One-sentence summary: Single-cell signaling and information theoretic analyses reveal that oncogenic PI3K/AKT activation leads to a gross reduction in signaling specificity, context-dependent EGF response amplification as well as increased phenotypic heterogeneity.

30   **Abstract**

31   Pathological activation of the PI3K/AKT pathway is among the most frequent defects in human
32   cancer and is also the cause of rare overgrowth disorders. Yet, there is currently no systematic
33   understanding of the quantitative flow of information within PI3K/AKT signaling and how it is
34   perturbed by disease-causing mutations. Here, we develop scalable, single-cell approaches
35   for systematic analyses of signal processing within the PI3K pathway, enabling precise
36   calculations of its information transfer for different growth factors. Using genetically-
37   engineered human cell models with allele dose-dependent expression of $PIK3CA^{H1047R}$, we
38   show that this oncogene is not a simple, constitutive pathway activator but a context-
39   dependent modulator of extracellular signal transfer. $PIK3CA^{H1047R}$ reduces information
40   transmission downstream of IGF1 while selectively enhancing EGF-induced signaling and
41   transcriptional responses. This leads to a gross reduction in signaling specificity, akin to
42   "blurred" signal perception. The associated increase in signaling heterogeneity promotes
43   phenotypic diversity in a human cervical cancer cell line model and in human induced
44   pluripotent stem cells. Collectively, these findings and the accompanying methodological
45   advances lay the foundations for a systematic mapping of the quantitative mechanisms of
46   PI3K/AKT-dependent signal processing and phenotypic control in health and disease.

47

INTRODUCTION

The class IA phosphoinositide 3-kinase (PI3K)/AKT pathway is essential for cellular and organismal homeostasis. It is used for signal transduction downstream of most if not all growth factors (GFs) as well as many hormones and cytokines. The pathway also represents a key therapeutic target due to its frequent hyperactivation across human cancers. This is often due to mutations in *PIK3CA*, the gene encoding the p110α catalytic subunit of the PI3Kα isoform. Based on early cellular studies (1–3), common cancer-associated *PIK3CA* mutations such as *PIK3CA^{H1047R}* are often regarded as constitutive "on" switches, or activators, of the pathway. Consequently, therapeutic targeting of aberrant PI3K/AKT activation in this context has focused on pathway switch-off (4). However, the efficacy of this approach is often limited by the toxicity of PI3K/AKT inhibition in healthy cells and tissues treated with high doses of PI3K/AKT inhibitors. This is true not only in cancer but also in the non-cancerous *PIK3CA*-related overgrowth spectrum (PROS) of congenital disorders caused by an identical spectrum of activating *PIK3CA* mutations as in cancer (5,6).

The "switch" view of the impact of activating *PIK3CA* mutations and the resulting therapeutic limitations reflect a more general, critical gap in the current knowledge of PI3K/AKT signaling. Specifically, there is limited understanding of how quantitative, dynamic patterns of PI3K/AKT activation are used by cells to specify (i.e., encode) the identity of the myriad environmental signals sensed by this pathway (7,8). It therefore also remains unknown if and how disease-causing mutations in PI3K/AKT pathway components may perturb this temporal code. For example, corruption of dynamic signal encoding has been documented in the related RAS/MAPK signaling cascade in response to certain oncogenic BRAF mutations and targeted inhibitors (9).

This type of quantitative mapping of the input-output relationships in the PI3K/AKT pathway is technically very challenging. It requires capture of multimodal biochemical responses with high temporal resolution and quantitative precision (7,8). Moreover, unlike conventional protein phosphorylation cascades, the key first step in PI3K pathway activation is the generation of the plasma membrane-localized lipid second messenger phosphatidylinositol-3,4,5-trisphosphate (PIP$_3$), and its derivative PI(3,4)P$_2$. The detection of these low-abundance lipids presents a technical challenge, and thus the vast majority of studies of oncogenic PI3K signaling do not feature direct evaluation of this critical first signal encoding step in PI3K pathway activation, focusing instead on bulk measurements of downstream effector responses (8).

Lastly, a breakthrough in translating our currently semi-quantitative view of the PI3K/AKT pathway into a fully quantitative framework is contingent upon access to systematic measurements of PI3K/AKT signaling at the single-cell level (7,8). This is important for two reasons. First, the fidelity of information transfer within a system depends both on the strength of the signal and on its uncertainty, or variability (10). The latter refers to the biochemical response heterogeneity that would typically be observed at the level of individual cells in an otherwise homogenous cell population. This concept is at the core of mathematical information theoretic analyses of signaling pathways, a powerful approach pioneered by Levchenko and colleagues to study quantitative signaling fidelity (11,12). Second, robust approaches to measurements of PI3K/AKT signaling heterogeneity at the single-cell level are required for mapping signaling thresholds to phenotypic decision making according to a probabilistic framework (8,13,14). This contrasts with the conventional view of deterministic outputs downstream of PI3K/AKT pathway activation.

Here, we first set out to address the technical limitations that preclude systematic studies of single-cell PI3K/AKT signaling at scale. Following extensive benchmarking of available PIP$_3$/PI(3,4)P$_2$ biosensors and optimization of available live-cell and mass-cytometry-based protocols, we have developed robust experimental and analytical approaches for studies of single-cell PI3K/AKT biology. We then used these approaches to study quantitative signal transfer in cell models with allele dose-dependent expression of *PIK3CA^{H1047R}*. We discovered

100   that this oncogene corrupts the fidelity of signal transmission in cervical cancer (HeLa) cells
101   and in induced pluripotent stem cells. The associated increase in PI3K/AKT and RAS/MAPK
102   signaling heterogeneity manifested phenotypically in the emergence of co-existing cell states.
103   Our findings and methodological advances provide the basis for quantitative mapping of
104   PI3K/AKT-dependent signal processing and phenotypic control in health and disease.

105

106   **RESULTS**

107   **Optimized workflow for PI3K activity measurements at the plasma membrane**

108   For quantitative studies of the immediate phosphoinositide lipid outputs of PI3K activation
109   in individual cells and at high temporal resolution, we established a robust, semi-automated
110   live-cell imaging pipeline (**Fig. S1A**). Using total internal reflection fluorescence (TIRF) and
111   the small-molecule PI3Kα activator 1938 (15) to monitor PI3Kα outputs specifically at the
112   plasma membrane, we first systematically benchmarked the quantitative fidelity (dynamic
113   range, technical variability) of several PH domain-based phosphoinositide biosensors (**Fig.
114   S1B**). These included the PH domain of BTK (with or without the adjacent TH domain (16,17)),
115   a tandem-dimer version of the PH domain of ARNO (with modifications to minimize
116   interactions with other proteins (18)), and the PH domain of AKT2 (of note, this is not the full-
117   length protein to avoid internalization independent of PIP$_3$ binding (19)). For consistent
118   comparisons, all biosensors were expressed from the same plasmid backbone, featuring a
119   GFP tag at the C-terminus and a nuclear export sequence at the N-terminus (**Fig. S1B**). As
120   control for specificity, all experiments with wild-type biosensors also featured co-expression
121   of an mCherry-tagged version of each construct, with an arginine-to-alanine mutation that
122   ablates phosphoinositide binding (**Fig. S1B**) (20).

123   The PH domain of AKT2 consistently performed as an optimal biosensor, based on the
124   dynamic range, reproducibility across experiments, low sensitivity to technical noise, and rapid
125   response upon activation as well as inhibition of PI3Kα (**Fig. S1C, S1D**). We note, however,
126   that while this measures the total PIP$_3$/PI(3,4)P$_2$ output of PI3K activation at the plasma
127   membrane, the original N terminal-tagged version of the PH-TH of BTK would be a better
128   option for studies that seek to selectively study PIP$_3$ independent of PI(3,4)P$_2$ (**Fig. S1E**).

129   Our final optimized TIRF-based workflow for PI3K activity measurements allowed profiling
130   of up to 4 different cellular conditions (e.g., genotypes) and 60 single cells per experiment,
131   with live-cell measurements taken every 70 sec over 60 min while exposing the cells to
132   controlled perturbations, giving rise to more than 3000 individual data points.

133   **Temporal measurements of class IA PI3K activation identify conserved, dynamic**
134   **encoding of growth factor signals**

135   Using a set of independent cellular model systems (human HeLa cervical cancer cells,
136   human A549 lung adenocarcinoma cells, immortalized mouse embryonic fibroblasts) with or
137   without endogenous functional PI3Kα, we next tested the hypothesis that the identity of
138   different growth factors is captured in the cellular dynamics of PIP$_3$/PI(3,4)P$_2$. Using saturating
139   doses of IGF1 and EGF in serum-free medium, we observed remarkably consistent responses
140   that suggested conservation of the dynamic signal encoding of these growth factors across
141   different cell models and species (**Fig. 1**). At the population level, both IGF1- and EGF-induced
142   PIP$_3$/PI(3,4)P$_2$ reporter responses exhibited a characteristic overshoot, with a peak within the
143   first 10 min of stimulation, followed by a sustained quasi steady-state above baseline. The key
144   difference between the two growth factors was in the response amplitude, with PI3Kα wild-
145   type cell lines reaching a peak PIP$_3$/PI(3,4)P$_2$ fold-change of ~1.55 for IGF1 and ~1.25 for EGF
146   **(Fig. 1)**.

147   The combined genetic and pharmacological (BYL719) inactivation of PI3Kα in these
148   experiments also revealed cell type- and growth factor-specific quantitative differences in the

149 contribution of the PI3Kα isoform to each growth factor response (**Fig. 1**). For example, in
150 HeLa cells, approximately 60% and 50% of the IGF1 and EGF response, respectively, was
151 mediated by PI3Kα. In mouse embryonic fibroblasts, PI3Kα contributed 40% of the IGF1
152 response and up to 60% of the peak EGF response yet only up to 50% of the sustained EGF-
153 induced PIP$_3$/PI(3,4)P$_2$ reporter response. This would therefore suggest that the observed
154 stereotypical IGF1- and EGF-dependent PIP$_3$/PI(3,4)P$_2$ response patterns are robust to the
155 relative contribution of individual class IA PI3K isoforms (**Fig. 1**).

156 Collectively, these data identify conserved dynamic PI3K-dependent encoding of IGF1 and
157 EGF, with high temporal and isoform-specific resolution.

158

159 Oncogenic _PIK3CA^{H1047R}_ reduces the PIP$_3$/PI(3,4)P$_2$ information capacity of IGF1

160 We next tested whether the dynamic signal encoding of growth factor identity is equally
161 robust to the expression of _PIK3CA^{H1047R}_, one of the most commonly observed oncogenic
162 PI3Kα mutations in cancer and PROS. Allele dose-dependent, endogenous expression of this
163 variant was engineered in HeLa cells, using CRISPR/Cas9 (**Fig. S2A, S2B**). We chose this
164 cell model due to its low baseline PI3K/AKT signaling (**Fig. S2**), absence of pathway-specific
165 mutations, in-depth characterization at multiple biological levels (transcriptomics, proteomics
166 (21)), experimental tractability and, in particular, its cervical cancer origin. Genomic profiling
167 of human cervical tumors has revealed this cancer to be among the most enriched for multiple
168 _PIK3CA_ mutations in _cis_ or _trans_ (22,23). We therefore reasoned that HeLa cells may allow to
169 capture allele dose-dependent effects of _PIK3CA^{H1047R}_ on quantitative signal transfer. So far,
170 such allele dose-dependent effects have only been studied mechanistically in a developmental
171 model system (24,25).

172 Several quality control assays were applied to all final CRISPR/Cas9 clones to identify
173 possible confounders. Assays included whole-exome sequencing (**Fig. S2C**), transcriptomics
174 (**Fig. S2D**) and candidate-based mRNA and protein expression evaluations (**Fig. S2E, S2F,
175 S2G**). None of these assays revealed any systematic differences across the different clones
176 except for the desired knock-in of _PIK3CA^{H1047R}_ and evidence for an associated yet subtle
177 baseline PI3K/AKT pathway activation by immunoblotting. This is important because it
178 enables to study the consequences of the oncogenic perturbation on signaling response
179 independent of widespread transcriptional changes that could modify the topology of the
180 relevant signaling networks.

181 To assess dynamic signal encoding of IGF1 and EGF as a function of _PIK3CA_ genotype,
182 cells were stimulated with one of three different doses (1 nM, 10 nM, 100 nM) of each growth
183 factor, and PIP$_3$/PI(3,4)P$_2$ responses were captured using TIRF microscopy as described
184 above (**Fig. 2A**). The resulting temporal measurements of PI3K activity at the single-cell level
185 were processed for mathematical information-theoretic analyses of trajectory responses (26),
186 resulting in formal quantification of the fidelity of dose-dependent signal transfer through PI3K
187 activation. Given three different stimulus doses for each growth factor, the theoretical
188 maximum information capacity captured in the PIP$_3$/PI(3,4)P$_2$ response would be 1.58 bits
189 (log2(3)), corresponding to the case where the PIP$_3$/PI(3,4)P$_2$ response alone is sufficient to
190 distinguish between the different doses of the growth factor perfectly. While this is unlikely to
191 be reached given technical noise, values that are substantially lower than 1.58 would imply
192 that the PIP$_3$/PI(3,4)P$_2$ response alone is not sufficient to distinguish the different doses of
193 each growth factor with high certainty.

194 We found that HeLa cells with wild-type _PIK3CA_ expression reached a relatively high mean
195 information capacity of 1.2 bits for IGF1, suggesting that the majority of information about the
196 dose of IGF1 is captured in the PIP$_3$/PI(3,4)P$_2$ response (**Fig. 2B**). Conversely, there was
197 higher cellular uncertainty about the EGF doses based on the PIP$_3$/PI(3,4)P$_2$ trajectory alone,
198 with _PIK3CA_ wild-type HeLa cells reaching a mean information capacity of 0.75 bits. Notably,
199 expression of the _PIK3CA^{H1047R}_ oncogene resulted in a substantial drop in information transfer

5

200 downstream of IGF1, particularly in cells expressing a single copy of the mutation. Conversely,
201 single-copy $PIK3CA^{H1047R}$ trended towards increased information capacity downstream of
202 EGF (**Fig. 2B**).

203   Three conclusions can be drawn from these data. First, these results demonstrate that
204 oncogenic $PIK3CA^{H1047R}$ can erode signaling fidelity in a growth factor-specific manner.
205 Second, $PIK3CA^{H1047R}$ HeLa cells' ability to distinguish between distinct doses of IGF1 on the
206 basis of their $PIP_3/PI(3,4)P_2$ response degrades, reaching similar levels of information capacity
207 as seen for EGF. Third, evaluation of temporal trajectories from the same cells and with high
208 technical precision is key for accurate calculations of information transfer in signaling
209 responses. As shown in **Fig. 2C**, information capacity calculations on snapshot measurements
210 from the same data but without the temporal connection reveal erroneously low measures of
211 PI3K signaling fidelity for both growth factors.

212

$PIK3CA^{H1047R}$ corrupts the specificity of dynamic signal encoding

214   Further examination of the $PIP_3/PI(3,4)P_2$ trajectories in **Fig. 2A** suggested another key
215 difference between wild-type and $PIK3CA^{H1047R}$ HeLa cells. Consistently, the EGF-induced
216 $PIP_3/PI(3,4)P_2$ reporter response in mutant cells appeared amplified and largely
217 indistinguishable from that of IGF1 in wild-type cells. This led us to hypothesize that
218 $PIK3CA^{H1047R}$ expression may corrupt the cellular ability to resolve different growth factor
219 inputs from one another. For this to have any significance, however, it would need to be
220 reflected in the activity of key effectors downstream of $PIP_3/PI(3,4)P_2$ generation.

221   We therefore turned to live-cell imaging of a stably-expressed, high-fidelity FOXO-based
222 kinase translocation reporter (KTR) (27), whose nucleocytoplasmic distribution provides a
223 proxy measure for AKT activity (**Fig. S3A**) and is amenable to high-content-based, quantitative
224 analyses (**Fig. S3B**). Compared to TIRF, widefield fluorescence imaging of the FOXO-based
225 KTR response benefits from lower technical noise and allows capture of a much larger number
226 of individual cells for robust information theoretic analyses across stimulations with different
227 growth factors. We chose to compare IGF1, insulin, EGF and epigen due to their paired
228 similarities at the level of activation of distinct RTKs (IGF1R/INSR vs EGFR). In *PIK3CA* wild-
229 type cells, IGF1 and insulin elicited stronger and relatively similar FOXO-based KTR
230 responses compared to EGF and epigen (**Fig. 3A, Fig. S3C,D**). Moreover, the temporal
231 trajectories of IGF1/insulin remained highly distinct from those of EGF and epigen (**Fig. 3A,
232 Fig. S3C,D**).

233   However, simply observing the average trajectories on their own is not enough to determine
234 whether the FOXO-based KTR signaling dynamics are sufficiently distinct to allow individual
235 growth factor inputs to be differentiated from one another. We therefore leveraged the entire
236 set of single-cell trajectories to calculate the mutual information between IGF1 and every other
237 growth factor. Mutual information takes into account the probabilistic and thus variable nature
238 of individual growth factor responses. IGF1 was used as the control due to its highly robust
239 single-cell KTR responses, both in terms of magnitude and temporal dynamics. Consistently,
240 $PIK3CA^{H1047R}$ mutant cells exhibited an allele dose-dependent reduction in mutual information
241 for all growth factors compared to IGF1 (**Fig. 3B**; note that mutual information is measured in
242 bits, i.e., log2 scale). This drop was most pronounced for EGF and epigen, in line with the
243 notion of selective amplification of the PI3K/AKT response downstream of EGFR seen in the
244 mutant context. Consequently, the FOXO-based KTR response in mutant cells was no longer
245 sufficiently distinct to resolve different growth factor inputs from one another. We therefore
246 conclude that $PIK3CA^{H1047R}$ corrupts the dynamic encoding of signal identity, giving rise to
247 cells with "blurred biochemical vision" (**Fig. 3C**).

248

249

6

$PIK3CA^{H1047R}$ amplifies EGF signaling in cycling cells in 3D culture

250

251 A limitation of the approaches presented so far is reliance on exogenous reporters for
252 evaluation of signaling responses. Moreover, TIRF-based measurements of the $PIP_3/PI(3,4)P_2$
253 reporter response are incompatible with joint tracking of the miniFOXO KTR reporter, limiting
254 analyses to one response at a time. Finally, two-dimensional cell culture models do not capture
255 the biological heterogeneity and additional complexity of three-dimensional (3D) culture
256 systems. We therefore developed an orthogonal approach for single-cell-based signaling
257 measurements in more complex culture settings, whilst retaining the ability to perform
258 temporal perturbation experiments at scale.

259 Specifically, we adapted a recently published highly-multiplexed, mass cytometry workflow
260 (28) for use with a new method that we developed for scalable generation of scaffold-free
261 spheroids, including fixation for preservation of signaling responses and subsequent non-
262 enzymatic single-cell dissociation (**Figure 4A**). We turned to mass cytometry given its
263 versatility, compatibility with cell state-dependent gating and ability to multiplex up to 126
264 distinct conditions, with gains in sensitivity and technical robustness.

265 Experiments with saturating doses of IGF1 and EGF revealed that robust growth factor
266 signaling responses in HeLa spheroid cells were restricted to a cell cycling and non-apoptotic
267 cell state (i.e., pRB Ser807/811-positive and cleaved Caspase3 D175-negative cells; **Fig. S4**).
268 This aligns with recent findings of a multimodal, cellular state-conditioned sensitivity to growth
269 factor stimulation in the human 184A1 breast epithelial cell line (29). Remarkably however,
270 even when gating on the $pRB^+/cCASP3^-$ cell state, a comparison of the single-cell response
271 distribution shifts relative to control treatments showed discernible, growth factor-specific
272 temporal responses for phosphorylated AKT^{S473} ($pAKT^{S473}$), $ERK1/2^{T202/Y204; T185/Y187}$ and
273 $S6^{S240/S244}$ ribosomal protein (**Fig. 4B**). For example, in wild-type cells, the single-cell
274 distribution shift for AKT phosphorylation was strongest upon stimulation with 100 nM IGF1
275 stimulation and peaked after 5-10 min. The same was true for ERK1/2 phosphorylation in
276 response to EGF. Further downstream, a positive distribution shift for S6 phosphorylation
277 ($pS6^{S240/S244}$) followed with a delay relative to $pAKT^{S473}$ (**Fig. 4B**), consistent with prior studies
278 of bulk responses.

279 Next, to capture the temporal, signaling transitions present in this multidimensional dataset,
280 we turned to PHATE (potential of heat diffusion for affinity-based transition embedding).
281 PHATE produces a non-linear, low-dimensional embedding that preserves both local and
282 global structure in the data (30). We first calculated an earth mover's distance (EMD) score
283 for each response distribution relative to untreated wild-type control cells; this score provides
284 a concise measure of how different a single-cell distribution for a given signaling marker is
285 relative to another (the corresponding wild-type control distribution in this case). PHATE was
286 then applied to the EMD scores of all measured signaling markers ($pAKT^{S473}$, $pERK1/2^{T202/Y204;}$
287 $^{T185/Y187}$, $pNDRG1^{T346}$, $pS6^{S240/S244}$, $pSMAD2/3^{S465/S467; S423/S425}$). This revealed a time-
288 dependent convergence in signaling space of IGF1 and EGF responses for $PIK3CA^{H1047R}$
289 mutant cells (**Fig. 4C**), consistent with the "blurring" concept shown in **Fig. 3C**. This analysis
290 also confirmed a clear distinction between HeLa cells with one *versus* two endogenous copies
291 of $PIK3CA^{H1047R}$, with the latter featuring higher baseline levels of the mTORC2 activation
292 marker $pNDRG1^{T346}$ (**Fig. S5A,B**).

293 In line with our 2D live-cell studies of PI3K/AKT signaling dynamics (**Fig. 1, Fig. 2**), we also
294 observed that both single and two-copy $PIK3CA^{H1047R}$ mutant cells exhibited an amplified
295 response to EGF stimulation (**Fig. 4B, 4C, S5A**). This resulted in stronger and more sustained
296 responses both at the level of $pAKT^{S473}$ and $pERK1/2^{T202/Y204; T185/Y187}$. Relative to wild-type
297 controls, the signaling responses in both single- and double-copy $PIK3CA^{H1047R}$ mutant HeLa
298 cells also exhibited increased single-cell variability as a function of time and growth factor
299 stimulation, most notably for $pAKT^{S473}$ (**Figs. 4B**). This was reproduced with independent
300 clones (**Fig. S5B**), and in additional dose-response, time course experiments using 1 nM, 10
301 nM, and 100 nM IGF1 or EGF (**Fig. S6A,B**). We therefore conclude that oncogenic

7

302   *PIK3CA^H1047R* does not simply shift the PI3K/AKT signaling response to a higher mean but
303   also acts to enhance signaling heterogeneity.

304

**305   Corrupted signal transfer in *PIK3CA^H1047R* mutant cell models translates into increased
306   phenotypic heterogeneity in the context of EGF sensitization**

307   We next set out to test whether the observed signal corruption in *PIK3CA^H1047R* mutant cells
308   translates into altered transcriptional and phenotypic responses. First, enhanced EGF
309   signaling through AKT and ERK should lead to an amplification of EGF-specific transcriptional
310   responses. These are known to be sensitive to the relative amplitude and duration of upstream
311   signals such as ERK activation (31,32). Consistent with this prediction, we observed increased
312   and more sustained mRNA expression of known EGF-dependent immediately early and
313   delayed early genes in *PIK3CA^H1047R* spheroids stimulated with EGF (**Fig. 5A**). This was
314   specific to *PIK3CA^H1047R*, as simply combining saturating concentrations of IGF1 and EGF to
315   elicit strong activation of both AKT and ERK was not sufficient to amplify the transcriptional
316   response in *PIK3CA* wild-type cells. Consistent with EGF's known role as an epithelial-
317   mesenchymal transition (EMT)-inducing factor (33,34), we also observed increased
318   expression of the EMT-associated transcription factor *SNAIL (SNAI1)* in bulk *PIK3CA^H1047R*
319   HeLa spheroids (**Fig. 5A**). The apparent allele dose-dependent pattern of these responses
320   was non-linear, however, with single-copy *PIK3CA^H1047R* mutant cells exhibiting the strongest
321   relative induction of EGF-dependent transcripts. These transcripts have also previously been
322   associated with epithelial-mesenchymal transitions downstream of diverse inputs (33).

323   Second, the increased variability in signaling responses in *PIK3CA^H1047R* HeLa cells would
324   be expected to cause increased phenotypic heterogeneity. To evaluate this, we visualized cell
325   appearance in standard 2D culture (**Fig. 5B**). Whereas wild-type HeLa cells grew as epithelial-
326   like cell clusters, single- and double-copy *PIK3CA^H1047R* cells were more dispersed and
327   exhibited a higher proportion of cells with irregular, mesenchymal-like morphologies (**Fig. 5B-
328   D, Fig. S7A**). The mesenchymal shapes were most pronounced in single-copy *PIK3CA^H1047R*
329   mutant cells (**Fig. 5B,C**), in line with their higher expression of *SNAIL* upon EGF stimulation
330   (**Fig. 5A**). Conversely, a higher proportion of the double-copy *PIK3CA^H1047R* cells exhibited
331   large, flattened morphologies (**Fig. 5B,D**).

332   The phenotypic heterogeneity observed in these HeLa cell models with endogenous, allele
333   dose-dependent *PIK3CA^H1047R* expression bore notable resemblance to the only other
334   available model system of this kind – an allelic series of non-transformed, human iPSCs with
335   heterozygous and homozygous expression of *PIK3CA^H1047R*. Specifically, homozygous
336   *PIK3CA^H1047R* iPSC cultures were previously shown to exhibit coexisting epithelial and
337   mesenchymal-like cellular morphologies (24) (Fig. S7B). We hypothesized that this phenotypic
338   heterogeneity reflects corrupted signal transfer in homozygous *PIK3CA^H1047R* iPSCs, including
339   amplification of EGF-dependent responses and increased signaling heterogeneity as
340   observed in the HeLa cervical cancer cell model. To test this, we applied our mass cytometry-
341   based, single-cell signaling pipeline (**Fig. 4A**) on 3D-cultured, IGF1- or EGF-stimulated iPSCs
342   from the aforementioned allelic series. As expected, both heterozygous and homozygous
343   *PIK3CA^H1047R* iPSCs had higher baseline phosphorylation of AKT (pAKT^S473) relative to wild-
344   type cells, and this increased further upon IGF1 stimulation (**Fig. 6A,B**). However, only
345   homozygous *PIK3CA^H1047R* iPSCs showed an amplified EGF response both at the level of AKT
346   and ERK phosphorylation. Importantly, this was accompanied by a notable increase in the
347   heterogeneity of the underlying *PIK3CA^H1047R/H1047R* single-cell responses (**Fig. 6A,B**),
348   revealing a conserved signaling phenotype that had remained inaccessible to conventional
349   workflows based on bulk signaling measurements.

350   In conclusion, compromised – or corrupted – signal transfer downstream of *PIK3CA^H1047R*
351   translates into increased signaling and phenotypic heterogeneity in the context of a selective
352   amplification of EGF responses (**Fig. 6C**).

8

Discussion

Despite tremendous advances in understanding of the core topology of the PI3K/AKT pathway over the last 30 years, the quantitative mechanisms of signal-specific information transfer in this pathway have remained elusive due to technical and analytical limitations (7,8). In this work, we present a suite of optimized single-cell-based, kinetic workflows for systematic mapping of quantitative signaling specificity in PI3K/AKT pathway activation. Supported by information theoretic analyses, we have shown that endogenous expression of the $PIK3CA^{H1047R}$ cancer hotspot variant results in quantitative blurring of growth factor-specific information transfer, amplification of EGF-induced responses and increased phenotypic heterogeneity in an allele dose-dependent manner. We note that an early study of bulk PI3K signaling responses in non-transformed breast epithelial cells also observed sensitization to EGF in the presence of either $PIK3CA^{H1047R}$ or the helical domain hotspot variant $PIK3CA^{E545K}$ (35). Our quantitative framework now allows these results to be contextualized into a coherent model of growth factor-specific mechanisms of action of oncogenic $PIK3CA$.

We propose a model in which oncogenic $PIK3CA^{H1047R}$ is not a simple ON switch of the PI3K/AKT pathway but acts as a context-dependent signal modifier, determined by the principles of quantitative biochemistry (8,36). Accordingly, the most parsimonious explanation for the selective amplification of EGF-dependent responses by $PIK3CA^{H1047R}$ is the ability of this mutation to increase p110α residency times at lipid membranes (37,38), alongside the lack of high-affinity phospho-Tyrosine (pTyr) binding sites for the regulatory p85 subunit on EGFR and its associated adaptor proteins (39). This would make the interaction between p110α and RAS essential for efficient PI3K-dependent signal transduction downstream of the EGFR (40–43), which would explain two key observations in our data: 1) the substantial increase in EGF-induced ERK phosphorylation in cell models expressing only mutant $PIK3CA^{H1047R}$; 2) the complete suppression of AKT KTR responses following PI3Kα-selective inhibition in the context of EGF but not IGF1/insulin stimulation (Figs. 3 and S3). It is clear both from our PIP_3/PI(3,4)P_2 and AKT/FOXO (KTR) trajectories that IGF1 (and insulin) signals through both PI3Kα and an additional class IA PI3K isoform. This is unsurprising given the known ability of p85 to bind efficiently to pTyr (pYxxM) sites on IGF1R and insulin receptor substrate (IRS) proteins irrespective of the catalytic p110 subunit (44,45). It also explains the convergence of IGF1/insulin-induced AKT/FOXO (KTR) trajectories in $PIK3CA$ loss-of-function and $PIK3CA^{H1047R}$ cells following PI3Kα-selective inhibition (Fig. S3). The only cell line in this work in which PI3Kα appeared dispensable for EGF-induced PI3K signaling was A549, a lung adenocarcinoma cell line with amplified EGFR (46). This aligns with the above biochemical considerations; a higher concentration of EGFR would allow for more successful engagement of low-affinity interactors such as p85, thus making PI3K activation less dependent on RAS binding via p110α. This follows from the fact that p110β, which is the other main catalytic p110 isoform in the non-hematopoietic cell lineages used here, does not have the capability of direct interaction with RAS (47).

The above model is nevertheless a simplification because it does not account for another salient property of oncogenic $PIK3CA$, revealed by our quantitative single-cell measurements of PI3K/AKT signaling dynamics. Thus, we consistently observed an increase in signaling and phenotypic heterogeneity downstream of allele dose-dependent $PIK3CA^{H1047R}$ expression. It is interesting that an increased heterogeneity in PI3K pathway activation was also noted in an early study of $PIK3CA^{H1047R}$ overexpression in breast epithelial cells (48). The consequences of this heterogeneity are two-fold. First, it increases the uncertainty in the ability to predict the outputs of oncogenic PI3K/AKT pathway activation, i.e. the outputs are probabilistic rather than deterministic. This calls for increased attention to single-cell PI3K signaling responses in the ongoing evaluation of the many PI3K/AKT pathway inhibitors entering preclinical and clinical use (4,49,50). Second, such heterogeneity endows cells with the ability to sample multiple phenotypic states, or attractors (51), as shown by the emergence of co-existing cellular phenotypes in otherwise isogenic cells with $PIK3CA^{H1047R}$ expression. This may offer

405 a mechanistic underpinning for the remarkable phenotypic heterogeneity found in *PIK3CA*-
406 driven breast cancer models (52–54) as well as benign but highly debilitating human PROS
407 disorders (5)*.* It is likely that the observed increase in single-cell "noise" endows the population
408 of mutant *PIK3CA^{H1047R}* cells with a selective advantage in the face of unpredictable and
409 rapidly changing environments as shown in other systems (55).

410   Finally, our quantitative PI3K signaling framework also makes possible the prospective
411 development and application of pharmacological approaches to tune pathological PI3K
412 signaling responses back to normal, for example through allosteric modulation of receptor-
413 specific coupling mechanisms. This has also been suggested for RAS/MAPK signaling (56),
414 in light of recent findings that oncogenic mutations in this pathway also remain dependent on
415 upstream growth factor inputs yet fail to transmit these reliably (9). Given the likely
416 dependence on a direct PI3Kα-RAS interactions for the EGF response amplification in
417 *PIK3CA^{H1047R}* cells, the recently released PI3Kα-RAS breaker (57) may be an excellent
418 candidate for testing of quantitative, growth factor-specific PI3K signaling dynamics as a
419 pharmacological target.

420

10

421 **MATERIALS AND METHODS**

422   Where referenced, the Open Science Framework (OSF) project containing all source
423 datasets underpinning this work can be accessed via doi: 10.17605/OSF.IO/4F69N.
424

425 **Immortalized cell culture**

426   HeLa cells and mouse embryonic fibroblasts (MEFs) were cultured in complete medium
427 consisting of DMEM (with 4 mM L-Glutamine and 1 mM sodium pyruvate; Thermo Fisher
428 Scientific #41966-029) supplemented with another 2 mM of L-Glutamine (Sigma #G7513) and
429 10 % fetal bovine serum (FBS; Pan-Biotech #P30-8500).
430   Lung adenocarcinoma A549 cells were cultured in complete medium consisting of RPMI-
431 1640 with GlutaMax and Sodium Bicarbonate (#61870-036, Thermo Fisher Scientific),
432 supplemented with 1 mM of Sodium Pyruvate (#11360-039, Thermo Fisher Scientific) and 10
433 % FBS.
434   Cells were cultured in T25 flasks (Corning or TPP) and passaged every two-to-three days
435 when 80-90% confluent. Briefly, the spent medium was removed and the cells washed with 5
436 ml DPBS (Sigma #RNBH8966 or Thermo Fisher Scientific # 14190-094). Following removal
437 of the wash, the cells were incubated at 37°C in 0.75 ml TrypLE™ Express Enzyme (Thermo
438 Fisher Scientific #12605028 or #1260421) for 6-8 min until dissociated. The cells were
439 resuspended in complete medium and distributed to new flasks at appropriate ratios.
440

441 **Human induced pluripotent stem cell culture**

442   The male human iPSCs used in this work were derived from the WTC11 line, following
443 CRISPR/Cas9 engineering for endogenous expression of *PIK3CA^{H1047R}* as described
444 previously (24). The cells were maintained in Essential 8 Flex Medium (Thermo Fisher
445 Scientific #A2858501) on plates coated with 10 µg/cm^2 Cultrex Stem Cell Qualified Reduced
446 Growth Factor Basement Membrane (R&D Systems #3434-010-02). Cells were cluster-
447 passaged every 3-4 days with 0.5 mM EDTA and seeded into medium supplemented with 10
448 µM Y-27632 dihydrochloride (Bio-Techne #1254/10) for the first 24 h. For details of the
449 spheroid set-up, see dx.doi.org/10.17504/protocols.io.3byl4bnrrvo5/v1. The cells were single-
450 cell dissociated with StemPro Accutase (Thermo Fisher Scientific # A1110501) and seeded at
451 1000 cells/spheroids in 200 µl Essential 8 Flex supplemented with 10 µM Y-27632
452 dihydrochloride. The following day, the medium was replenished without Y-27632. Spheroids
453 were processed for experimental perturbations two days following formation.

454 **Cell line quality control**

455   All cell lines were cultured in the absence of antibiotics except if processed for selection
456 post-engineering as indicated. Cells were routinely tested negative for mycoplasma and
457 genotyped by Sanger sequencing (knock-in lines) or immunoblotting (knock-out lines) to
458 confirm the correct identity prior to experimental use.

459 **CRISPR/Cas9 gene editing of *PIK3CA* exon 21 in HeLa cells**

460   Low-passage (P5) HeLa cells were used for CRISPR/Cas9 engineering for knock-in of the
461 *PIK3CA* H1047R variant (c.CAT>c.CGT) using a modified version of the protocols described
462 in Refs. (24,58). Briefly, a total of 200,000 cells were targeted with a total of 200 pmol single-
463 stranded oligodeoxynucleotides (ssODNs) introducing either the targeting mutations along
464 with silent mutations or silent mutations without the targeting mutation:

465 *HDR001 ssODN (targeting mutation and silent mutations): 5′-*
466 *TAGCCTTAGATAAAACTGAGCAAGAGGCTTTGGAGTATTTCATGAAACAAATGAACGAC*

467 *GCACGTCATGGTGGCTGGACAACAAAAATGGATTGGATCTTCCACACAATTAAACAGCA*
468 *TGCATTGAACTGAAAAGATAACTGAGAAAATG-3'*

469 *HDR002 ssODN (silent mutation only): 5'-*
470 *TAGCCTTAGATAAAACTGAGCAAGAGGCTTTGGAGTATTTCATGAAACAAATGAACGAC*
471 *GCACATCATGGTGGCTGGACAACAAAAATGGATTGGATCTTCCACACAATTAAACAGCA*
472 *TGCATTGAACTGAAAAGATAACTGAGAAAATG-3'*

473 Three different mixtures of ssODNs (HDR001 alone, HDR002 alone, 1:1 mixture
474 HDR001:HDR002) were set up to ensure generation of a dose-controlled allelic series for
475 *PIK3CA^{H1047R}*. Targeting was performed using recombinant ribonucleotide proteins (RNPs) at
476 ratio 1:1.2 (Cas9:sgRNA; 4 µM:4.8 µM). The synthetic sgRNA (5'-
477 AUGAAUGAUGCACAUCAUGG-3') was obtained from Synthego (modified for extra stability).
478 The high-fidelity Alt-R™ S.p. Cas9 Nuclease V3 (IDT # 1081061) was used to limit off-
479 targeting risk. Cells were targeted by nucleofection using the SE Cell Line 4D-Nucleofector™
480 X Kit S (Lonza #V4XC-1032). Cells were allowed to recover from nucleofection before sib-
481 selection-based subcloning to isolate pure clonal cultures. To aid recovery, conditioned
482 medium (1:1 mixture with fresh medium) was used for 7 days during subcloning.

483 An initial screen for correct genotypes was performed using DNA extracted with
484 QuickExtract (Cambridge Bioscience # QE0905T) and subjected to PCR amplification and
485 Sanger sequencing with primers: 5'- CAGCATGCCAATCTCTTCAT-3' (forward), 5'-
486 ATGCTGTTCATGGATTGTGC-3'. As HeLa cells are triploid on average, genotypes were
487 called following deconvolution with Synthego's ICE tool (59). Putative pure wild-type (or silent
488 mutation only) and *PIK3CA^{H1047R}* clones were expanded and subjected to final validation by
489 next-generation sequencing using MiSeq, with Illumina adaptor-appending primers:

490 *5'-*
491 *TCGTCGGCAGCGTCAGATGTGTATAAGAGACAGATAAAACTGAGCAAGAGGCTTTGGA-*
492 *3' (forward);*

493 *5'- GTCTCGTGGGCTCGGAGATGTGTATAAGAGACAGATCGGTCTTTGCCTGCTGAG-*
494 *3' (reverse).*

495 The MiSeq output was analyzed using CRISPResso2 (60). All raw and analyzed files are
496 deposited on the accompanying OSF project site (doi: 10.17605/OSF.IO/4F69N, component:
497 *MiSequencing_CRISPR_clone_validation*).

498 Note that HeLa cells are nominally triploid. All knock-in lines with one or two copies of
499 *PIK3CA^{H1047R}* therefore harbor two or one allele(s), respectively, with a C-terminal frameshift
500 equivalent to those in the loss-of-function 3xFS clone (**Fig. S2**). This frameshift is too close to
501 the stop codon of p110α to result in nonsense-mediated decay and instead causes a change
502 of the last 20-30 C-terminal amino acids. This abolishes the critical p110α WIF motif required
503 for membrane binding and catalytic function (38), effectively creating a loss-of-function knock-
504 in that nevertheless remains expressed and thus does not carry the risk of altering the
505 stoichiometry of p85 regulatory and p110 catalytic subunits in these cells. In separate QC
506 tests, we also used a clone with 2xWT and 1xFS *PIK3CA* alleles and confirmed that its
507 PIP$_3$/PI(3,4)P$_2$ reporter response by TIRF microscopy is identical to those in the 3xWT clones.
508 Combined with data from the 3xFS clone, this provides confidence that the frameshift p110α
509 allele(s) present alongside *PIK3CA^{H1047R}* do(es) not impact the observed signaling responses.

510 **Exome sequencing**

511 All CRISPR/Cas9-engineered HeLa clones used in this work were profiled by whole-exome
512 sequencing at an early passage (13 or 14) and compared to the parental HeLa culture prior
513 to editing (passage 4) and following another 10 passages (passage 14) in the absence of
514 editing. This approach enabled rigorous evaluation of the extent of mutagenesis caused by
515 the gene editing and single-cloning procedures relative to the expected baseline acquisition

516 of mutations upon prolonged cell culture. High-quality DNA was extracted using the
517 NucleoSpin Micro Kit XS (Takara #740901.5) and submitted to Novogene for exome library
518 preparation and sequencing. Briefly, libraries were prepared with the Next Ultra DNA Library
519 Prep Kit (NEB #E7370L) and enriched for exons using Agilent's SureSelectXT Reagent Kit
520 and Agilent SureSelect Human All ExonV6 (#G9611B). The final libraries were pooled and
521 paired-end (150 bp) sequenced on a NovaSeq 6000 instrument, with 6G of raw data output
522 per sample. Subsequent read processing was performed with the nf-core/sarek pipeline
523 (v2.6.1), with alignment against the human genome (hg38) and Agilent's reference .bed file
524 corresponding to the SureSelect Human All Exon V6 60MB S07604514 design. Somatic
525 variant calling was performed with Strelka2 (61) according to a tumor/normal pairs setup
526 where CRISPR/Cas9-edited clones and the long-term passage parental cultures were
527 assigned the "tumor" label and the low-passage parental culture assigned the "normal" label.
528 Subsequent variant annotation was performed using both the snpEff (62) and VEP pipelines
529 (63). The VEP pipeline, however, failed to capture the H1047R variants in the mutant lines
530 correctly and its output was therefore deemed unreliable. Detailed scripts and multiQC reports
531 for reproducing the all nf-core/sarek outputs have been made available on the OSF project
532 site.

533 The snpEff-annotated variants with SomaticEVS filter = PASS were processed with GATK
534 VariantsToTable and imported into R for identification of non-synonymous protein-coding
535 variants that are common to a minimum of two samples when compared to the low-passage
536 parental culture prior to CRISPR/Cas9 gene editing. Intersection plots and heatmaps were
537 generated using the ComplexHeatmap R package (64). Clustering was performed according
538 to Euclidean distance with the Ward.D2 method. Raw sequencing data and annotated R
539 processing scripts are provided on the accompanying OSF project site (doi:
540 10.17605/OSF.IO/4F69N, component: *Exome_sequencing_processed_file_analysis*).

Total mRNA sequencing

542 All CRISPR/Cas9-edited HeLa clones were processed for total mRNA sequencing at
543 baseline to determine transcriptional similarities and differences across individual genotypes.
544 Individual clones (passages 16-18) were collected at subconfluence following refeeding with
545 fresh complete medium for 3 h. Following a single wash with DPBS, cells were snap-frozen
546 and stored at -80°C until further processing. Following thawing on ice, total RNA was extracted
547 using the Direct-zol RNA Miniprep Kit from ZymoResearch (#R2051), with final elution in 30
548 μl nuclease-free water. Samples were submitted to Novogene for library preparation (NEB
549 Next® Ultra™ RNA Library Prep Kit) and paired-end (150bp) sequencing on a NovaSeq 6000
550 instrument. Note that the library preparation is strand-agnostic.

551 Raw read processing was performed with the Nextflow (version 20.07.1) nf-core RNAseq
552 pipeline (v1.1) (65), with Spliced Transcripts Alignment to a Reference (STAR) (66) for read
553 alignment to the human genome (Homo_sapiens.GRCh38.96.gtf) and featureCounts (67) for
554 counting of mapped reads (multimapped reads were discarded). All subsequent data
555 processing was performed in R, with differential gene expression analysis following the limma-
556 voom method (68). Filtering of low gene expression counts was performed with the
557 TCGAbiolinks package with quantile value 0.75 (chosen empirically based on the observed
558 count distribution). Next, read count normalization was performed with the gene length-
559 corrected trimmed mean of M-values (GeTMM) method (69). PCA was done using the
560 PCAtools package. The mean-variance relationship was modelled with voom(), followed by
561 linear modelling and computation of moderated t-statistics using the lmFit() and eBayes()
562 functions in the limma package (68). Experimental replicate was included as a batch effect
563 term in the model. The associated p-values for assessment of differential gene expression
564 were adjusted for multiple comparisons with the Benjamini-Hochberg method at false-
565 discovery rate (FDR) = 0.05 (70). Adjustments were performed with option = "separate",
566 comparing *PIK3CA^{H1047R}* mutant clones against wild-type clones. No differentially expressed
567 genes were identified across the different genotypes at baseline. All R processing scripts to

568   replicate   the   analyses   are   provided   on   the   accompanying   OSF   project   site   (doi:
569   10.17605/OSF.IO/4F69N, component: *RNAseq_processing*). The raw sequencing files are
570   available via GEO under accession number: GSE251956.

571   **Sleeping Beauty transposon engineering of cells for expression of AKT kinase**
572   **translocation reporter (KTR)**

573   The Sleeping Beauty transposon-based and optimized miniFOXO kinase translocation
574   reporter (KTR) developed by Gross *et al.* (27) was used to generate stable cell lines from the
575   original CRISPR/Cas9-engineered HeLa cell clones. This was performed at two different sites
576   in two independent sets of wild-type and mutant clones, with a time gap of one year. For further
577   testing of reproducibility of the results irrespective of reporter expression levels, stable cell line
578   generation was performed using two different molar ratios of transposon to transposase (the
579   following molar units are for cells seeded in 12-well plates at a density of 50,000 cells/well;
580   these units were scaled by a factor of 2 for cells seeded in 6-well plates at 100,000 cells/well).
581   For a 1:1 molar ratio, engineering was performed with approximately 100 fmol of transposon
582   and SB100X transposase-expressing plasmids (the plasmid maps are deposited on the OSF
583   project site, with code names MB40 and MB43, respectively). For a 1:10 molar ratio and thus
584   low reporter expression, engineering was performed with approximately 10 fmol transposon
585   plasmid and 100 fmol transposase plasmid. Plasmid were delivered to cells using Fugene HD
586   Transfection Reagent (Promega #E5912) at a 3:1 Fugene volume:DNA mass ratio for
587   transfection complex formation in Opti-MEM I Reduced Serum Medium (Thermo Fisher
588   Scientific #31985070). Puromycin (Sigma Aldrich #P9620 or #P4512-1MLX10) selection at 1
589   µg/ml was started 24-48 h after seeding, with replenishment of selection medium at least every
590   second day. Stable cell lines were usually established and banked within 2 weeks of the initial
591   transfection.
592

593   **Western blotting**

594   A step-by-step Western blotting protocol is publicly available on protocols.io with the
595   following doi: dx.doi.org/10.17504/protocols.io.4r4gv8w. Cells were lysed from 10-cm dishes
596   with RIPA Lysis and Extraction buffer (Thermo Fisher Scientific #89900), and 10-15 µg of
597   protein were loaded on 4-12% Bis-Tris Midi NuPage Protein Gels (Thermo Fisher Scientific)
598   and separated at 120V for 2 h in MES running buffer. Protein transfer was performed with an
599   iBlot2 system (Thermo Fisher Scientific) using program P3. All primary and secondary
600   antibodies used are provided in Tables 1 & 2. Final signal detection was by enhanced
601   chemiluminescence (ECL) with the Immobilon Forte Western HRP substrate from Sigma
602   Aldrich (#WBLUF0500) or ECL Western Blotting Substrate from Promega (#W1015). Images
603   were acquired on the Amersham ImageQuant 800 system with 5x5 binning. All raw Western
604   blots   have   been   deposited   on   the   accompanying   OSF   project   site   (doi:
605   10.17605/OSF.IO/4F69N, component: *Western_blots_Fig.S2*).

606   **Small molecule reconstitution and usage**

607   The following growth factors were obtained from Peprotech: human IGF1 (#100-11, lots:
608   022201-1, 092101-1, 041901-1), human EGF (#AF-100-15, lots: 0922AFC05, 0222AFC05,
609   0820AFC05), human Epigen (#100-51, lot: 0706386). Lyophilised stocks were reconstituted
610   in sterile, molecular-grade, non-DEPC-treated water from Ambion (#9937), allowed to dissolve
611   for 15-20 min at 4°C followed by aliquoting in PCR strip tubes and long-term (up to 1y) storage
612   at -80°C. Aliquots were freeze-thawed maximum once to limit loss of potency.
613   Human insulin (10 mg/ml) was from Sigma (#91077C, lot: 21M018) and stored at 4°C.
614   BYL719 was obtained from SelleckChem (#S2814, lots: 03, 06) at 10 mM in DMSO. The
615   stock solution was diluted to 1 mM in sterile DMSO, aliquoted in PCR strip tubes and stored
616   at -80°C long-term (up to 2 years).

617 TGX221 was obtained from MedChemExpress (#HY-10114) and reconstituted in sterile
618 DMSO at 10 mM DMSO, prior to long-term storage (up to 3 years) at -80°C.
619   1938 was synthesised by Key Organics or SAI Life Sciences, and is now available through
620 CancerTools (#161068).
621

Phosphoinositide reporter constructs

623   To minimize confounding effects on reporter performance arising from usage of different
624 plasmid backbone, all PH domain derivatives were cloned into the same plasmid backbone
625 construct (pNES-EGFP-C1 for wild-type PH domains; pNES-mCherry-C1 for mutant PH
626 domains). The generation of each individual reporter is detailed below. Note that all PH
627 domains will now be coupled to a nuclear export sequence (NES) and harbor an N-terminal
628 fluorescent protein tag. All plasmids were verified by restriction enzyme digest and Sanger
629 sequencing. Plasmid maps have been deposited on the accompanying OSF project site (doi:
630 10.17605/OSF.IO/4F69N; component *Other*).

ARNO

632   The pNES-EGFP-C1-PH-ARNO(I303E)x2 PIP$_3$ reporter construct was a gift from Dr Gerry
633 Hammond (University of Pittsburgh) and was generated as described in Ref. (18). In this
634 construct, the PH domain is C-terminally tagged with an enhanced GFP (EGFP) which is itself
635 preceded by a nuclear export sequence. To generate a tandem-dimer mutant version
636 equivalent to R280A in the native PH domain of ARNO (Unitprot #P63034), a 996 bp gene
637 fragment corresponding to the tandem-dimer PH-ARNO(I303E) domain with the mutated
638 residues was synthesized as a gene fragment in a pUC vector by GeneWiz, including 5' and
639 3' HindIII and BamHI recognition sites, respectively. Next, five reactions each with 250 fmol of
640 the construct carrying the mutant fragment or the original wild-type pNES-EGFP-C1-PH-
641 ARNO(I303E)x2 construct were digested with 20 U each of BamHI-HF (NEB #R3136S) and
642 HindIII-HF (NEB #R3104S), alongside 5 U of quick alkaline phosphatase (calf intestinal, NEB
643 #M0525S), all in a 30 µl rCutSmart buffer (NEB) reaction. The digests were run at 37°C
644 overnight (16 h), followed by heat inactivation at 80°C for 20 min. The digests were then un
645 on a Tris acetate-EDTA agarose gel (1%), followed by gel purification of the pNES-EGFP-C1
646 destination vector and the mutant PH-ARNO(I303)x2 domain with compatible sticky ends,
647 using the Monarch DNA gel extraction kit (NEB #T020S) according to the manufacturer's
648 instructions. The insert and the destination vector were ligated in a 10 µl reaction with 2X
649 instant sticky-end ligase master mix (NEB #M0370S), using a 1:5 molar ratio of backbone-to-
650 insert and otherwise following the manufacturer's instructions. Next, 2 µl of the ligation reaction
651 were heat-shock transformed into high-efficiency 5-alpha competent *E. coli* (NEB #C2987I),
652 followed by conventional colony picking and bacterial culture expansion for subsequent
653 plasmid DNA extraction with the Maxi Plus kit from Qiagen (#12964). Next, the EGFP tag in
654 the new construct containing the mutant PH-ARNO(I303)x2 domain was replaced with an
655 mCherry tag obtained from a pNES-mCherry-C1-TAPP1-cPHx3 construct (a gift from Dr Gerry
656 Hammond; described in Ref. (18)). The restriction enzyme digest-based subcloning protocol
657 used to generate this construct was as described above.
658

BTK

660

661   The BTK-PH domain was obtained from Addgene construct #51463 (a gift from Dr Tamas
662 Balla). This construct was used for site-directed mutagenesis of a key arginine in the signature
663 motif (FKKRL) of the BTK PH domain (20) using the following primers: 5'-
664 CTTCAAGAAGgcCCTGTTTCTCTTG-3' (forward); 5'-TTTAGAGGTGATGTTTTCTTTTTC-3'
665 (reverse). Site-directed mutagenesis was performed with the Q5® Site-Directed Mutagenesis
666 Kit from New England Biolabs (#E0554S), using 0.5 µM of each primer and 0.2 ng/µl plasmid
667 DNA in a 25-µl reaction. The thermocycling conditions were as follows: denaturation at 98°C
668 for 30s; 25 cycles of 98°C for 10s, 56°C for 20s, 72°C for 2.5 min; final extension at 72 °C for

669 5 min. The PCR product was subsequently processed for KLD (kinase, ligase, DpnI) treatment
670 as per the manufacturer's instructions.
671   The wild-type and mutant versions of the BTK PH domain were PCR-amplified, including
672 addition of 5' and 3' BamHI and HindIII restriction enzyme recognition sites, respectively. The
673 following primers were used (with highlights to indicate the recognition sites): 5'-
674 AGCAG`AAGCTT`CGATGGCCGCAGTGATTCTGG   -3'   (forward);   5'-
675 CCGGT`GGATCC`TCACCGGATTACGTTTTTGAGCTGG - 3' (reverse; note this primer also
676 adds a stop codon). A two-step PCR amplification was performed using Platinum SuperFi
677 DNA Polymerase (Thermo Fisher Scientific #12351-010) with the following thermocycling
678 conditions: denaturation at 98 °C for 30s; 5 cycles of 98°C for 10s, 60°C for 10s, 72°C for 15s;
679 20 cycles of 98°C for 10s, 65°C for 10s, 72°C for 15s; final extension at 72°C for 5 min. The
680 PCR products were gel-purified and processed for HindIII- and BamHI-based subcloning into
681 the pNES-EGFP-C1 and pNES-mCherry-C1 backbones as described above for ARNO.

683 AKT2

685   The AKT2-PH domain was obtained from a plasmid encoding the full length AKT2 protein
686 (a gift from Dr James Burchfield; described in Ref. (71)). This construct was used for site-
687 directed mutagenesis of a key arginine in the signature motif (WRP<u>R</u>Y) of the AKT2 PH
688 domain (20) using the following primers: 5'- CTGGAGGCCAgcGTACTTCCTG-3' (forward);
689 5'- GTCTTGATGTATTCACCAC-3' (reverse). Site-directed mutagenesis was performed as
690 described for BTK except for use of 57°C as annealing temperature and 4 min of extension
691 time in each cycle. The wild-type and mutant versions of the AKT2 PH domain were PCR-
692 amplified, including addition of 5' and 3' BamHI and HindIII restriction enzyme recognition
693 sites, respectively. The following primers were used (with highlights to indicate the recognition
694 sites):   5'-AGCAG`AAGCTT`CGATGAATGAGGTGTCTGTCATC-3'   (forward);   5'-
695 CCGGT`GGATCC`TCAGTTGGCGACCATCTGGA-3' (reverse; note this primer also adds a
696 stop codon). The procedure was as described for BTK above, with subsequent subcloning
697 into the pNES-EGFP-C1 and pNES-mCherry-C1 backbones as described for ARNO.

699 **Live-cell total internal reflection fluorescence (TIRF) microscopy**

700   A detailed protocol of how to prepare HeLa cells for live-cell microscopy by TIRF, including
701 Matrigel coating of the dishes, cell seeding, transfection with phosphoinositide reporters and
702 subsequent treatment has been made publicly available on protocols.io via the following doi:
703 dx.doi.org/10.17504/protocols.io.kxygx37jkg8j/v1
704   The above protocol was also followed for experiments with MEFs and A549 with the
705 following modifications. MEFs were seeded at a density of 2000 cells per well (0.35 cm^2).
706 A549 cells were seeded either at 2000 or 3000 cells per well and transfected either with 25 ng
707 or 50 ng wild-type and mutant reporter constructs; these different conditions were tested due
708 to the low transfection efficiency of these cells, however the final results did not differ and were
709 thus pooled together. Note that 20 ng of a pUC19 (NEB #09052008) carrier plasmid was
710 included in all transfection conditions with 25 ng of each reporter plasmid for a more even
711 uptake of the latter.
712   Time-lapse TIRF images were obtained on a 3i Spinning Disk Confocal microscope fitted
713 with a sCMOS Prime95B (Photometric) sensor for TIRF, with full temperature (37°C) and CO_2
714 (5%) control throughout the acquisitions. A 100X 1.45 NA plan-apochromatic oil-immersion
715 TIRF objective was used to deliver the laser illumination beam (488 nm or 561 nm; 40-50%
716 power) at the critical angle for TIRF and for acquisition of the images by epifluorescence (200-
717 300 msec exposure) using single bandpass filters (445/20 nm and 525/30 nm). Acquisition
718 was performed in sequential mode, without binning, using Slidebook 6.0 and an acquisition
719 rate of 70s.
720   Image analyses of total reporter intensities were performed with the Fiji open source
721 image analysis package (72). The regions of interest (ROI) corresponding to the footprint of
722 the individual cell across time points were defined using minimal intensity projection to select

723 only pixels present across all time points, following prior background subtraction with the
724 rolling ball method (radius = 500 pixels) and xy drift correction. Mean intensity levels for each
725 reporter were measured within the ROI and exported for subsequent data processing in R.
726 Final trajectory normalizations to the median signal of pre-stimulus or post-BYL719 time points
727 were performed using the Time Course Inspector package *LOCnormTraj* function (73). The
728 Time Course Inspector package was also used for calculating the mean and bootstrapped
729 confidence intervals of replicate time series data. The image analysis pipeline, including all
730 macros and R analysis scripts used for reporter normalizations and final replicate data
731 processing are provided on the OSF project site (doi: 10.17605/OSF.IO/4F69N, components:
732 *TIRF_analysis_pipeline*, *TIRF_datasets_Figs.1,2*).

**Live-cell epifluorescence microscopy of FOXO-based AKT kinase translocation
reporter (KTR)**

736 A detailed protocol of how HeLa cells were prepared for KTR measurements by live-cell
737 widefield microscopy, including Matrigel coating of the dishes, cell seeding, and subsequent
738 treatment has been made publicly available on protocols.io via the following doi:
739 dx.doi.org/10.17504/protocols.io.261gedjkjv47/v1
740 Time-lapse epifluorescence images were obtained on a Nikon Ti2-E Inverted microscope
741 fitted with a high-sensitivity CMOS Prime BSI (Photometric) sensor, with full temperature
742 (37°C) and CO_2 (5%) control throughout the acquisitions. A 10X 0.45 NA plan-apochromatic
743 dry objective (Nikon) was used for illumination using the following set-up: LED-
744 CFP/YFP/mCherry-3X-A Filter Cube; Triple Dichroic 459/526/596; Triple Emitter 475/543/702.
745 Exposure times were 20 msec (for CLOVER) and 50 msec (for mCherry). Acquisition was
746 performed in sequential mode, without binning, using an acquisition rate of 6 min.
747 Nuclear segmentation based on the NLS-mCherry fluorescence intensity was performed
748 with Stardist in Fiji (74). Then, using custom-written Python scripts, the nuclear intensity
749 KTR_{nuc} was calculated as the average intensity of the KTR channel within a 5-by-5 pixel
750 square around the centroid coordinates. Nuclear masks were then expanded by a width of 2
751 pixels, and the original mask was subtracted from the expanded one to generate the
752 cytoplasmic ring mask. The cytoplasmic KTR intensity KTR_{cyto} was calculated as the average
753 value of the brightest 50% pixels contained within this cytoplasmic ring mask. This was to
754 avoid inclusion of background pixels in the calculations, in cases where cells were thin and
755 elongated. The nuclear-to-cytoplasmic ratio CN_R was then computed as the ratio of
756 cytoplasmic over total cellular intensities of the KTR sensor:

758 $$CN_R = \frac{KTR_{cyto}}{KTR_{nuc} + KTR_{cyto}} \ .$$

760 The CN_R values were therefore bounded by 0 in the case of pure nuclear intensity (low
761 pAKT levels), and 1 in the case of complete nuclear exclusion of the biosensor (high pAKT
762 levels).
763 For trajectory generation, cells were first tracked using Trackmate (75) in Fiji, based on the
764 centroids generated by the segmentation step. Tracks were filtered by length (only tracks
765 persisting through the full time-course were conserved), and (x,y,t) coordinates from cellular
766 tracks were matched with the corresponding CN_R values using custom-written Python scripts.
767 All subsequent data processing was performed in R for mean and bootstrapped confidence
768 interval calculations (73), including visualization. All source data and scripts to reproduce the
769 results are deposited on the OSF project site (doi: 10.17605/OSF.IO/4F69N, components
770 *KTR_datasets_Figs.3,S3*, *KTR_datasets_2_Figs.3,S3, KTR_analysis_pipeline*).

Scaffold-free spheroid generation and experimental processing

773 Scaffold-free spheroids were generated according to a new protocol developed in house
774 for this study and made publicly available via the following doi:
775 dx.doi.org/10.17504/protocols.io.3byl4bnrrvo5/v1. Spheroids were seeded at 1000-2000

776 cells/spheroid and used for experimentation 48h later. Prior to growth factor or inhibitor
777 treatments, HeLa spheroids were serum-starved for 4h by an initial wash in 200 µl (96-well
778 plate) or 3 ml (24-well plate) DMEM high-glucose (Thermo Fisher Scientific #41966-029)
779 supplemented with another 2 mM of L-Glutamine. Human iPSC spheroids were washed and
780 growth factor-depleted using DMEM/F12 (Thermo Fisher Scientific #21331-046) for 2 h prior
781 to stimulation. In each case, the wash was removed and replaced with 100 µl (96-well plate)
782 or 1 ml (24-well plate) of the same solution. Growth factor and inhibitor solutions were
783 prepared as 3x working solutions and 50 µl (96-well plate) or 500 µl (24-well plate) of each
784 added to the cells when required for a final dilution to 1x (1-100 nM for IGF1 or EGF; 500 nM
785 for BYL719). Corresponding control solutions containing DMSO or non-DEPC-treated sterile
786 water (Ambion #9937) were also applied. At the end of a time course, the spheroids were
787 either processed for multiplexed mass cytometry (96-well plates) or RT-qPCR (24-well plates)
788 as described below.

789

790 **Multiplexed mass cytometry (CyTOF) using 3D spheroids**

791 A detailed step-by-step protocol for spheroid fixation, TOB*is* barcoding, enzyme-free
792 single-cell dissociation and subsequent antibody staining for mass cytometry has been made
793 publicly available via protocols.io: dx.doi.org/10.17504/protocols.io.4r3l22bz4l1y/v1. Final cell
794 acquisition was performed either on a Helios or an XT mass cytometer, both developed by
795 Fluidigm (now Standard Biotools). Raw mass cytometry data were normalized using bead
796 standards (76) and debarcoded as per the computational algorithm developed by Zunder et
797 al. (77). The Mahalanobis and separation cutoff were set to 10 and 0.1, respectively.
798 Debarcoded .fcs files were imported into Cytobank (http://www.cytobank.org/) and gated with
799 Gaussian parameters to remove debris, followed by gating on DNA (Ir-191/193), total S6,
800 pRB$^{S807/S811}$ and cCASP3^{D175} to separate cell populations according to cell state. For the
801 iPSCs, there were no distinct populations of cCASP3^{D175}-posite and -negative cells, which
802 meant that this marker was not used for gating.

803 Gated populations of interest were exported as untransformed .txt files (excluding header
804 with filename) and pre-processed using the CyGNAL package as described in Sufi et al. (28).
805 The pre-processed .fcs files were imported into R as an object of the *SingleCellExperiment*
806 class and *arcsinh* (inverse hyperbolic sine) transformed with cofactor = 5 using the flowCore
807 (78) and CATALYST (79) packages in R. Individual marker histograms were generated using
808 the ggridges R package. Exact gate settings, debarcoded and gated .fcs files as well as
809 detailed scripts to reproduce all results are available on the OSF project site in dedicated
810 subfolders   (doi: 10.17605/OSF.IO/4F69N;   component:
811 *Mass_cytometry_CyTOF_HeLa_Figs.4,S4,S5,S6*). These subfolders also contain exact
812 single-cell numbers for each experimental analysis in plots saved with the file suffix
813 "_total_cell_count_plot.png".

814 For EMD-PHATE analyses, the pre-processed .fcs files were imported into Python and
815 processed using a custom-written script deposited on the OSF project site. The following
816 markers were used for EMD-PHATE plot generation: "151Eu_pNDRG1 T346",
817 "167Er_pERK1_2_T202_Y204", "173Yb_pS6_S240_S244", "155Gd_pAKT S473",
818 "168Er_pSMAD2_3_S243_S245".

819

820 **Reverse transcription-quantitative polymerase chain reaction (RT-qPCR)**

821 Cellular RNA was extracted as described above for total mRNA Sequencing, and 250 ng
822 used for complementary DNA (cDNA) synthesis with Thermo Fisher's High-Capacity cDNA
823 Reverse Transcription Kit (#4368814). Subsequent SYBR Green-based qPCRs were
824 performed on 2.5 ng total cDNA.

825 A 5-fold cDNA dilution series was also prepared and used as standard curve for relative
826 quantitation of gene expression. *TBP* was used as normalizer following confirmation that its
827 gene expression was changing systematically as a function of the tested conditions, which

828 was not the case for *ACTB* (tested as an additional housekeeping gene). Melt curve analyses
829 and separate agarose gel electrophoresis confirmed amplification of the correctly-sized, single
830 product by each primer pair. All primers had amplification efficiencies 95%-105%. Samples
831 were loaded in duplicate in 384-well plates.

832 All qPCR data were acquired on a Quant Studio™ 6 Real-Time PCR System (Thermo
833 Fisher Scientific). The thermocycling conditions (SYBR Green reactions) were as follows
834 (ramp rate 1.6°C/s for all): 50°C for 2 min, 95°C for 10 min, 40 cycles at 95°C for 15 sec and
835 60°C for 1 min, followed by melt curve analysis (95°C for 15 sec, 60°C for 1 min, and 95°C for
836 15 min with ramp rate 0.075°C/sec). All relevant primer sequences are included in Table S4.
837 Source data and scripts to reproduce the results have been deposited on the OSF project site
838 (doi: 10.17605/OSF.IO/4F69N, component: *RT_qPCR_replicates_combined_Fig.5*).

839
840 **Evaluation of cellular morphology**

841 HeLa cells were seeded at a density of 4,000 cells/well in black Perkin Elmer ViewPlate-96
842 dishes (TC-treated, #6005182) coated with Matrigel as per the protocol for TIRF and KTR
843 imaging. After 24 h, 33 μl of 16 % methanol-free formaldehyde (Polysciences #18814-20) was
844 added to 100 μl of culture medium in each well to fix the cells in 4% final formaldehyde
845 concentration. Following 15 min of incubation at room temperature away from light, the fixative
846 was removed and cells washed once with 100 μl DPBS, dispensed slowly and at a 45 degrees
847 angle to prevent the cells from dislodging. Next, 75 μl of DPBS was added, followed by 19 μl
848 of 5X fish skin gelatin blocking agent (Biotium #22010) diluted in PBS/T (PBS with 0.05 %
849 Tween-20) with 0.5% Triton-X100 (5X concentration, diluted to 0.1 % once added to the
850 DPBS). The cells were left to permeabilize and block for 10 min, after which the block/perm
851 solution was removed and replaced with DPBS supplemented with Phalloidin iFlouor 555
852 (Abcam #ab176756) and HCS CellMask Blue (Thermo Fisher Scientific #H32720), both
853 diluted 1:1000. Following 30 min incubation at room temperature away from light, the staining
854 solution was removed and the cells washed twice with 100 μl DPBS. Another 100 μl of DPBS
855 was added after the last wash, followed by epifluorescence acquisition on a Nikon Ti2 Eclipse
856 microscope fitted with a 10X 0.45 NA plan-apochromatic dry objective (Nikon), used for
857 imaging with the following set-up: LED-CFP/YFP/mCherry-3X-A Filter Cube; Triple Dichroic
858 459/526/596; Triple Emitter 475/543/702. Exposure times were 20 msec (for CellMaskBlue)
859 and 60 msec (for Phalloidin and mCherry).
860 The CellMask blue images were converted to jpg for segmentation using Cellpose (v1) (80),
861 and the resulting masks converted to regions of interests (ROIs) using the LabelsToROI plugin
862 in Fiji/ImageJ. All edge ROIs were removed. The remaining ROIs were used for calculating
863 the shape properties of the cell masks using the "Measure" function in Fiji/ImageJ.
864 Analysis of variance (ANOVA) models was fit in R to test for differences in solidity and area
865 as a function of genotype. Of note, although the normality assumption was violated for these
866 models, the impact of this is likely to be minimal given the large number of single cell
867 observations and the assumptions of the central limit theorem. Tukey's Honest Significant
868 Differences method was used to test for statistically significant (adjusted p-value < 0.05)
869 differences in shape properties as a function of genotype.
870 All raw images, segmentation masks, quantification scripts and a final montage of all
871 composite images are deposited on the OSF project site (doi: 10.17605/OSF.IO/4F69N,
872 component: *HeLa_cell_morphology_image_analysis_Fig.5*).

873
874 **Information theoretic analyses**

875 For the estimation of mutual information and information capacity, the SLEMI (Statistical
876 Learning-based Estimation of Mutual Information) R package was used (26). SLEMI uses a
877 logistic regression model to learn the discrete probability $P(S|Z)$ of the signal (S) given the

19

878 response (Z) and subsequently estimates the mutual information, $I(Z; S)$, from the following
879 formula:
880
881 $I(Z; S) = H(S) - H(S|Z)$
882
883 Here, $H(S) = -\sum_s P(s)\log_2(P(s))$ is the entropy of the signal calculated based on the input
884 signal distribution $P(S)$; and $H(S|Z) = E[-\sum_s P(s|Z)\log_2(P(s|Z))]$ is the conditional entropy of
885 the signal given the response. A uniform signal distribution was used in all cases for mutual
886 information estimation, while information capacity is estimated by maximizing the mutual
887 information over possible signal distributions. This approach does not rely on any form of data
888 binning and is therefore particularly well-suited for the case of high-dimensional outputs such
889 as the time course measurements in our live cell experiments.
890 The specific scripts used to calculate mutual information are deposited on the OSF project
891 site (doi: 10.17605/OSF.IO/4F69N, components: *TIRF_datasets_Figs.1,2*,
892 *KTR_datasets_2_Figs.3,S3*).
893
894 **Statistics and reproducibility**

895 Bespoke data and statistical analyses are detailed in the relevant methods sections. Note
896 that the information theoretic analyses detailed above also provide the appropriate statistical
897 description of the trajectory datasets as justified by Bayesian decision theory (81). The mass
898 cytometry datasets are shown as individual distributions, with probability-based thresholding
899 as opposed to use of metrics such as standard deviation and variance given the non-normal
900 distribution of the data. In general, rather than applying conventional statistical tests that would
901 be violated by the structure of our data, we chose to focus on orthogonal validation in
902 independent model systems.

903 Source data and annotated scripts to reproduce all results are included on the OSF project
904 site (doi: 10.17605/OSF.IO/4F69N).

Author contributions: R.R.M. conceived and supervised the project, acquired funding, conducted experiments, analyzed data, developed analytical pipelines, prepared figures and wrote the manuscript. A.L.M. conducted KTR experiments and developed the associated analytical pipeline. O.M. conducted KTR experiments, analyzed data, developed an open-source version of the KTR analysis pipeline and provided routine technical assistance. M.V. performed all information theoretic analyses. S.Y. conducted TIRF and RT-qPCR experiments, analyzed data and provided routine technical assistance. D.M., J.S., S.J.Z., J.G. and L.D. provided technical assistance. X.Q. wrote the EMD-PHATE analysis code. B.V. helped with project supervision, acquired funding and provided extensive feedback on the first manuscript draft. C.T. helped with project supervision and acquired funding. E.H. acquired funding. V.K. helped with project supervision. All authors reviewed the final manuscript.

Competing interests: R.R.M. has received consulting fees from Nested Therapeutics (Cambridge, U.S.) and serves on the Scientific Advisory Board of CLOVES Syndrome Community. B.V. is a consultant for iOnctura (Geneva, Switzerland), Pharming (Leiden, the Netherlands) and a shareholder of Open Orphan (Dublin, Ireland). E.S. is a consultant for Phenomic AI (Toronto, Canada) and Theolytics (Oxford, UK), receives research funding from AstraZeneca, MSD and Novartis. V.I.K. is a scientific advisor for Longaevus Technologies.

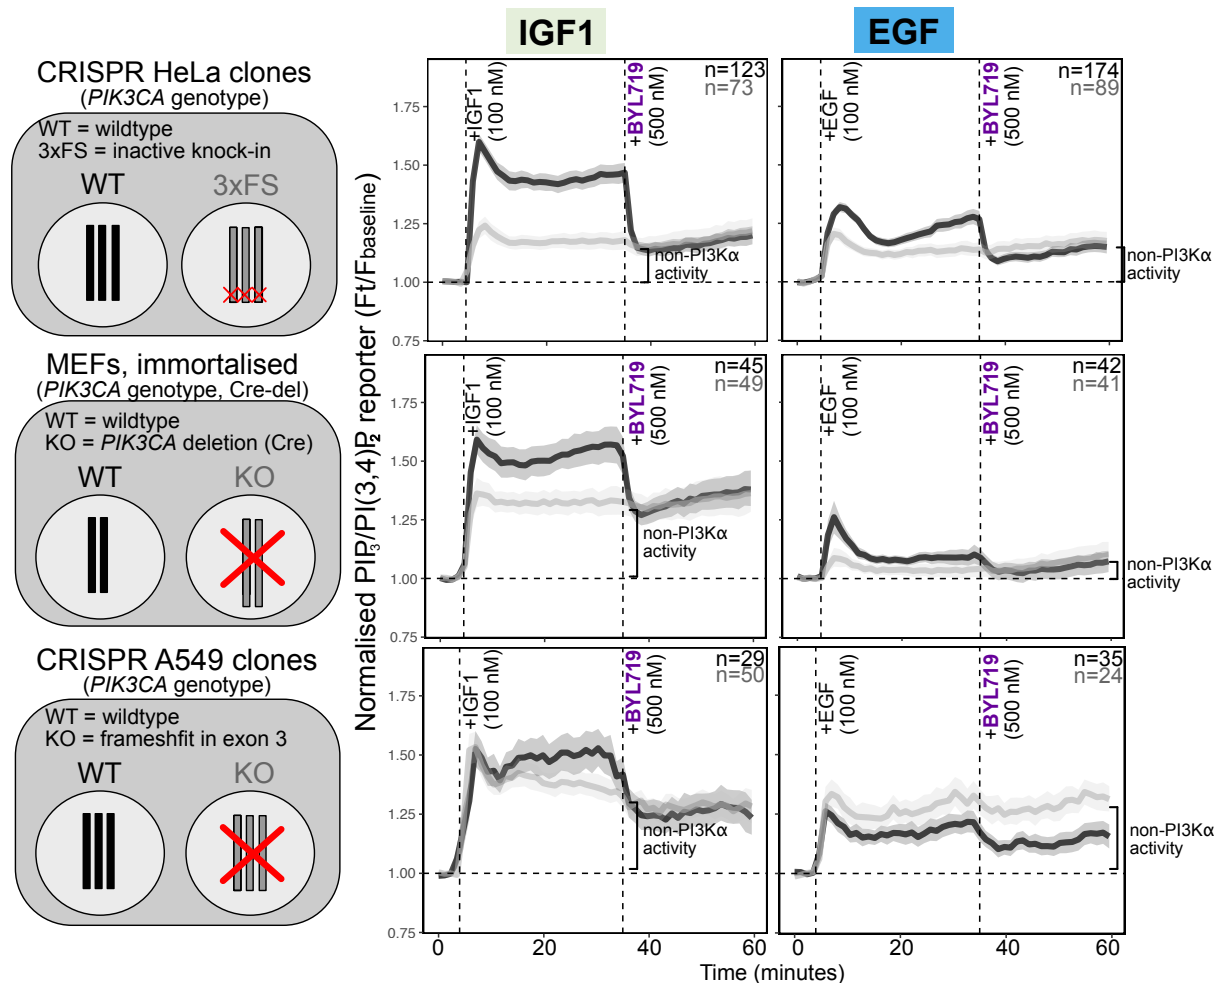

Figure 1. IGF1 and EGF induce stereotypical PIP$_3$/PI(3,4)P$_2$ signaling dynamics. TIRF microscopy measurements of dynamic IGF1- and EGF-induced PIP$_3$/PI(3,4)P$_2$ levels in live HeLa, MEF or A549 cells with wild-type or loss-of-function *PIK3CA* as indicated. The cells were serum-starved for 3 h prior to stimulation with either saturating doses (100 nM) of IGF1 or EGF, followed by PI3Kα-selective inhibition with 500 nM BYL719. The traces represent the mean PH$_{AKT2}$ reporter fold-change relative to baseline (the median signal of the first four time points). The shading signifies bootstrapped 95% confidence intervals of the mean. The number (n) of single cells for each genotype is indicated on the plots. For wild-type (WT) HeLa cells, two independent CRISPR/Cas9 clones were used, with and without silent mutations. The 3x FS HeLa cells originate from a single CRISPR/Cas9 clone, engineered with a frameshift mutation in all three *PIK3CA* alleles (see also Fig. S2). The MEFs were from polyclonal cultures established from mice with the respective *PIK3CA* genotypes, followed by immortalization *in vitro* (82). The A549 cells were from a single CRISPR/Cas9 clone per genotype. HeLa datasets for IGF1 and EGF are from 6 and 7 independent experiments, respectively. MEF and A549 IGF1 and EGF data are from 3 independent experiments each. Non-PI3Kα activity refers to the class IA PI3K activity that remains following pharmacological inhibition of PI3Kα.
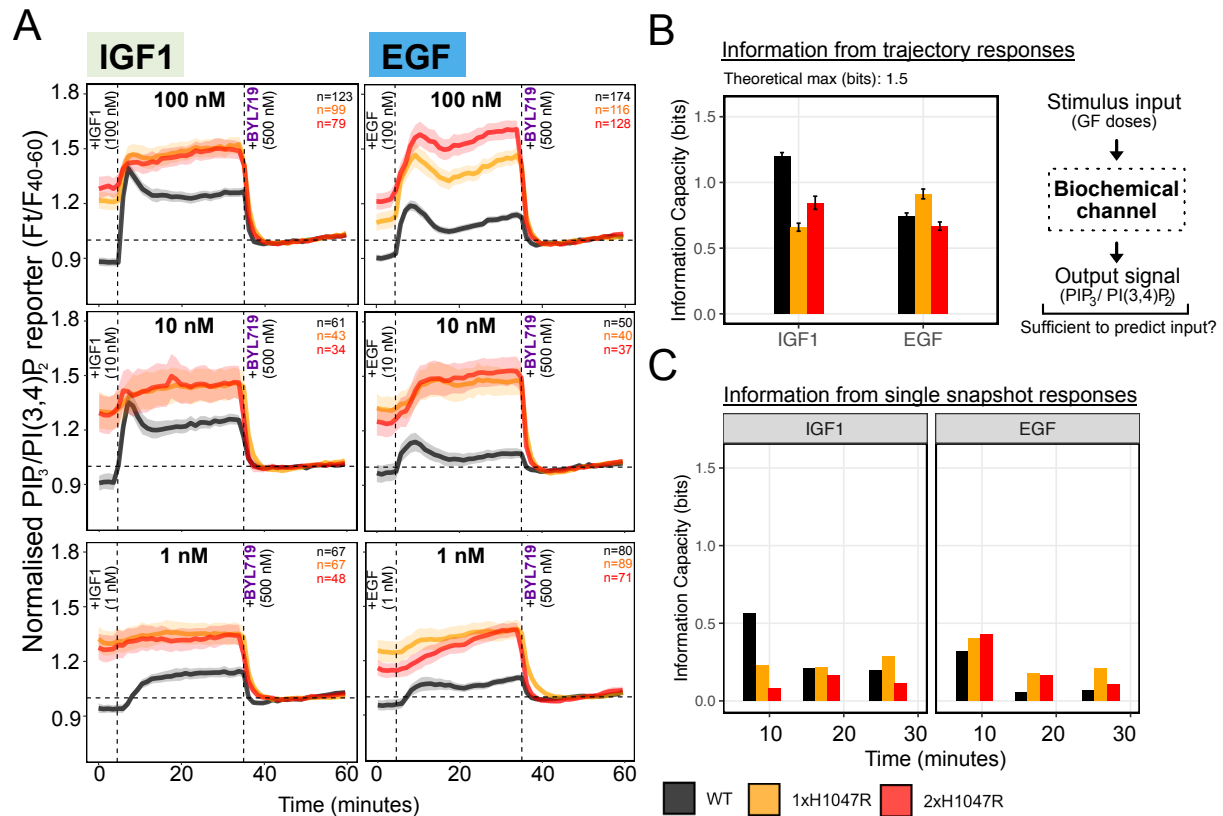

Figure 2. Oncogenic *PIK3CA^H1047R* reduces the information capacity in the PIP$_3$/PI(3,4)P$_2$ dynamics for IGF1 but not EGF. (A) Total internal reflection (TIRF) microscopy measurements of IGF1- and EGF-induced PIP$_3$/PI(3,4)P$_2$ kinetics in live HeLa cells with endogenous, dose-controlled expression of *PIK3CA^H1047R* (see also Fig. S2). Note that the wild-type traces correspond to those shown in Fig.1, shown separately across two figures for clarity. The cells were serum-starved for 3 h prior to stimulation with the indicated growth factors, followed by PI3Kα-selective inhibition with 500 nM BYL719. Measurements were obtained every 70 sec for a total of 60 min. The traces represent the mean PH$_{AKT2}$ reporter fold-change relative to the median signal for the time window 35-60 min, used here to capture the baseline signaling elevation in *PIK3CA^H1047R* mutant cells. The shaded areas represent bootstrapped 95% confidence intervals of the mean. The shading signifies the 95% confidence intervals of the mean. The number (n) of single cells for each genotype is indicated on the plots. For wild-type (WT) HeLa cells, two independent CRISPR/Cas9 clones were used, with and without silent mutations. The data are from 2 independent WT, 2 independent 1xH1047R and 3 independent 2xH1047R CRISPR/Cas9 clones. The data are from the following number (n) of independent experiments: n=6 for 100 nM IGF1; n=7 for 100 nM EGF; n=2 for 10 nM IGF1 and 10 nM EGF; n=3 for 1 nM IGF1; n=4 for 1 nM EGF. **(B)** Median information capacity in bits (log2) for IGF1 and EGF calculated from the trajectory responses in A. Capacity is a measure of the maximum amount of information that flows from the pathway input to its output. The theoretical maximum for 3 inputs (doses) is 1.5 bits if all the information is captured by the PIP$_3$/PI(3,4)P$_2$ dynamics. The error bars indicate interquartile range. **(C)** Median information capacity in bits (log2) calculated from snapshot measurements at the indicated time points from the datasets in A.
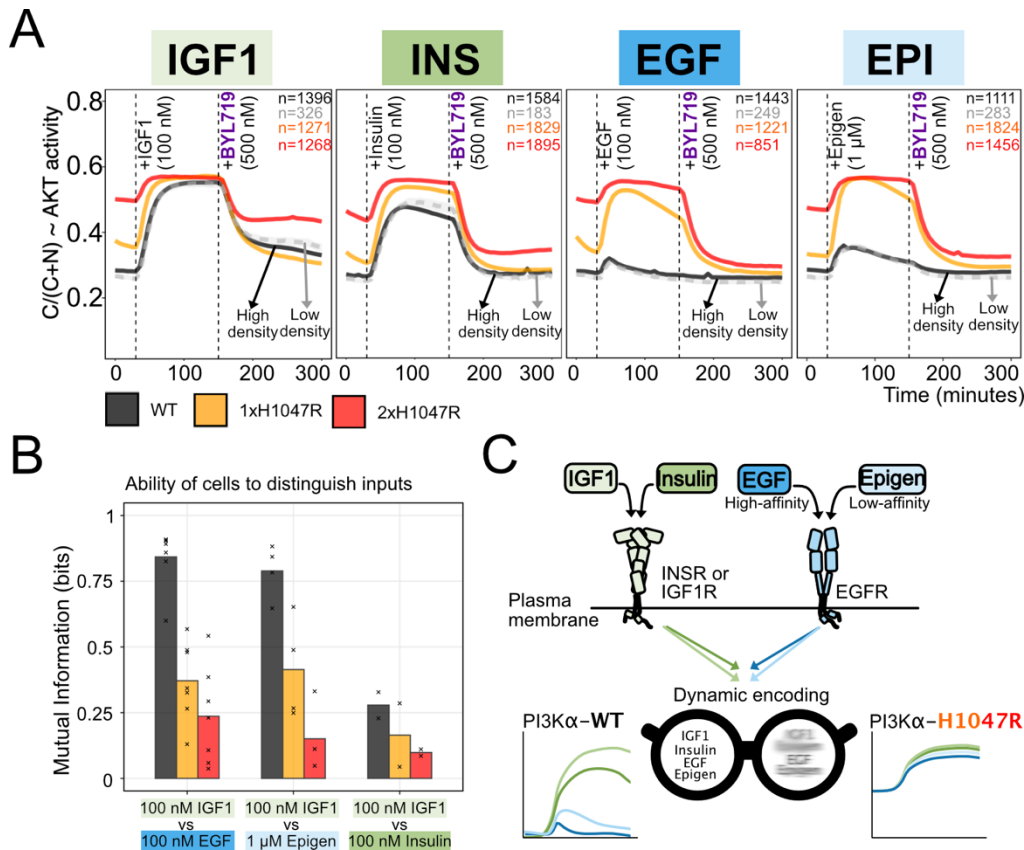

**Figure 3. Oncogenic *PIK3CA^{H1047R}* blurs the dynamic encoding of ligand identity. (A)** Live-cell fluorescence-based measurements of a miniFOXO-based AKT kinase translocation reporter (KTR) (27), stably expressed in HeLa clones with the indicated *PIK3CA* genotypes. The total duration of the time course is 300 min, with measurements obtained every 6 min. For each time point, the traces correspond to the mean proportion of cytoplasmic KTR signal, with shaded areas representing bootstrapped 95% confidence intervals of the mean (note that these may be too small to be seen on the figure). C, cytoplasmic; N, nuclear. Single-cell numbers (n) are shown in the plots. For each condition, *PIK3CA* wild-type set were also seeded at low density to confirm intra-experimental consistency irrespective of cell crowding. The data are representative of a minimum of two independent experiments per condition, performed in two independent CRISPR/Cas9 clones per genotype. Plots from all independent experiments are shown in Fig. S3 and include control experiments with the 3xFS *PIK3CA* LOF mutant line. **(B)** Mutual information (MI) in bits (log2) for IGF1 *versus* each one of the indicated growth factors (EGF, epigen, insulin), calculated using the corresponding KTR trajectory responses (A) prior to inhibitor addition. MI values from individual experimental replicates are indicated as dots overlayed on barplots which correspond to the respective mean of each set of measurements. Note that IGF1 gave highly robust KTR dynamics, associated with relatively low single-cell noise as reflected in consistently high MI values. It was therefore chosen as control stimulus in all experimental replicates. **(C)** A graphic metaphor summarizing the biochemical signal blurring caused by oncogenic *PIK3CA^{H1047R}*.

1260
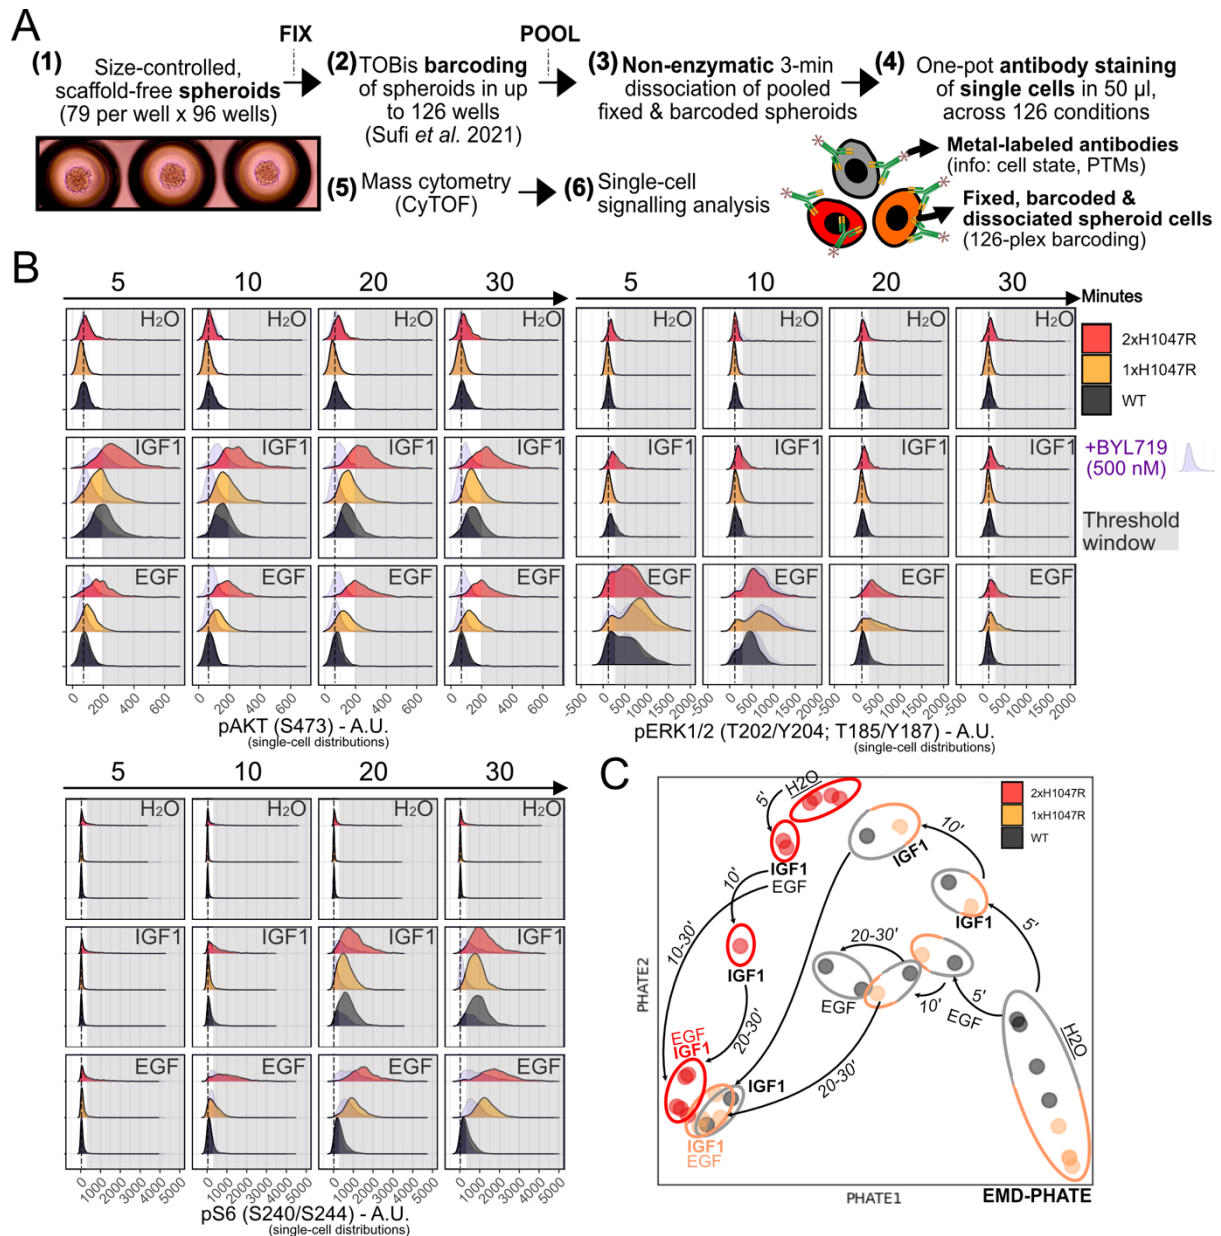

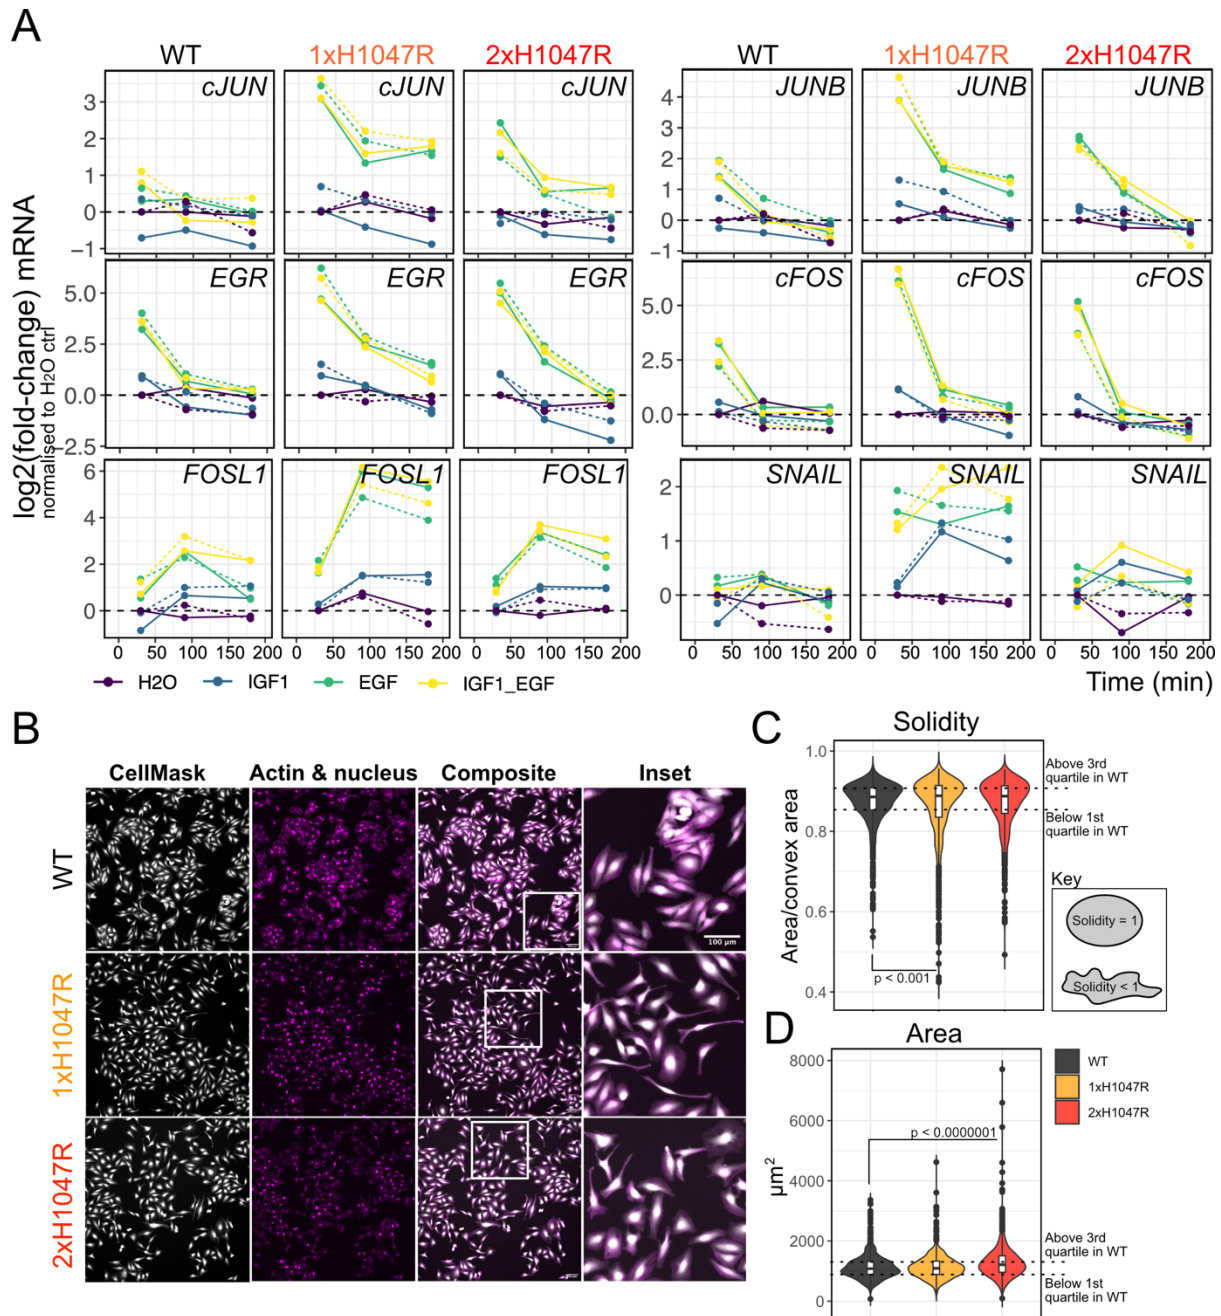

Figure 4. *PIK3CA^{H1047R}* amplifies EGF-dependent signaling in a time- and allele dose-dependent manner. (A) Overview of the multiplexed mass cytometry workflow for profiling of single-cell signaling markers in scaffold-free spheroid models. Following fixation and thiol-reactive organoid barcoding in situ (83,28), up to 126 conditions are combined into a single sample for non-enzymatic single dissociation which ensures preservation of antibody epitopes, including post-translational modifications (PTMs). Subsequent staining with experimentally validated, metal-conjugated antibodies captures information about cell cycle state (e.g., cycling, non-cycling, apoptotic) as well as signaling state. **(B)** Mass cytometry (CyTOF) data from cycling, non-apoptotic HeLa spheroid cells with endogenous expression of wild-type (WT) *PIK3CA*, or one (1xH1047R) or two (2xH1047R) copies of the oncogenic *PIK3CA^{H1047R}*. The spheroids were serum-starved for 4 h prior to stimulation with 100 nM EGF or IGF1, with and without 500 nM BYL719 (alpelisib; PI3Kα-specific inhibitor) as a control for signal specificity. Note that BYL719 was added at the same time as the growth factor, not as pre-treatment. The stippled line indicates the position of the peak in wild-type spheroids treated with vehicle (H$_2$O). The grey shading highlights the response region that is not accessible to *PIK3CA* wild-type cells in the absence of stimulation. **(C)** Earth mover's distance (EMD)-PHATE embedding of the signaling trajectories observed in the indicated HeLa cell

33

1278   genotypes. Single-cell distributions for the following signaling markers were used for EMD-
1279   PHATE processing (see also Fig. S5): $pAKT^{S473}$, $pERK1/2^{T202/Y204;\ T185/Y187}$, $pNDRG1^{T346}$,
1280 $pS6^{S240/S244}$, $pSMAD2/3^{S465/S467;\ S423/S425}$.

1281

Figure 5. *PIK3CA^{H1047R}* amplifies an EGF-driven transcriptional signature and increases phenotypic diversity in an allele dose-dependent manner. (A) Bulk transcriptional profiling of EGF-dependent immediate early and delayed early gene expression in HeLa spheroids with endogenous expression of either wild-type (WT) *PIK3CA*, one or two copies of *PIK3CA^{H1047R}* (1-2xH1047R). Expression values are relative and represented as log2 fold-changes, normalized internally to each genotype's control (H_2O) response after 30 min of stimulation. All data were normalized to the expression values of *TBP* (housekeeping gene). The data are representative of two independent experiments (indicated with solid and stippled lines) with one CRISPR-derived clone per genotype. IGF1 and EGF were used at 100 nM, either alone or in combination as indicated. Note the log2 scale of the y-axis. **(B)** Representative fluorescence images of HeLa cells with the indicated genotypes during normal maintenance culture. The cells express a nuclear mCherry marker and were further stained with CellMaskBlue and Phalloidin to demarcate their cytoplasm and actin cytoskeleton, respectively. The cells are representative of three technical replicates and one CRISPR/Cas9 clone per genotypes (see also Fig. S6A for brightfield images of additional HeLa clones for

35

1299   each genotype). The cytoplasmic images from all replicates were used for deep learning-
1300   based segmentation (80), followed by quantification of cell shape solidity (**C**) and area (**D**).
1301   The scale bar in (B) corresponds to 100 µm. The p-values in **(C)** and **(D)** were calculated
1302   according to a one-way ANOVA with Tukey's Honest Significant Difference to correct for
1303   multiple comparisons.
1304
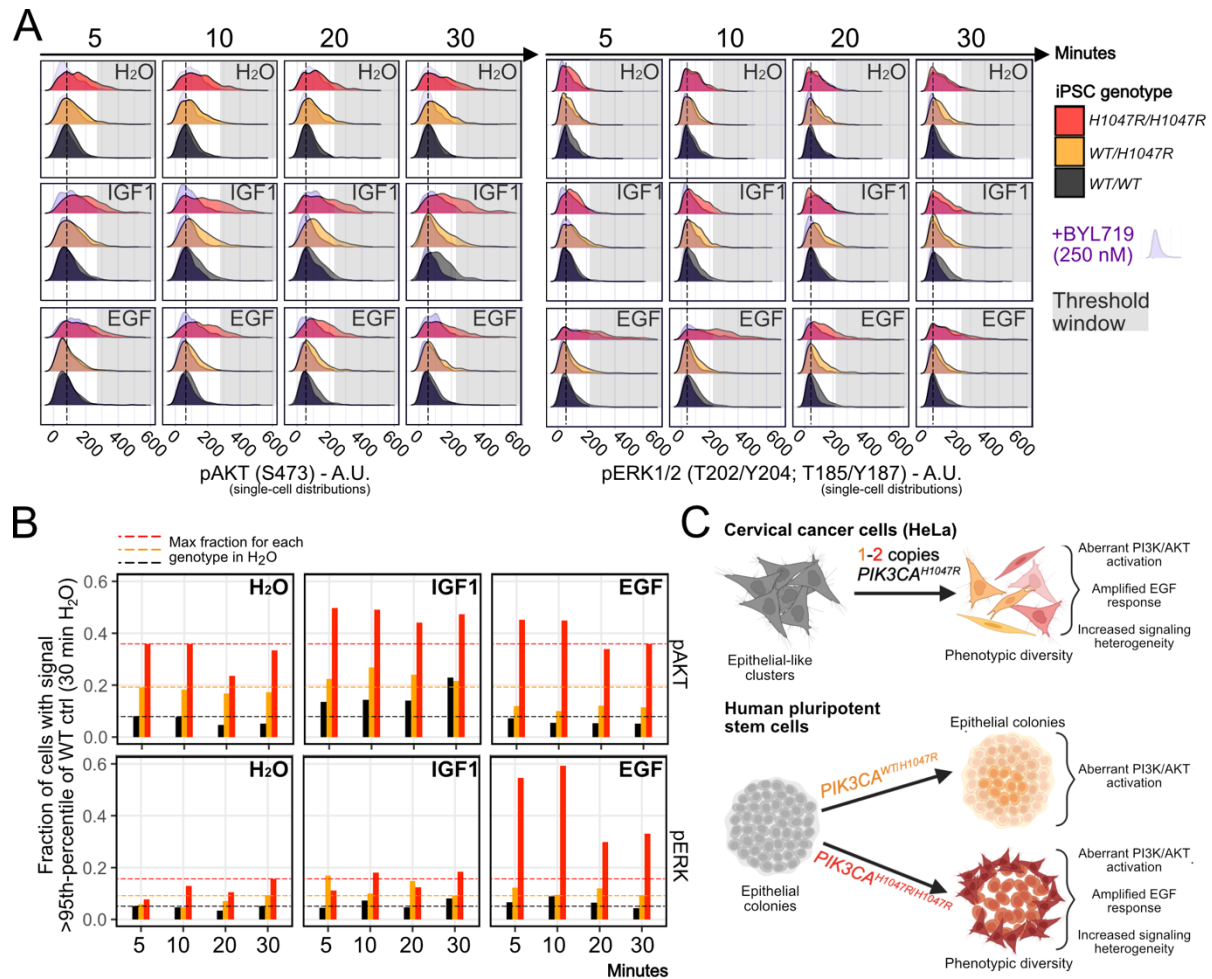

Figure 6. Corrupted signal transfer and EGF response amplification is conserved in homozygous *PIK3CA^{H1047R}* iPSCs. (A) Mass cytometry data from cycling (pRB⁺) iPSC spheroid cells with wild-type (WT) *PIK3CA*, heterozygous or homozygous *PIK3CA^{H1047R}* expression. The spheroids were serum-starved for 4 h prior to stimulation with 100 nM EGF or IGF1, with and without 250 nM BYL719 (alpelisib; PI3Kα-specific inhibitor) as a control for signal specificity. Note that BYL719 was added at the same time as the growth factor, not as pre-treatment. The stippled line indicates the position of the peak in wild-type spheroids treated with vehicle (H_2O). The grey shading highlights the response region that is not accessible to *PIK3CA* wild-type cells in the absence of stimulation. **(B)** Thresholding of the data in (A) to quantify the percentage of cells within each condition with a pAKT or pERK signal above the corresponding 95th percentile of vehicle (H_2O)-treated WT iPSCs at 30 min. The stippled lines indicate the maximum fraction of cells within this threshold for each genotype prior to growth factor stimulation. The data are from a single experiment with one iPSC clone and n > 260 single cells per genotype. **(C)** Graphical summary of the key observations of the impact of *PIK3CA^{H1047R}* expression in HeLa and iPSC cells.

1340
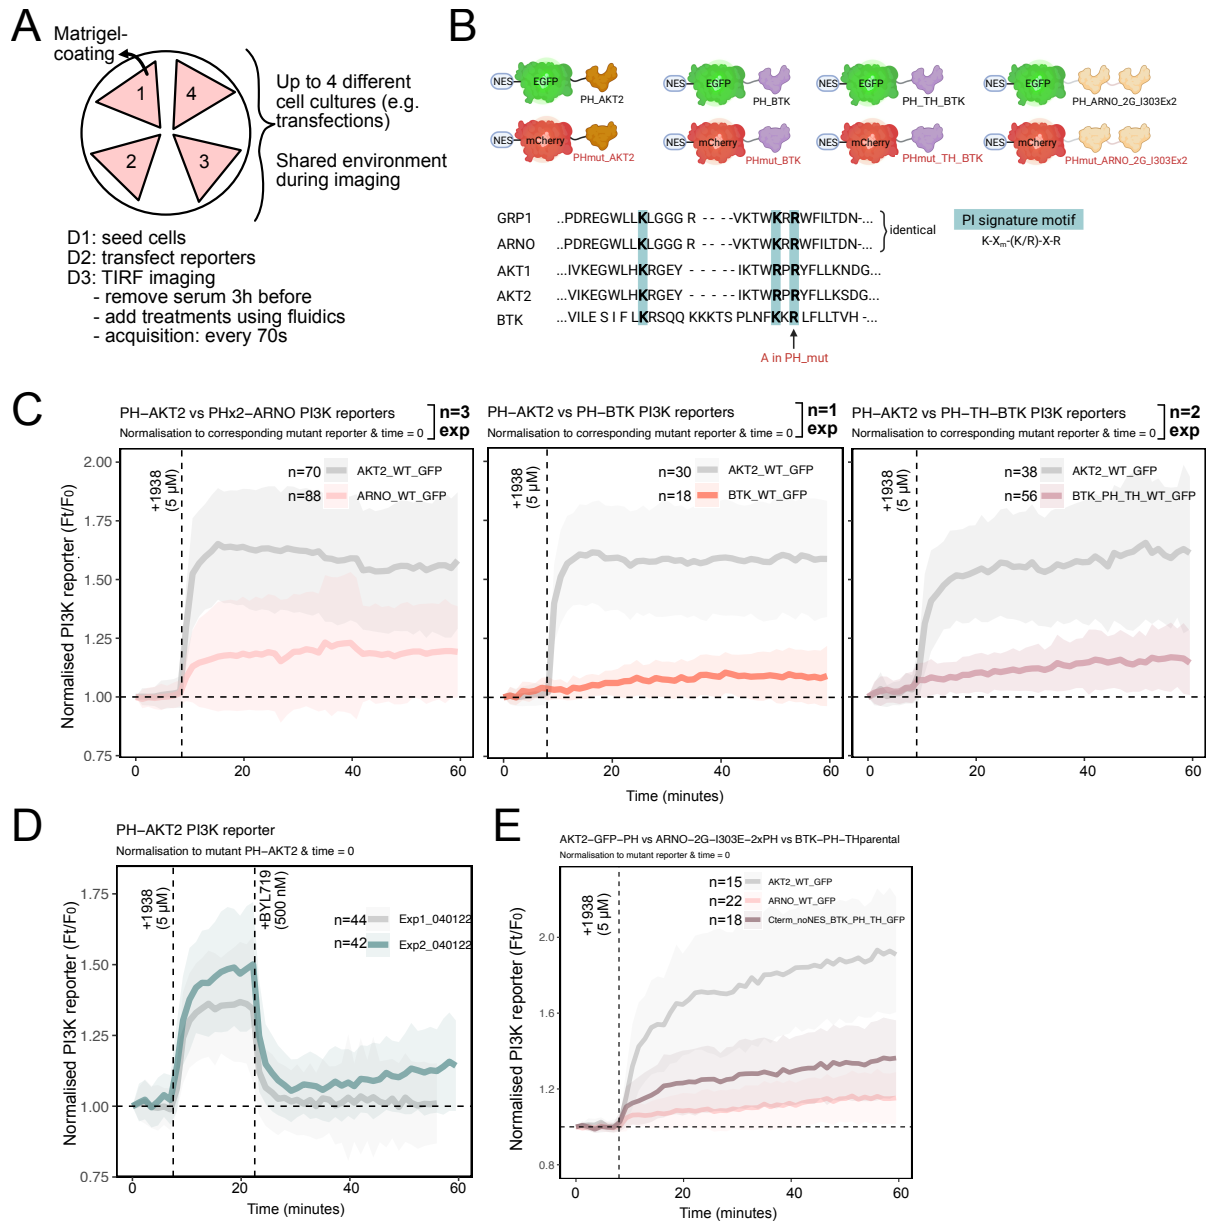

Figure S1. Systematic benchmarking of pleckstrin homology (PH) domain-based class I PI3K biosensors. (A) Schematic of the optimized live-cell imaging set-up to ensure that multiple comparisons could be performed in the same microenvironment, aided by fluidics for minimal physical perturbation during compound additions. To bring down the baseline of PI3K signaling, serum was removed from the cells 3 h prior to imaging start. D1, D2, D3 refer to day 1, day 2 and day 3 of the experimental workflow. **(B)** Schematic of the different wild-type and mutant PH domains used for benchmarking, all cloned into the same plasmid backbone for consistent comparisons. The PH domain of GRP1 has often been used for live-cell detection of PIP_3 in the literature. Its sequence in the region responsible for PIP_3 is identical to the ARF GEF ARNO. We therefore chose to include the latter in our comparisons given the recently reported a tandem-dimer, modified version of this PH domain as an improved biosensor for PIP_3 (18).The shown alignments cover the conserved $\beta1$ strand, variable loop 1, and $\beta2$ strand of the PH domain fold. Of the four PH domains, only PH-AKT2 is capable of binding both PIP_3 and $PI(3,4)P_2$. The remaining PH domains only bind PIP_3. The Alanine (A) mutation in the phosphoinositide (PI) signature motif renders the mCherry-tagged mutant PH domain versions unable to bind phosphoinositides. **(C)** Quantification of total internal reflection fluorescence (TIRF) microscopy experiments comparing the response rate and dynamic range of individual PH domain-based PI3K reporters in response to pharmacological PI3Kα activation in HeLa

1361 cells. To correct for non-specific increases in biosensor signal at the plasma membrane, the
1362 intensity of each GFP-tagged wild-type PH domain was normalized to that of its mCherry-
1363 tagged mutant version. The traces represent mean fold-change relative to baseline (the
1364 median signal of the first four time points), with shaded areas representing +/- 1 standard
1365 deviation (SD). Experimental replicates and single-cell numbers are indicated. Two different
1366 constellations were tested for BTK-derived PH domain: with and without the adjacent Tec
1367 homology (TH) domain. Only one experiment was performed with PH-BTK without TH as most
1368 of the cells failed to tolerate its expression. **(D)** TIRF-M of the PH-AKT2-derived biosensor in
1369 HeLa cells stimulated with 5 µM 1938, followed by pharmacological PI3Kα inhibition with 500
1370 nM BYL719. Two independent experiments are superimposed to illustrate the expected inter-
1371 experimental variability. All plots represent mean normalized reporter signal relative to time 0,
1372 with shading corresponding to standard deviation. **(E)** The performance of the PH-TH version
1373 of BTK could be improved when switching from N-terminal to C-terminal fluorescent protein
1374 fusion, with simultaneous removal of the nuclear export sequence, as in the original plasmid
1375 DNA used for subcloning of this reporter.

1378
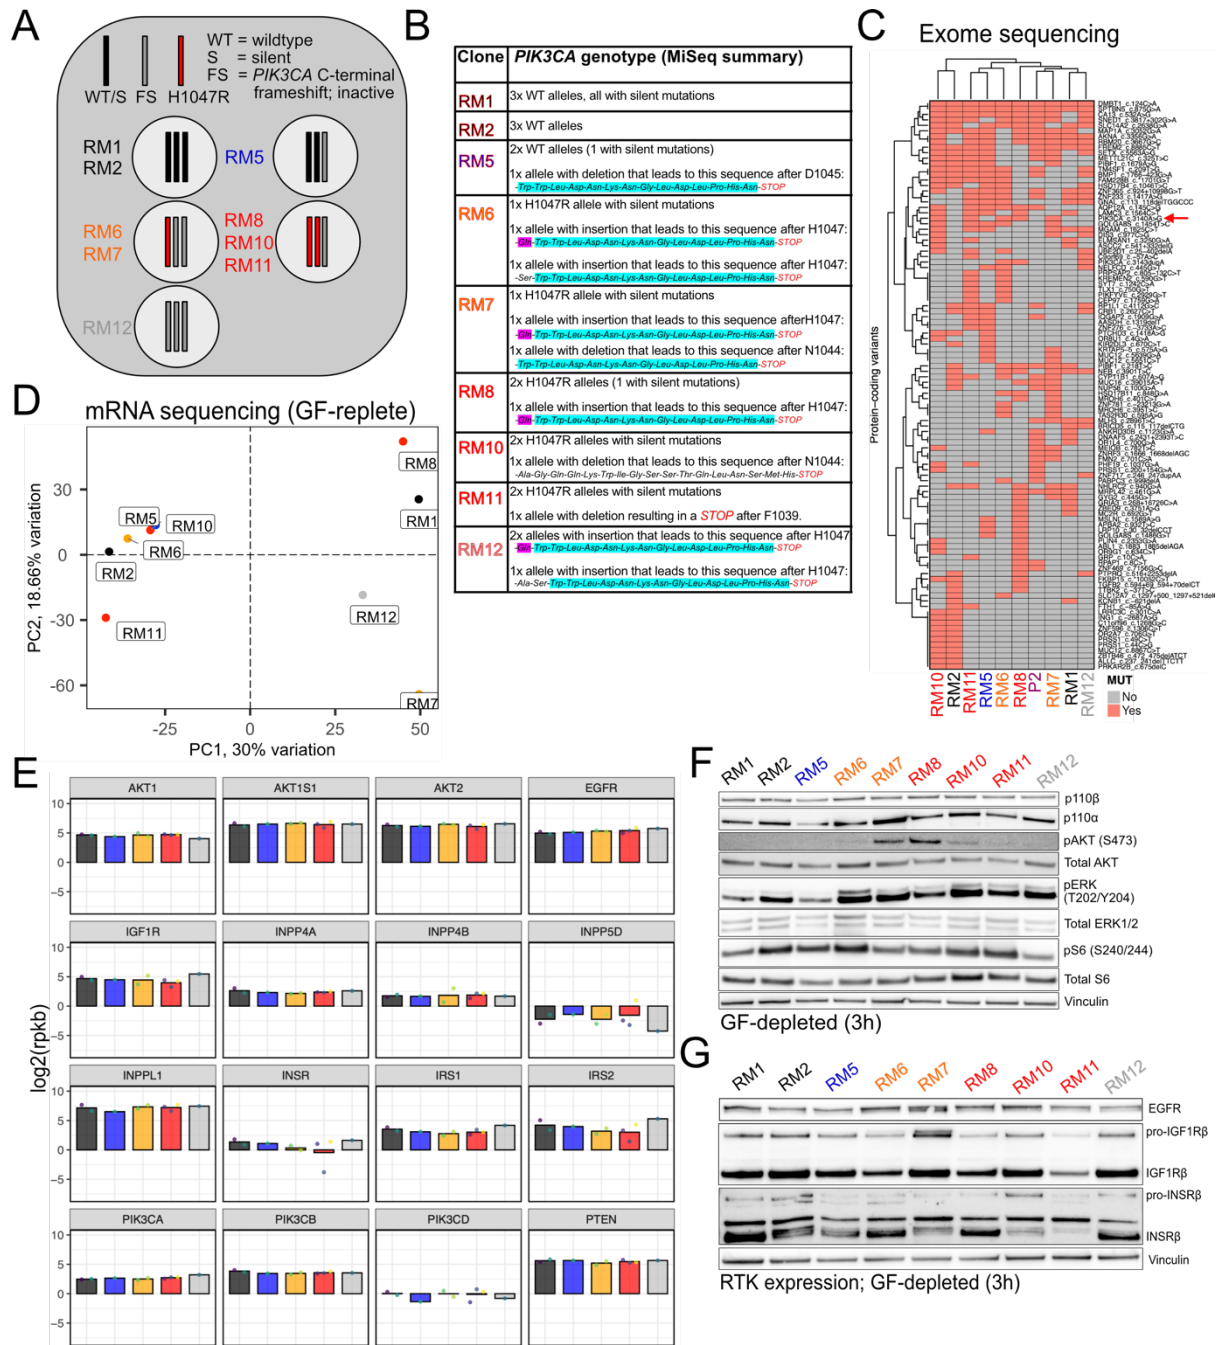

1379
1380
1381 **Fig. S2. CRISPR/Cas9 *PIK3CA* exon21 engineering and quality control assays of HeLa**
1382 **clones. (A)** Summary of the final set of clones that were banked and validated following
1383 engineering. As HeLa cells are nominally triploid, the edited clones either have three wildtype
1384 *PIK3CA* alleles or either one of the following: 0-2 wildtype *PIK3CA* alleles, 0-2 *PIK3CA*^{H1047R}
1385 alleles and/or 0-3 C-terminal frameshift alleles. **(B)** The C-terminal frameshift truncation results
1386 in recoding of the last c. 20-30 amino acids of the p110α protein (common reading frames are
1387 highlighted in purple and turquoise). This abolishes the critical p110α WIF motif required for
1388 membrane binding and catalytic function (38), effectively creating a loss-of-function knock-in
1389 that does not carry the risk of a complete knock-out in terms of altering the stoichiometry of
1390 regulatory and catalytic p110 subunits. The exact allelic sequence was obtained following
1391 targeted next generation sequencing of the edited *PIK3CA* exon21 region. **(C)** Clustering of
1392 individual HeLa cultures based on protein-coding gene variants found in two or more
1393 CRISPR/Cas9 engineered HeLa clones relative to the parental culture prior to gene editing.
1394 Gene variants were captured using whole exome sequencing, which included a control HeLa

1395   culture passaged alongside the CRISPR/Cas9-edited clones without any editing or
1396   subcloning. A red arrow is used to indicate the *PIK3CA^H1047R* edit which is the only protein-
1397   coding variant common to all *PIK3CA^H1047R* mutant cell lines. **(D)** Principal component analysis
1398   (PCA) of CRISPR/Cas9-engineered HeLa clones based on total mRNA sequencing data
1399   obtained in baseline culture condition following fresh medium replenishment 3 h prior to
1400   sample collection. The observed clustering is similar to that observed with the exome
1401   sequencing data in (C), without any systematic differences driven by the presence of the
1402   *PIK3CA^H1047R* variant. **(E)** Barplots comparing the expression levels in log2(reads per kilobase)
1403   for selected PI3K pathway-relevant genes and receptor tyrosine kinases. **(F)** Western blots
1404   for PI3K signaling components and pERK1/2 following 3 h of serum or growth factor (GF)
1405   removal, using all CRISPR/Cas9-engineered HeLa clones. **(G)** As in F but focusing on the
1406   expression levels of relevant receptor tyrosine kinases. EGFR, epidermal growth factor
1407   receptor; IGF1R, insulin-like growth factor 1 receptor; INSRβ, insulin receptor β chain.
1408
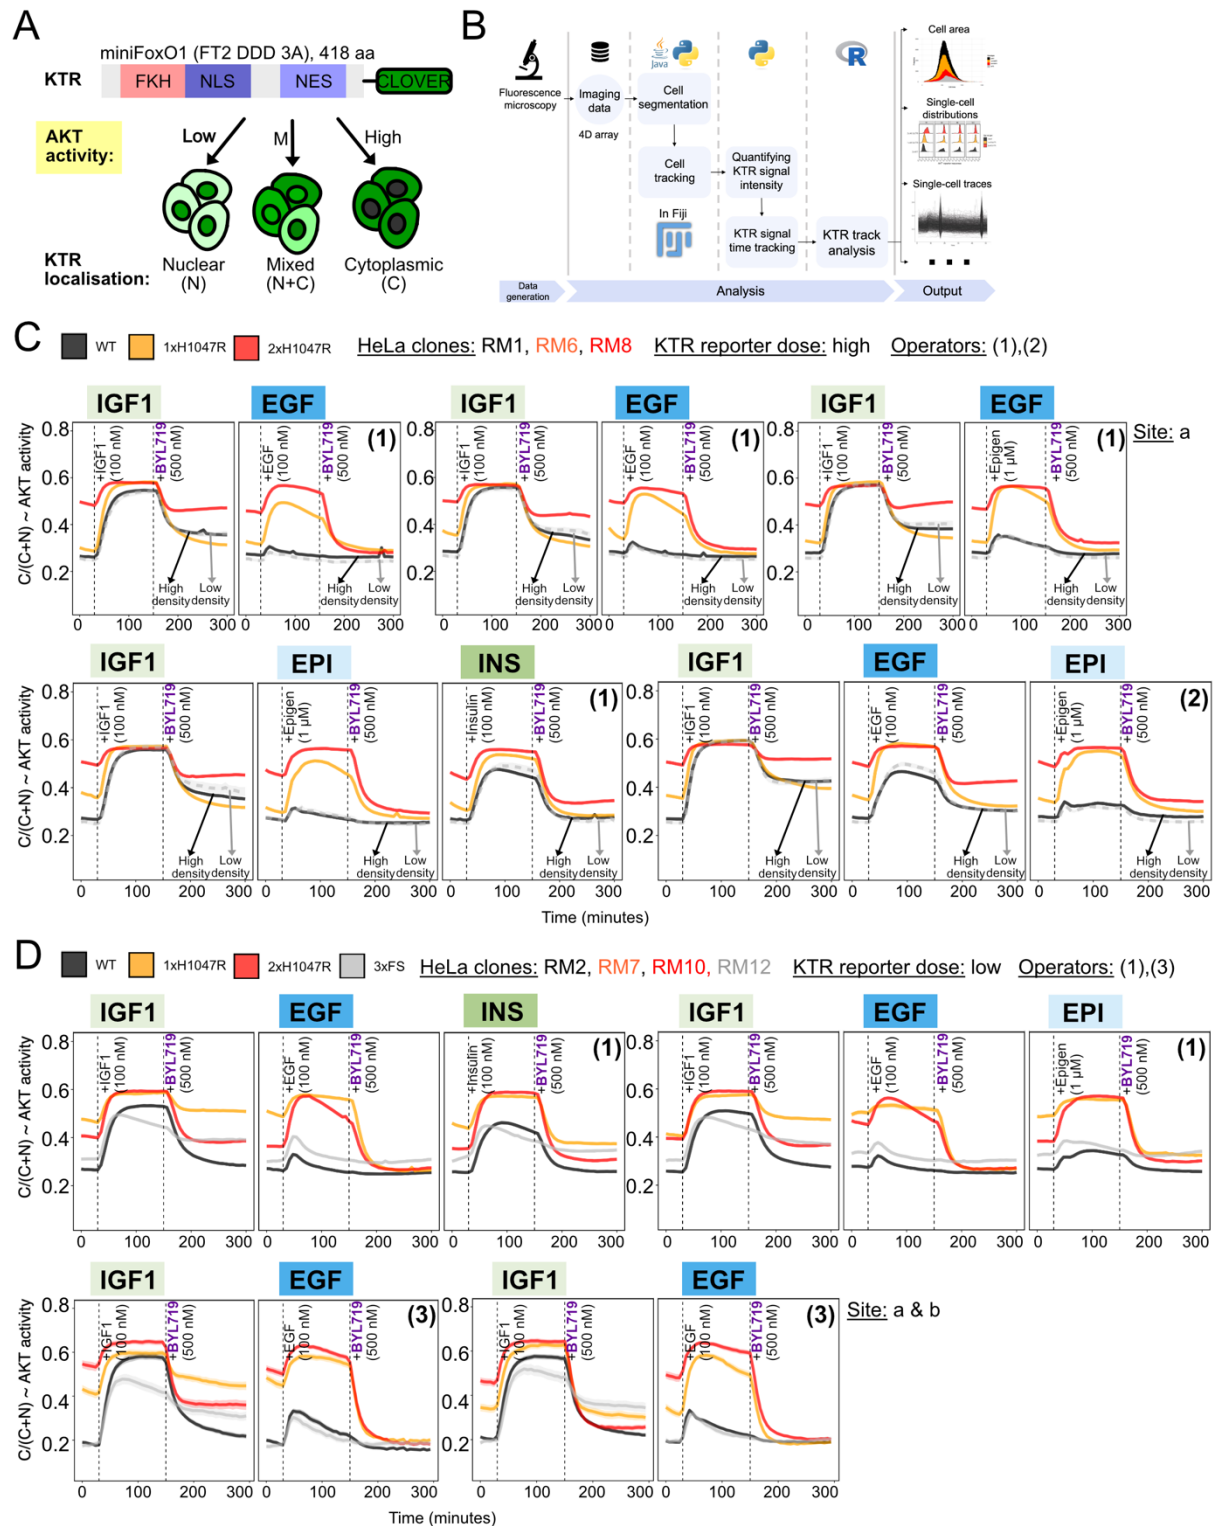

Figure S3. FOXO-based AKT kinase translocation reporter (KTR) set-up and full set of experimental outputs. (A) Schematic of the reporter and its mechanism of action. Note that the reporter was delivered into cells using transposon-based technology for stable expression. **(B)** Overview of the computational image and KTR data analysis pipeline which has been deposited on the accompanying OSF project site (doi: 10.17605/OSF.IO/4F69N). The data in **(C)** and **(D)** are from all independent experiments performed across different genotypes, HeLa clones, cell densities, KTR reporter doses, operators and experimental sites for a robust evaluation of reproducibility. For each time point, the traces correspond to the mean proportion of cytoplasmic KTR signal, with shaded areas representing bootstrapped 95% confidence

1420   intervals of the mean (note that these may be too small to be seen on the figure). Note that
1421   we observed operator-dependent differences in EGF-induced signaling dynamics in wild-type
1422   cells, yet the overall pattern relative to IGF1, including the blurring of the response in mutant
1423   cells, remained consistent. This technical variability in EGF responses in wild-type cells is
1424   likely due to their sensitivity to the pressure/rate of delivery of the stimulus through the manual
1425   fluidics system (see doi: dx.doi.org/10.17504/protocols.io.261gedjkjv47/v1).
1426
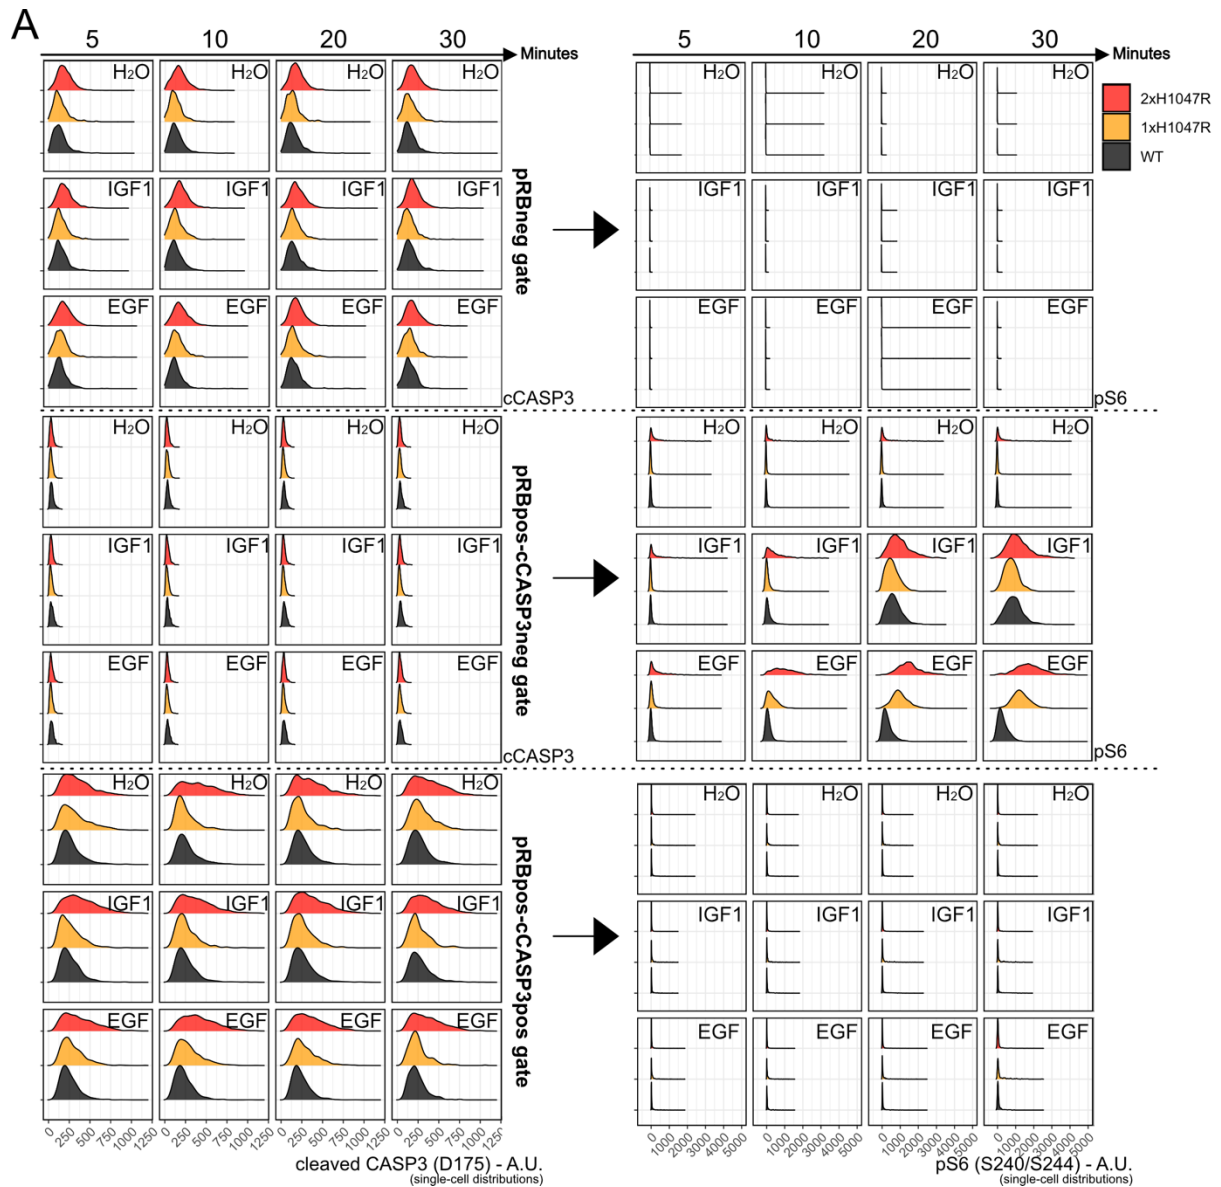

Fig. S4. Example data demonstrating that growth factor-induced signaling responses are only observed in pRB$^{S807/S811}$-positive (cycling) and cleaved Caspase^{D175}-negative (non-apoptotic) HeLa spheroid cells. The plots on the left-hand side show the single-cell cCASP3^{D175} signal in the different pRB gates as indicated. The plots on the right show the corresponding pS6$^{S240/S244}$ signal in each gate. The overall experimental setup is as shown in Fig. 4.

**Figure S5. Additional CyTOF data and independent experimental replicate with independent clones. (A)** The pNDRG1 and pSMAD2/3 signaling responses captured as part of the dataset shown in Fig. 4. The phosphorylation of NDRG1 on T346 is a known

1443 marker of mTORC2 activation (84). The phosphorylation of SMAD2/3 (S465/S467;
1444 S423/S425) is a marker for activated TGFβ signaling which is associated with *PIK3CA^H1047R*
1445 phenotypes in human iPSCs (25). **(B)** CyTOF data from a repeat of the experiment in Fig. 4,
1446 using independent CRISPR/Cas9-engineered, 3D-cultured HeLa clones, including the
1447 *PIK3CA* loss-of-function 3xFS clone as an additional control. The spheroids were serum-
1448 starved for 4 h prior to the indicated perturbations. The shown signaling data are from
1449 cycling, non-apoptotic cells. The stippled line indicates the position of the peak in wild-type
1450 spheroids treated with vehicle (H_2O). The grey shading highlights the response region that is
1451 not accessible to *PIK3CA* wild-type cells in the absence of stimulation.
1452
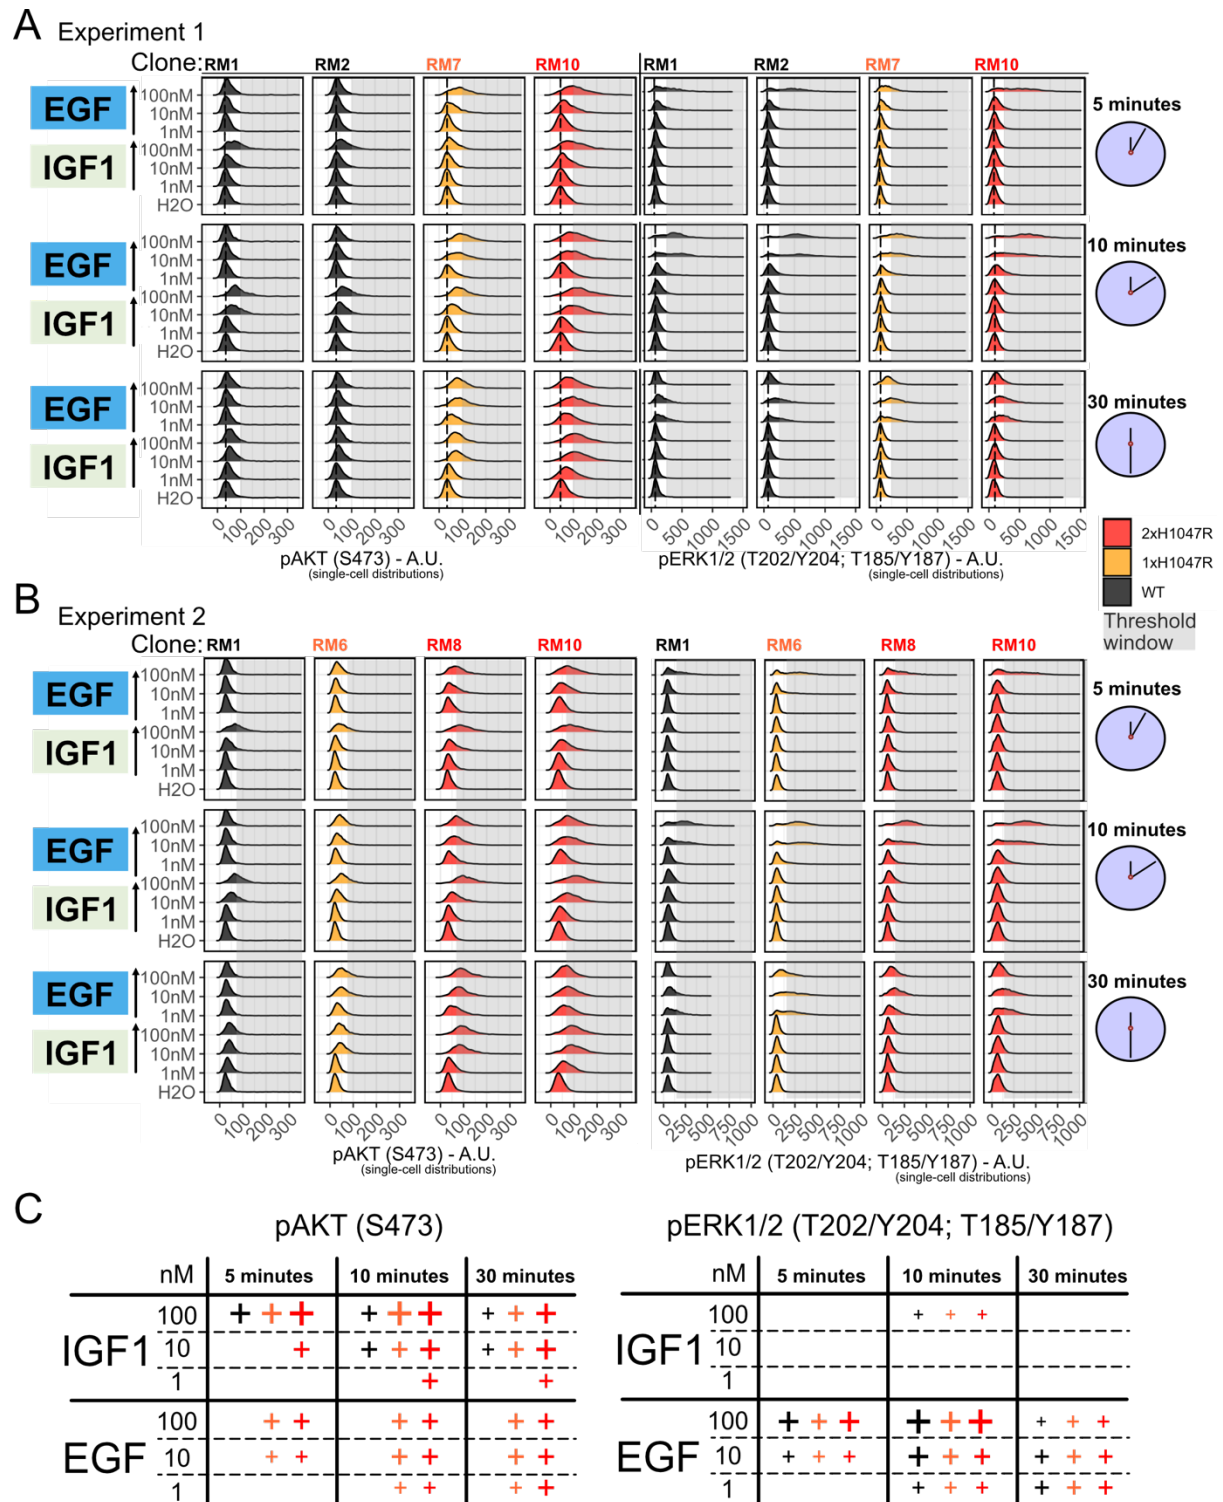

Figure S6. **Dose- and time-dependent IGF1 and EGF single-cell signaling responses in HeLa spheroid cells with wild-type or *PIK3CA^H1047R* (1-2 copies) expression.** The plots in **(A)** and **(B)** are from two independent CyTOF datasets using independent CRISPR/Cas9-engineered, 3D-cultured HeLa clones stimulated with 1, 10 or 100 nM of IGF1 or EGF as a function of time. The spheroids were serum-starved for 4 h prior to the indicated perturbations. The shown signaling data are from cycling, non-apoptotic cells. The stippled line indicates the position of the peak in wild-type spheroids treated with vehicle (H$_2$O). The grey shading highlights the response region that is not accessible to *PIK3CA* wild-type cells in the absence

1464   of stimulation. **(C)** Graphical summary of the key observations in the datasets in (A) and (B).
1465   A positive response is indicated with (+), the size of which indicates the response magnitude.
1466
Figure S7. Light microscopy images of HeLa (A) and iPSC (B) maintenance cultures with different _PIK3CA_ genotypes. The cultures in A correspond to independent CRISPR/Cas9-engineered HeLa clones to those used for staining in Fig. 5B. The red arrows in (B) point to example regions with disorganized colony growth and mesenchymal-like morphology changes in homozygous _PIK3CA_^{H1047R} iPSCs.
