## **Implementing rapid algorithms for high sensitivity troponin – economic benefits and caveat emptor.**

High sensitivity cardiac troponin (hs cTn) assays are now available world-wide. The aim of the diagnostics industry as a whole is to provide and support the implementation of hs cTn. Provision of the previous generation assays will occur only until regulatory approval is obtained for the high sensitivity version in the relevant geographic area, with the objective of phasing out the previous generation assays (personal communication). In Europe there is almost complete conversion to hs cTn(1) although in the United States conversion has been slower due to regulatory delays.

The merits of switching to hs cTn assays have been debated. Earlier fears of increased resource utilisation arising from greater diagnostic sensitivity have not even born out in clinical practice(2-4). However, enthusiastic over requesting in the Emergency Department (ED) can often produce inappropriate cardiac referrals where cardiac troponin (cTn) elevation is not due to acute coronary syndromes (ACS). Indeed, ACS is now the minority cause of elevated cTn in the unselected ED population(4, 5).

The current hs cTn assays can achieve very low imprecision (the variation between repeated measurements of the same sample) at low absolute values of cTn, those values within the lower 25% of the reference interval. This property has been exploited in a number of clinical studies that have shown that measurements of cTn made on admission(6, 7) or in the 1-2 hours following admission(8) can be used to predict the subsequent risk of myocardial infarction as defined by the conventional 99<sup>th</sup> percentile threshold(9). Although often described as diagnostic algorithms these are in fact predictive algorithms, something which

1 should always be remembered. They are risk stratification tools based on the troponin and the  
2 result they provide should be combined with clinical findings and the electrocardiogram. An  
3 admission level that is very low or low but does not significantly change predicts a low risk.  
4  
5 Conversely, an initially high value or one within the reference interval which significantly  
6  
7 changes predicates admission to the coronary care unit. This predictive risk stratification  
8  
9 approach has been endorsed both following evidence based review by the UK National  
10  
11 Institute of health and Care Excellence (NICE)(10, 11) and by the European Society of  
12  
13 Cardiology (ESC) (12).  
14  
15  
16  
17  
18  
19  
20  
21

22 Are these algorithms likely to be clinically useful and improve resource utilisation? Although  
23  
24 the appeal of rapid emptying of the ED of patients who do not need to be there is apparently  
25  
26 self-evident, there is a lack of real world studies to address this point. Although the switch to  
27  
28 hs cTn in Europe is near universal, uptake of rapid diagnosis is less so(1). The recent paper by  
29  
30 Cohen and colleagues in this issue of the Journal is therefore timely in supporting the  
31  
32 introduction of rapid diagnostic algorithms by providing an assessment of both the clinical  
33  
34 and economic benefits.  
35  
36  
37  
38  
39  
40

41 The authors undertook an audit of test requesting practices and clinical decisions over a 58  
42  
43 month period for patients presenting with suspected non-ST elevation myocardial infarction  
44  
45 (NSTEMI) to the ED. During this period, all patients had cardiac troponin T (cTnT)  
46  
47 measured by a high sensitivity assay (hs cTnT) but patients were managed according to the  
48  
49 local diagnostic protocol which utilised the 99<sup>th</sup> percentile and pre-test probability for  
50  
51 significant coronary artery disease for management decisions. The reason for this was  
52  
53 although the assay has high sensitivity characteristics, only results above 13 ng/L were  
54  
55 reported numerically and available to the clinicians managing the patient. The authors  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1 therefore had the opportunity to compare actual management based on, effectively, the 99th  
2 percentile (14 ng/L) and clinical judgement with what might have happened if management  
3 had occurred according to ESC recommendations. They then undertook operational and  
4 financial modelling to assess the impact on resource utilisation. The unique aspect of the  
5 study is that it reviews real world data in a real world decision making environment with the  
6 clinicians blinded to the hs cTn results. The authors identified a cohort of 3775 out of 11477  
7 consecutive patients who were triaged and met the ESC rapid rule out criteria but were  
8 nevertheless admitted. Only 0.32% of the patients had a primary outcome of index myocardial  
9 infarction or all cause death within 30 days. For those patients with a cTnT value <5 ng/L  
10 there was zero 30 day mortality. More than half of the patients who presented had cTnT  
11 values that met the rule out criteria but approximately one third underwent further clinical  
12 investigation. The prognosis in this group was statistically indistinguishable to those patients  
13 who met ESC rule out criteria and were discharged from the ED. The admitted patients used  
14 significant health care resources including ED stay, hospital stay and the use of invasive and  
15 non-invasive cardiac tests but did not have clinical findings requiring revascularisation.

35  
36  
37  
38

39 The study therefore confirms the findings from other large studies that a very low troponin  
40 either at or close to the limit of detection of the assay defines a very low risk group of  
41 individuals who do not need hospital admission and intensive investigation(13). Indeed, they  
42 were able to identify a cohort where no benefits of further investigations were demonstrated.

63  
64  
65

1 conclusion is therefore that rapid rule out of patients based on low troponin values is both safe  
2 and cost-effective.  
3  
4  
5  
6

7 The study also sheds light on requesting patterns in cTn testing. First, only approximately one  
8 third of troponin tests were part of investigation of suspected ACS. Second, of those patients  
9 evaluated 38.2% had a cTnT between 5-14 ng/L but did not have a repeat test performed as  
10 recommended by current guidelines. This is consistent with other studies where rapid  
11 diagnostic algorithms have been implemented(15).  
12

14  
15  
16  
17  
18  
19  
20  
21

22 There is an interesting caveat to this study. The study was only possible as the product  
23 labelling reported that the limit of quantitation of the assay, usually considered to be the  
24 lowest reportable numeric values of the assay, to be 13 ng/L. This may well have contributed  
25 to the unnecessary repeat testing occurred in patients with cTnT values <5 ng/L. Closer  
26 reading of the current package insert for the hs cTnT assay shows that this is indeed the  
27 wording used but applies to the 10% coefficient of variation (CV) of the assay. Limit of  
28 quantitation is usually considered to represent a CV of 20%. The assay performance reported  
29 by the manufacturer on the International Federation of Clinical Chemists cardiac biomarkers  
30 webpage is consistent with the ESC recommendations for cTnT with a 20% CV of 1-3 ng/L.  
31 ([https://www.ifcc.org/media/479435/high-sensitivity-cardiac-troponin-i-and-t-assay-  
32 analytical-characteristics-designated-by-manufacturer-v052022.pdf](https://www.ifcc.org/media/479435/high-sensitivity-cardiac-troponin-i-and-t-assay-analytical-characteristics-designated-by-manufacturer-v052022.pdf)). The study laboratory  
33 confirmed that the analytical performance of the assay was consistent with high sensitivity  
34 criteria. The company website supports the use of the ESC guideline. It is important that  
35 information supplied by manufacturers is consistent across electronic data sources and  
36 package inserts (instructions for use, IFU) and reflects accepted scientific publications and  
37 current guidelines. Caveat emptor indeed.
