Abstract

This article provides a comparison of the vascular alien flora of Sardinia (Italy) and that of Corsica (France), both territories belonging to the Western Mediterranean biogeographic subregion. The study has recorded 598 (90 doubtful) alien taxa in Sardinia (18% of the total flora) while 553 (87 doubtful) in Corsica (17%); six are new report to Sardinia and 27 to Corsica. A total of 234 taxa are common to both islands. Neophytes are 344 taxa (68% of the total) in Sardinia and 399 taxa (73%) in Corsica. The invasive component includes 64 taxa in Sardinia (13% of the alien flora) and 99 taxa (21%) in Corsica, 33 of them common to both territories. The total 740 alien taxa of Sardinia and Corsica are included in 93 families; being *Fabaceae* the richest. The comparison of the biological spectrum reveals that phanerophytes (202 taxa, 40%) are the most represented in Sardinia and therophytes (149 taxa, 32%) in Corsica. A study of the geographical origin shows supremacy of the American element in Sardinia (170 taxa, 34%) and in Corsica (136 taxa, 29%). The majority of taxa arrived as a result of intentional human introductions, mainly for ornamental use (247 taxa, 49% in Sardinia; 208 taxa, 45% in Corsica). Semi-natural, agricultural and synanthropic are the most occupied habitats. These data show the need for joint action to stem the increasingly worrying phenomenon of the alien flora in order to reduce the negative effects on natural habitats and native flora.

Keywords: alien vascular flora, conservation, invasions, Mediterranean Basin, Tyrrhenian islands

Introduction

Alien plant species, especially in their invasive and naturalized component, are considered one of the major threats to the conservation of endangered plant species and habitats (Mack *et al.*, 2000; Genovesi and Shine, 2004; Millennium Ecosystem Assessment, 2005; Lambdon *et al.*, 2008). There are many ways alien plants can directly and indirectly menace the preservation of native flora. As regards, among other effects on biodiversity, it is reported that they can change ecosystems through the alteration of soil stability, the promotion of erosion, being vector of parasites and diseases, the colonization of free spaces, the exploitation of natural resources, the accumulation of litter,

the promotion or suppression of fire and, together with the more or less massive human intervention, the homogenization of the floras (Vitousek, 1990; Richardson *et al.*, 2000; Winter *et al.*, 2009).

Regarding the severe degree of the impact of alien plants on island ecosystems compared to mainland, different points of view have been developed so far. In fact, if on the one hand there is who sustains that island ecosystems, and especially those of the Mediterranean Basin, are more susceptible to alien plant invasions (Sala *et al.*, 2000; Sax and Gaines, 2008), on the other hand more recent doubts have been expressed concerning the different impact that plant invasions could actually have on the native floras of mainland respect to islands (Vilà *et al.*, 2011).

Notwithstanding, islands usually harbour very particular floras, due to their geographical isolation, by the presence of a high number of endemics that deserve absolute protection from the various menaces that threaten the integrity of their populations up to the survival of the species (Fenu *et al.*, 2014; Thompson, 2005).

Sardinia (Italy) and Corsica (France) are two important centres of plant biodiversity belonging to the Tyrrhenian Islands hotspot (Cañadas *et al.*, 2014; Médail and Quézel, 1997, 1999; Médail and Diadema, 2009; Zachos and Habel, 2011).

With regard to the latest checklist updates, the Sardinian flora included 2494 *taxa* (Conti *et al.*, 2005, 2007) of which 347 are endemics (Bacchetta *et al.*, 2005), while Corsica, though being pretty smaller, harbours a flora of 2680 *taxa*, with an endemic component of 284 *taxa* (Jeanmonod *et al.*, 2015). The high percentages of endemics, many of them being strictly exclusive to Sardinia and/or Corsica, meet the also relatively high amount of alien plant species of the floras of the two islands: according to the last report made by Podda *et al.* (2012), the alien component for Sardinia reached the amount of 541, of which 58 are invasive, while in the latest study of the Corsican alien flora carried out by Jeanmonod *et al.* (2011, 2015) non-native component accounted 443 *taxa*, of which 31 are invasive or potentially invasive.

Unfortunately, it cannot be omitted that both in Sardinia and Corsica many fragile habitats and some endangered and endemic *taxa* are at risk of disappearance (Bacchetta *et al.*, 2012; Cañadas *et al.*, 2014). It is also noteworthy that the two islands are major touristic destinations in the Mediterranean, especially concerning beach tourism thus entailing an exceptional land use in coastal areas that, together with other natural and semi-natural habitats, are also constantly threatened by other menaces such as recurring fires, exaggerated herbivory, overexploitation of natural resources, increasing urbanization and the subsequent land degradation (Vacca *et al.*, 2002; Delbosc, 2015).

In a context of an increasing menace by the continuous rising percentages of alien plant *taxa*, an update of the checklist of the alien vascular flora and the analysis of its components is useful to get a snapshot of the current composition of the non-native components. Moreover, the comparison of the invasive alien floras of two biogeographically related areas such as the islands of Sardinia and Corsica – especially in the framework of a broad survey on the alien plants distribution in islands of the Mediterranean Basin – can provide an insight of which are the processes that act as primary drivers of the introduction and the subsequent invasion of alien plants in Mediterranean insular habitats.

In this paper, the results of the comparison between the alien floras of Sardinia and Corsica are reported, as inferred from field investigations and from the latest literature. Special care has been put into the analysis of the chorology, the life form, the type (if neophyte or archaeophyte), the diffusion (if invasive, naturalized or casual), the pathway of introduction and the most affected habitats in relation to the two alien floras.

Materials and Methods

The basis of the current comparative analysis is the latest update of the Sardinian alien flora checklist (Podda *et al.*, 2012) and the recent revisions of the “Catalogue des Tracheophytes de Corse” (CBNC, 2014). The two checklists have been subjected to revision and updated based on field investigations, literature and herbarium data. Those *taxa* that had been recorded in the past and for which there is no certainty concerning their actual presence in the studied areas, were considered of doubtful presence and marked by the letter D.

Plant *taxa* have been classified as archaeophytes or neophytes on the basis of their introduction before or after 1492/1500 A.D., respectively. Concerning the *taxa* for which doubts still persist, regarding their status (alien or native), we have preferred the attribution of doubtful alien (Da).

The status of invasiveness has followed that proposed by Richardson *et al.* (2000) and subsequently elaborated and reviewed by Pyšek *et al.* (2004) and Richardson *et al.* (2011).

In particular, Sardinian *taxa* have been attributed to the classes of invasive, naturalized and casual plants on the basis of the current literature as well as on field observations, while for Corsican *taxa* we mainly followed what was reported by the Conservatoire Botanique National de Corse (2014) with minor modifications together with what was observed during field investigations.

From a nomenclatural point of view and for the attribution of the *taxa* to the plant families we have followed the on-line databases of The Plant List website (2016) and that of the Med-Checklist website (Euro+Med, 2006-onwards).

Plant families have been validated according to what is reported in the Angiosperm Phylogeny Group III (Chase and Reveal, 2009; Stevens, 2001-onwards) and in the works of Christenhusz *et al.* (2011a, 2011b). Moreover, when available, dedicated taxonomic revisions have been taken into account.

Regarding biological forms, Raunkiaer life form classification (Raunkiaer, 1934) was followed, with the variations and abbreviations used by Pignatti (1982), while geographic origin was based on what was basically reported by Podda *et al.* (2012) and by Jeanmonod and Gamisans (2013).

The way of introduction of the alien *taxa*, when known, was first defined as intentional or unintentional, according to the definitions proposed by the Convention on Biological Diversity (CBD) (Miller *et al.*, 2006). Regarding introduction pathways, the categories proposed by Sanz-Elorza *et al.* (2004) and Hulme *et al.* (2008), already adopted by Podda *et al.*, (2012), have been followed: (1) ornamental; (2) agriculture; (3) forestry; (4) seed contaminants; (5) hitchhikers.

Each *taxon* has been linked to the habitat where it mostly shows its invasiveness and then ordered in the following seven categories as already proposed by Podda *et al.*, (2012): (1) agricultural; (2) synanthropic; (3) coastal; (4) matorral; (5) woodland; (6) riparian; (7) wetland.

The *taxa* that are known to be cultivated for ornamental or forestry purposes and that do not show any degree of spontaneization have not been taken into account in the present work.

Calculations have been made excluding those *taxa* from the category of doubtful species in relation to their actual presence in the studied area (D) or to their alien or native status (Da).

In order to study differences among the alien floras of Sardinia and Corsica the non-parametric U test Mann-Whitney was applied using version 16 (Minitab Inc.) of MINITAB®.

Results

The total alien flora of the two territories includes 740 *taxa*. Sardinian alien flora in total is composed of 598 *taxa*, representing the 18% of the whole Sardinian vascular flora. An increase of 61 *taxa* has been registered in comparison to the last update (Podda *et al.*, 2012). Corsican alien flora is composed of 553 *taxa*, representing the 17% of the whole Corsican flora. An increase of 40 *taxa* has been registered in comparison to the last update (Jeanmonod and Gamisans, 2013) (Annex 1).

Considering the previous known data, six new alien *taxa* have been found in the island of Sardinia (Table 1).

Regarding the island of Corsica, 27 new alien *taxa* are reported (Table 2).

The proportion of doubtful entities in Sardinia in relation to the total alien *taxa* (598) is of around a 15%, from which 23

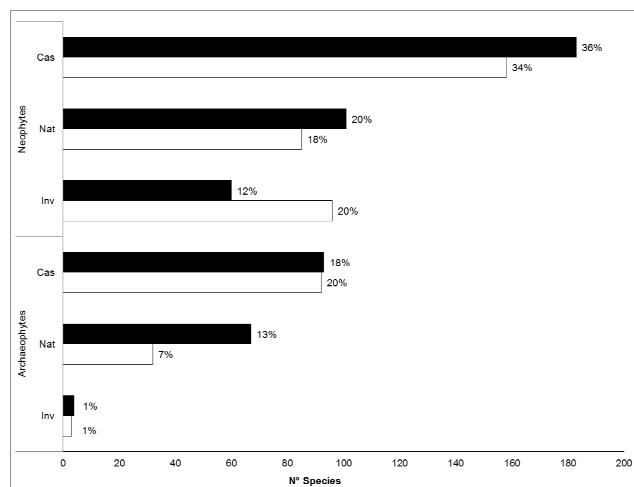

Fig. 1. Numerical and percentage comparison of invasive (Inv), naturalized (Nat) and casual species (Cas), distinguishing archaeophytes and neophytes from the total alien flora in Sardinia (black) and the Corsica (white)

taxa are considered of doubtful presence ("D"), 62 are in doubt in relation to their alien or native status ("Da") and five are both "D" and "Da".

Regarding Corsica, from the 553 alien *taxa*, 31 are considered of doubtful presence ("D"), 47 of doubtful alien origin ("Da") and nine both "D" and "Da".

Of the 508 remaining alien *taxa* (without considering "D" and "Da" entities) in Sardinia, 164 are archaeophytes (32%) and 344 neophytes (68%) while Corsican alien flora includes 466 *taxa*, of which 127 are archaeophytes (27%) and 339 neophytes (73%) (Fig. 1).

The number of invasive neophytes is 60 (12%) and 96 (20%) for Sardinia and Corsica respectively. The amount of other neophytes (naturalized and casual) is of 101 and 183 respectively (20% and 36%) for Sardinia and 85 and 158 respectively (18% and 34%) for Corsica. Regarding archaeophytes, only a small percentage is invasive (1%), both for Sardinia and Corsica, while for those naturalized and casual it is higher (13% and 18% Sardinia; 7% and 20% Corsica) (Fig. 1). The Mann-Whitney test confirmed no significant differences between the medians of the samples considered ($U = 4, p = 0.8852$).

A total of 234 taxa are common to Sardinia and Corsica, from which the 33% are naturalized, the 45% casual and the 22% invasive in Sardinia, while in Corsica the 24% are naturalized, the 48% casual and the 28% invasive (Table 3). The Mann-Whitney test confirmed no significant differences between the medians of the samples considered ($U = 3$, $p =$

1,00000) for section "Total" and for the section "In common".

Invasive taxa common to both territories are 33. Regarding the other invasive taxa, 19 are exclusive to Sardinia and 33 to Corsica. The number of taxa behaving as invasive in Sardinia and naturalized in Corsica is 15, while 20 are invasive in Corsica and naturalized in Sardinia (Fig. 2). Regarding the

Table 3. Comparison of the number of common alien taxa of Sardinia and Corsica

Status of invasivity	Total		In common	
	Sardinia	Corsica	Sardinia	Corsica
Naturalized	168	117	77	55
Casual	276	250	105	113
Invasive	64	99	52	66
Total	508	466	234	234

Detailed description: This bar chart compares the number of species across various plant families in Sardinia (SA) and Corsica (CO). The y-axis represents the number of species (Nº Species), ranging from 0 to 60. The x-axis lists families: Fabaceae, Poaceae, Asteraceae, Brassicaceae, Solanaceae, Rosaceae, Asparagaceae, Amaranthaceae, Cactaceae, and Crassulaceae. For each family, there are two bars: a white one for SA and a black one for CO. Percentage values are labeled above each bar.

Family	SA (White)	CO (Black)	% SA
Fabaceae	7%	42%	93%
Poaceae	20%	37%	80%
Asteraceae	18%	36%	82%
Brassicaceae	26%	19%	74%
Solanaceae	37%	13%	63%
Rosaceae	0%	18%	100%
Asparagaceae	25%	10%	75%
Amaranthaceae	27%	8%	73%
Cactaceae	15%	12%	85%
Crassulaceae	50%	50%	100%

Fig. 3. Comparison of the number of invasive species (white) and naturalized plus casual (black) for each family in Sardinia and in Corsica

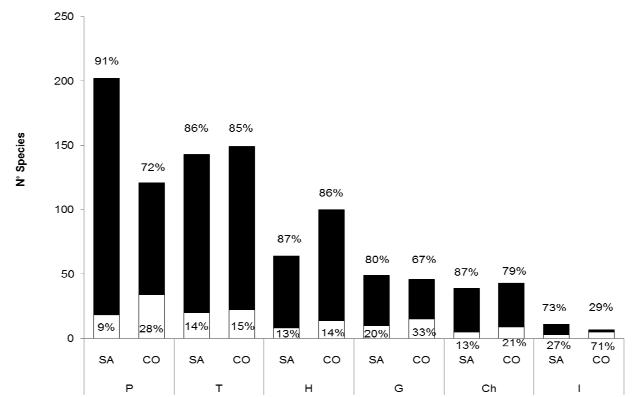

Fig. 4. Comparison of the life forms of invasive (white) alien flora and other (black) alien species (naturalized and casual) in Sardinia and Corsica. Note: T: therophytes, P: phanerophytes, H: hemicryptophytes, Ch: chamaephytes, G: geophytes, I: hydrophytes

status, the Mann-Whitney test showed no significant differences between the medians of the samples considered ($U = 4$, $p = 1,0000$).

The alien flora of Sardinia includes 93 families; *Fabaceae* is the richest one (46 taxa), followed by *Poaceae* (39), *Asteraceae* (35), *Brassicaceae* and *Solanaceae* (both 19). Corsican alien flora

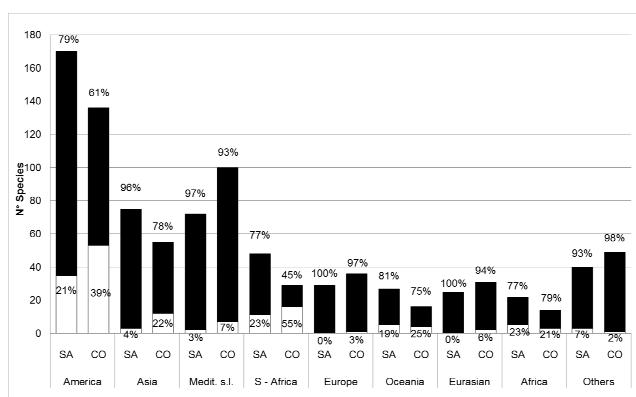

Fig. 5. Comparison of the geographical origin of invasive (white) alien flora and other (black) alien taxa (naturalized and casual) in Sardinia and Corsica

also includes 93 families, among which the most represented are *Asteraceae* (65), *Poaceae* (50), *Fabaceae* (46), *Brassicaceae* (19) and *Solanaceae* (18) (Fig. 3). The Mann-Whitney test showed no significant differences between the medians of the different families of the samples considered ($U = 14$, $p = 0,6959$).

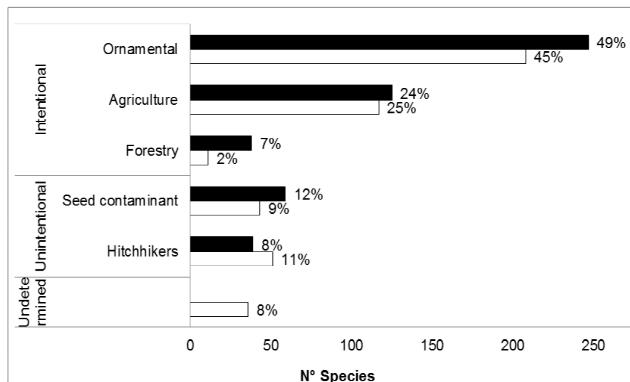

Fig. 6. Comparison of different introduction pathways of alien flora in Sardinia (black) and Corsica (white)

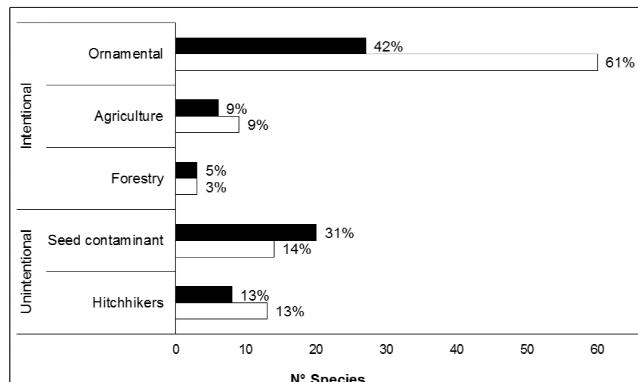

Fig. 7. Comparison of different introduction pathways of invasive species in Sardinia (black) and Corsica (white)

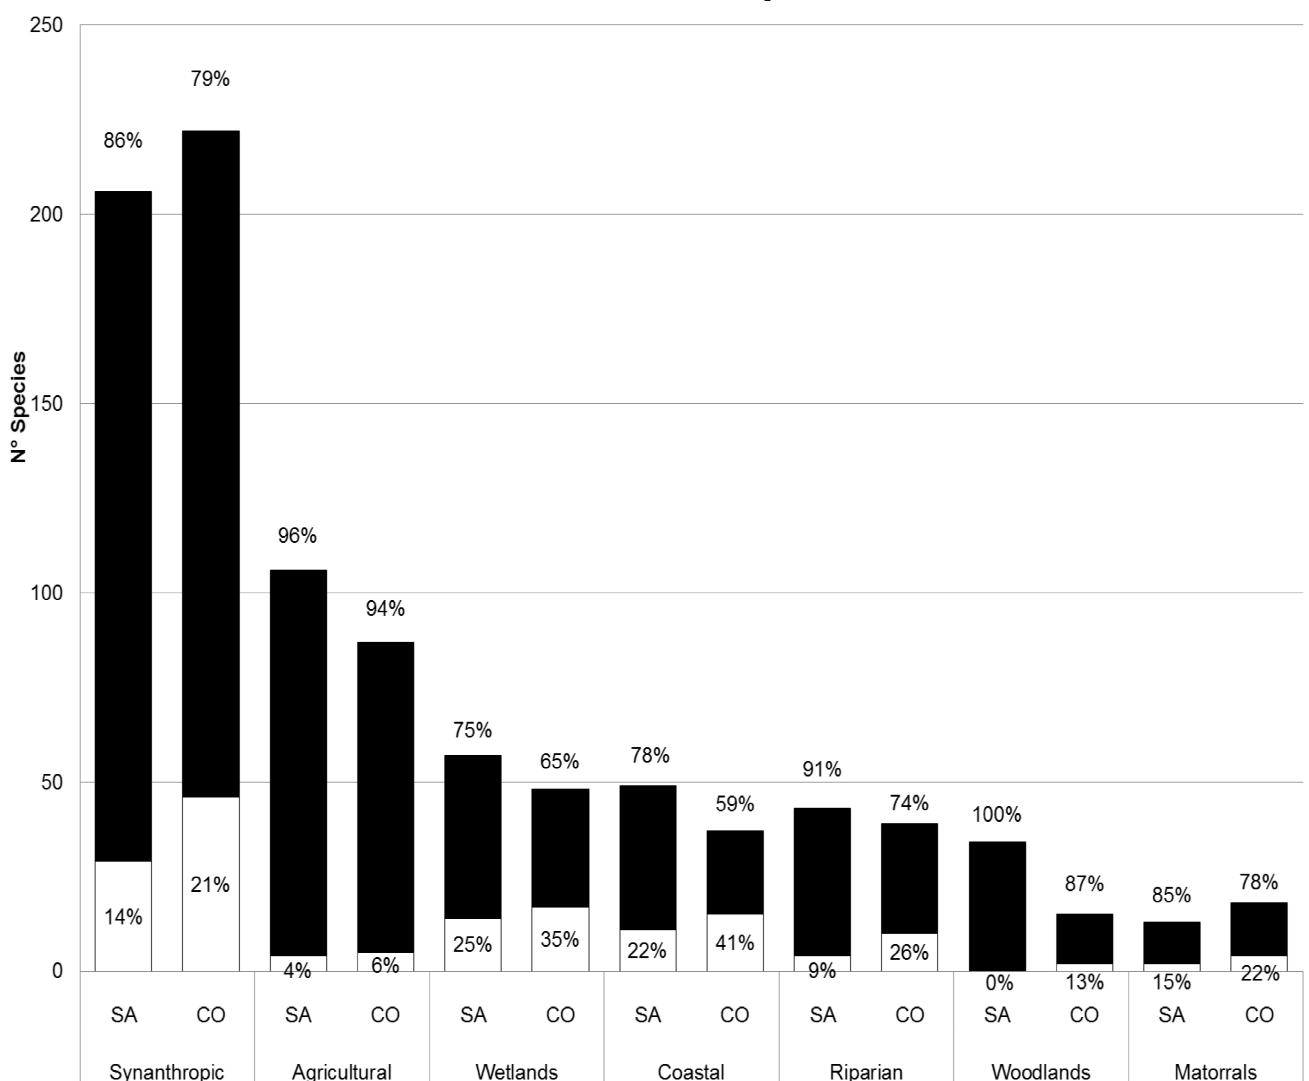

Fig. 8. Comparison of habitats affected by invasive (white) alien taxa and other (black) alien plants (naturalized and casual) in Sardinia and Corsica

Concerning invasive taxa, the most represented families in Sardinia and Corsica are *Asteraceae* (9 and 15 taxa respectively), *Poaceae* (7 and 13 taxa), *Solanaceae* (7 and 5 taxa) and *Fabaceae* (3 and 9 taxa) (Fig. 3). In this case the Mann-Whitney test also showed no significant differences between the medians of the different families of the samples considered

($U = 14$, $p = 0,5938$).

Considering life forms, Sardinian alien flora shows a net preponderance of phanerophytes (202 taxa, 40%) and therophytes (143 taxa, 28%), while minor contributions come from hemicryptophytes, geophytes and chamaephytes (Fig. 4). In Corsica alien therophytes, phanerophytes and

hemicyclopediae compose the major group being represented by 149 (32%), 121 (26%) and 100 (21%) *taxa* respectively, followed by geophytes and chamaephytes. The Mann-Whitney test showed no significant differences between the medians of the samples considered ($U = 6$, $p = 1,0000$).

The analysis of the invasive component of Sardinia shows that therophytes and phanerophytes are again the most abundant life forms with 20 (31%) and 18 *taxa* (28%) respectively followed by a substantial contribution of geophytes. Among the invasive alien plants of Corsica phanerophytes constitute the relative majority with 34 *taxa* (35%) against therophytes (22 *taxa*, 22%), while the other life forms provide minor contributions. Both in Sardinia and Corsica hydrophytes are poorly represented (Fig. 4). The Mann-Whitney test showed no significant differences between the medians of the samples considered ($U = 6$, $p = 0,9362$).

Regarding the geographical origin, the major source of alien *taxa* for Sardinia is represented by the American component (170 *taxa*, 34%), followed by the Asian (75 *taxa*, 15%) and the Mediterranean *sensu lato* (72 *taxa*, 14%). For Corsica, the American origin also makes far the largest group with 136 *taxa* (29%) while other important contributions are provided by the Mediterranean *sensu lato* plants (100 *taxa*, 22%) and the Asian (55 *taxa*, 12%) (Fig. 5). The Mann-Whitney test confirmed no significant differences between the medians of the samples considered ($U = 9$, $p = 1,0000$).

Invasive units of the Sardinian alien flora are mostly of American (35 *taxa*, 55%) and South African origin (11 *taxa*, 17%). With regard to the invasive flora from Corsica, the most represented element is also the American (53 *taxa*, 53%), followed by the South African (16 *taxa*, 16%) (Fig. 5). Mann-Whitney test confirmed no significant differences between the medians of the samples considered ($U = 9$, $p = 0,8595$).

Concerning the ways of introduction, *taxa* that are cultivated as ornamental are far the most frequent in the Sardinian alien flora, counting 247 entities (49%), followed by crops, with 125 *taxa* (24%), while seed contaminant *taxa* account for up to 59 (12%), hitchhikers 39 (8%) and forestry 38 (7%) (Fig. 6). As far as Sardinian invasive *taxa* are concerned, ornamental units still represent the most numerous group with 27 *taxa* (42%), while there is a net decrease of the crops and an increase of the seed contaminants and of hitchhikers (Fig. 7). In Corsica the ornamental and agricultural paths are also the ways of introduction that provide more than half of the whole alien flora [208 (45%) and 117 *taxa* (25% respectively)], while similar and much more modest contributions come from hitchhikers and seed contaminant *taxa* and a very low quota of *taxa* introduced for forestry (Fig. 6). When only taking the invasive units into account, the ornamental component in Corsica is represented by 60 *taxa* (61%), followed by seed contaminants (14 *taxa*, 14%) and by hitchhikers (13 *taxa*, 13%) (Fig. 7).

For the situation of alien *taxa* in general and in the specific case of invasive units, the Mann-Whitney test confirmed no significant differences between the medians of the samples considered ($U = 6$, $p = 0,8102$) and ($U = 5$, $p = 1,0000$) respectively.

The analysis of the habitats occupied by alien *taxa* in Sardinia shows that synanthropic environments are those where alien units are found more frequently (206 *taxa*, 40%),

followed by agricultural habitats with 106 *taxa* (21%), while the remaining ones provide minor and nearly comparable contributions, with the exception of *matorrals*, that account for only 13 *taxa* (3%). In Sardinia invasive *taxa* tend to invade mostly synanthropic habitats (29 *taxa*, 45%) and at a lesser extent wetlands and coastal habitats. A similar situation is seen in Corsica, where the habitats that aliens tend to occupy are commonly synanthropic (222 *taxa*, 48%), followed by agricultural lands (87 *taxa*, 19%). These data are coincident with the highest number of invasive *taxa* in Corsica, that occur in synanthropic habitats (46 *taxa*, 46%). By contrast, important differences regarding agricultural habitats are found, when comparing alien and invasive Corsican flora, with a decrease to 14% (5 *taxa*). Important differences are also found in wetlands and coasts, where invasive units nearly double their percentage (17 *taxa* (17%) and 15 *taxa* (15%) respectively) (Fig. 8). The Mann-Whitney test confirmed no significant differences between the medians of the samples considered ($U = 7$, $p = 0,7983$) and ($U = 7$, $p = 1,0000$) for the general and only invasive cases respectively.

Discussion

The alien vascular flora of Sardinia and Corsica constitutes the 18% and 17% of the total vascular flora of each island, respectively. These data are consistent with those observed in other contexts of the Mediterranean islands, e.g., the Balearic Islands (19%, Podda *et al.*, 2010), and are significantly higher than those reported for Sicily (12.55%, Raimondo *et al.*, 2010) and for the Tuscan Archipelago (10%, Lazzaro *et al.*, 2014).

The prevalence of invasive neophytes on archeophytes, is evident in both islands, with an outstanding higher proportion in Corsica, although the territory is mostly mountainous and smaller than that of Sardinia. The high disproportion of invasive *taxa* found between neophytes and archeophytes also characterizes other contexts such as the Balearic Islands (Podda *et al.*, 2011) and the Tuscan Archipelago (Lazzaro *et al.*, 2014). In the case of the Balearic Islands (14% of invasive *taxa*) and the Tuscan Archipelago (22% of invasive *taxa*), the proportion of such invasive entities is higher than in Sardinia and Corsica. This fact could be attributed to the greater anthropization of the territories than those analysed in this paper.

Among the invasive units common to the two islands, some are also spread worldwide [*Acacia mearnsii* De Willd., *Ailanthus altissima* (Mill.) Swingle, *Arundo donax* L., *Carpobrotus edulis* (L.) N.E. Br., *Cortaderia selloana* (Schult. & Schult. F.) Asch. & Graebn., etc.], or around Europe (*A. altissima*, *C. edulis*, *C. selloana*, *Cyperus eragrostis* Lam. non Vahl., etc.) (DAISIE, 2009), and there are others that are emerging in other countries with a similar (Mediterranean-like) climate to Sardinia and Corsica. These include *Agave americana* L. (Badano and Puignaire, 2004; Smith and Figueiredo, 2007), *Asclepias fruticosa* L. (Fernández Haeger *et al.*, 2010), *Cotula coronopifolia* L. (Brunel *et al.*, 2010), *Malephora crocea* Schwantes (Cal-IPC, 2006) and *Phytolacca americana* L. (Dumas, 2011).

With regard to the plant families, *Asteraceae*, *Poaceae* and *Fabaceae*, are the most represented when considering the alien flora as a whole, while if taking into consideration only the invasive component, a relatively high contribution from the

Solanaceae, *Amaranthaceae* and *Aizoaceae* families has been recorded. These values are consistent with what has been observed in other Mediterranean islands and archipelagos, such as the Balearic Islands and the Tuscan Archipelago (Podda *et al.*, 2011; Lazzaro *et al.*, 2014) and in the continent, as Spain (Sanz Elorza *et al.*, 2004).

When considering the life forms that characterize both the alien and invasive component of Sardinia and Corsica, the predominance of phanerophytes -mainly introduced for reforestation, forestation and ornamental use-, of therophytes -spread as seed contaminants, due to the degradation of habitats and fires- and, to a lesser extent of hemicryptophytes, were also observed in other islands, such as the Balearic (Podda *et al.*, 2010) and the Tuscan Archipelago (Lazzaro *et al.*, 2014) and continental areas, like Spain (Sanz Elorza *et al.*, 2004). The substantial contribution of geophytes is due to their mechanisms of adaptation and resistance to fire, very common in the Mediterranean area. This situation is to be interpreted on the basis of an extended period of summer drought representative of the Mediterranean climates, usually occurring as a particularly long period that obviously leads to a strong selection in favour of arboreal and annual *habitus* (Lloret *et al.*, 2004; Allen, 2001) or of just the arboreal component, based on the massive use for ornamental purposes, as already reported by Richardson and Rejmanek (2011).

The American predominance featuring alien flora -invasive and not invasive- of Sardinia and Corsica, is a constant in many Mediterranean areas, both islands -such as the Balearic Islands (Podda *et al.*, 2011, 2010), Crete (Dal Cin D'Agata *et al.*, 2009) and the Tuscan Archipelago (Lazzaro *et al.*, 2014)- and continental, as Spain (Sanz Elorza *et al.*, 2004) and Greece (Arianoutsou *et al.*, 2010). Other relatively important contributions to the exotic flora of Sardinia and Corsica, as for the other mentioned territories, come from Asia, from the Mediterranean basin and the African continent; with respect to the invasive flora, it is to be noted that the Mediterranean component is significantly reduced. In light of what emerges from the analysis of introduction pathways in Sardinia and Corsica as well as in other Mediterranean contexts (Lazzaro *et al.*, 2014; Podda *et al.*, 2010; Sanz Elorza *et al.*, 2004), the greater invasiveness that characterizes neophytes has been confirmed, associated to intentional introductions, in particular to the entities cultivated for ornamental purposes.

The analysis of the habitats where the largest number of alien *taxa* occur, or where some of these plants show an increased invasiveness indicates, as noted above for other territories (Podda *et al.*, 2010; Sanz Elorza *et al.*, 2004), that one of the basic factors explaining the arrival of non-indigenous entities, of their permanence in the two islands and their possible tendency to invade, is the loss of wilderness, phenomenon usually favoured by human activities and by changes in land use, as revealed in synanthropic and ruderal habitats. In contrast, although aquatic, coastal and riparian habitats host a relatively small number of alien *taxa*, it is equally true that being these habitats clearly marked by similar ecological conditions regardless of geographical and climatic conditions, these habitats are particularly susceptible to invasions and suffer the presence of some of the most invasive entities of both islands (Blondel and Médail, 2009; Mascia *et al.*, 2009; Nucci *et al.*, 2012; Schnitzler *et al.*, 2007; Zedler and Kercher, 2004). Instead, the habitats less susceptible to

invasions are *matorrals*, typically Mediterranean habitats with greater resilience (Di Castri, 1991).

Conclusions

Although there are important differences in the size and geography, as well as in the number of alien *taxa* present in the two islands, the analysis of the two alien floras shows a remarkable consistency between the two islands on the various aspects analysed. Nevertheless, in light of the high proportion of alien entities that characterizes the flora of Sardinia and Corsica, it is reasonable to speak of a full-scale invasion. In this sense, although it is possible to lead back at least part of the competitive success of some alien *taxa* -linked to their ability to settle down in anthropic environments, it is undeniable that other natural habitats, such as wetlands and coastal areas, are particularly sensitive to the entry of alien and in particular invasive entities. Therefore, a need for greater combined efforts, both geographically, and with regard to the various thematic areas of the phenomenon of biological invasions is necessary, in order to address the issue of the presence and the increasing danger of alien plant *taxa* through similar actions and common conservation policies.

Acknowledgements

This work was supported by the Provincia di Cagliari - Assessorato Tutela Ambiente, Agenzia Forestas and Regione Autonoma della Sardegna - Assessorato Difesa Ambiente (Italy) and by the Territorial Collectivity of Corsica and the French Ministry of Environment, Energy and the Sea. The authors would like to thank the CCB and CBNC staff for technical support. In particular, V. Lazzeri and F. Mascia helped with specimens collecting.
