# Metabolic Model for Tetrasphaera in

Enhanced Biological Phosphorus Removal Plants

#### **INTRODUCTION**

Enhanced biological phosphorus removal (EBPR) is an environmentally friendly and cost-effective phosphorus removal process for wastewater. It is believed to be carried out mainly by certain polyphosphate accumulating organisms (PAOs) called *Candidatus* Accumulibacter. Recently, actinobacteria belonging to the genus *Tetrasphaera* have been identified as putative polyphosphate accumulating organisms. New investigations show that they comprise a larger fraction of the biomass in full-scale Danish wastewater treatment plants than *Candidatus* Accumulibacter (8-12% and 3-7%, respectively) and may therefore be more important in the phosphorus removal process. Little is known about the diversity and physiology of *Tetrasphaera* but preliminary results indicate that their ecological niche is different from *Candidatus* Accumulibacter.

#### AIM

- Determine the diversity and abundance of *Tetrasphaera* in Danish treatment plants with enhanced biological phosphorus removal (EBPR).
- Develop a metabolic model for phosphate-removing *Tetrasphaera* based on genomic investigations and pure culture studies.

#### **METHODS**

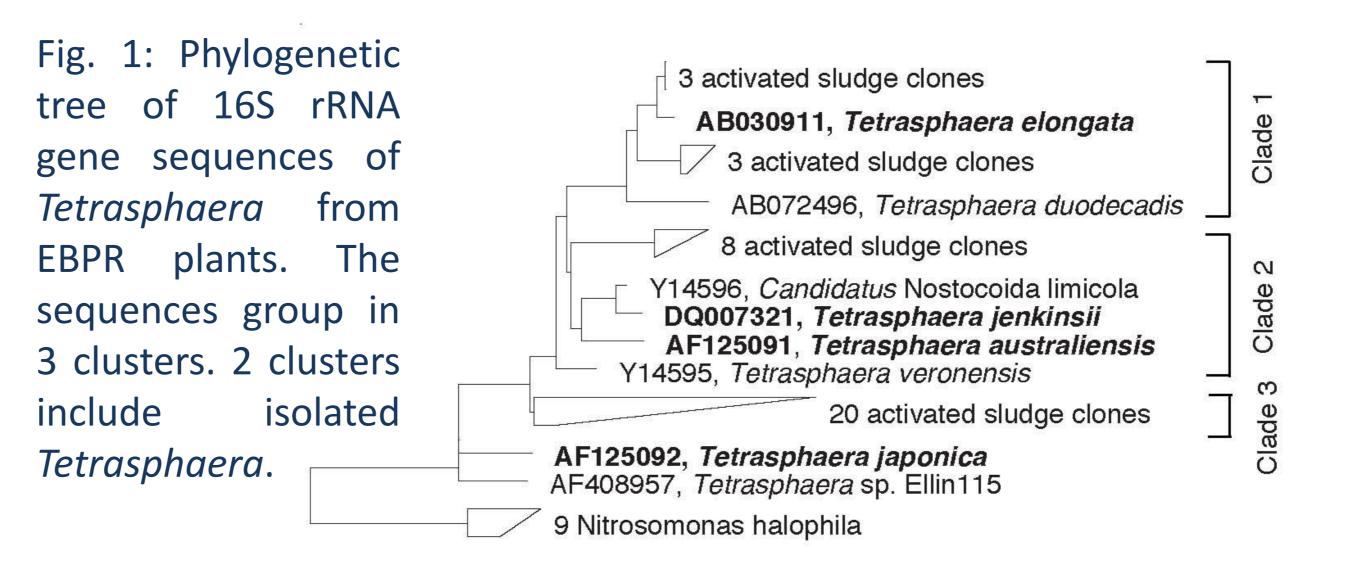

#### Identification and quantification

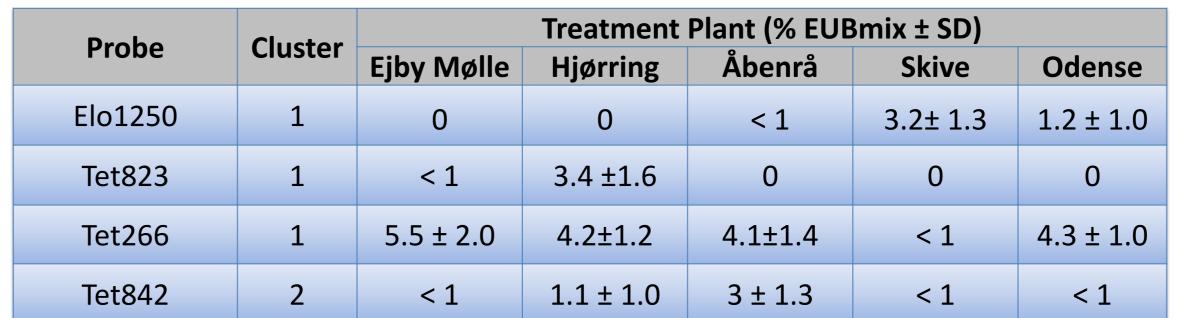

Quantitative FISH using published and novel species-specific probes

#### **Development of metabolic model**

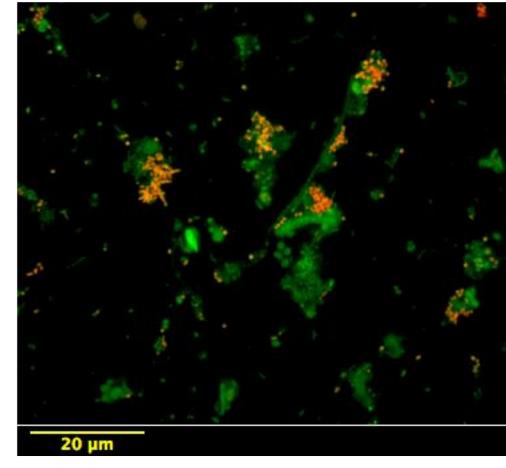

- Paired-end genome sequencing of four *Tetrasphaera* isolates using the Illumina platform.
- Annotation using MaGe (Microbial Genome Annotation Platform) from MicroScope.
- Validating the genomic findings with pure culture studies.

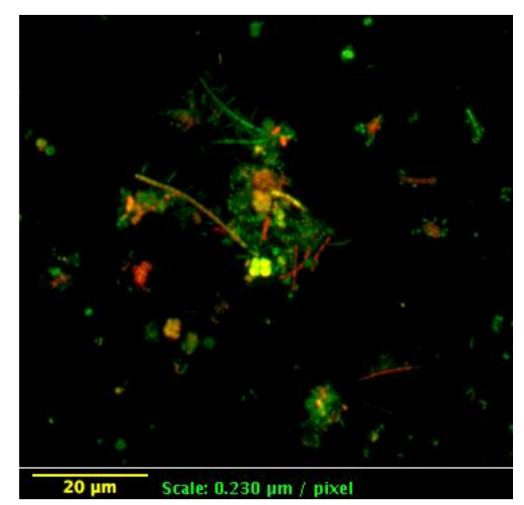

## Identification and quantification

# Fig. 2: FISH images of *Tetrasphaera*.

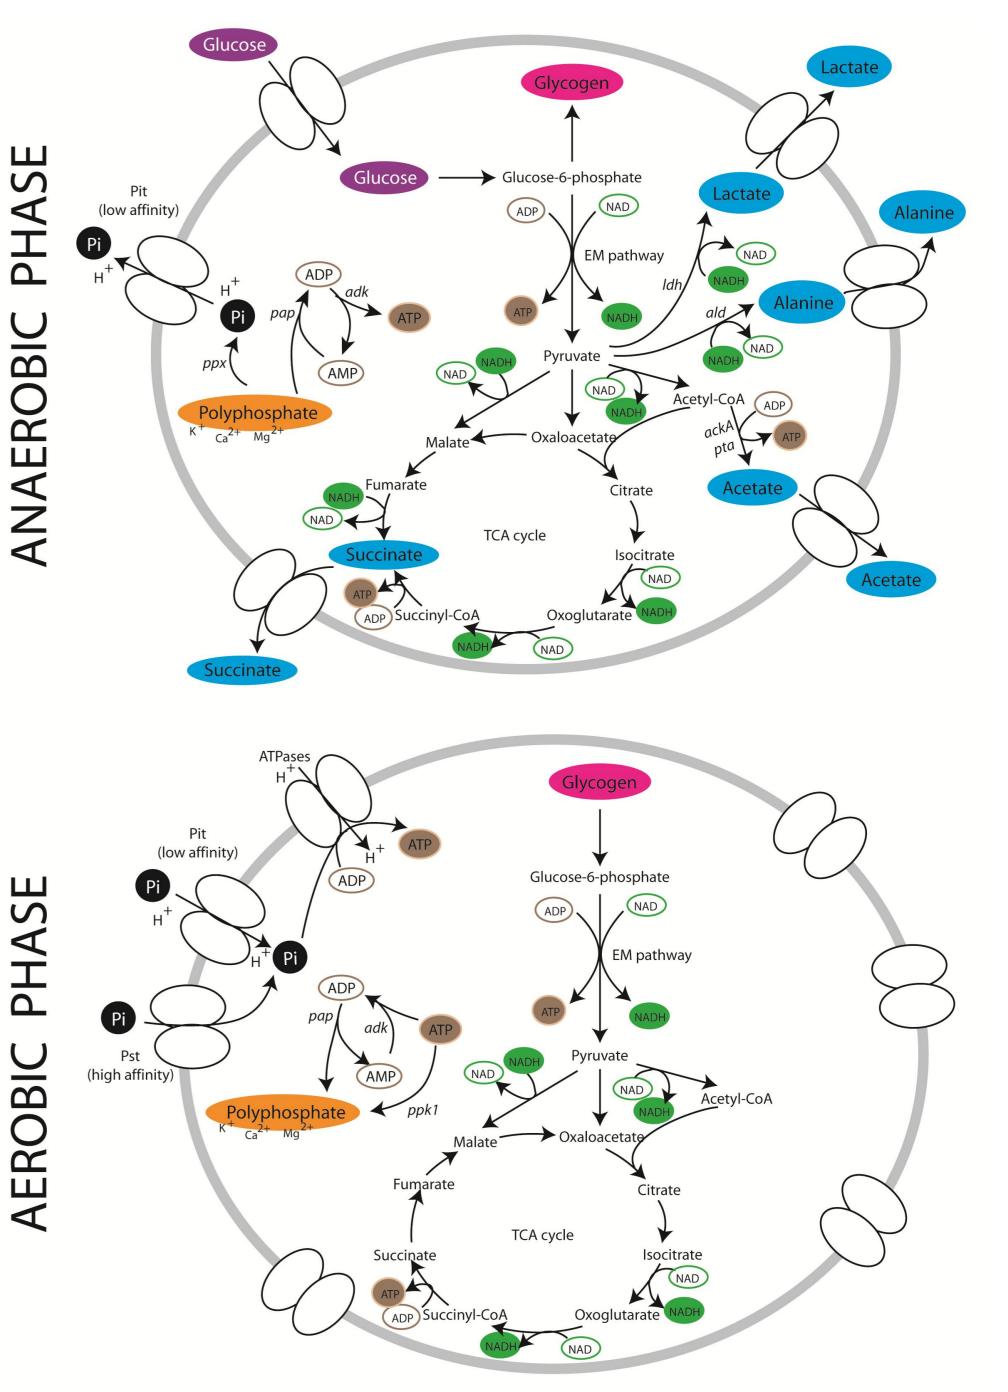

## CONCLUSIONS

- A high abundance and diversity of *Tetrasphaera* were identified in Danish full-scale EBPR plants.
- Tetrasphaera are potentially novel and ecologically relevant polyphosphate accumulating organisms in fullscale EBPR plants with a different physiology in EBPR plants compared to Candidatus Accumulibacter.
