DEFEAT-polypharmacy: Deprescribing anticholinergic and sedative medicines

3

# **DEFEAT-polypharmacy: Deprescribing anticholinergic and sedative medicines**

## Feasibility Trial in Residential Aged Care Facilities

# 4 5

### Introduction

- 6 Prescribing medicines is practiced routinely and is often driven by test results, symptoms or a confirmed
- 7 disease diagnosis [1], with some prescribers considering continuing prescribed medicines as the safer
- 8 course of action [2]. However, older adults with co-morbidities may benefit to a lesser degree from
- 9 medicines due to competing risks of negative health outcomes, including medication-related harms and
- death before benefits can be accrued [3].
- 11 Deprescribing, the supervised withdrawal of unnecessary medications to minimize polypharmacy [4] is
- 12 linked to potential health gains including improvements in cognition [5], reduction in falls and hip
- fractures [6, 7], improved medication adherence [8] and other positive health outcomes [5-7, 9]. However,
- 14 this is not perceived as an easy process and the challenges of reviewing medication are many and
- transverse multiple healthcare processes [10].
- With ever-increasing demands on the healthcare system by an ageing population worldwide [11, 12], it is
- important to address the challenges of implementing deprescribing in a safe and feasible manner. In New
- 18 Zealand, these challenges include time constraints, fear of consequences and lack of accessibility to
  - guidelines and processes that empower physicians to deprescribe medication [10, 13]. The best approach to
- implementing deprescribing, addressing major deprescribing barriers, is not yet clearly understood [14].
- 21 This study examines the feasibility of deprescribing anticholinergics and sedatives in older people in
  - residential care facilities using a pharmacist-led intervention.

23

31

22

19

- 24 These medicines are commonly prescribed [15] and are associated with both cognitive and physical
- functioning impairment [16]. Several tools can be used to measure the anticholinergic and sedative burden
- 26 [17]. We chose the Drug Burden Index (DBI) as this has been validated in several older populations
- worldwide [18] and studies have shown a correlation between increasing DBI and worse patient outcomes,
- 28 including mortality, cognition, frailty and falls [18]. Each additional unit of DBI exposure has a negative
- 29 effect on older people's physical function similar to that of three additional comorbidities [19]. Therefore,
- 30 the DBI provides a useful tool to help inform improved prescribing patterns.

### Aim of the study

- 32 Our overarching aim was to test the feasibility of a collaborative pharmacist-led medication review with
- 33 General Practitioners (GPs). The review utilised a patient-centred approach to implement deprescribing
- 34 recommendations based on peer-reviewed deprescribing guidelines. We hypothesise that DBI could be
- reduced in residential aged care facilities (RACFs) utilising this intervention.

# **Ethics Approval**

Ethics approval was obtained from the Health and Disability Ethics Committee (16/NTA/61).

### 38 **Methods**

39

36

- 40 This trial's methods are outlined in a published protocol [20]. The trial was registered in the Australasian
- 41 Clinical Trials Registry (ACTRN12616000721404). The Template for Intervention Description and

- Replication (TIDieR) checklist was used when designing the study (Supplementary Table 1). The study 42
- 43 is diagrammatically represented using CONSORT Reporting Guidelines in **Supplementary Figure 1** [21].

#### 45 **Study Design**

44

46

56 57

60 61

62 63

66

73

A single group (pre- and post- comparison) feasibility study was carried out in people aged 65 years and 47 48

older living in a residential care setting. **Figure 1** provides an overview of the intervention. Participants

were recruited from three RACFs in New Zealand.

### Power and sample size

- 52 To detect a clinically significant difference in the primary outcome (reduction in DBI total score of 0.5 or
- more) with 80% power and alpha of 0.05, the total sample size required was 72 participants [20]. This 53
  - effect size is derived from a study conducted in Australian RACFs that aimed at decreasing the DBI load
  - [22]. Power calculations were generated using Stata 13.1 (Copyright 1985-2013 StataCorp LP).

### **Inclusion and Exclusion Criteria**

- 58 Participants who are aged  $\geq 65$  years who are prescribed at least one anticholinergic or sedative medicine
- (i.e. DBI≥0.5) were included. The target medicine list was adapted from Hilmer et al. [23]. Those who 59
  - were expected to have a limited life expectancy, receiving palliative care or those admitted for hospice care
  - were excluded.

### **Recruitment and consent**

- The RACF's e-prescribing program was screened for residents who fulfilled the inclusion criteria. Of 64
- these, nurse(s) determined residents who were able to provide consent. The pharmacist provided these 65
  - residents with a participant information sheet and consent form. For residents with cognitive impairment;
- the pharmacist gained consent via their enduring power of attorney (EpoA). Recruitment continued for 4 67
- 68 months.

#### 69 **Intervention**

- A collaborative pharmacist-led medication review with GPs was employed, as this model has been shown 70
- 71 to improve the success of deprescribing [24].

#### 72 Step 1: Medical history

- The InterRAI-Long Term Care Facility (LTCF) is a comprehensive assessment database system, utilised in 74
- 75 RACFs internationally and in New Zealand to standardise the evaluation of older people's complex care
- needs. It is used routinely to collect data regarding patients' medical and functional status [25]. We used 76
- this along with clinical notes, to collect participants' data. The reliability of InterRAI-LTCF has been 77
- 78 tested and shown to meet the standard cut-offs for acceptable reliability [26].

#### 79 Step 2: Initial consultation

- After completing an initial consultation, potential medicine(s) that could be deprescribed were discussed 80
- and any patient concerns were noted. For participants with diminished cognition, the pharmacist invited a 81
- nurse and/or the EpoA to help facilitate communication. When a response from the participant was not 82
- 83 possible, the test was recorded as 'not assessed' and the information was gathered from clinical notes.

### Step 3: Deprescribing medication review

The deprescribing medication review utilised peer-reviewed deprescribing guidelines developed as part of the principal investigator's doctoral studies [20]. When these target medicines are reduced/discontinued, adverse drug withdrawal effects (ADWEs) may develop including increased agitation, pain, confusion, or disturbed sleep patterns [27]. Therefore, it is important to slowly taper these medicine(s) whilst monitoring the participant. Medicine(s) that can be deprescribed were discussed with each participant and their consent to deprescribe was sought. When participants disagreed, these recommendations were removed from the review ensuring this is a patient-centred approach. Similarly, for participants with diminished cognition, approval for deprescribing recommendations was sought from their EpoA before putting forward these recommendations to the GP. The GP reviewed, endorsed, adjusted or rejected the recommendations. Any reasons for rejection were recorded.

### Step 4: Medication management plan

- We developed a medication management plan (MMP) that included individualised tapering and monitoring recommendations for the participant, GP and residential care staff. The MMP listed the medicines to be deprescribed, the recommended order of deprescribing, specific tapering guidance, anticipated ADWEs, monitoring and appropriate management options for withdrawal effects. The participant and/or their relative/representative were provided with a copy of the plan. The GP then initiated deprescribing and all other aspects of follow up care.
- Step 5: Monitoring and follow-up
- After the cessation/dose reduction of the first target medicine, participants were monitored twice weekly by the pharmacist for ADWEs. If none were reported, dose reduction continued until the medicine was stopped. The participant continued to be reviewed twice weekly for a further two weeks, and if symptoms were stable, the dose of the next target medication was reduced until it was ceased. This process was repeated until all target medicines were withdrawn. The participant was monitored by the pharmacist on a weekly basis for two more visits and, if stable, no additional visits were conducted. Monitoring also took place independently by nursing staff. GPs were notified if their resident developed an ADWE to facilitate a GP visit and/or re-prescribing of medicine(s) as appropriate.

### 114 Data Collection and Analysis:

During the initial consultation, frailty was assessed using the Edmonton Frailty Scale [28], depression was assessed using the Geriatric Depression Scale (GDS) [29], side effects attributed by target medicines were assessed using UKU- Side Effect Rating Scale (UKU-SERS) score [30] and quality of life (QoL) was assessed using EQ-5D-3L [31]. Covariates were collected at baseline (T0), after three months (T1) and after six months (T2) as detailed in the study protocol [20] and **supplementary Table 2**. Data was be stored in a password-protected Excel spreadsheet.

Primary Outcome: The change in the participant's DBI three and six months after the deprescribing intervention had been implemented. PRN 'as required' DBI medicines that had been administered more than once in the past three months were included in the total DBI score. A separate DBI PRN was also calculated.

Secondary Outcomes: An in-depth description of these outcomes is included in the study protocol [20] and in Supplementary Table 3.

128

126

127

129

130

136

137

138

139

140

### **Statistical Methods**

- Data were analysed on an intention-to-treat basis. R was used for statistical analyses [32]. The primary 131 outcome of change in the DBI at three and six months was assessed with a Wilcox-signed Rank Test 132 (WSR). Depending on the distribution of secondary outcome data, either a paired t-test or WSR were used 133 134
  - for analysis at three and six months. Fisher's exact test was used to analyse the uptake of deprescribing
- 135 recommendations.

### **Results**

In total, 46 of 65 potentially eligible participants consented and were enrolled (Figure 2). Our study attrition rate was 8.7%, with four residents passing away for reasons unrelated to the deprescribing intervention. Participant demographics are summarised in **Table 1**. Almost half of participants had a high falls risk (41%) and the majority (93%) had polypharmacy, which was defined as the prescription of five or more medicines [33].

141 142 143

144

145

146

147

In total, the pharmacist suggested 45 deprescribing recommendations among 46 residents. Of these, 82% were agreed upon by the residents' GP and 96% were agreed upon by the resident or the resident's relatives/family (**Table 2**). In total, 33 recommendations (72%) were implemented (p=0.01; Fisher's exact test); and the medicines were re-prescribed by the GP in only five instances (15.2%). Deprescribing processed could not be completed in 13 residents (28.2%) due to mood changes, increased pain levels or overall health deterioration.

**Table 3** illustrates the analysis of primary and secondary outcomes three months after deprescribing and **Table 4** illustrates the analysis six months after deprescribing. Participant's overall DBI and DBI PRN were significantly less three months after deprescribing. Six months after deprescribing (Table 4), the DBI remained statistically significantly decreased by a median of 0.34. Six months after deprescribing, total regular medicines were reduced statistically, by a mean difference of 2.13 medicines per patient, among patients were deprescribing was initiated. However, the use of PRN medicines remained the same. Falls risk was determined using an in-house falls risk assessment tool utilised by most RACFs in New Zealand and 41% of residents had a high falls risk at the time of recruitment. This remained the same six months after deprescribing. Fall rate defined as the number of falls in the past 90 days was determined by interRAI and showed a statistically significant reduction. Frailty, assessed using the Edmonton Frailty Scale, also showed a significant decrease; the mean difference was 1.35 (p<0.05, 95%, CI: -2.22; -0.48). OoL assessed using EQ-5D-3L was not significantly different six months after deprescribing.

161 162

163

164

165

166 167

168

Six months after deprescribing, total regular medicines were reduced statistically, by a mean difference of 2.13. However, the use of PRN medicines remained the same. Fall rate was determined using falls data recorded in interRAI, where the number of falls that occurred in the past 90 days was noted. Falls risk was determined using an in-house falls risk assessment tool utilised by most RACFs in New Zealand. Forty-one percent of residents had a high falls risk at the time of recruitment. This remained the same six months after deprescribing. On the other hand, the participants' number of falls statistically significantly dropped.

- Frailty assessed by the Edmonton Frailty Scale also dropped by a mean difference of 1.35 (p<0.05, 95%,
- 170 CI: -2.22; -0.48). QoL assessed by EQ-5D-3L did not improve six months after deprescribing.

- Participants reported significantly less adverse effects of psychotropic medication at 3 and 6 months after deprescribing than at the time of recruitment. Psychiatric, neurological, autonomic and other adverse effects dropped significantly 3 and 6 months after deprescribing. Psychiatric adverse effects decreased by a mean difference of 1.8 (p<0.05; 95%, CI: -2.6; -1.0) 3 months after deprescribing, and by a mean difference of 2.24 (p<0.05; 95%, CI: -3.63; -1.12) after 6 months of deprescribing.
- Potential adverse drug reactions (ADRs) had decreased by a mean difference of 2.8 three months after deprescribing (p<0.05; 95%, CI: -4.00; -1.64) and by 4.24 after six months (p<0.05; 95%, CI: -5.66; -2.83). We found no change in cognition three or six months after deprescribing. However, participants' levels of depression scored using the GDS significantly improved (Median difference: -2; p<0.05).

### **Discussion**

- This feasibility study implemented a targeted systematic intervention of deprescribing anticholinergic and sedative medicines using a five-step patient-centred approach. We aimed to explore the feasibility of a pharmacist-led deprescribing intervention that can address some of the major barriers associated with deprescribing, and our results support the feasibility of such an approach [20].
- The findings from this feasibility trial support existing research that shows that despite the challenges, rationalising the use of medicines in older people through deprescribing is feasible and may realise potential benefit [27]. Our results are consistent with other studies that illustrate that deprescribing contributes to an overall reduction in pill burden [5, 9, 27].

Most eligible patients or their EpoAs, consented to participation and overall, 45 recommendations were suggested to the residents' GPs. Eighty-two percent of these were agreed upon by the residents' GP; 72% of them were implemented. Despite previous studies reporting residents' unwillingness to discontinue medicines, we found that the majority of residents and/or their representatives (96%) agreed with the deprescribing recommendations. This finding is echoed in another cross-sectional survey, which showed that most residents (78.9%) reported a desire to stop taking one or more of their medicines [34].

Though not powered to detect a significant difference, this study sheds light on the effect that deprescribing has on participants' DBI scores and relevant patient health outcomes. The statistically significant reduction in DBI scores by 0.34 may support clinical relevance in a larger study; as although in our feasibility study this represents a small decrease, studies have shown an association between increasing DBI and impaired functioning [23, 33, 35, 36].

Participants reported lower depression and frailty scores six months after deprescribing. Cognition, however, did not improve after deprescribing, nor did participants' QoL scores. Our study was not powered to detect these differences and we can only speculate that six months is not long enough to observe such differences, especially in older patients who may suffer from cognitive impairment. However, the lack of QoL deterioration over the period of the study could be a positive finding attributed to deprescribing that ought to be explored in further studies [14].

Psychotropic-related ADEs were reduced six months after the deprescribing intervention. This finding supports existing evidence that the withdrawal of specific medication classes, including benzodiazepines, leads to the reduction of ADRs [15]. There were no adverse events noted as a result of deprescribing. Approximately, fifteen percent of the participants had to have one or more of their deprescribed medicines re-prescribed. Despite this, the overall number of medicines prescribed was reduced significantly. This illustrates that deprescribing was well tolerated, supporting previous research that has shown that frail older people's medication burden can be reduced without any detrimental effects to their health [5, 9].

### **Strength and Limitations**

The study design meant that the participants and outcome assessment were not blinded. However, several outcomes were objective measures, such as the DBI, hence mitigating the risk of assessment. ADWEs were assessed subjectively by the pharmacist and the residential care staff; introducing possibility of bias. The potential that a placebo effect may underpin some changes seen is another limitation that is inherent to pre-post intervention studies. However, this does not affect the study's primary outcome; the change in DBI scores. Time-period effects cannot be ruled out, as controls were not included in the study design.

No restrictions were put in place to prevent medicines being re-prescribed. This pragmatic approach mimics real-life clinical scenarios where medicines are often re-prescribed after being stopped for several, often appropriate, reasons. Despite having a relatively high recruitment rate of 71%, we were unable to recruit the calculated sample size (n=72) due to strict eligibility criteria. We had anticipated this, as other deprescribing studies had shown recruitment could be challenging mainly due to the fear associated with deprescribing medicines [37]. Although our study showed improvement in the majority of outcome measures, six months is not an adequate term to observe changes related to cognitive function.

We found that some participants perceived deprescribing as 'going against' their GPs' initial decision of prescribing the target medicine(s) in question. Re-assuring them that recommendations would be discussed and finalised with and by their GP appeared to support participation in decisions regarding their medicines [38]. Other challenges we encountered included time constraints faced by GPs [39]. Scheduling face-to-face GP appointments for the pharmacist to discuss recommendations was challenging. However, once scheduled, thirty-minute visits were adequate to review recommendations and implement any necessary medicine changes.

Engaging a patient-centred approach was crucial, as the aim of deprescribing is to address patients' health concerns [1] and respect their preferences. This has been shown to significantly improve medication adherence [8]. Utilising a clinical pharmacist to perform the reviews; helped address time constraints faced by GPs [40]. Assuring GPs that residents are receiving adequate monitoring may also have increased the confidence of GPs by diminishing concerns around potentially harmful effects often associated with deprescribing [40].

### Conclusion

This study provides important data indicating the feasibility and benefits of reducing anticholinergic and sedative medication in frail older people. The approach used resulted in high uptake of deprescribing

DEFEAT-polypharmacy recommendations by both residents and GPs. At six months, deprescribing showed signals of significant benefits across a range of important health outcomes including mood, frailty, and falls and resulted in a smaller number of reported adverse effects. Implementing deprescribing utilising this patient-centred approach appears to be safe and feasible and can yield potential health benefits in older people.
Funding statement
This study was semied out as port of NA's destard studies at the University of Otega. School of Dharmany

This study was carried out as part of NA's doctoral studies at the University of Otago, School of Pharmacy and is funded by the Lotteries Health Research (LHR). No other funding was received for this study.

### **Conflicts of interest**

The author(s) declare no competing interests and are responsible for this report's content.

### Acknowledgments

The authors thank LHR for funding the first author's doctoral studies and the co-operation of the residential care provider who agreed to take part in the study.

 ABS\*: Aggressive Behaviour Scale. Scale scores range from 0-12 with higher scores indicative of greater frequency and diversity of aggressive behaviour. CHESS: Changes in Health, End-Stage Disease, Signs, and Symptoms Scale. EQ-VAS: EQ Visual Analogue Scale.

**Table 2: Deprescribing recommendations** 

Resident	Number of recommendation s put forward to	Number of recommendation agreed by the	Number of recommendations agreed by resident/resident's				
number	GP	GP	family	Deprescribing recommendations put forward to GP with clinical reasoning	Summary	Represcribed	Deprescribed
				Loratadine: Resident prescribed promethazine as well as loratadine for eczema. Resident however reported that promethazine is more effective at relieving their symptoms. Therefore, the suggestion was made to the GP* to discontinue loratadine and monitor the control of itching symptoms with promethazine alone. GP* agreed with this suggestion.	Loratadine (discontinued)		
1	2	2	2	Tramadol: Resident reported feeling sleepy during the day and drifting off to sleep regularly. Reducing her tramadol dose from 100mg SR* BD* to 50mg SR* mane* or BD* could help to	Tramadol (reduced)	N	Y
	Z.	2		increase energy levels during the day, whilst still providing long-acting pain relief.  Nortriptyline: Resident suffers from pain that had been well managed with paracetamol. A reduced dose of nortriptyline was therefore thought to be beneficial to improve the resident's energy levels during the day. GP* agreed with this suggestion.	Nortriptyline (reduced)	IN.	1
2	2	1	2	Risperidone: Has a past history of paranoid schizophrenia; so continuing risperidone is necessary. However, resident's mood seemed to be well controlled and stable over the past five years; suggested to the GP* to trial reducing the dose from 1mg to 0.5mg. GP had attempted to reduce risperidone dose in the past and this resulted in relapse of symptoms. Therefore risperidone was continued.	Risperidone (continued)	N	Y
3	1	1	1	Quetiapine: Low dose quetiapine prescribed for aggressive behaviour exhibited by resident upon admission into the residential care facility approximately a year and a half prior to assessment date. As resident did not exhibit any recent acts of aggressive behaviour, the suggestion was put forward to deprescribe quetiapine; whilst continue to prescribe this 'as required'. After three months, this change was well tolerated with no relapse of symptoms and the quetiapine did not need to be administered 'as required'. Therefore, it was successfully discontinued.	Quetiapine (discontinued)	N	Y
4	1	1	1	Carbamazepine: A dose reduction from 200mg BD* to 100mg BD* was suggested as resident's epileptic symptoms have been well controlled with no attacks during the entirety of the resident being admitted into the residential care facility (approximately 5 years). The resident had also expressed that they do not believe they require to continue taking this medication. Discussed with GP who agreed and reduced the dose of carbamazepine. Resident passed away on the 24/09/16 due to chest infection	Carbamazepine (discontinued)	N	Y
				Nortriptyline: Resident prescribed several medicines for neuropathic pain caused by ulcers secondary to Type 2 Diabetes Mellitus. Resident reported feeling drowsy and loss of concentration during the day. This affected their ability to partake in social activities. Suggestion was made to GP* to reduce nortriptyline dose from 50mg to 25mg. GP* agreed. After three months, the dose reduction was well tolerated and GP* decided to discontinue the use of nortriptyline.  Zopiclone: Resident had been prescribed this long-term for sleep aid. However, resident still experienced difficulty falling asleep and staying asleep. Attempting to reduce the resident's	Nortriptyline (discontinued)  Zopiclone (discontinued)		
5	4	2	2	high drug burden index by reducing/discontinuing nortriptyline that caused sleepiness during the day; was thought to provide the opportunity for better quality sleep at night therefore		N	Y

	Г	ı	T				
				reducing the reliance on continuing this medication. Resident refused the zopiclone tablet			
				three months after discontinuing nortriptyline, as they felt they no longer needed it and slept			
				well without it. The GP* therefore discontinued zopiclone.			
				Other medicines that were expressed for reduction were trained and acharantic often			
				Other medicines that were suggested for reduction were tramadol and gabapentin after			
				nortriptyline and zopiclone were successfully deprescribed. However, GP did not want to risk			
				reducing these medicines as resident's pain might not be well managed at lower doses.	O		
				Quetiapine: Indication for prescribed low dose quetiapine was not documented and unclear.	Quetiapine		
				Therefore, suggestion was made to reduce quetiapine with the aim of completely discontinuing	(reduced)		
1				this. GP* agreed. However, resident passed away on 14/04/17 before further tapering of the			
				dose was possible.			
				Resident had a high drug burden index. Other deprescribing recommendations put forward			
				included a step wise approach to reduce the dose of zopiclone, amitriptyline and lorazepam.			
				GP* felt comfortable with reducing quetiapine and was hesitant to reduce other medicines as			
6	4	1	4	the resident had been prescribed them for a long time.		N	Y
_	-	_		Lamotrigine: At the time of assessment, it seemed appropriate to trial the reduction of	Lamotrigine		
				lamotrigine as the resident had not suffered from a recent attack. However, shortly after this	(continued)		
				the patient had a seizure, and due to her moods being chronically low, the decision to continue	(continued)

not had a previous trial of reducing or discontinuing temazepam. Therefore, suggested (reduced)		U	U	U		Т	IN	IN
	23	1	1	1	prescribing half a tablet (5mg) with the other half being prescribed 'as required. GP* agreed	(reduced)	N	Y

				and resident tolerated the reduction well			
24	1	1	1	Amitriptyline: 10mg prescribed for an unclear indication. Resident prescribed several other sedative medicines for pain control. Therefore, questioned the need for amitriptyline. Both resident and daughter voiced that amitriptyline is probably not needed. Therefore, suggested tapering then discontinuing amitriptyline. GP* agreed. However, resident complained of increased insomnia and GP* re-prescribed it	Amitriptyline (reduced, discontinued, then re- prescribed)	Y	N
25	1	1	1	Citalopram: Reduced citalopram from 20mg to 10mg over three months and eventually discontinued this medicine as the resident tolerated the reduction well. However, the patient's moods deteriorated and re-prescribing of citalopram was necessary.	Citalopram (reduced, discontinued, then re- prescribed)	Y	N
26	1	1	1	Sertraline: Initiated upon admission into the residential care facility approximately 1 year and a half years prior to assessment date. Resident has settled into the residential care facility and moods stable. Suggested slow tapering and discontinuation. GP* agreed and resident tolerated this well.	Sertraline (discontinued)	N	Y
27	1	0	1	Deprescribing zopiclone is not feasible as they had recently lost their spouse and had been unsettled.	All medicines continued	N	N
28	1	1	1	Terazosin: Resident recently had an in-dwelling catheter (IDWC) inserted, so deprescribed terazosin	Terazosin (discontinued)	N	Y
29	1	0	1	Escitalopram: Resident suffers from bipolar disorder. Prescribed multiple antidepressants. Resident had scored 3 on the geriatric depression scale (<5: not depressed) at the time of assessment. Therefore, suggested monotherapy antidepressant therapy to the GP* by reducing escitalopram. However, resident suffered from an episode of bipolar low shortly afterwards, and it was not suitable to deprescribe escitalopram	All medicines continued	N	N
30	1	1	1	Clonazepam: Prescribed 0.5mg BD* for an unclear indication. Resident reported increased sedation during the day. Therefore, recommended trialling a reduction of this medicine to help improve resident's level of sedation.	Clonazepam (reduced)	N	Y
31	0	0	0	All medicines prescribed are clinically appropriate and required medically. No deprescribing recommendations put forward.	All medicines continued	N	N
32	1	1	1	Codeine: Prescribed 60mg BD*. Suggested reducing codeine dose to 30mg BD. GP agreed. However, resident experienced increased pain from stoma and codeine was increased.	Codeine (reduced, then increased)	Y	N
33	1	1	1	Escitalopram: Resident prescribed 20mg of escitalopram with no clear indication. Resident scored 3 on geriatric depression scale suggesting no active depression and reports good moods. Suggested trialling the reduction of escitalopram. GP* agreed and resident tolerated this well.	Escitalopram (reduced)	N	Y
34	1	1	1	Escitalopram: Indication unclear. Resident reports good moods and scored 2 on the geriatric depression scale. Discussed with resident and resident's daughter the need to continue escitalopram and they both agreed to a trial of reduction. GP* agreed with the recommendation. Escitalopram was reduced over three months and eventually discontinued.	Escitalopram (discontinued)	N	Y
35	1	1	1	Tramadol: On multiple sedatives, in addition to paracetamol and gabapentin. Reviewed the need for tramadol given the complex medicine regimen. Discussed this with the resident and resident's family who agreed to reducing tramadol. GP* agreed. Resident tolerated this well and eventually tramadol was discontinued.	Tramadol (discontinued)	N	Y
36	0	0	0	Unable to implement any deprescribing recommendations as resident passed away due to a myocardial infarction on 10/08/2016, before the date of the initial assessment	All medicines continued	N	N
37	1	0	0	Sertraline: Recommended slow tapering of sertraline as moods have been stable. However, moods deteriorated shortly after assessment and deprescribing was not feasible	All medicines continued	N	N

				Citalopram: Prescribed for an unclear indication. Resident scored 2 on geriatric depression scale and reports good moods. Spoke to resident and son who agreed to a trial of	Citalopram (discontinued)		
38	1	1	1	deprescribing. GP* agreed. Resident tolerated reduction well and citalopram was discontinued.	,	N	Y
				Codeine: Prescribed high doses of codeine for shoulder/hip pain. Suggested to GP* to increase regular paracetamol use for more effective pain relief and gradually taper codeine use.	Codeine (reduced)		
39	1	1	1	Resident tolerated this well and no longer needed higher doses of codeine.	` ´	N	Y
				Alprazolam: Prescribed 500mcg of alprazolam TDS* for severe anxiety/post-traumatic stress disorder for over 15 years after the sudden loss of loved ones. Suggested to resident the	Alprazolam (reduced)		
				gradual reduction of alprazolam. Resident and GP* agreed with this suggestion. Alprazolam	(reduced)		
				250mcg TDS* was prescribed regularly along with 250mcg TDS* as required, in case the resident needed it during the first few weeks of reduction. Resident tolerated the reduction			
40	1	1	1	well and did not request alprazolam as required.		N	Y
41	1	1	1	Ropinirole: Prescribed with no clear indication. Resident and GP* agreed to stop ropinirole. Patient tolerated this well.	Ropinirole (discontinued)	N	Y
		1	1	Clonazepam: Resident prescribed 0.5mg three years ago after an outburst of aggression.	Clonazepam		
42	1	1	1	Resident's mood had settled and no further acts of aggression have occurred. Therefore, suggested discontinuing clonazepam. GP* agreed and resident tolerated this.	(discontinued)	N	Y
	-	_	_	Suffers from hallucinations and severe insomnia. Therefore, not feasible to deprescribe any	All medicines
