	Atomic concentrations (%)			Atomic ratios (%)		
	Ce	O	S*	$Ce^{3+}/(Ce^{3+}+Ce^{4+})$	$O_{\beta}/(O_{\alpha}+O_{\beta}+O_{\gamma})$	$S^{6+}/(S^{6+}+S)$
	CeO <sub>2</sub>	36.16	63.84	-	31.34	44.16
CeO <sub>2</sub> -CS <sub>2</sub> +COS	32.15	63.24	4.61	31.75	44.69	80.60

CeO <sub>2</sub> -CS <sub>2</sub> +COS-H <sub>2</sub> O(5.0%)	33.25	62.73	4.02	33.15	45.19	85.98

444 \* The sum of S and S<sup>6+</sup>.

### 445 3.5. Thermogravimetric analysis

446 Thermogravimetric analysis was done to further investigate the influence of H<sub>2</sub>O  
447 introduction on the formed sulfur-containing species over CeO<sub>2</sub>-CS<sub>2</sub>+COS-H<sub>2</sub>O catalyst. The  
448 results are shown in Fig. 9. It can be clearly seen that there exists an apparent weight-loss for the  
449 TG-DTG curves as the temperature increases, which can be divided into three parts. The weight  
450 loss peak observed in the range of 30-200 °C is attributed to the desorption of physically  
451 absorbed water and dehydroxylation [52,72], and the desorbed values in this stage are 2.14%,  
452 2.44% and 2.37% for CeO<sub>2</sub>-CS<sub>2</sub>+COS, CeO<sub>2</sub>-CS<sub>2</sub>+COS-H<sub>2</sub>O(0.33%) and  
453 CeO<sub>2</sub>-CS<sub>2</sub>+COS-H<sub>2</sub>O(5.0%), respectively. Consequently, the introduction of H<sub>2</sub>O slightly  
454 increases the content of physically adsorbed water and hydroxyl groups in the sulfated CeO<sub>2</sub>  
455 catalysts by organic CS<sub>2</sub>+COS at 50 °C, which might be beneficial to the NH<sub>3</sub>-SCR activity of  
456 catalyst. Guo et al. [79] claimed that SO<sub>4</sub><sup>2-</sup>, O<sub>2</sub><sup>2-</sup> and hydroxyl-like (-OH) species could function  
457 as Brønsted acid sites to enhance the adsorption of NH<sub>3</sub> and consequently improved the NO<sub>x</sub>  
458 removal efficiency of catalyst. Peng et al. [80] also mentioned that sulfate species promoted the  
459 ionization of water adsorbed on the catalyst surfaces, resulting in the formation of more hydroxyl  
460 group and more Brønsted acid sites. In addition, the XRD and XPS analyses validate the  
461 formation of sulfur element in the sulfated CeO<sub>2</sub>-CS<sub>2</sub>+COS, CeO<sub>2</sub>-CS<sub>2</sub>+COS-H<sub>2</sub>O(0.33%) and  
462 CeO<sub>2</sub>-CS<sub>2</sub>+COS-H<sub>2</sub>O(5.0%) catalysts. Thus, the slight weight losses observed between 200-600  
463 °C might be ascribed to the emission of SO<sub>2</sub> due to the oxidation reaction of sulfur and  
464 oxygen-containing functional groups in this temperature range. Finally, the third stage of weight  
465 losses began at 650 °C is attributed to the thermal decomposition of sulfate species [37,38], and  
466 approximately 5.44 %, 4.07 % and 3.07 % were calculated for CeO<sub>2</sub>-CS<sub>2</sub>+COS,  
467 CeO<sub>2</sub>-CS<sub>2</sub>+COS-H<sub>2</sub>O(0.33%) and CeO<sub>2</sub>-CS<sub>2</sub>+COS-H<sub>2</sub>O(5.0%) catalysts, respectively. Therefore,  
468 the introduction of H<sub>2</sub>O decreases the formed amount of sulfate species in the sulfated CeO<sub>2</sub>  
469 catalysts, although they had been reported to adsorb NH<sub>3</sub> as a stable acidic site and presented a  
470 strong thermal stability. And it can be inferred that there exists a competitive adsorption of H<sub>2</sub>O  
471 and CS<sub>2</sub>+COS on cubic fluorite CeO<sub>2</sub> surface, which reduces the formation of sulfate species, but  
472 the hydroxyl groups dissociated by H<sub>2</sub>O enhances the interaction between organic CS<sub>2</sub>+COS and  
473 cubic fluorite CeO<sub>2</sub>, which affects the physical and chemical properties of catalyst. Furthermore,  
474 the appropriate amount of -OH group as the additives for Brønsted acid sites enhances the

475 adsorption capacity of  $\text{NH}_3$  [46]. However, excess water significantly inhibits the chemical  
476 adsorption of  $\text{CS}_2$  and  $\text{COS}$  on catalyst surfaces due to a stronger competitive adsorption among  
477 them and depresses the hydrolysis of organic sulfur, thus further reduces the production of  
478 sulfate species in  $\text{CeO}_2$  catalyst. This demonstrates that the positive impact of hydroxyl groups  
479 might be outweighed by the negative effect of the competitive adsorption of  $\text{H}_2\text{O}$  and  $\text{COS}/\text{CS}_2$   
480 under the condition of excess water [26,81], although the enhancement of  $\text{H}_2\text{O}$  concentration  
481 from 0.33 vol.% to 5.0 vol.% further improves the molar ratio of  $\text{S}^{6+}/(\text{S}^{6+}+\text{S})$  on  $\text{CeO}_2$  surface  
482 calculated from the results of XPS spectra.

483  
484 **Fig. 9.** The TG-DTG curves of  $\text{CeO}_2\text{-CS}_2\text{+COS}$ ,  $\text{CeO}_2\text{-CS}_2\text{+COS-H}_2\text{O}(0.33\%)$  and  $\text{CeO}_2\text{-CS}_2\text{+COS-H}_2\text{O}(5.0\%)$ .  
485 catalysts.

486 **3.6. The properties of redox ability**

487  
 488 **Fig. 10.** The H<sub>2</sub>-TPR patterns of CeO<sub>2</sub>, CeO<sub>2</sub>-CS<sub>2</sub>+COS, CeO<sub>2</sub>-CS<sub>2</sub>+COS-H<sub>2</sub>O(0.33%) and  
 489 CeO<sub>2</sub>-CS<sub>2</sub>+COS-H<sub>2</sub>O(5.0%) catalysts.

490 H<sub>2</sub>-TPR was carried out to investigate the influence of H<sub>2</sub>O introduction on the reducibility  
 491 of CeO<sub>2</sub>-CS<sub>2</sub>+COS catalyst and the results are shown in Fig. 10. It is reported that two reduction  
 492 peaks of pure CeO<sub>2</sub> at about 495 °C and 830 °C belongs to the reduction of surface Ce<sup>4+</sup> to Ce<sup>3+</sup>  
 493 and bulk Ce<sup>4+</sup> to Ce<sup>3+</sup> [61], respectively. Meanwhile, the low-temperature gas-phase sulfation of  
 494 CS<sub>2</sub>+COS makes the reduction peak of CeO<sub>2</sub> at 495 °C shifting to left and disappearing due to  
 495 the formation of surface sulfate and the interaction of Ce and S species in the catalyst [70,82].  
 496 Furthermore, this treatment also leads the reduction peak of bulk CeO<sub>2</sub> at 830 °C shifting to a  
 497 lower temperature owing to the enhanced mobility of the lattice oxygen for cubic fluorite CeO<sub>2</sub>  
 498 by the gas-phase sulfation of reductive organic CS<sub>2</sub>+COS [83], thus improves the reducibility of  
 499 bulk CeO<sub>2</sub>. It should be mentioned that a new high peak attributed to the reduction of surface  
 500 sulfate species appears at 605 °C, 585 °C and 571 °C for the sulfated CeO<sub>2</sub>-CS<sub>2</sub>+COS,  
 501 CeO<sub>2</sub>-CS<sub>2</sub>+COS-H<sub>2</sub>O(0.33%) and CeO<sub>2</sub>-CS<sub>2</sub>+COS-H<sub>2</sub>O(5.0%) catalysts, respectively [34].  
 502 According to previous studies, the formation of sulfate species increased the surface active  
 503 oxygen concentration, thus enhanced the adsorption of NH<sub>3</sub> and promoted the low-temperature  
 504 oxidation of NO [40,65]. This indicates that the gas-phase sulfation of organic CS<sub>2</sub>+COS  
 505 increases the reducibility of CeO<sub>2</sub> catalyst effectively. Furthermore, the introduction of H<sub>2</sub>O

506 makes the reduction peak ascribed to sulfate species of  $\text{CeO}_2\text{-CS}_2\text{+COS}$  moving to the low  
507 temperature direction, which implies that the gas-phase sulfation of organic  $\text{CS}_2\text{+COS}$  at the  
508 presence of water helps to further improve the reducibility of sulfate species although their  
509 formed amounts also decrease. Therefore, the introduction of  $\text{H}_2\text{O}$  further contributes to improve  
510 the reducibility of  $\text{CeO}_2\text{-CS}_2\text{+COS}$ , which is beneficial to the  $\text{NH}_3\text{-SCR}$  activity of the catalyst.

### 511 **3.7. The properties of surface acidity**

512 Similar to the redox ability, the surface acidity is regarded as another critical factor of  
513 influencing the  $\text{NH}_3\text{-SCR}$  activity of catalyst. Therefore, the  $\text{NH}_3\text{-TPD}$  test was carried out to  
514 investigate the effect of  $\text{H}_2\text{O}$  introduction on the surface acidity of  $\text{CeO}_2\text{-CS}_2\text{+COS}$  during the  
515 low-temperature gas-phase of organic  $\text{CS}_2\text{+COS}$ . According to the  $\text{NH}_3\text{-TPD}$  spectrum in Fig. 11,  
516 a wide desorption peak of  $\text{NH}_3$  species was observed at 50-450 °C, which was attributed to weak  
517 acid sites and medium-strong acid sites via fitting it into five desorption peaks (labeled as I, II,  
518 III, IV and V) [84]. Previous studies indicate that there exists a positive correlation between the  
519 surface acid sites and the desorption temperature of  $\text{NH}_3$  species for the  $\text{NH}_3\text{-SCR}$  catalysts  
520 [85,86]. Therefore, the relative ratio of the integrated area for these five  $\text{NH}_3$  desorption peaks  
521 were calculated, as summarized in Table 3. Pure  $\text{CeO}_2$  has a considerable proportion of weak  
522 acid sites (74.83 %), but the low-temperature gas-phase sulfation of  $\text{CS}_2\text{+COS}$  significantly  
523 increases the proportion of medium-strong acid sites, which is further enhanced by introducing  
524  $\text{H}_2\text{O}$  during the sulfation process, although the introduction of  $\text{H}_2\text{O}$  decreases the formed amount  
525 of surface or/and bulk sulfation species according to the results of XPS spectra and TG-DTG  
526 curves. Jin et al. [87] pointed out that the inclusion of HSiW resulted in an increase of the surface  
527 acid sites of  $\text{CeO}_2$ , especially the number of medium-strong acid sites, thus improved the  
528  $\text{NH}_3\text{-SCR}$  activity of catalyst. This phenomenon was also reported in the Cu-SSZ-13 catalyst  
529 [88]. Therefore, the intensity of medium-strong acid sites plays a significant impact on the  
530  $\text{NH}_3\text{-SCR}$  activity, and the formation of sulfate species helps to enhance the intensity of  
531 medium-strong acid sites for  $\text{CeO}_2$  catalyst, which has also been proven by the gas-phase  
532 sulfation of  $\text{CS}_2\text{+COS}$  at 50 °C. Furthermore, the introduction of 0.33 vol.%  $\text{H}_2\text{O}$  makes the  
533  $\text{CeO}_2\text{-CS}_2\text{+COS-H}_2\text{O}(0.33\%)$  catalyst presenting the best medium-strong acid intensity, although  
534 it decreases the formed amount of surface or/and bulk sulfation species. The increase of  $\text{H}_2\text{O}$   
535 content from 0.33 vol.% to 5.0 vol.% increases the amount of sulfate species detected on

536 CeO<sub>2</sub>-CS<sub>2</sub>+COS-H<sub>2</sub>O(0.33%) surface according to XPS results, but slightly reduces its  
 537 medium-strong acid sites. This may be one of the reasons for the decrease of the catalytic  
 538 performance of CeO<sub>2</sub>-CS<sub>2</sub>+COS-H<sub>2</sub>O(0.33%), and thus both the surface sulfate species and the  
 539 bulk sulfate species can affect the NH<sub>3</sub>-SCR acidity of CeO<sub>2</sub> catalyst.

540

541 **Fig. 11.** The fitted NH<sub>3</sub>-TPD curves of CeO<sub>2</sub>, CeO<sub>2</sub>-CS<sub>2</sub>+COS, CeO<sub>2</sub>-CS<sub>2</sub>+COS-H<sub>2</sub>O(0.33%) and

548

549

As an essential reactant for the hydrolysis of organic CS<sub>2</sub> or/and COS, the introduction of appropriate H<sub>2</sub>O could enhance the adsorption and conversion performance of organic sulfur on the surface of metal oxide catalysts [89,90]. Therefore, water was introduced into the low-temperature gas-phase sulfation of CS<sub>2</sub>+COS over CeO<sub>2</sub> catalyst in order to further improve its NH<sub>3</sub>-SCR activity for the first time, and the introduction of 0.33 vol.% H<sub>2</sub>O promotes the adsorption of CS<sub>2</sub>+COS on cubic fluorite CeO<sub>2</sub> surface and the interaction among them, thus

550 further enhances the optimization effect of reducing organic  $\text{CS}_2+\text{COS}$  on the electronic state of  
551  $\text{CeO}_2$ . This increases the content of  $\text{Ce}^{3+}$  ions, chemisorbed oxygen ( $\text{O}_\beta$ ) and oxygen vacancies  
552 on  $\text{CeO}_2\text{-CS}_2+\text{COS}$  surface. Furthermore, the introduction of appropriate amount of  $\text{H}_2\text{O}$   
553 effectively enhances the redox cycle of  $\text{Ce}^{4+}/\text{Ce}^{3+}$  ion pairs, and further increases the  
554 medium-strong acid although it decreases the formed amount of surface or/and bulk sulfation  
555 species for the sulfated  $\text{CeO}_2$  catalyst by organic  $\text{CS}_2+\text{COS}$  at 50 °C. These all help to improve  
556 the  $\text{NH}_3\text{-SCR}$  performance of  $\text{CeO}_2$  catalyst. However, excess water (5.0 vol.%) enhances the  
557 competitive adsorption of  $\text{H}_2\text{O}$  and  $\text{COS}/\text{CS}_2$ , which is slightly unbeneficial to the promotional  
558 effect of water introduction on the  $\text{NH}_3\text{-SCR}$  activity of  $\text{CeO}_2$  catalyst during the gas-phase  
559 sulfation of  $\text{CS}_2+\text{COS}$  at 50 °C.

#### 560 **4. Conclusions**

561 In summary, as an indispensable key reactant for the hydrolysis reaction of organic sulfur,  
562  $\text{H}_2\text{O}$  was introduced during the low-temperature gas-phase sulfation of  $\text{CS}_2+\text{COS}$ , which has  
563 been verified to be a simple and effective method to improve the  $\text{NH}_3\text{-SCR}$  performance of  $\text{CeO}_2$   
564 catalyst. The formation of hydroxyl groups dissociated from  $\text{H}_2\text{O}$  are beneficial to the adsorption  
565 of  $\text{CS}_2$  and  $\text{COS}$  on  $\text{CeO}_2$  surface, and enhances the interaction among them, although the  
566 introduction of  $\text{H}_2\text{O}$  decreases the formed amount of surface or/and bulk sulfation species.  
567 Furthermore, the introduction of  $\text{H}_2\text{O}$  increases the concentrations of  $\text{Ce}^{3+}$  ions, chemisorbed  
568 oxygen ( $\text{O}_\beta$ ) and oxygen vacancies on  $\text{CeO}_2\text{-CS}_2+\text{COS}$  surface, which also effectively enhances  
569 the redox cycle of  $\text{Ce}^{4+}/\text{Ce}^{3+}$  ion pairs and increases the medium-strong acid sites. These all  
570 contributes to further improving the promotional effect of  $\text{CS}_2+\text{COS}$  low-temperature gas-phase  
571 sulfation on the  $\text{NH}_3\text{-SCR}$  activity of  $\text{CeO}_2$ . However, it is imperative to be noted that the  
572 introduction of excessive  $\text{H}_2\text{O}$  might result in a reduced diffusion of  $\text{COS}$  and  $\text{CS}_2$  on the  
573 hydrolysis center of  $\text{CeO}_2$  and weakens their interaction during the low-temperature gas-phase  
574 sulfation, negating the promotional effect of  $\text{H}_2\text{O}$  introduction on the  $\text{NH}_3\text{-SCR}$  activity of the  
575  $\text{CeO}_2\text{-CS}_2+\text{COS}$  catalyst. The study can provide a scientific reference for the development of the  
576  $\text{CeO}_2$ -based catalysts in the practical application of  $\text{NH}_3\text{-SCR}$  technology.
