ABSTRACT

We prove that any suitable generalization of Laver forcing to the space κ^κ , for uncountable regular κ , necessarily adds a Cohen κ -real. We also study a dichotomy and an ideal naturally related to generalized Laver forcing. Using this dichotomy, we prove the following stronger result: if $\kappa^{<\kappa} = \kappa$, then every $<\kappa$ -distributive tree forcing on κ^κ adding a dominating κ -real which is the image of the generic under a continuous function in the ground model, adds a Cohen κ -real. This is a contribution to the study of generalized Baire spaces and answers a question from [1].

1. Introduction

In set theory of the reals, a basic question is whether a forcing adds Cohen reals or dominating reals. It is well-known that Cohen forcing adds Cohen but not dominating reals while Laver forcing does the opposite. In the language of cardinal characteristics of the continuum, this means that an appropriate iteration of Cohen forcing starting from CH yields a model where $\mathfrak{b} < \text{cov}(\mathcal{M})$, while an appropriate iteration of Laver forcing starting from CH yields a model where $\text{cov}(\mathcal{M}) < \mathfrak{b}$.

In recent years, the study of “generalized Baire spaces” has caught the attention of an increasing number of set theorists. For a regular, uncountable cardinal κ one considers elements of κ^κ as “ κ -reals” and looks at the corresponding space with the bounded topology, i.e., the topology generated by basic open sets of the form $[\sigma] := \{x \in \kappa^\kappa : \sigma \subseteq x\}$ for $\sigma \in \kappa^{<\kappa}$ (analogously for 2^κ).

It is straightforward to generalize the above notions from the classical to the generalized Baire spaces. Thus, we have the concepts dominating κ -real and the cardinal characteristic \mathfrak{b}_κ (see Definition 2.1). Likewise, we can define \mathcal{M}_κ as the ideal of κ -meager sets, i.e., those obtained by κ -unions of nowhere dense, giving rise to the cardinal characteristic $\text{cov}(\mathcal{M}_\kappa)$ defined in the usual way. κ -Cohen forcing is the partial order of basic open sets ordered by inclusion.

It is not hard to see that κ -Cohen forcing does not add dominating κ -reals, so an appropriate iteration of κ -Cohen forcing, starting from a model of GCH, yields a model in which $\mathfrak{b}_\kappa < \text{cov}(\mathcal{M}_\kappa)$, mirroring the classical situation. A natural method for the converse direction, i.e., proving the consistency of $\text{cov}(\mathcal{M}_\kappa) < \mathfrak{b}_\kappa$, would be to iterate a forcing which adds dominating κ -reals but not Cohen κ -reals. The authors of [1, p. 1003] asked whether a forcing with such a property existed, and in particular, whether some generalization of Laver forcing had this property.

In this paper, we show that any generalization of Laver forcing necessarily adds a Cohen κ -real (Theorem 3.5). If we assume $\kappa^{<\kappa} = \kappa$, then this holds for an even wider class of trees (Theorem 3.7). Later, we use a dichotomy result and similar techniques to show that if $\kappa^{<\kappa} = \kappa$ and \mathbb{P} is any $<\kappa$ -distributive forcing whose conditions are limit-closed trees on $\kappa^{<\kappa}$, and which adds a dominating κ -real obtained as the image of the generic under a continuous function in the ground model, then \mathbb{P} necessarily adds a Cohen κ -real (Theorem 5.10). It is an open question whether there exists some other $<\kappa$ -distributive and/or $<\kappa$ -closed forcing which adds dominating κ -reals but not Cohen κ -reals (Question 5.1).¹

We should note that a model for $\text{cov}(\mathcal{M}_\kappa) < \mathfrak{b}_\kappa$ could also be constructed by a different method. One could start from a model in which

$$\text{cov}(\mathcal{M}_\kappa) = \mathfrak{b}_\kappa = 2^\kappa > \kappa^+$$

and add a witness to $\text{cov}(\mathcal{M}_\kappa) = \kappa^+$ by a short forcing iteration.

When working in generalized Baire spaces, a common assumption is $\kappa^{<\kappa} = \kappa$, which is sufficient to prove many pleasant properties of generalized Baire spaces, e.g., that the topology has a base of size κ . Nevertheless, our first main theorem (Theorem 3.5) is proved in generality and does not depend on this assumption, whereas the other main results (Theorem 3.7 and Theorem 5.10) do.

The first main result is proved in Section 3. Motivated by the methods used there, in Section 4 we look at the ideal related to generalized Laver forcing and prove a somewhat surprising result concerning a generalization of the dichotomy for Laver forcing from [5]. This dichotomy is used in Section 5 to extend our first main result to arbitrary $<\kappa$ -distributive tree forcings.

¹ In an earlier version of this paper, we claimed that every $<\kappa$ -closed forcing adding dominating κ -reals adds Cohen κ -reals, but the proof contained a gap, so, to our knowledge, the question is still open.

2. Preliminaries and definitions

We work in the setting where κ is an uncountable, regular cardinal, and consider the **generalized Baire space** κ^κ with the bounded topology generated by basic open sets of the form $[\sigma] := \{x \in \kappa^\kappa : \sigma \subseteq x\}$ for $\sigma \in \kappa^{<\kappa}$. The **generalized Cantor space** 2^κ is defined analogously.

We refer the reader to [3] for a good introduction to generalized Baire spaces, and to [10] for an overview of the current state of the field and a list of open problems.

Definition 2.1: Let $f, g \in \kappa^\kappa$. We say that g **dominates** f , denoted by $f \leq^* g$, if $\exists \alpha_0 \forall \alpha > \alpha_0 (f(\alpha) \leq g(\alpha))$. The generalized bounding number \mathfrak{b}_κ is defined as the least size of a family $F \subseteq \kappa^\kappa$ such that for all $g \in \kappa^\kappa$ there is $f \in F$ such that $f \not\leq^* g$. If M is a model of set theory, then d is a **dominating κ -real** over M if d dominates every $f \in \kappa^\kappa \cap M$.

A **tree** in $\kappa^{<\kappa}$ is a subset closed under initial segments. If T is a tree, we use $[T]$ to denote the set of branches (of length κ) through T , that is,

$$[T] := \{x \in \kappa^\kappa : \forall \alpha < \kappa (x \upharpoonright \alpha \in T)\}.$$

The same holds for trees in $2^{<\kappa}$. For $\sigma \in T$ we use the notation

$$T \uparrow \sigma := \{\tau \in T : \sigma \subseteq \tau \vee \tau \subseteq \sigma\}.$$

A tree $T \subseteq \kappa^{<\kappa}$ is called **limit-closed**² if for any limit ordinal $\lambda < \kappa$ and any \subseteq -increasing sequence $\langle \sigma_\alpha : \alpha < \lambda \rangle$ from T , the limit of the sequence $\sigma := \bigcup_{\alpha < \lambda} \sigma_\alpha$ is itself an element of T . We call a set C **superclosed** if $C = [T]$ for a limit-closed tree T .

Every closed subset of κ^κ is the set of branches through a tree but not necessarily a limit-closed tree, so one could say that being superclosed is a topologically stronger property than being closed. We will also need to consider sets of branches of length shorter than κ . For any limit ordinal $\lambda < \kappa$ we use the notation $[T]_\lambda := \{\sigma \in \kappa^\lambda : \forall \alpha < \lambda (\sigma \upharpoonright \alpha \in T)\}$. Notice that T is limit-closed iff $[T]_\lambda \subseteq T$ for all limit ordinals $\lambda < \kappa$.

For a tree T (on the classical or generalized Baire space) we call the **stem of T** , denoted by $\text{stem}(T)$, the maximal node $\sigma \in T$ (if it exists) such that for all $\tau \in T$ either $\tau \subseteq \sigma$ or $\sigma \subseteq \tau$. The notation $\text{Succ}_T(\sigma)$ denotes the set of

² Other terminology used in the literature is “ $<\kappa$ -closed” and “sequentially closed”.

immediate successors of σ in T , i.e., the collection

$$\{\tau \in T : \tau = \sigma \hat{\ } \langle \alpha \rangle \text{ for some } \alpha\}.$$

Definition 2.2: A **Laver tree** is a tree $T \subseteq \omega^{<\omega}$ with the property that for every $\sigma \in T$ extending $\text{stem}(T)$, $|\text{Succ}_T(\sigma)| = \omega$. **Laver forcing** \mathbb{L} is the partial order of Laver trees ordered by inclusion.

Laver forcing adds dominating reals while satisfying the so-called **Laver property**, a well-known iterable property implying that no Cohen reals are added. There have been several attempts in the literature to generalize Laver forcing to κ^κ .

Definition 2.3: A **κ -Laver tree** is a tree $T \subseteq \kappa^{<\kappa}$ which is limit-closed and such that for every $\sigma \in T$ extending $\text{stem}(T)$, $|\text{Succ}_T(\sigma)| = \kappa$. Let \mathbb{L}_κ denote the partial order of all κ -Laver trees ordered by inclusion.

This partial order itself is probably not well-suited as a forcing on κ^κ and has not been proposed as an option.³ But there have been other attempts at generalizations of Laver forcing, usually by putting stronger requirements on “splitting” in the tree. For example, club Laver forcing (see [4]) consists of trees satisfying the additional condition “ $\text{Succ}_T(\sigma)$ contains a club on κ ” for all σ beyond the stem. This forcing is $<\kappa$ -closed and adds a dominating κ -real, but it is easy to see that it also adds a Cohen κ -real: if S is a stationary, co-stationary subset of κ and $\varphi : \kappa^\kappa \rightarrow 2^\kappa$ is given by $\varphi(x)(\alpha) = 1 \Leftrightarrow x(\alpha) \in S$, then $\varphi(x_{\text{gen}})$ is a Cohen κ -real.

Yet another attempt is **measure-one Laver forcing**, where the requirement is strengthened to “ $\text{Succ}_T(\sigma) \in U$ ” for some $<\kappa$ -complete ultrafilter on a measurable cardinal κ . This forcing is also $<\kappa$ -closed and adds a dominating κ -real, and until now it was not known whether it adds a Cohen κ -real. Of course, one could think of further clever requirements on Laver trees in order to ensure that no Cohen κ -reals are added.

However, by the results of this paper, none of these approaches can work.

³ It is not hard to see that \mathbb{L}_κ is not $<\kappa$ -closed, and in fact not even ω -distributive; this follows from [7, Lemma 30.23]. In fact, we conjecture that \mathbb{L}_κ collapses the generalized continuum 2^κ . Compare this to a recent result of Mildenerger and Shelah [13] showing that, if $\kappa^{<\kappa} = \kappa$, then a similarly “plain” version of κ -Miller forcing collapses 2^κ .

3. The supremum game

In this section we will prove our first main result. The main ingredient of our proofs in this and subsequent sections is the following game.

Definition 3.1: Let $S \subseteq \kappa$. The **supremum game** $G^{\text{sup}}(S)$ is played by two players, for ω moves, as follows:

$$\begin{array}{c} \text{I} \\ \hline A_0 \quad A_1 \quad \dots \\ \hline \text{II} \\ \beta_0 \quad \beta_1 \quad \dots \end{array}$$

where $A_n \subseteq \kappa$, $|A_n| = \kappa$ and $\beta_n \in A_n$ for all $n < \omega$. Player II wins iff

$$\sup\{\beta_n : n < \omega\} \in S.$$

LEMMA 3.2: *Let S be a stationary subset of $\text{Cof}_\omega(\kappa) = \{\alpha < \kappa : \text{cf}(\alpha) = \omega\}$. Then Player I does not have a winning strategy in $G^{\text{sup}}(S)$.*

Proof. Let σ be a strategy for Player I in $G^{\text{sup}}(S)$. We will show that σ is not a winning strategy. Let θ be sufficiently large and let $M \prec \mathcal{H}_\theta$ be an elementary submodel such that $\sigma \in M$, $|M| < \kappa$, and $\delta := \sup(M \cap \kappa) \in S$. Note that we can always do that, because the set

$$\{\sup(M \cap \kappa) : M \prec \mathcal{H}_\theta, \sigma \in M, |M| < \kappa\}$$

contains a club.

Fix a sequence $\langle \gamma_n : n < \omega \rangle$, cofinal in δ , such that every $\gamma_n \in M$ (but the sequence itself is not). Inductively, we will construct a run of the game in which Player I played according to strategy σ .

At each step n , inductively assume A_k and β_k for $k < n$ have been fixed according to the rules of the game and the strategy σ , and assume they are all in M . Let $A_n := \sigma(A_0, \beta_0, \dots, A_{n-1}, \beta_{n-1})$. Since the finite sequence was in M and the strategy σ is in M , A_n is also in M . Furthermore, since $|A_n| = \kappa$, the following statement is true:

$$\exists \beta > \gamma_n (\beta \in A_n).$$

This statement holds in \mathcal{H}_θ , so by elementarity, it also holds in M . Thus, there exists $\beta_n \in M$ with $\beta_n > \gamma_n$ and $\beta_n \in A_n$. This completes the construction.

We have produced a sequence $\langle \beta_n : n < \omega \rangle$ with $\beta_n \in M$ for all n . But clearly $\sup_n \beta_n = \sup_n \gamma_n = \delta \in S$, so Player II wins this game, proving that the strategy was not winning for Player I. ■

Definition 3.3: A **short κ -Laver tree** is a tree $L \subseteq \kappa^{<\omega}$ (i.e., height ω) such that for all $\sigma \in L$ extending $\text{stem}(L)$ we have $|\text{Succ}_L(\sigma)| = \kappa$.

COROLLARY 3.4: Let $S \subseteq \kappa$ be a stationary subset of $\text{Cof}_\omega(\kappa)$. For every short κ -Laver tree L there exists a branch $\eta \in [L]_\omega$ such that $\sup_n \eta(n) \in S$.

Proof. The short κ -Laver tree L induces a strategy σ_L for Player I in the supremum game:

$$\sigma_L(A_0, \beta_0, \dots, A_n, \beta_n) := \text{Succ}_L(\text{stem}(L) \frown \langle \beta_0, \dots, \beta_n \rangle).$$

Whenever $\langle A_0, \beta_0, A_1, \beta_1, \dots \rangle$ is a run of the game in which Player I follows σ_L , $\text{stem}(L) \frown \langle \beta_0, \beta_1, \dots \rangle$ is an element of $[L]_\omega$.

However, by Lemma 3.2, there exists a run where Player I follows σ_L but Player II wins. This yields a branch $\eta \in [L]_\omega$ such that $\sup_n \eta(n) \in S$. ■

With this, we immediately obtain our main result.

THEOREM 3.5 (Main Theorem 1): Let \mathbb{P} be any subforcing of \mathbb{L}_κ , i.e., any forcing whose conditions are κ -Laver trees ordered by inclusion, and which is closed under the following condition: if $T \in \mathbb{P}$ and $\sigma \in T$, then $T \uparrow \sigma \in \mathbb{P}$. Then \mathbb{P} adds a Cohen κ -real.

Proof. We will use the following notation: if $T \in \kappa^{<\kappa}$ is a tree and $\sigma \in T$, then

$$T \upharpoonright^\omega \sigma := \{ \tau \in \kappa^{<\omega} : \sigma \frown \tau \in T \}.$$

Note that if T is a κ -Laver tree, then for every $\sigma \in T$ extending $\text{stem}(T)$, $T \upharpoonright^\omega \sigma$ is a short κ -Laver tree (with empty stem).

Let $S_0 \cup S_1$ be a stationary/co-stationary partition of $\text{Cof}_\omega(\kappa)$ and consider the mapping $\varphi : \kappa^\kappa \rightarrow 2^\kappa$ defined by

$$\varphi(x)(\alpha) = 1 \Leftrightarrow \sup \{ x(\omega \cdot \alpha + n) : n < \omega \} \in S_1.$$

In other words, partition x into κ -many blocks of length ω , and map each piece to 0 or 1 depending on whether its supremum lies in S_0 or S_1 . We claim that if x_{gen} is \mathbb{P} -generic then $\varphi(x_{\text{gen}})$ is κ -Cohen-generic.

We use $\tilde{\varphi} : \kappa^{<\kappa} \rightarrow 2^{<\kappa}$ to denote the function as above but defined only on initial segments (i.e., $\varphi(x) = \bigcup_{\alpha < \kappa} \tilde{\varphi}(x \upharpoonright \alpha)$). Let $T \in \mathbb{P}$ be given and let D be open dense in κ -Cohen forcing. Let $\sigma := \text{stem}(T)$, w.l.o.g. $\text{len}(\sigma)$ is a limit ordinal. Let $t \in D$ extend $\tilde{\varphi}(\sigma)$. Suppose $\tilde{\varphi}(\sigma) \frown \langle 0 \rangle \subseteq t$. By Corollary 3.4 there is $\eta \in [T \upharpoonright^\omega \sigma]_\omega$ such that $\sup_n \eta(n) \in S_0$. If, instead, we have $\tilde{\varphi}(\sigma) \frown \langle 1 \rangle \subseteq t$, we

can apply Corollary 3.4 and find a branch $\mu \in [T \upharpoonright^\omega \sigma]_\omega$ such that $\sup_n \mu(n) \in S_1$. Note that, since T is limit-closed, $\sigma \frown \eta$ resp. $\sigma \frown \mu$ are elements of T . Now proceed analogously until reaching τ , such that $\tilde{\varphi}(\tau) = t$. By assumption $T \upharpoonright \tau \in \mathbb{P}$, and now clearly $T \upharpoonright \tau \Vdash \tau \subseteq \dot{x}_{\text{gen}}$ and therefore $T \upharpoonright \tau \Vdash t \subseteq \varphi(\dot{x}_{\text{gen}})$. Thus $\varphi(x_{\text{gen}})$ is a Cohen κ -real. ■

Another way of looking at the above proof is as follows: the sets

$$\{\eta \in \kappa^\omega : \sup_n \eta(n) \in S_0\} \quad \text{and} \quad \{\eta \in \kappa^\omega : \sup_n \eta(n) \in S_1\}$$

form Bernstein sets with respect to short κ -Laver trees in $\kappa^{<\omega}$. Note that due to cardinality reasons, we cannot use standard diagonalization arguments to produce such sets.

If we additionally assume $\kappa^{<\kappa} = \kappa$, we can obtain an even stronger theorem.

Definition 3.6: A tree $T \subseteq \kappa^{<\kappa}$ is called a **pseudo- κ -Laver tree** if it is limit-closed and has the following property: every $\sigma \in T$ has an extension $\tau \in T$ such that $T \upharpoonright^\omega \tau$ is a short κ -Laver tree. We use $\mathbb{P}\mathbb{L}_\kappa$ to denote the partial order of pseudo- κ -Laver trees ordered by inclusion.

THEOREM 3.7 (Main Theorem 2): *Assume $\kappa^{<\kappa} = \kappa$. Let \mathbb{P} be any forcing whose conditions are pseudo- κ -Laver trees (i.e., $\mathbb{P} \subseteq \mathbb{P}\mathbb{L}_\kappa$) and which is closed under the following condition: if $T \in \mathbb{P}$ and $\sigma \in T$, then $T \upharpoonright \sigma \in \mathbb{P}$. Then \mathbb{P} adds a Cohen κ -real.*

Proof. The method is similar, except that now we let $\{S_t : t \in 2^{<\kappa} \setminus \{\emptyset\}\}$ be a partition of $\text{Cof}_\omega(\kappa)$ into κ -many disjoint stationary sets, which we index by $2^{<\kappa} \setminus \{\emptyset\}$. This is possible due to the assumption $\kappa^{<\kappa} = \kappa$. Define the mapping $\pi : \kappa^\kappa \rightarrow 2^\kappa$ by

$$\pi(x) := t_0 \frown t_1 \frown t_2 \frown \dots,$$

where for all $\alpha < \kappa$, t_α is such that $\sup\{x(\omega \cdot \alpha + n) : n < \omega\} \in S_{t_\alpha}$ and $t_\alpha = \langle 0 \rangle$ in case it is not of cofinality ω . We also use $\tilde{\pi}$ to denote the same operation but from $\kappa^{<\kappa}$ to $2^{<\kappa}$.

Let x_{gen} be the \mathbb{P} -generic κ -real; we show that $\pi(x_{\text{gen}})$ is κ -Cohen. Let D be open dense in κ -Cohen forcing, and let $T \in \mathbb{P}$. Find $\sigma \in T$ such that $T \upharpoonright^\omega \sigma$ is a short κ -Laver tree. Let $t \in D$ be such that $\tilde{\pi}(\sigma) \subseteq t$. Let $u \neq \emptyset$ be such that $\tilde{\pi}(\sigma) \frown u \supseteq t$. By Corollary 3.4 there is $\eta \in [T \upharpoonright^\omega \sigma]_\omega$ such that $\sup_n \eta(n) \in S_u$. It follows that $\tilde{\pi}(\sigma \frown \eta) = \tilde{\pi}(\sigma) \frown u \supseteq t$. Therefore

$$T \upharpoonright (\sigma \frown \eta) \Vdash t \subseteq \pi(\dot{x}_{\text{gen}}). \quad \blacksquare$$

4. The generalized Laver dichotomy

The supremum game and the arguments from Theorem 3.5 naturally lead us to consider a question in generalized descriptive set theory (this connection is explained in Remark 4.6).

We need the following strengthening of the concept of a dominating real, which has been studied in the classical context in [5, 11, 2, 9].

Definition 4.1: For $f : \kappa^{<\kappa} \rightarrow \kappa$ and $x \in \kappa^\kappa$, we say that x **strongly dominates** f if

$$\exists \alpha_0 \forall \alpha > \alpha_0 (x(\alpha) \geq f(x \upharpoonright \alpha)).$$

If M is a model of set theory with the same $\kappa^{<\kappa}$, then x is called **strongly dominating over** M if for all $f : \kappa^{<\kappa} \rightarrow \kappa$ with $f \in M$, x strongly dominates f .

Clearly, if x is strongly dominating, then it is also dominating. The converse is false in general, e.g., let d be dominating over M and let x be defined by $x(\alpha) := d(\alpha)$ for odd α and $x(\alpha) := d(\alpha + 1)$ for even and limit α . Then x is dominating but not strongly dominating. However, the following is true:

LEMMA 4.2: Assume $\kappa^{<\kappa} = \kappa$. Let M be a model of set theory such that $\kappa^{<\kappa} \cap M = \kappa^{<\kappa}$. Then, if there is a dominating κ -real over M there is also a strongly dominating κ -real over M .

Proof. Let d be the dominating κ -real, and fix a bijection between $\kappa^{<\kappa}$ and κ in M . Use this to define a new dominating function $d^* : \kappa^{<\kappa} \rightarrow \kappa$ such that for every $f : \kappa^{<\kappa} \rightarrow \kappa$ in M , $f(\sigma) \leq d^*(\sigma)$ holds for all but $<\kappa$ -many $\sigma \in \kappa^{<\kappa}$. Now define inductively

$$e(\alpha) := d^*(e \upharpoonright \alpha).$$

Then e is strongly dominating. ■

Definition 4.3: A collection $X \subseteq \kappa^\kappa$ is a **strongly dominating family** if for every $f : \kappa^{<\kappa} \rightarrow \kappa$ there exists $x \in X$ which strongly dominates f . \mathcal{D}_κ denotes the ideal of all $X \subseteq \kappa^\kappa$ which are not strongly dominating families.

For $\kappa = \omega$, the ideal $\mathcal{D}_\omega = \mathcal{D}$ is the well-known **non-strongly-dominating ideal**, introduced in [5] and independently in [15], and studied among others in [2]. The main interest in it stems from a perfect-set-like dichotomy theorem for Laver trees.

THEOREM 4.4 (Goldstern et al. [5]): *If $T \subseteq \omega^{<\omega}$ is a Laver tree then $[T] \notin \mathcal{D}$. Every analytic set $A \subseteq \omega^\omega$ is either in \mathcal{D} or contains $[T]$ for some Laver tree T . In particular, there is a dense embedding from the order of Laver trees into the algebra of Borel subsets of ω^ω modulo \mathcal{D} .*

Dichotomies such as this one are common in classical descriptive set theory, the most notable example being the perfect set property and the closely related K_σ -dichotomy ([8]), which are false for arbitrary sets of reals but true for analytic sets. Interest in generalizing such dichotomies to the κ^κ -context was recently spurred by a result of Schlicht [14] showing that the generalized perfect set property for generalized projective sets is consistent, and Lücke–Motto Ros–Schlicht [12] showing that the generalized Hurewicz dichotomy for generalized projective sets is consistent. Thus, it might initially come as a surprise that the generalized Laver dichotomy fails for closed sets, provably in ZFC.

THEOREM 4.5: *There is a closed subset of κ^κ which is neither in \mathcal{D}_κ nor contains the branches of a generalized Laver tree.*

Proof. Let φ be as in the proof of Theorem 3.5. Let z be the constant 0 function (or any other fixed element of 2^κ). We show that

$$C := \varphi^{-1}[\{z\}]$$

is a counterexample to the dichotomy. Given any $T \in \mathbb{L}_\kappa$, we can easily find $x \in [T]$ such that $\varphi(x) \neq z$, therefore $[T] \not\subseteq C$. We claim that C is strongly dominating. Let $f : \kappa^{<\kappa} \rightarrow \kappa$ be given. Let

$$T_f := \{\sigma \in \kappa^{<\kappa} : \forall \beta < \text{len}(\sigma)(\sigma(\beta) \geq f(\sigma \upharpoonright \beta))\}.$$

Clearly T_f is a generalized Laver tree and $\text{stem}(T_f) = \emptyset$. As in the proof of Theorem 3.5, we can find $x \in [T_f]$ such that $\varphi(x) = z$. But then x strongly dominates f and $x \in C$, completing the argument. ■

Remark 4.6: The relevance of this theorem is that it explains why Theorem 3.5 does not (as one might initially assume) yield a ZFC-proof of $\mathfrak{b}_\kappa \leq \text{cov}(\mathcal{M}_\kappa)$. Indeed, it is not hard to verify that $\text{cov}(\mathcal{D}_\kappa) = \mathfrak{b}_\kappa$ and that if $X \in \mathcal{M}_\kappa$ then $\varphi^{-1}[X]$ does not contain a κ -Laver tree. Thus, if the dichotomy would hold for generalized Borel (or just F_σ) sets then one could have concluded

$$\mathfrak{b}_\kappa = \text{cov}(\mathcal{D}_\kappa) \leq \text{cov}(\mathcal{M}_\kappa).$$

One could wonder whether there is any dichotomy for the ideal \mathcal{D}_κ , i.e., whether there is any collection \mathbb{P} of limit-closed trees such that for every $T \in \mathbb{P}$, $[T] \notin \mathcal{D}_\kappa$, and every analytic (or at least closed) set not in \mathcal{D}_κ contains $[T]$ for some $T \in \mathbb{P}$. In fact, this is not the case either.

LEMMA 4.7: *Let $T \subseteq \kappa^{<\kappa}$ be a tree such that $[T]$ is strongly dominating. Then there exists $s \in T$ such that $T \upharpoonright^\omega s$ contains a short κ -Laver tree.*

Proof. We use a slightly modified version of the game from [5]. Given $A \subseteq \kappa^\omega$ let $G^*(A)$ be the game defined by:

$$\begin{array}{c|ccc} \text{I} & \alpha_0 & \alpha_1 & \dots \\ \hline \text{II} & \beta_0 & \beta_1 & \dots \end{array}$$

where $\alpha_n, \beta_n < \kappa$, $\alpha_n \leq \beta_n$ for all n , and Player II wins iff

$$\langle \beta_n : n < \omega \rangle \in A.$$

It is easy to see that if Player II has a winning strategy in $G^*(A)$ then there exists a short κ -Laver tree L (with empty stem) such that $[L]_\omega \subseteq A$. Also it is well-known and easy to see that if A is closed (in the topology on κ^ω) then $G^*(A)$ is determined.⁴

Suppose, towards contradiction, that there is no $s \in T$ such that $T \upharpoonright^\omega s$ contains a short κ -Laver tree. Then Player II does not have a winning strategy in $G^*([T \upharpoonright^\omega s]_\omega)$ for any $s \in T$, and therefore Player I has a winning strategy, call it σ_s . Define $f : \kappa^{<\kappa} \rightarrow \kappa$ as follows: for every $t \in T$, let $s \subseteq t$ be the maximal node of limit length, let u be such that $t = s \hat{\ } u$, and define $f(t) := \sigma_s(u)$. Since $[T]$ is strongly dominating there is $x \in [T]$ and α such that $x(\beta) \geq f(x \upharpoonright \beta)$ for all $\beta > \alpha$. In particular, there is $s \subseteq x$, of limit length, such that $x(|s| + n) \geq f(x \upharpoonright (|s| + n))$ for all $n < \omega$. Letting $z \in \kappa^\omega$ be such that $s \hat{\ } z = x \upharpoonright (|s| + \omega)$, we see that

$$z(n) \geq f(s \hat{\ } z \upharpoonright n) = \sigma_s(z \upharpoonright n),$$

for every n . Also $z \in [T \upharpoonright^\omega s]_\omega$, therefore z satisfies the winning conditions for Player II in the game $G^*([T \upharpoonright^\omega s]_\omega)$, contradicting the assumption that σ_s was a winning strategy for Player I. ■

⁴ Here, the topology on κ^ω is the finite-support product topology, i.e., the one generated by basic open sets of the form $[s]$ for $s \in \kappa^{<\omega}$. The fact that $G^*(A)$ is determined follows by the standard Gale–Stewart argument (see, e.g., [7, Proposition 27.1]).

COROLLARY 4.8: *There exists a closed strongly dominating set without a super-closed strongly dominating subset.*

Proof. Consider again the closed set $C := \varphi^{-1}[\{z\}]$ from the proof of Theorem 4.5. Towards contradiction suppose there is a limit-closed tree T such that $[T] \subseteq C$ and $[T]$ is strongly dominating. Without loss of generality, we may assume that T is **pruned**, in the sense that for every $s \in T$ there is a proper extension $t \in T$.

By Lemma 4.7 there is $s \in T$ such that $T|^\omega s$ contains a short κ -Laver tree L . By Corollary 3.4 there is $\eta \in [L]_\omega$ such that $\sup_n \eta(n) \in S_1$, and by limit-closure, $s \frown \eta \in T$. Moreover, since T is limit-closed and pruned, there is $x \in [T]$ such that $s \frown \eta \subseteq x$. But then $\varphi(x)$ contains a “1” and thus is not equal to z , the constant 0-function, contradicting the assumption. ■

Lemma 4.7, whose proof is based on the game argument from [5], will be an important ingredient in the following section.

5. $<\kappa$ -distributive tree forcings

We would like to generalize the results from Section 3 about Laver trees to a wider class of forcing notions. Recall that a forcing \mathbb{P} is **$<\kappa$ -closed** if for every decreasing sequence of conditions of length $<\kappa$, there is a condition below all of them. A forcing \mathbb{P} is **$<\kappa$ -distributive** if the intersection of $<\kappa$ -many open dense sets is open dense. Since $<\kappa$ -distributive forcings do not add new elements of $\kappa^{<\kappa}$, it is a natural class to consider in the context of generalized Baire spaces (after all, forcing in the ordinary Baire space does not add new finite sequences). If a forcing is $<\kappa$ -closed, then it is $<\kappa$ -distributive, although the converse does not hold. One interesting difference between the two, in the context of generalized descriptive set theory, is that generalized $\mathbf{\Pi}_1^1$ -absoluteness holds between $<\kappa$ -closed forcing extensions (see [4, Lemma 2.7]), while it may fail for $<\kappa$ -distributive forcing extensions. In this sense, the most natural question is the following:

Question 5.1: Is it true that every $<\kappa$ -distributive forcing adding a dominating κ -real adds a Cohen κ -real? Is it at least true for every $<\kappa$ -closed forcing?

Although we cannot answer this question in generality, we can answer the question for $<\kappa$ -distributive forcings whose conditions are limit-closed trees, and such that a dominating κ -real can be defined from the generic by a ground-model continuous function. More generally, this holds whenever the interpretation tree of the dominating κ -real is limit-closed.

In this section, we will always assume that

$$\kappa^{<\kappa} = \kappa.$$

Definition 5.2: Let \mathbb{P} be any forcing notion, let \dot{x} be a name, and let $p \in \mathbb{P}$ be such that $p \Vdash \dot{x} \in \kappa^\kappa$. Then the **interpretation tree** of \dot{x} below p is defined by:

$$\mathfrak{T}_{\dot{x},p} = \{\sigma \in \kappa^{<\kappa} : \exists q \leq p (q \Vdash \sigma \subseteq \dot{x})\}.$$

It is clear that $\mathfrak{T}_{\dot{x},p}$ is always a tree in the ground model, but in general it need not be a limit-closed tree.

LEMMA 5.3: *Suppose \mathbb{P} is a $<\kappa$ -distributive forcing, and suppose $p \Vdash \dot{d}$ is a strongly dominating κ -real". Additionally, assume that for every $q \leq p$, the interpretation tree $\mathfrak{T}_{\dot{d},q}$ is limit-closed. Then $p \Vdash$ "there is a Cohen κ -real".*

Proof. Let π be the function defined in Theorem 3.7. We will show that $p \Vdash \pi(\dot{d})$ is κ -Cohen". Let D be κ -Cohen dense and $q \leq p$ arbitrary.

CLAIM: $[\mathfrak{T}_{\dot{d},q}]$ is a strongly dominating set.

Proof. Let $f : \kappa^{<\kappa} \rightarrow \kappa$. Since q forces that \dot{d} is strongly dominating, in particular $q \Vdash \exists \beta \forall \alpha > \beta (\dot{d}(\alpha) \geq \check{f}(\dot{d}\upharpoonright\alpha))$. By $<\kappa$ -distributivity, there is a β_0 and $q_0 \leq q$ which decides $\dot{d}\upharpoonright\beta_0 =: \sigma_0$ and forces the following:

$$(*) \quad \forall \alpha > \beta_0 \quad (\dot{d}(\alpha) \geq \check{f}(\dot{d}\upharpoonright\alpha)).$$

Consider the interpretation tree $\mathfrak{T}_{\dot{d},q_0}$. Let x be any branch in $[\mathfrak{T}_{\dot{d},q_0}] \subseteq [\mathfrak{T}_{\dot{d},q}]$. To see that such a branch exists, notice that for any $\sigma \in \mathfrak{T}_{\dot{d},q_0}$ there is a condition q' deciding $\sigma \subseteq \dot{d}$, and by $<\kappa$ -distributivity, we can find a stronger condition $q'' \leq q'$ deciding $\tau \subseteq \dot{d}$ for a proper extension τ of σ . Moreover, at limit nodes we can continue since $\mathfrak{T}_{\dot{d},q_0}$ is limit-closed by assumption.

Now we see that for any initial segment $\sigma \subseteq x$ which is longer than σ_0 , we know that some $q' \leq q_0$ forces $\sigma \subseteq \dot{d}$. Since q' also forces $(*)$, we must have $\sigma(\alpha) \geq f(\sigma\upharpoonright\alpha)$ for all α in the domain of σ with $\alpha > \beta_0$. Thus we conclude that $x(\alpha) \geq f(x\upharpoonright\alpha)$ holds for every $\alpha > \beta_0$. ■

From the Claim and Lemma 4.7, it follows that there is $\sigma \in \mathfrak{T}_{\dot{d},q}$ such that $\mathfrak{T}_{\dot{d},q} \upharpoonright^\omega \sigma$ contains a short κ -Laver tree. Just as in the proof of Theorem 3.7, let $t \in D$ be such that $\tilde{\pi}(\sigma) \subseteq t$, u such that $\tilde{\pi}(\sigma) \frown u = t$, and find $\eta \in [\mathfrak{T}_{\dot{d},q} \upharpoonright^\omega \sigma]_\omega$ such that $\sup_n \eta(n) \in S_u$. Now, notice that by the assumption that $\mathfrak{T}_{\dot{d},q}$ is limit-closed, $\sigma \frown \eta \in \mathfrak{T}_{\dot{d},q}$, hence there is $r \leq q$ forcing $\sigma \frown \eta \subseteq \dot{d}$. But then

$$r \Vdash t = \tilde{\pi}(\sigma) \frown u = \tilde{\pi}(\sigma \frown \eta) \subseteq \pi(\dot{d}),$$

and so $r \Vdash \pi(\dot{d}) \in [t]$. ■

Next we look at forcings \mathbb{P} whose conditions are limit-closed trees on $\kappa^{<\kappa}$.

Definition 5.4: A forcing partial order \mathbb{P} is called a **tree forcing** if its conditions are limit-closed trees $T \subseteq \kappa^{<\kappa}$ ordered by inclusion, and for every $T \in \mathbb{P}$ and $\sigma \in T$, the restriction $T \upharpoonright \sigma \in \mathbb{P}$.

We need to review continuous functions on κ^κ . Let us call a function $h : \kappa^{<\kappa} \rightarrow \kappa^{<\kappa}$ **pre-continuous** if:

- (1) $\sigma \subseteq \tau \Rightarrow h(\sigma) \subseteq h(\tau)$, and
- (2) $\forall x \in \kappa^\kappa, \{\text{len}(h(\sigma)) : \sigma \subseteq x\}$ is cofinal in κ .

If h is pre-continuous, let $f = \text{lim}(h)$ be the function defined as

$$f(x) := \bigcup \{h(\sigma) : \sigma \subseteq x\}.$$

Just as in the classical situation, it is easy to check that if h is pre-continuous, then $\text{lim}(h)$ is continuous, and conversely if f is continuous, then the function defined by

$$h(\sigma) := \bigcup \{\tau : f''[\sigma] \subseteq [\tau] \text{ and } \text{len}(\tau) \leq \text{len}(\sigma)\}$$

is pre-continuous and $f = \text{lim}(h)$.⁵

Unlike the classical situation, “being pre-continuous” is not necessarily an absolute notion. The statement (2) above is a generalized Π_1^1 -statement, so it will be absolute between $<\kappa$ -closed forcing extensions, but it might not be absolute between arbitrary $<\kappa$ -distributive forcing extensions.⁶

⁵ The second condition in the definition of h is needed to avoid $h(\sigma)$ being an element of κ^κ when f is constant on some $[\sigma]$.

⁶ The fact that generalized Π_1^1 -absoluteness holds for $<\kappa$ -closed forcing notions is well-known, see, e.g., [4, Lemma 2.7]. On the other hand, the canonical forcing to add a club to a stationary set in the ground model is $<\kappa$ -distributive (see [6, Lemma 23.9]) but fails to preserve Π_1^1 -sentences.

However in our case, this will not present a problem. We will always talk about pre-continuous functions in the ground model, and implicitly assume that the continuous function in the extension is well-defined at least on the generic κ -real.

The main point is that for tree forcings, the interpretation trees are directly related to the forcing conditions. For a tree T and a pre-continuous function h , we will consider the tree generated by the image of T under h :

$$\text{tr}(h''T) := \{\tau : \exists \sigma \in T (\tau \subseteq h(\sigma))\}.$$

LEMMA 5.5: *Let \mathbb{P} be a $<\kappa$ -distributive tree forcing, \dot{x} a name for a κ -real, h a pre-continuous function in the ground model with $f = \lim(h)$, and suppose that $T \in \mathbb{P}$ is such that $T \Vdash \dot{x} = f(\dot{x}_{\text{gen}})$ (i.e., T forces that $\{\text{len}(h(\sigma)) : \sigma \subseteq \dot{x}_{\text{gen}}\}$ is cofinal, therefore that $f(\dot{x}_{\text{gen}})$ is well-defined, and also that $f(\dot{x}_{\text{gen}}) = \dot{x}$). Then*

$$\mathfrak{T}_{\dot{x},T} = \text{tr}(h''T).$$

Proof. First suppose $\sigma \in T$. Then $T \upharpoonright \sigma \Vdash \sigma \subseteq \dot{x}_{\text{gen}}$, therefore

$$T \upharpoonright \sigma \Vdash h(\sigma) \subseteq f(\dot{x}_{\text{gen}}) = \dot{x}.$$

Therefore $h(\sigma) \in \mathfrak{T}_{\dot{x},T}$.

Conversely, let $\tau \in \mathfrak{T}_{\dot{x},T}$ be given. We want to find $\sigma \in T$ such that $\tau \subseteq h(\sigma)$. By definition there is $S \leq T$ such that $S \Vdash \tau \subseteq \dot{x}$. But since $S \Vdash \dot{x} = f(\dot{x}_{\text{gen}})$, we also have

$$S \Vdash \exists \sigma \subseteq \dot{x}_{\text{gen}} (\tau \subseteq h(\sigma)).$$

By $<\kappa$ -distributivity, there exists $S' \leq S$ which decides σ , i.e., we may assume that σ is in the ground model, $\tau \subseteq h(\sigma)$ holds, and $S' \Vdash \sigma \subseteq \dot{x}_{\text{gen}}$. Moreover,

$$\sigma \subseteq \text{stem}(S'),$$

because otherwise there would be some incompatible $\sigma' \in S'$, and we would have $S' \upharpoonright \sigma' \Vdash \sigma' \subseteq \dot{x}_{\text{gen}}$, contradicting $S' \Vdash \sigma \subseteq \dot{x}_{\text{gen}}$. We conclude that $\sigma \in S' \subseteq S \subseteq T$ and $\tau \subseteq h(\sigma)$ as desired. ■

Taking h to be the identity, an immediate corollary is that if \mathbb{P} is a $<\kappa$ -distributive tree forcing, then the interpretation trees for the generic \dot{x}_{gen} are limit-closed. If, in addition, the generic is strongly dominating, then by Lemma 5.3 we immediately know that \mathbb{P} adds Cohen κ -reals.

For our stronger result, we want to consider pre-continuous functions h other than the identity. In those cases, it is not guaranteed that $\text{tr}(h''T)$ is limit-closed, even if T was. To avoid this problem we prove two technical lemmas. The main idea is that, even if the original continuous function does not preserve limit-closure, we may change it to another one which does.

Definition 5.6: A pre-continuous function h is called **limit-closure-preserving** if for every limit-closed tree T , the tree $\text{tr}(h''T)$ is also limit-closed.

LEMMA 5.7: For every pre-continuous function h , there exists a pre-continuous and limit-closure-preserving function j such that for all σ and all α in the domain of both $h(\sigma)$ and $j(\sigma)$, we have:

$$h(\sigma)(\alpha) \leq j(\sigma)(\alpha).$$

Proof. Fix a function $R : \kappa^{<\kappa} \times \kappa^{<\kappa} \rightarrow \kappa^{<\kappa}$ such that:

- (1) $\text{len}(R(\rho, \sigma)) = \text{len}(\sigma)$ for all ρ and σ .
- (2) If $\sigma \neq \emptyset$, then $\sigma(\alpha) \leq R(\rho, \sigma)(\alpha)$ for all ρ and all $\alpha < \text{len}(\sigma)$.
- (3) If $\rho \neq \rho'$, then for any $\sigma, \sigma' \neq \emptyset$, we have $R(\rho, \sigma)(0) \neq R(\rho', \sigma')(0)$.

In words: R takes every non-empty sequence σ and shifts it coordinate-wise to a higher sequence of the same length depending on ρ ; this happens in such a way that for different $\rho \neq \rho'$, the first coordinates of $R(\rho, \dots)$ and $R(\rho', \dots)$ are never the same. It is easy to see that such a function exists since $\kappa^{<\kappa} = \kappa$.

Let h be a pre-continuous function. Define j inductively:

- If $j(\sigma)$ is defined, then for every β define $j(\sigma \frown \langle \beta \rangle)$ as follows: let w be such that $h(\sigma) \frown w = h(\sigma \frown \langle \beta \rangle)$ ($w = \emptyset$ is also allowed). Then let

$$j(\sigma \frown \langle \beta \rangle) := j(\sigma) \frown R(\sigma \frown \langle \beta \rangle, w).$$

- For σ of limit length (including $\sigma = \emptyset$), let w be such that

$$h(\sigma) = \bigcup_{\sigma' \subset \sigma} h(\sigma') \frown w.$$

Note that this is always possible because $h(\sigma') \subseteq h(\sigma)$ for all $\sigma' \subset \sigma$ ($w = \emptyset$ is allowed). Then let

$$j(\sigma) := \left(\bigcup_{\sigma' \subset \sigma} j(\sigma') \right) \frown R(\sigma, w).$$

We claim that j is as required.

Notice that, inductively, $\text{len}(j(\sigma)) = \text{len}(h(\sigma))$ for every σ . It is also clear, by construction, that $\sigma \subseteq \sigma'$ implies $j(\sigma) \subseteq j(\sigma')$. Therefore j is pre-continuous. Moreover, by construction we immediately see that $h(\sigma)(\alpha) \leq j(\sigma)(\alpha)$ holds for every σ and $\alpha < \text{len}(\sigma)$. It remains to prove that j is limit-closure-preserving.

Let T be an arbitrary limit-closed tree, and let

$$U := \text{tr}(j''T).$$

Let $\{u_i : i < \lambda\}$ be an increasing sequence in U of length $\lambda < \kappa$. We need to show that this sequence has an extension in U . For each i , let $s_i \in T$ be \subseteq -minimal such that $u_i \subseteq j(s_i)$.⁷

CLAIM: $s_i \subseteq s_{i'}$ for all $i < i' < \lambda$.

Proof. Suppose, towards contradiction, that $s_i \not\subseteq s_{i'}$. First, $s_{i'} \subset s_i$ (proper extension) is clearly not possible, since this would imply $u_i \subseteq u_{i'} \subseteq j(s_{i'}) \subseteq j(s_i)$, and thus we would have picked $s_{i'}$ instead of s_i . Therefore, s_i and $s_{i'}$ are incompatible. Let r be maximal such that $r \subseteq s_i$ and $r \subseteq s_{i'}$.

Next, notice that $j(r) \subset u_i$: otherwise, we would have $u_i \subseteq j(r)$, so we would have picked r instead of s_i .

So we also know that $j(r) \subset j(s_i)$ and $j(r) \subset j(s_{i'})$. Let r_0 be minimal such that

$$r \subseteq r_0 \subseteq s_i \quad \text{and} \quad j(r) \subset j(r_0)$$

and let r_1 be minimal such that

$$r \subseteq r_1 \subseteq s_{i'} \quad \text{and} \quad j(r) \subset j(r_1).$$

Note that both r_0 and r_1 are proper extensions of r , see Figure 1. First we consider r_0 : there are two cases.

- Suppose r_0 is of successor length. Then there is r_{00} such that

$$r_0 = r_{00} \hat{\ } \langle \beta \rangle \quad \text{and} \quad j(r) = j(r_{00}).$$

Also (since $j(\sigma)$ and $h(\sigma)$ always have the same length) there exists $w \neq \emptyset$ such that $h(r_{00} \hat{\ } \langle \beta \rangle) = h(r_{00}) \hat{\ } w$. Then by definition we have:

$$j(r_0) = j(r_{00}) \hat{\ } R(r_0, w) = j(r) \hat{\ } R(r_0, w).$$

⁷ The s_i 's do not need to be distinct; e.g., they could be all equal to a unique s , or there could be $\text{cf}(\lambda)$ -many distinct s_i 's, etc.

- Now suppose r_0 is of limit length. Then $j(r) = j(r')$ for all r' with $r \subseteq r' \subset r_0$, but $j(r_0) \supset \bigcup_{r' \subset r_0} j(r')$. So (again because $j(\sigma)$ and $h(\sigma)$ have the same length) there exists $w \neq \emptyset$ such that

$$h(r_0) = \bigcup_{r' \subset r_0} h(r') \frown w.$$

By definition, we have

$$j(r_0) = \left(\bigcup_{r' \subset r_0} j(r') \right) \frown R(r_0, w) = j(r) \frown R(r_0, w).$$

Thus, in both cases we have $j(r_0) = j(r) \frown R(r_0, w)$ for some non-empty w .

By exactly the same argument but looking at r_1 , we see that

$$j(r_1) = j(r) \frown R(r_1, v)$$

for some non-empty v .

But $r_0 \neq r_1$, so by condition 3 of the definition of R , the first coordinates of $R(r_0, w)$ and of $R(r_1, v)$ are not the same. However, we also know $j(r) \frown R(r_0, w) \subseteq j(s_i)$ while $j(r) \frown R(r_1, v) \subseteq j(s_{i'})$. Together with the fact that $j(r) \subset u_i \subseteq j(s_i)$ and $j(r) \subset u_{i'} \subseteq j(s_{i'})$, this gives us the desired contradiction (see Figure 1). We conclude that the only option is $s_i \subseteq s_{i'}$. ■

Figure 1. Contradiction assuming $s_i \perp s_{i'}$.

So we have an increasing sequence $\{s_i : i < \lambda\}$ in T , and since T is limit-closed, there is $s_\lambda \in T$ with $s_i \subseteq s_\lambda$ for all i . Then $u_i \subseteq j(s_i) \subseteq j(s_\lambda)$ holds for all i . This completes the proof that U is limit-closed. ■

The point of this lemma is that if h is pre-continuous in the ground model with $f = \lim(h)$ and T forces that $f(\dot{x}_{\text{gen}})$ is a dominating κ -real, then letting j be as in the lemma with $g = \lim(j)$, we know that T also forces that $g(\dot{x}_{\text{gen}})$ is a dominating κ -real.

The next step is to convert the dominating into a strongly dominating real. In Lemma 4.2 we mentioned how to convert a dominating to a strongly dominating real, and it is easy to see that this conversion can be coded by a continuous function in the ground model. The problem is, this function may again fail to be limit-closure-preserving, so we need to use a similar method as above to construct such a conversion function which is, in addition, limit-closure-preserving.

Let us fix a bijective enumeration $\{\sigma_i : i < \kappa\}$ of $\kappa^{<\kappa}$ such that

$$\sigma_i \subseteq \sigma_j \Rightarrow i \leq j,$$

using the notation $\ulcorner \sigma \urcorner = i$ iff $\sigma = \sigma_i$. Recall that in Lemma 4.2, the conversion was given by $e(\alpha) = d^*(e \upharpoonright \alpha) = d(\ulcorner e \upharpoonright \alpha \urcorner)$. However, we may relax the condition to $e(\alpha) \geq d(\ulcorner e \upharpoonright \alpha \urcorner)$, and the conversion would still work.

Definition 5.8: A function $\gamma : \kappa^\kappa \rightarrow \kappa^\kappa$ is called **strongly-converting**, if for all x and all α :

$$\gamma(x)(\alpha) \geq x(\ulcorner \gamma(x) \upharpoonright \alpha \urcorner).$$

LEMMA 5.9: *There exists a pre-continuous and limit-closure-preserving function k such that $\gamma = \lim(k)$ is strongly-converting.*

Proof. Fix a function $R : \kappa^{<\kappa} \times \kappa \rightarrow \kappa$ which is injective and $R(\rho, \alpha) \geq \alpha$ for all ρ and all α .

Define $k : \kappa^{<\kappa} \rightarrow \kappa^{<\kappa}$ inductively as follows:

- $k(\sigma \frown \langle \beta \rangle) := \begin{cases} k(\sigma) \frown \langle R(\sigma \frown \langle \beta \rangle, \beta) \rangle & \text{if } \text{len}(\sigma) = \ulcorner k(\sigma) \urcorner, \\ k(\sigma) & \text{otherwise.} \end{cases}$
- For σ of limit length (and $\sigma = \emptyset$), $k(\sigma) := \bigcup \{k(\sigma') : \sigma' \subset \sigma\}$.

To check that the non-trivial condition of k being pre-continuous is satisfied, notice that inductively “ $\text{len}(\sigma) \leq \ulcorner k(\sigma) \urcorner$ ” always holds, and therefore the case “ $\text{len}(\sigma) = \ulcorner k(\sigma) \urcorner$ ” in the definition of $k(\sigma \frown \langle \beta \rangle)$ must occur cofinally often as σ increases in length along any $x \in \kappa^\kappa$.

We claim that $\gamma = \text{lim}(k)$ is as required. Let us check that γ is strongly-converting. By construction, for every α , $\gamma(x)(\alpha) = \beta'$ iff there is some $\sigma \smallfrown \langle \beta \rangle \subseteq x$ such that

- (1) $\beta' = R(\sigma \smallfrown \langle \beta \rangle, \beta)$,
- (2) $k(\sigma) = \gamma(x) \upharpoonright \alpha$,
- (3) $\text{len}(\sigma) = \ulcorner k(\sigma) \urcorner$.

Therefore

$$\gamma(x)(\alpha) = \beta' \geq \beta = x(\text{len}(\sigma)) = x(\ulcorner k(\sigma) \urcorner) = x(\ulcorner \gamma(x) \upharpoonright \alpha \urcorner).$$

It remains to prove that k is limit-closure-preserving. Since this is very similar to the proof of Lemma 5.7, we will leave out some details. Let T be a limit-closed tree, $U := \text{tr}(k''T)$, and $\{u_i : i < \lambda\}$ an increasing sequence in U . For each i , let $s_i \in T$ be minimal such that $u_i \subseteq k(s_i)$ (in this case, we actually have $u_i = k(s_i)$, but this is not relevant). As before, we will be done if we prove the following claim:

CLAIM: $s_i \subseteq s_{i'}$ for all $i < i'$.

Proof. Suppose $s_i \not\subseteq s_{i'}$. Since $s_{i'} \subset s_i$ is impossible, we must have $s_i \perp s_{i'}$, so let r be maximal with $r \subseteq s_i$ and $r \subseteq s_{i'}$. Again we must have $k(r) \subset u_i \subseteq u_{i'}$, hence we can find least r_0 with $r \subseteq r_0 \subseteq s_i$ and $k(r) \subset k(r_0)$, and least r_1 with $r \subseteq r_1 \subseteq s_{i'}$ and $k(r) \subset k(r_1)$. Moreover r_0 and r_1 are both of successor length, say with last digit β_0 and β_1 , respectively. Then $k(r_0) = k(r) \smallfrown \langle R(r_0, \beta_0) \rangle$ and $k(r_1) = k(r) \smallfrown \langle R(r_1, \beta_1) \rangle$. Since $r_0 \neq r_1$ and R is injective, we obtain a contradiction as before. ■

It is clear that if γ is strongly-converting and $T \Vdash \text{“}\dot{d} \text{ is dominating”}$, then $T \Vdash \text{“}\gamma(\dot{d}) \text{ is strongly dominating”}$. With this, we are ready to prove the final result.

THEOREM 5.10 (Main Theorem 3): *Assume $\kappa^{<\kappa} = \kappa$. Suppose \mathbb{P} is a $<\kappa$ -distributive tree forcing, h a pre-continuous function in the ground model with $f = \text{lim}(h)$, and assume that $T \Vdash \text{“}f(\dot{x}_{\text{gen}}) \text{ is a dominating } \kappa\text{-real”}$. Then $T \Vdash \text{“there is a Cohen } \kappa\text{-real”}$.*

Proof. First we apply Lemma 5.7 to obtain a pre-continuous and limit-closure-preserving function j . Then, for $g = \text{lim}(j)$, it follows that

$$T \Vdash \text{“}g(\dot{x}_{\text{gen}}) \text{ is a dominating } \kappa\text{-real”}.$$

Now let k and γ be as in Lemma 5.9. Then $T \Vdash “\gamma(g(\dot{x}_{\text{gen}}))$ is strongly dominating”.

Let \dot{e} be the name such that $T \Vdash “\gamma(g(\dot{x}_{\text{gen}})) = \dot{e}”$. Since k and j are limit-closure-preserving, so is $k \circ j$. Therefore, by Lemma 5.5, $\mathfrak{T}_{\dot{e}, T} = \text{tr}((k \circ j)''T)$ is limit-closed. Of course, the same applies for any stronger condition $S \leq T$, i.e., $\mathfrak{T}_{\dot{e}, S}$ is also limit-closed for every $S \leq T$. This is all we need to apply Lemma 5.3, from which it follows that $T \Vdash “\text{there is a Cohen } \kappa\text{-real}”$. ■

Unfortunately, none of the methods in this section seem to settle Question 5.1, which the authors consider very significant in the context of forcing over κ^κ : “Is it true that every $<\kappa$ -distributive forcing adding a dominating κ -real adds a Cohen κ -real? Is it at least true for every $<\kappa$ -closed forcing?”

ACKNOWLEDGMENTS. We would like to thank Hugh Woodin and Martin Goldstern for useful discussion and advice, and the anonymous referee for his/her careful reading and helpful suggestions.
