Disclaimer: The findings and conclusions in this report are those of the authors and do not necessarily represent the official position of the International Severe Acute Respiratory and Emerging Infection Consortium (ISARIC), the National Institutes of Health (NIH), and the World Health Organization (WHO). The project has received input from World Health Organization technical teams during the study design, data collection and analysis.

Contributions: DM conceived the idea for the study. DM led the methodological team and supervised the research team work throughout the project. DM, TN, PRW, DMN and NSe designed the study protocol. DM, TN, PRW, and DMN carried out the methodological discussions at the start of the project. DM, NSe and AC were responsible for the day-to-day running of the project. AM, ND, AA, LX, PB, PR, KA undertook the literature review, identified outcome measures and outcome measurement instruments and categorised them for inclusion in the online Delphi survey and expert Delphi survey. NSe and AC coordinated the data revision process. NSe and AC developed the online Delphi surveys and contributed to the day-to-day management of the project. NSe, AC, AM, ND were responsible for setting up the Delphi Manager. DM, NSe, AC, AM, ND were responsible for communication with stakeholders. NSe, AC, AM, ND prepared the instructions and materials for Delphi process participants. NSe, AM, ND were involved in the process of setting up and updating the website. DM, NSe, AC, AM, ND, AA, LX organised the ‘What to measure’ Consensus meeting. DM, NSe, AC, AM were responsible for instrument cards design and contents. DM, AC, NSe, AM, AA, LX organised the ‘How to measure’ Consensus meeting. DM, AC, NSe, DB, CB and SV participated in the project methodology discussions throughout the duration of the project. NN undertook the data analysis. NSe and AC organised the consensus meeting and consensus workshop. KK, NSc and JVD led the WHO administrative aspects of the study. SM provided and coordinated invaluable perspectives of people with lived experience throughout the study into its design and implementation. DM, NSe and AC drafted the manuscript; all authors reviewed and approved the final manuscript.

The authors alone are responsible for the views expressed in this publication and they do not necessarily represent the decisions, policy or views of the World Health Organization.

Declaration of Interests: DM is a Co-Chair of International Severe Acute Respiratory and Emerging Infection Consortium (ISARIC) Global Paediatric Long COVID Working Group, member of ISARIC working group on long-term follow-up in adults. CA reports grants or contracts from Dr Wolff Group, Bionorica and The European Cooperation in Science and Technology (COST). He also acknowledges consulting fees from the Dr Wolff Group, Bionorica, Sanofi and LEO Pharma. He serves as a Co-Chair Harmonising Outcome Measures for Eczema (HOME) initiative and Co-Chair Hand Eczema Core Outcome Set (HECOS) initiative and is core principal investigator of the KUNOKids Health Study (Regensburg, Germany) JP was employed by WHO in the Case Management team, HQ, WHE at the time of the manuscript writing. He is also a chair of the e-Learning committee and member of the Council at the European Society of Intensive Care Medicine. JVD is the lead of the clinical management response pillar for COVID-19 and in that capacity convene the WHO Clinical Characterization and Management Research working group. The Post COVID-19 COS steering committee was a sub working group of this bigger group. OLA has received research grants from UCB, Kidney Research UK, Gilead Sciences Ltd, The Health Foundation, NIHR Birmingham BRC, NIHR ARC, NIHR BTRU, Innovate UK, Merck, GSK, Anthony Nolan, and Sarcoma UK. He has also received personal fees from GSK, Gilead Sciences, Innovate UK, and Merck. CRO receives grant support from the National Institutes of Health (NIH), grant numbers OT2HL161847, and K23AI159518. PRW is chair of the Core Outcome Measures in Effectiveness Trials (COMET) Management Group. Other authors declare that they have no competing interests.

147 **Summary**

148
149 The COVID-19 pandemic substantially impacted different age groups, with children and young people
150 (CYP) not exempted. Many have experienced enduring health consequences. Presently, there is no
151 consensus on the health outcomes to assess in CYP with post COVID-19 condition. Furthermore, it is
152 unclear which measurement instruments are appropriate for use in research and clinical management
153 of CYP with post-COVID-19. To address these unmet needs, we conducted a consensus study, aiming to
154 develop a core outcome set (COS) and an associated core outcome measurement set (COMS) for
155 evaluating post-COVID-19 condition in CYP. Our methodology comprised of two phases. In phase 1 (to
156 create a COS), we performed an extensive literature review and categorisation of outcomes, and
157 prioritised those outcomes in a two-round online modified Delphi process followed by a consensus
158 meeting. In phase 2 (to create the COMS), we performed another modified Delphi consensus process to
159 evaluate measurement instruments for previously defined "core outcomes" from phase 1, followed by an
160 online consensus workshop to finalise recommendations regarding the most appropriate instruments
161 for each core outcome. In phase 1, 214 participants from 37 countries participated, with 154 (72%)
162 contributing to both Delphi rounds. The subsequent online consensus meeting resulted in a final COS
163 which encompassed seven critical outcomes: fatigue; post-exertion symptoms; work/occupational and
164 study changes; as well as functional changes, symptoms, and conditions relating to cardiovascular,
165 neuro-cognitive, gastrointestinal, and physical outcomes. In phase 2, 11 international experts were
166 involved in a modified Delphi process, selecting measurement instruments for a subsequent online
167 consensus workshop where 30 voting participants discussed and independently scored the selected
168 instruments. As a result of this consensus process, four instruments met a priori consensus criteria for
169 inclusion: 'PedsQL multidimensional Fatigue scale' for 'fatigue'; 'PedsQL Gastrointestinal symptom
170 scales' for 'gastrointestinal'; 'PedsQL Cognitive Functioning Scale' for 'Neuro-cognitive' and 'EQ5D
171 family' for 'physical functioning'. Despite proposing outcome measurement instruments for the
172 remaining three core outcomes ('cardiovascular', 'post-exertional malaise', 'work/occupational and
173 study changes'), a consensus was not achieved. Our international, consensus-based initiative presents a
174 robust framework for evaluating post-COVID-19 condition in CYP in research and clinical practice via a
175 rigorously defined COS and associated COMS. It will aid in the uniform measurement and reporting of
176 relevant health outcomes worldwide.

194 **Introduction**

195
196 While the majority of people infected with SARS-CoV-2 recover quickly, a significant number experience ongoing
197 or relapsing symptoms for a prolonged period of time. Most research on post COVID-19 condition has focused on
198 adults, with a much smaller number of paediatric studies. The prevalence of signs/symptoms after COVID-19 in
199 children and young people (CYP) remains largely unknown due to heterogeneous terminology across the studies,
200 but a recent systematic review estimated prevalence of symptoms one month after infection to be up to 25% ¹.
201 Estimation of post COVID-19 condition prevalence is somehow difficult due to heterogeneity in terminology used
202 and methodology applied ². A large multinational study estimated that around three percent of individuals under
203 20 years old with symptomatic SARS-CoV-2 infections had persistent fatigue, cognitive, and respiratory symptom
204 clusters upon recovery from the acute infection ^{3,4}, while reassuring data from the recent UK Office for National
205 Statistics suggests that the incidence of post COVID-19 condition is now less than one percent ⁵. Some studies
206 estimated cumulative incidence of persistent symptoms following SARS-CoV-2 infection between 24% and 58%
207 of CYP ⁶.

208
209 A diversity of outcomes is being evaluated in research on post COVID-19 condition in CYP. This heterogeneity
210 hinders the ability to compare findings and conduct meta-analyses to inform evidence-based decisions. There is
211 also a risk that ongoing or future interventional trials will not address some critically important outcomes as some
212 outcomes important in one group may not be important in another or vice versa. These issues highlight the need
213 for core outcome set (COS) development, to ensure that important outcomes are not missed in research or clinical
214 practice on post COVID-19 condition in CYP ⁷. COS are useful in various medical fields and can improve data
215 quality, harmonisation, and comparability between different studies and clinical practices ^{8,9}. A COS is a
216 universally agreed-upon, harmonised set of outcomes that, at a minimum, should be measured and reported in
217 every clinical trial within a specific medical area. These sets are also developed in other types of research and
218 clinical practice. They represent a consensus on the most critical outcomes for people with lived experience, their
219 families, researchers, health professionals and other key stakeholders. The “gold standard” approach to COS
220 development has been outlined by the Core Outcome Measures in Effectiveness Trials (COMET) framework and
221 consists of two steps: (a) “what to measure?”, and (b) “how to measure?” Once the COS is developed, the most
222 appropriate outcome measurement instruments for assessing the “core outcomes” should be defined to provide
223 practical measurement instruments for researchers and practitioners ⁹.

224
225 In 2021, an international group of experts defined the COS domains recommended to be used in all future
226 research and clinical care for adults with post COVID-19 condition ¹⁰ and the second phase of this project defined
227 the Core Outcome Measurement Set (COMS) in 2022 ¹¹. However, adults and CYP have distinct physiological and
228 developmental characteristics, which may result in different presentations and long-term implications of post
229 COVID-19 condition. Hence, it is crucial to have a tailored COS and COMS specifically designed for CYP to
230 accurately capture and address these nuances as COS/COMS potentially may be required for different groups of
231 paediatric population. To this end, we conducted an international study to develop a COS and COMS for post
232 COVID-19 condition in CYP for use in clinical research and practice.

234 **Methods**

235 **First phase (COS development)**

236
237 The development of the COS involved three stages: (1) reviewing the outcomes reported in studies on post COVID-
238 19 condition in CYP to develop a list of outcomes for stakeholder consideration; (2) a two-round online modified
239 Delphi consensus process to rate the importance of the outcomes for the COS; (3) an online interactive consensus
240 meeting to review and agree upon the final COS. The study protocol was developed a priori, and the project was
241 registered (<https://www.comet-initiative.org/Studies/Details/1847>). Ethical approval for the study was obtained
242 from the Sechenov University Ethics Committee on 20.01.2022 (protocol number 01-22).

243

244 The intended COS was developed for CYP below 18 years old, to be applied to post COVID-19 condition in clinical
245 research and practice settings. The terms post COVID-19 condition and Long COVID were used interchangeably
246 throughout the process.

247

248 **Study group and participants**

249

250 An international and multidisciplinary group of experts, including CYP with post COVID-19 experience and their
251 caregivers, conducted a project under the International Severe Acute Respiratory and Emerging Infection
252 Consortium (ISARIC) umbrella. The Core Outcome Measures in Effectiveness Trials (COMET) Initiative and the
253 World Health Organization (WHO) collaborated with this project.

254

255 Participants were categorised into three distinct stakeholder groups: (a) CYP with post COVID-19 condition and
256 their carers; (b) health professionals working with CYP with post COVID-19 condition; and (c) researchers
257 studying post COVID-19 condition in CYP. For health professionals and researchers, prerequisites for
258 participation included experience in treating CYP with post COVID-19 condition and conducting research in CYP
259 with post COVID-19 condition, respectively. More details can be found in the appendix 5, p 4.

260 **Developing a list of outcomes**

261 The COS consensus process was informed by a comprehensive search of Medline, Embase, and the WHO COVID-
262 19 Research Database (from inception until December 29, 2021). An additional search was performed on June 1,
263 2023, prior to consensus meeting, to screen for more recent evidence. The search was limited to English-language
264 publications and protocols. The detailed search strategy can be found in the appendix 1, pp 5-9.

265

266 Data from research protocols were extracted from two clinical trials registries, Clinical Trials.gov and the
267 International Clinical Trials Registry Platform, and reviewed by the reviewers (NS, AC, AM, ND, AA, LX, PB, PR,
268 KA), with two reviewers extracting the data from each record independently. We classified unique outcomes from
269 the list into domains (appendix 1, pp 27-82) using an existing taxonomy by Dodd and colleagues ¹².

270 **Delphi process and definitions**

271 We conducted a two-round online modified Delphi consensus process ⁹. In the first round, survey participants
272 anonymously rated each outcome using the Grading of Recommendations Assessment, Development and
273 Evaluation (GRADE) scale ¹³, which is a nine-point scale commonly divided into three categories for COS projects:
274 not important (1-3), important but not critical (4-6), and critically important (7-9). Each outcome had an "unable
275 to rate" option and an option to add text-based comments. More details can be found in the appendix 5, p 4.

276

277 In the second round of the Delphi process, participants were shown their original rating from the first round
278 alongside overall ratings of each of the three stakeholder groups for each outcome. They were then asked to rate
279 each outcome again using the same scale.

280

281 Consensus for inclusion of an outcome in the COS was defined a priori as 80% or more of participants in each
282 stakeholder group rating the outcome as critically important . Consensus for exclusion of an outcome from the
283 COS was defined as 50% or less of respondents in each stakeholder group rating the outcome as critically
284 important . Outcomes that did not meet these criteria were discussed at the consensus meeting.

285

286 The Delphi materials and all participant information were available in English, Chinese, Russian, French, and
287 Spanish. The Delphi survey was delivered using DelphiManager software (<http://www.comet->

288 [initiative.org/delphimanager](https://www.initiative.org/delphimanager)). Further details of the Delphi consensus process are included in appendix 1, pp 80-
289 106.

290

291 **Consensus meeting**

292

293 We conducted an interactive online consensus meeting via Zoom, extending invitations to individuals with
294 firsthand experience and their caregivers. The consensus meeting was conducted in English under the guidance
295 of an experienced independent facilitator. The meeting was organised around the results from the second round
296 of the Delphi.

297

298 The agenda prioritised outcomes that met the inclusion consensus by at least one stakeholder group, despite not
299 being agreed upon by all. Additionally, outcomes deemed 'critically important' by at least 50% (but not more than
300 80%) of the participants in each stakeholder group were also selected for discussion.

301

302 Each of three stakeholder groups assessed outcomes independently, utilising the aforementioned threshold for
303 defining inclusion — i.e., an outcome rated as critically important by 80% or more participants in all stakeholder
304 groups. For further details regarding the consensus meeting process, please refer to appendix 2.

305

306 **Data analysis**

307

308 Descriptive statistics were used to show the overall scores of each stakeholder group for the three GRADE
309 categories for all outcomes considered at each stage, to determine whether they met the predefined criteria for
310 inclusion or exclusion.

311

312 Similarly to the PC-COS adult project ¹⁰, we agreed a priori that only responses from Delphi participants who
313 rated at least 50% of outcomes would be included in the analysis. Free-text comments were translated into English
314 from the French, Russian, Spanish, and Chinese surveys and collated and reviewed by the core group. Bar plots
315 displaying the distribution of ratings for each outcome, faceted by stakeholder group, were produced using R
316 (version 4.2.1) and shown to participants in the second Delphi round.

317

318 **Second phase (Outcome measurement instruments consensus)**

319

320 **Literature review of outcome measurement instruments**

321

322 The core group reviewed all measurement instruments that emerged from our literature search. More details can
323 be found in the appendix 5, p 4.

324 Given that the measurement properties of non-COVID specific instruments had not been assessed in a post
325 COVID-19 population, assessment of the measurement properties of these instruments was not undertaken ¹¹.

326 For all instruments, feasibility-related data (e.g. time, cost, language/translations) were considered by the experts
327 and presented at consensus meeting to the participants. It was decided a priori that instruments requiring trained
328 personnel, additional software, clinical facilities, or not pertaining to "core outcomes" would be excluded to
329 ensure applicability of COMS across different settings. The instruments needed to be available for use even in
330 "low resource areas" and not require in person assessment or medical equipment.

331

332 **Expert Delphi Consensus**

333

334 The core group refined a comprehensive list of instruments derived from systematic literature and clinical trials
335 review. Instruments requiring trained personnel, additional software, clinical facilities, or not pertaining to "core
336 outcomes" were excluded.

A group of independent international experts, with extensive experience in post COVID-19 condition research and/or clinical practice, anonymously reviewed these instruments over two rounds. They provided feedback in excel spreadsheets on each instrument and suggested potential additions, which were assessed for feasibility and applicability by the core group. Approved new instruments were presented in the second round for further review. In the second round, each expert received a list of instruments accompanied by anonymised expert feedback from the first round. After reviewing the comments from the first round, they had the opportunity to modify their initial selection or retain it. Each expert indicated their preference for each instrument's inclusion in the consensus workshop.

Instruments that garnered "include" or "maybe" responses from more than 50% of the experts were forwarded to the online consensus meeting. We prepared "instrument cards", modified for the purposes of the project from the previous studies (<https://www.improvelto.com/instruments/>), for each outcome, collating a summary table of instruments selected for discussion. These were shared with the consensus workshop participants beforehand.

Consensus workshop

Upon obtaining expert review results, we convened at an online consensus workshop to discuss the shortlisted instruments. The consensus meeting was conducted in English and the study lead (DM) acted as a facilitator without voting rights.

Instruments selected as a result of 'expert review' as per criteria outlined above were discussed at the meeting. Consensus for an instrument to be included was defined as 70% or more participants from a total number of voting participants. If participants did not cast a vote on a given instrument, not less than 70% of voting participants were required to consider the vote valid.

Results

Literature review

We conducted a review of available studies and trial protocols on post COVID-19 condition in CYP. This review found 212 studies and protocols that met the inclusion criteria, as detailed in appendix 1, pp 10-27. These studies and protocols reported a total of 1097 outcomes, as detailed in appendix 1, pp 27-79.

The outcomes were classified and reviewed iteratively by the core group and project steering committee. After discussion, the steering committee approved 25 outcomes (appendix 1, pp 80-82) for consideration in the first round of the Delphi process. These 25 outcomes were categorised into four domains: survival (one outcome); physiological or clinical (17 outcomes); life impact (five outcomes); and resource use (two outcomes). Figure 1 summarises the steps taken in the development of the COS and COMS.

First phase (Core Outcome Set development)

Delphi process

The first round of the online Delphi process was conducted from November 23 to December 24, 2022. A total of 228 individuals registered to participate in the study, and 214 participants (94%) from 37 countries completed the first round, which required them to rate 50% or more of the 25 outcomes. Of these participants, 154 (72%) from 31 countries participated in the second round of the Delphi process and rated 50% or more of the outcomes in this subsequent round. Demographic characteristics of the participants for each Delphi round are presented in Table 1. Further details about the Delphi participants can be found in appendix 1 (pp. 83-90).

385 Upon completion of the first round of the Delphi process, the participant ratings indicated that the COS should
386 include three of the 25 outcomes, while four outcomes should be excluded, and consensus criteria for 18 outcomes
387 were not met. Table 2 and appendix 1, pp. 90-94 provide further details.
388

389 The core group reviewed 72 submitted free-text responses related to additional outcomes, with no new outcomes
390 added in the second Delphi round. Four participants suggested adding “recurrent infections” as a new outcome.
391 This suggestion was discussed within the core group with a decision made for not including it due to the lack of
392 evidence for post-COVID immune deficiency in children, the complexity of the outcome, and the difficulty in
393 differentiating it from infections stemming from other aetiologies. There was also overlap with some of the
394 outcomes already present as a part of the Delphi process, and core group highlighted practical challenges in
395 monitoring and documenting such infections.
396

397 The second Delphi round occurred from February 19 to March 31, 2023, during which 154 participants assessed
398 the 25 outcomes. Subsequently, four outcomes met criteria for inclusion, with three in the physiological or clinical
399 domain and one in the life impact domain. Eight outcomes were excluded. Thirteen other outcomes received
400 mixed ratings across the stakeholder groups, which led to their discussion at a subsequent consensus meeting.
401

402 **Consensus meeting**

403 The consensus meeting was conducted online on April 28, 2023. For feasibility purposes voting participants were
404 divided into two stakeholder groups: (a) CYP with post COVID-19 condition and their carers (n=11); (b) health
405 professionals working with CYP with post COVID-19 condition and researchers studying post COVID-19
406 condition in CYP (n=12). Detailed descriptions of the participants who attended the consensus meeting can be
407 found in appendix 2 (pp. 3-4).
408

409 Upon ratification of outcomes that were voted “in” and “out” upon the Delphi process the thirteen outcomes were
410 discussed in the following order: survival; post-exertion symptoms; mental/psychological functioning,
411 symptoms, and conditions; respiratory functioning, symptoms, and conditions; pain; sleep-related functioning,
412 symptoms, and conditions; gastrointestinal functioning, symptoms, and conditions; muscle and joint symptoms
413 and conditions; work/occupational and study changes; satisfaction with life or personal enjoyment; social role-
414 functioning and relationships problems; healthcare resource utilisation; family/carer burden.
415

416 After discussions and subsequent voting, three additional outcomes met the predefined consensus definition for
417 inclusion. These included “post-exertion symptoms” with 100% (11 out of 11) of the CYP with post COVID-19
418 condition and their carers and 84% (10 out of 12) of the health-care professionals and researchers rated it as
419 critically important, based on the GRADE rating of 7–9; “gastrointestinal functioning; symptoms; and conditions”
420 with 100% (11 out of 11) and 84% (10 out of 12) as well as “work/occupational and study changes” rate as critical
421 by 100% (11 out of 11) and 91% (11 out of 12) participants respectively. Consequently, three outcomes were
422 incorporated into the COS, joining the four previously agreed-upon outcomes. This brought the total number of
423 outcomes in the COS to seven. The results derived from both the Delphi process and the consensus meeting can
424 be accessed in appendix 1, pp. 90-106. A report of the consensus meeting is available in appendix 2.
425

426 **Second phase (Core Outcome Measurement Set development)**

428 **Literature review of outcome measurement instruments**

429 A comprehensive literature review found 1762 instruments used across post COVID-19 condition studies and trial
430 protocols. Following removal of duplicates and mapping of identified instruments to the core outcomes, the
431 number was reduced to 225. An independent assessment of these instruments by the core group, taking into
432 account a priori defined criteria, further reduced the list to 30. In addition to these, the study group identified five
433 relevant PROMIS instruments, bringing the total to 35 outcome measurement instruments. These instruments,

434 detailed in appendix 3, pp. 6-16, were mapped to seven “core outcomes” described above. The COS development
435 steps are summarised in Figure 1.

436

437 **Expert Delphi**

438 A group of eleven international experts anonymously reviewed instruments provided by the study team over two
439 Delphi rounds. Round 1 ran from June 8 to June 21, 2023, with all the experts completing this round. All the
440 experts were invited to participate in round two. Round 2 ran from July 3 to July 13, 2023; with all the experts
441 providing their feedback and scoring. Further details of experts involved in the Delphi process are detailed in
442 appendix 3, pp. 16-17.

443

444 Of the instruments reviewed in round 1, 18 out of 35 instruments met pre-specified criteria for inclusion for
445 discussion at consensus workshop. A single instrument (stomach reflux symptom by Visual Analog Score) was
446 excluded by the core group due to the non-specific nature of this VAS. All other instruments from round 1 were
447 taken forward to round 2. Additional potential instruments were assessed for feasibility and applicability by the
448 core group. 15 approved new instruments were presented in the second round for further review, including one
449 instrument that was specific to the post COVID-19 condition in adults which is currently in the process of
450 validation for CYP. A total of 49 instruments were reviewed in round 2 and 20 of them met pre-specified criteria
451 for inclusion for discussion at consensus workshop. The WHO Disability Assessment Schedule (WHODAS 2.0)
452 Children and Youth 36-Item Version instrument was found upon the pre-meeting literature search update and
453 included for discussion at the consensus workshop.

454

455 **Consensus workshop**

456

457 Ahead of the consensus workshop, materials were circulated to all individuals invited to the meeting. The online
458 consensus workshop was held on July 31, 2023, with 46 individuals participating in this three and a half-hour
459 session. This attendance included six study team members, nine observers, and 30 voting participants (eight
460 carers of CYP with post COVID-19 condition; and 22 health professionals and researchers with expertise in post
461 COVID-19 condition in CYP, mirroring the approach taken for the first phase of the project and previous process
462 of COS development for the adult population ^{10,11}). Details of those who participated in the consensus workshop
463 can be found in appendix 4, pp. 2-3.

464

465 At the start of the online workshop, participants were briefed about the process and a priori defined criteria for
466 consensus. Participants were reminded that multiple instruments could be chosen or voted ‘in’ within a domain.
467 Voting on each instrument was independent. The subsequent outcomes and measurement instruments discussed
468 were: Cardiovascular functioning, symptoms, and conditions (PedsQL Cardiac Module; Symptom Burden
469 Questionnaire for Long COVID (Circulation scale) and Malmo POTS score (MAPS)); Gastrointestinal functioning,
470 symptoms, and conditions (PedsQL Gastrointestinal Symptoms Scales; Questionnaire on Pediatric
471 Gastrointestinal Symptoms (QPGS) and Symptom Burden Questionnaire for Long COVID (Stomach and
472 Digestion Scale)); Neurocognitive functioning, symptoms, and conditions (PROMIS Pediatric Cognitive Function
473 - Short Form 7a; PedsQL Cognitive Functioning Scale and Symptom Burden Questionnaire for Long COVID
474 (Memory, Thinking & Communication scale, movement scale, muscles and joints, pain scales)); Fatigue (Chalder
475 fatigue questionnaire; PROMIS Paediatric Fatigue; PedsQL Multidimensional Fatigue Scale and Symptom
476 Burden Questionnaire for Long COVID (Fatigue scale)); Post-exertion symptoms (CDC symptom inventory for
477 CFS; PEM items from DePaul Symptom Questionnaire and Symptom Burden Questionnaire for Long COVID
478 (Fatigue scale)); and Physical functioning, symptoms, and conditions (EQ5DY instrument; PROMIS Physical
479 Activity and Symptom Burden Questionnaire for Long COVID (Impact on Daily Life Scale)); Work occupational
480 and study changes (Symptom Burden Questionnaire for Long COVID (Impact on Daily Life Scale) and WHO DAS
481 2 Children and Youth 36-Item Version).

482

483 Following discussion and voting, 'PedsQL multidimensional Fatigue scale' instrument for 'fatigue' with 26/26
484 (100%) of consensus meeting participants voting 'Yes' for inclusion so it was added to the COMS; 'PedsQL
485 Gastrointestinal symptom scales' for 'gastrointestinal' 23/26 (88%); 'PedsQL Cognitive Functioning Scale' for
486 'Neuro-cognitive' with 21/25 (84%) and 'EQ5D family' for physical functioning 24/25 (96%), respectively. Overall,
487 four measurement instruments were selected for inclusion into COMS (see Table 3 and Figure 2).
488

489 Consensus was not achieved for recommending measurement instruments for the remaining three core outcomes.
490 Table 3 indicates the voting results and reasons for exclusion for the instruments discussed at the meeting but
491 not reaching consensus. Detailed consensus workshop report is available in the appendix 4.
492

493 **Discussion**

494 This manuscript presents the findings of a large, rigorous international consensus study aimed at developing a
495 COS and a COMS for post COVID-19 condition that are intended for use in CYP in research and clinical practice
496 settings. Seven outcomes achieved the predefined consensus definition for inclusion in the COS: fatigue; post-
497 exertion symptoms; work, occupational and study changes; as well as functional changes, symptoms, and
498 conditions relating to cardiovascular, neuro-cognitive, gastrointestinal, and physical outcomes. Agreement
499 regarding the most appropriate instruments to be used was reached for four outcomes: these were the EQ5D
500 family (for physical functioning) and the fatigue, gastrointestinal symptoms and cognitive functioning scales of
501 the PedsQL. The consensus process reduced the number of potential instruments for measuring the seven core
502 outcomes from over 200, despite no single measurement instrument reaching consensus for the remaining three
503 outcomes.
504

505
506
507 Through our consensus process, we identified seven critical outcomes to be incorporated in both research and
508 clinical practice, ensuring that the most salient aspects of the condition are consistently and effectively addressed.
509 Five of the seven consensus-based outcomes in this COS are in the physiological or clinical outcomes domain and
510 cover many of the frequently reported symptoms in CYP. While the WHO clinical case definition of post COVID-
511 19 condition in CYP¹⁴ offers a consistent clinical terminology, the COS delineates the essential outcomes that
512 ought to be assessed in every study and clinical setting.
513

514 Across stakeholder groups, there was a broad consensus on the significance of most outcomes. Two outcomes,
515 namely 'sleep-related functioning, symptoms, and conditions' and 'pain', narrowly missed the predefined
516 threshold. A notable divergence in perspectives emerged regarding the 'family/carer burden' outcome. CYP with
517 post COVID-19 condition and their carers deemed this outcome as critically important. In contrast, only 34% of
518 health-care professionals and researchers viewed it with the same level of importance. Despite not meeting the
519 criteria for inclusion in the COS, the significance of this outcome was recognised by both groups, with 100% of
520 CYP and caregivers and 84% of health-care professionals and researchers rating it as either important or critically
521 important (appendix 2). The emphasis placed on these outcomes suggests that they warrant consideration in
522 research and clinical settings. It is important to note that COS is a necessary minimum that should always be
523 measured but do not preclude from measuring other outcomes.
524

525 It is also worth noting that a small number of "CYP with Long COVID and their family and carers" acknowledged
526 the critical importance of 'mental' outcome assessment, with concerns of stigmatisation being raised. Many
527 parents shared their experience of being troubled and hesitant to discuss mental problems of their child with
528 healthcare providers, as the symptoms in a child are often attributed to mental health challenges/issues. This is
529 in contrast to the COS for post COVID-19 condition in adults, which includes this outcome¹⁰. All health
530 professionals/researchers considered this outcome important with 7/12 (59%) feeling that it is critical. Mental
531 health-related symptoms are common, and it is understandable to suffer effects on emotional wellbeing due to

532 having an illness such as post COVID-19 condition as it has a direct effect on an individual's life. Concerns of
533 stigmatisation should not stand in the way of being able to assess the child or young person holistically and hence
534 provide necessary support. Health professionals and researchers need to approach this delicate topic with care,
535 while carers of CYP with post COVID-19 condition should not see attempt to assess mental health as lack of trust
536 to their concerns about their child.

537
538 Overall, the paediatric COS seems to focus more on functional and symptomatic outcomes directly relevant to
539 CYP's daily lives, such as school and physical activities, while the adult COS encompasses a broader range of health
540 aspects, including respiratory, mental health and survival, which are important for all age groups, but more
541 pertinent to the adult population. These differences underscore the unique health impacts and assessment needs
542 of these two age groups in post-COVID-19 condition research.

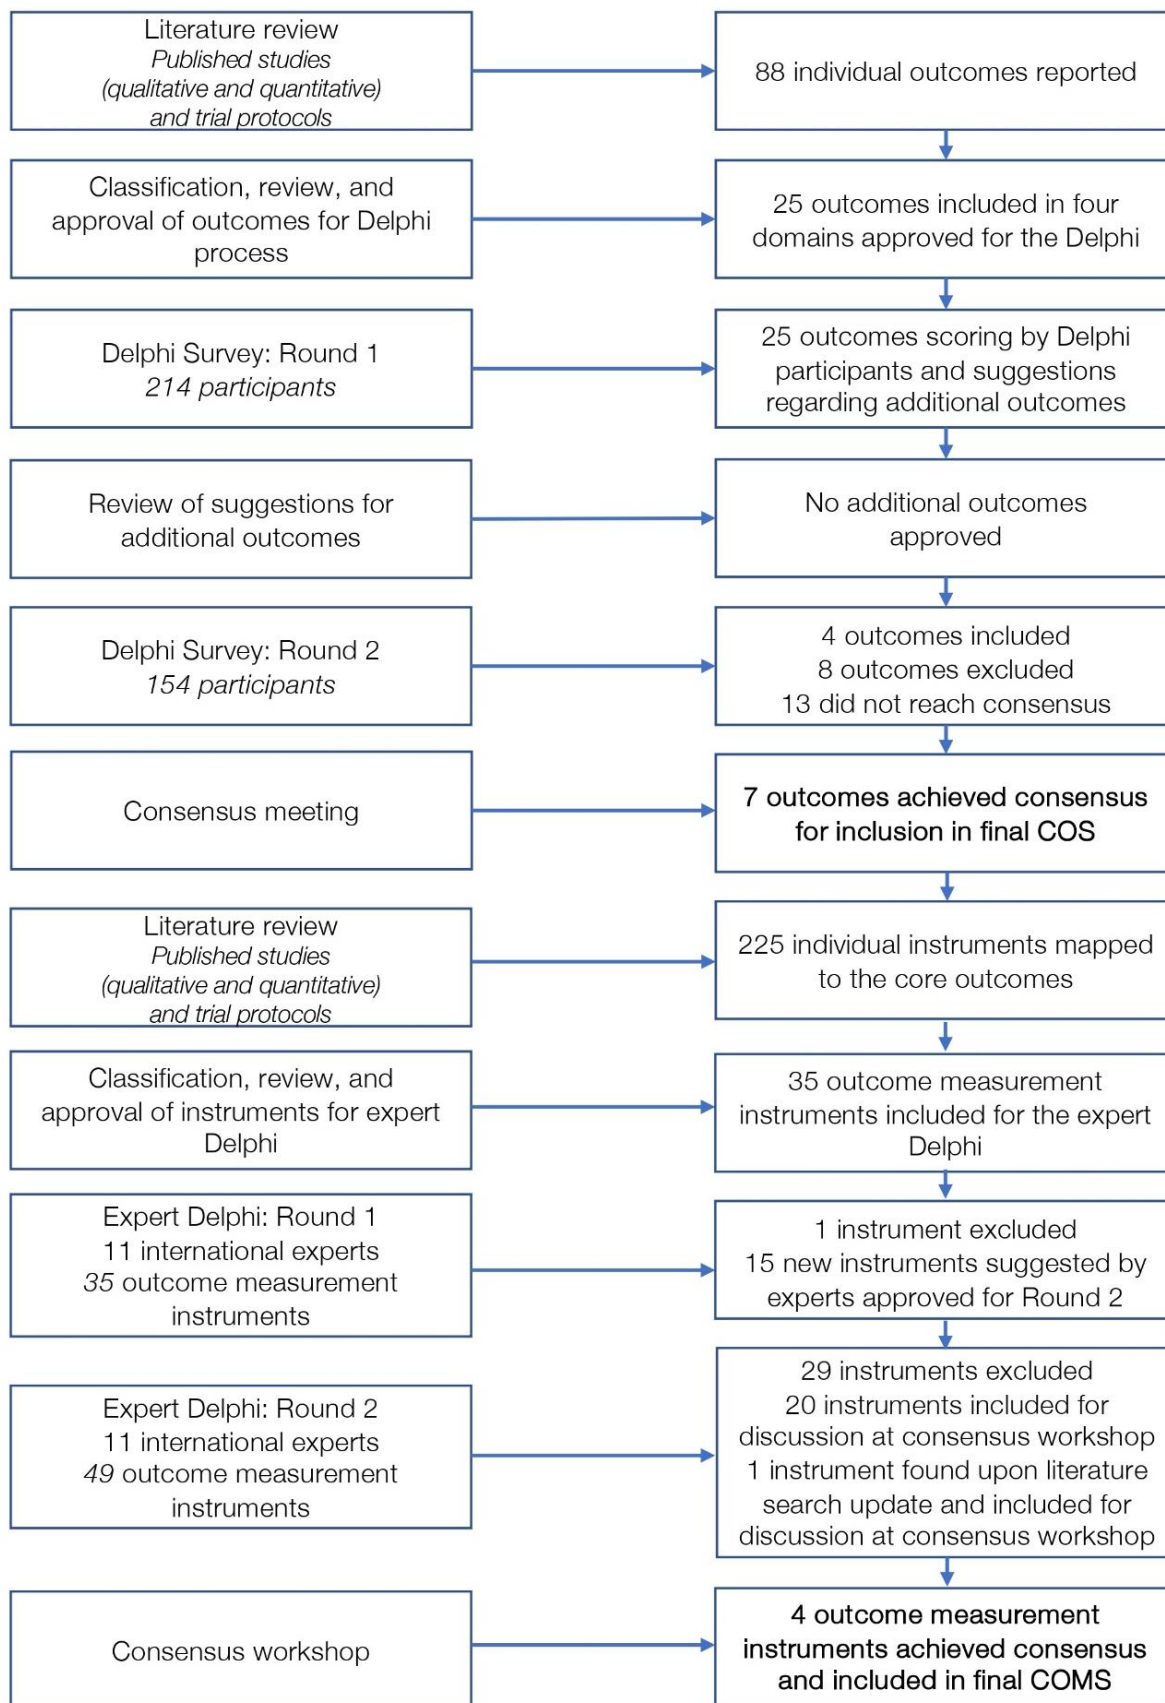

543
544 The PedsQL and EQ5D families of instruments offer multiple age-specific versions ^{15,16}. These versions contain
545 questions pertinent to a child's development, and they have been translated into various languages and are used
546 across different medical disciplines.

547
548 Consensus regarding measurement instruments was not achieved for three outcomes. There were several
549 potential reasons for this. Firstly, post COVID-19 condition is a recently discovered condition and the mechanistic
550 understanding in CYP is still in its infancy. This heterogeneity can influence instrument preference, and the
551 unique considerations of the paediatric population such as specific needs for different age groups or inability to
552 appropriately articulate their complaints in younger children, introduce added complexity. Secondly, past
553 experiences with various instruments may have introduced implicit bias, thereby influencing participant scoring.
554 At least one of these measurement instruments can be potentially considered for each core outcome although they
555 should be used with caution taking into account workshop participants feedback (appendix 4, pp. 4, 7, 10).

556
557 Our study has some limitations. Firstly, while the Delphi consensus process for the COS incorporated individuals
558 from diverse geographical locations, the majority were white, and were resident in the UK and the United States.
559 The Delphi process also saw an underrepresentation of male participants, which is a common problem in
560 survey/Delphi research, and particularly related to CYP, and has previously been acknowledged ^{18,19}. Both
561 imbalances could potentially result in a lack of external validity or generalisability. Although the Delphi has been
562 conducted in multiple languages some widely used languages (e.g. Hindi and Arabic) were missing. These
563 demographic imbalances might challenge the external validity of our findings. Long COVID disproportionately
564 impacts underprivileged groups, with potential rural vs. urban disparities in healthcare access and quality. This
565 might influence the utilisation rating among family and carers, who form a significant portion of participants.
566 Treatment for Long COVID can be costlier, hitting lower-income individuals and LMIC populations harder ²⁰.
567 Secondly, a consensus meeting during the first phase of the project included only a limited subset of Delphi
568 participants, whose perspectives might not encompass the full spectrum of views on the subject. However, this
569 limitation is an inherent component in the Delphi methodology. It is also important to note that the meeting did
570 not overturn the "in"/ "out" results from the Delphi, and it allowed discussion of those not reaching consensus
571 previously. Thirdly, given the pressing public health implications of COS development, we expedited our study.
572 Consequently, we did not gather data on chronicity, time since diagnosis, and participants' socioeconomic status.
573 A similar approach was previously employed for the adult COS development. Yet, it is worth noting that
574 comprehensive data collection on Delphi participants is not standard practice. In line with the WHO's definition,
575 our study included individuals with both confirmed and probable SARS-CoV-2 infections. However, it is possible
576 that some with a "probable" diagnosis might not have had the infection. Lastly, in the second phase of the project,
577 aiming at outcome measurement instrument selection, the Delphi process has been conducted without
578 involvement of CYP with post COVID-19 condition and their carers. Instead, an international panel of experts
579 conducted a Delphi process. This approach aimed to expedite the consensus process and reduce the potential
580 burden on participants, drawing insights from a similar process conducted for adults. This has been mitigated in

581 part by involvement of carers of CYP with post COVID-19 condition at the final consensus workshop. Another
582 limitation is absence of COSMIN methodology for selecting instruments implementation in the COMS
583 development, as measurement properties of non-COVID-19-specific instruments had not been assessed in a post-
584 COVID-19 population.
585

586 While the incidence of new acute SARS-CoV-2 cases has seen a decline, it is imperative to address the lingering
587 legacy of post COVID-19 condition, particularly due to its prolonged persistence. With the acute cases becoming
588 less frequent, there is a potential risk of the broader community adopting an 'out of sight, out of mind' perspective.
589 However, it is crucial to highlight the substantial absolute number of CYP globally who are grappling with Long
590 COVID. The long-term implications of this condition on their growth, maturation, and overall development
591 underscore the need to recognise post COVID-19 condition not merely as a transient concern but rather as a
592 chronic health issue. This rigorous international consensus study has successfully delineated a COS and a COMS
593 tailored for post COVID-19 condition in CYP. While the consensus provides clarity in a nascent and multifaceted
594 field, it also underscores the need for continued exploration, especially for outcomes where consensus remains
595 elusive. As we navigate the complexities of post COVID-19 conditions in CYP, this consensus serves as a guidance
596 for both research endeavours and clinical practices towards a more unified and informed approach (Box 1). The
597 outcomes of this study may also be useful not only within its immediate context but also as a model for future
598 pandemic situations. We believe that the generalisable knowledge derived from this COMS exercise can
599 significantly benefit the broader academic and medical communities in the future challenges.

Box 1: Key messages

Rationale and approach

- In children and young people, the post COVID-19 condition, also known as Long COVID is associated with a range of persistent symptoms following infection with SARS-CoV-2.
- Research on post COVID-19 condition varies in outcomes studied. A consensus on a minimum set of essential outcomes, referred to as Core Outcome Set (COS) is needed for better data comparison in children and young people.
- There is also an urgent need for decisions to be made on which measurement instruments are the most appropriate for assessing these core outcomes, in order to develop a Core Outcome Measurement Set (COMS), to optimise data comparability and synthesis.
- To develop the COS, we conducted a study that included a literature review, a two-round online Delphi process with over 214 participants from 37 countries, with over half of them being parents of children with post COVID-19 condition and children and young people, and an online consensus meeting. The Delphi process included rating 25 different outcomes.
- For the development of COMS, we then performed an expert online modified Delphi process and an online consensus workshop to discuss and then vote anonymously on measurement instruments.

Findings

- In the field of paediatric care, it is recommended that the following outcomes to be consistently measured in research and clinical practice when assessing post COVID-19 condition: fatigue; post-exertion symptoms; alterations in studies, work, or occupational activities; as well as functional changes, symptoms, and conditions relating to cardiovascular, neuro-cognitive, gastrointestinal, and physical health.
- Instruments for measurement of fatigue, gastrointestinal, neuro-cognitive outcomes and physical functioning were recommended for use in research and clinical practice for children and young people with post COVID-

19 condition. For the three other core outcomes, the most favoured measurement instruments identified from this consensus procedure have been documented, even though no individual measurement instrument met a priori criteria for consensus.

Future Directions and Implications

- To enhance our understanding of post COVID-19 condition in children, there is a need for further standardisation of clinical and research practices using the identified core outcomes and associated measurement instruments.
- Future research should focus on refining and validating the measurement instruments that were favoured but did not achieve consensus among participants.
- Incorporating the lived experiences and perspectives of children and young people affected by post COVID-19 condition as well as their carers is crucial for future research, including instrument development and improvements to patient care.
- Agreed measurement instruments should be considered in future work and insights from this research should guide policymakers in creating initiatives that address the effects of post-COVID-19 condition on children and young people in both healthcare and research environments.
