## 29 **Abstract**

30 *Klebsiella* species occupy a wide range of environmental and animal niches, and occasionally cause  
31 opportunistic infections that are resistant to multiple antibiotics. In particular, *Klebsiella pneumoniae*  
32 (*Kpne*) has gained notoriety as a major nosocomial pathogen, due principally to the rise in non-  
33 susceptibility to carbapenems and other beta-lactam antibiotics. Whilst it has been proposed that  
34 the urban water cycle facilitates transmission of pathogens between clinical settings and the  
35 environment, the level of risk posed by resistant *Klebsiella* strains in hospital wastewater remains  
36 unclear. We used whole genome sequencing (WGS) to compare *Klebsiella* species in  
37 contemporaneous samples of wastewater from an English hospital and influent to the associated  
38 wastewater treatment plant (WWTP). As we aimed to characterise representative samples of  
39 *Klebsiella* communities, we did not actively select for antibiotic resistance (other than for ampicillin),  
40 nor for specific *Klebsiella* species. Two species, *Kpne* and *K. (Raoultella) ornithinolytica* (*Korn*), were  
41 of equal dominance in the hospital wastewater, and four other *Klebsiella* species were present in  
42 low abundance in this sample. In contrast, despite being the species most closely associated with  
43 health-care settings, *Kpne* was dominant species within the WWTP influent. 29% of all isolates  
44 harboured the *bla*<sub>OXA-48</sub> gene on a pOXA-48-like plasmid, and these isolates were almost exclusively  
45 recovered from the hospital wastewater. This gene was far more common in *Korn* (68% of isolates)  
46 than in *Kpne* (3.4% of isolates). In general plasmid-borne, but not chromosomal, resistance genes  
47 were significantly enriched in the hospital wastewater sample. These data implicate hospital  
48 wastewater as an important reservoir for antibiotic resistant *Klebsiella*, and point to an unsuspected  
49 role of species within the *Raoultella* group in the maintenance and dissemination of plasmid-borne  
50 *bla*<sub>OXA-48</sub>.

## 51 **Impact statement**

52 *Klebsiella pneumoniae* is recognised as a high priority health-care associated pathogen due largely to  
53 the rapid emergence and global spread of resistance genes encoding extended-spectrum beta-  
54 lactamases (ESBLs) and, more recently, carbapenemases. These plasmid-borne resistance genes are  
55 readily transferred between other *Klebsiella* species and the *Enterobacteriaceae* family that inhabit  
56 multiple animal and environmental niches. Effective management of antimicrobial resistance in the  
57 *Klebsiella* spp. therefore needs to incorporate both a broad epidemiological perspective (the “One-  
58 Health” framework) and a broad phylogenetic perspective, as environmental *Klebsiella* species can  
59 act as important reservoirs of resistance, as well as directly causing serious infections. We used WGS  
60 to characterise isolates of *Klebsiella* spp. from wastewater of a UK hospital and from the influent to  
61 the WWTP processing this wastewater. Although we did not select for carbapenem non-  
62 susceptibility, the hospital wastewater yielded a high prevalence of the carbapenemase gene *bla*<sub>OXA-  
63 48</sub>. This gene was carried on a stable and highly transferable pOXA-48-like plasmid within multiple  
64 species, and in particular *Klebsiella (Raoultella) ornithinolytica*. This observation warrants increased  
65 surveillance of hospital wastewater, and a greater recognition of the potential public health impact  
66 of resistant strains belonging to the *Raoultella* group, both in the environment and in the clinic.

## 67 **Data Summary**

68 Sequencing reads are available from the European Nucleotide Archive (ENA) under the study  
69 accession number, PRJEB39942 (ERP123516). Individual accession numbers for raw sequence data  
70 are available in Table S1. All supporting metadata and tree (Newick) files are available to explore and  
71 download via the Microreact project at <https://microreact.org/project/Wastewater>. Sixteen  
72 supplementary figures, two supplementary tables and three supplementary notes are available with

73 the online version of this article. The authors confirm all supporting data, code and protocols have  
74 been provided within the article or through supplementary data files.

75 **Abbreviations**

76 CPE, carbapenemase producing *Enterobacteriaceae*; ESBL, extended-spectrum beta-lactamase; GTR,  
77 general time reversible; ICE, integrative conjugative element; *Kmic*, *K. michiganensis*; *Korn*, *K.*  
78 (*Raoultella*) *ornithinolytica*; *Kpla*, *K. (Raoultella) planticola*; *Kpne*, *Klebsiella pneumoniae*; *Kqps*, *K.*  
79 *quasipneumoniae* subspecies *similipneumoniae*; *Kvar*, *K. variicola*; SCAI, Simmons citrate agar with

## 89 **Introduction**

90 *Klebsiella pneumoniae* (*Kpne*) is recognised by the World Health Organisation as one of the most  
91 high priority bacterial pathogens due to its ability to cause life-threatening conditions that are  
92 increasingly difficult to treat with antibiotics [1]. Healthcare-associated clones of *Kpne* that are non-  
93 susceptible to carbapenems are of particular concern. Genes encoding carbapenemases, that confer  
94 non-susceptibility to carbapenems, are typically plasmid-borne and are widely disseminated among  
95 multiple *Klebsiella* species, as well as within the broader *Enterobacteriaceae* family. The resultant  
96 public health burden is significant; the mortality of patients infected with carbapenemase-producing  
97 *Enterobacteriaceae* (CPE) is 26–44% higher than in patients infected with carbapenem-susceptible  
98 isolates [2].

99 Five major types of carbapenemase genes have been described; KPC, OXA-48-like, NDM, VIM and  
100 IMP, and these genes primarily disseminate through the healthcare network via the movement of  
101 healthcare workers or patient referral [3]. However, many *Klebsiella* species, including *Kpne*, are  
102 commonly carried asymptotically in the human gut, and are also recovered from animals, plants,  
103 water or the rhizosphere. Environmental or animal reservoirs may play a role in the circulation of  
104 resistance strains or genes, and the urban water cycle in particular is implicated as a major “One  
105 Health” driver of resistance. However, direct transmission across different settings is very difficult to  
106 detect and monitor[4-6].

107 In this study, we use whole-genome sequencing to compare isolates of *Klebsiella spp.* recovered  
108 from the wastewater of a hospital in South West England, with those isolated from a  
109 contemporaneous sample of the influent to the wastewater treatment plant (WWTP) serving the  
110 hospital and the local population. By profiling the *Klebsiella* communities at these two sites we  
111 sought to gauge the extent to which the bacterial strains or resistance genes present in hospital  
112 wastewater penetrate through the wastewater network. We used a selective culturing approach  
113 incorporating ampicillin to sample representative isolates belonging to the *Klebsiella* or *Raoultella*  
114 groups, but otherwise did not enrich for antibiotic resistance. Nevertheless, we observed a high  
115 prevalence of *Klebsiella* isolates harbouring plasmid-borne *bla*<sub>OXA-48</sub> within the hospital wastewater  
116 sample (28/95; 29.5%). The pOXA-48-like plasmid is associated with multiple species, but most  
117 notably *Klebsiella* (*Raoultella*) *ornithinolytica* (*Korn*). In contrast, the WWTP influent sample  
118 contained very low levels of both *Korn* and the *bla*<sub>OXA-48</sub> bearing plasmids, consistent with a  
119 moderate level of environmental impact from the hospital wastewater.

## 120 **Methods**

### 121 **Sampling**

122 Wastewater samples were collected over 5 consecutive days (5-9 August 2019) from two main sites:  
123 a hospital outlet accounting for 60% of total wastewater originating from a large hospital in SW  
124 England (> 700 beds and a catchment of 500,000 people), and a WWTP serving 105,000 people,  
125 including the hospital. The WWTP influent is mostly of domestic origin, the contribution from  
126 industrial sources being only about 1%. There is approximately 10 km of pipe connecting the hospital  
127 to the WWTP. WWTP influent was collected as flow proportional 24 h composites with average  
128 sample collection frequencies of approximately 15 min using an ISCO 3700 autosampler.  
129 Wastewater from the hospital outlet was collected as time proportional composites, 24 h  
130 composites with 50 ml collected every 15 min using an ISCO 3700 autosampler. In addition, a single  
131 sample was taken from the local river at a depth of 30 cm, approximately 8 km upstream of the  
132 WWTP in May 2019. All samples were packed on ice to maintain 4°C and were transported to the  
133 laboratory within one hour.

## 134 Recovery of *Klebsiella* isolates, DNA extraction and sequencing

135 An aliquot (100 µl) of the samples from the hospital drains and WWTP influent were spread on  
136 Simmons citrate agar (Fisher) with 1% myo-inositol (Sigma), a culture medium that selectively  
137 favours the growth of *Klebsiella* spp without the use of antibiotics (SCAI media; [7]). The SCAI media  
138 was supplemented with 10 µg ml<sup>-1</sup> ampicillin (Oxoid) in order to further select against Gram-positive  
139 bacteria and other susceptible species, as *Klebsiella* species are typically intrinsically resistant to this  
140 antibiotic owing to a chromosomally encoded SHV beta-lactamase. Plates were incubated at 37 °C  
141 for 24 h. *Klebsiella* / *Raoultella* colonies were identified as yellow/orange and shiny, sometimes  
142 mucoid. Discrete colonies were picked and streaked on fresh SCAI amp<sub>10</sub> and incubated at 37 °C for  
143 48 h. Ninety-four isolates with large, yellow and shiny colonies were selected for DNA sequencing;  
144 49 from the hospital site (at least 7 from each of 5 days) and 45 from WWTP (at least 9 from each of  
145 four days). All of these colonies were confirmed as *Klebsiella* or *Raoultella* species by whole genome  
146 sequencing (WGS) without any other prior molecular characterisation. The single river water sample  
147 (250 ml) was filtered through a 0.45 µm pore membrane (Millipore) then transferred to LB broth  
148 (Miller; Fisher) with ampicillin (10 µg ml<sup>-1</sup>) and incubated at 37 °C overnight with shaking before  
149 spreading on SCAI amp<sub>10</sub> and incubating at 37 °C. A single yellow colony was selected for DNA  
150 sequencing, which was also subsequently confirmed as a *Klebsiella* species.

151 A single colony of each isolate was picked from a fresh SCAI amp<sub>10</sub> plate into LB broth (Miller) with  
152 ampicillin (10 µg ml<sup>-1</sup>) and incubated at 37 °C overnight with shaking. DNA was extracted using  
153 QIAamp DNA Mini Kit (Qiagen). Isolates were sequenced using the Illumina HiSeq platform (HiSeq 10  
154 X, 150 bp Paired End). Reads were trimmed with Trimmomatic v0.33 [8] and the trimmed reads were  
155 used to generate *de novo* assemblies using SPAdes 3.10.0 [9] using k-mer sizes of 41, 49, 57, 65, 77,  
156 85 and 93 and with the `-cov-cutoff` flag set to 'auto' as part of an in-house pipeline at the Wellcome  
157 Sanger Institute, Cambridge, UK. Genomes were annotated using Prokka v1.14.5 ([10];  
158 <https://github.com/tseemann/prokka>).

## 159 Phylogenetic analysis

160 Short reads of all isolates were mapped to the genome of *Kpne* isolate 5Sd using Snippy v4.3.6  
161 (<https://github.com/tseemann/snippy>). This reference was chosen as a high quality short-read  
162 assembly consisting of 15 contigs. A core alignment of 5,100,718 nucleotides with 184,671  
163 polymorphisms was used to generate an approximate maximum-likelihood phylogenetic tree based  
164 on a general time reversible (GTR) model using FastTree v2.1.11 [11, 12]. We constructed an  
165 additional tree that also included the publicly available *Kpne* ST983 genome (ED01500733, accession  
166 number NZ\_POWS00000000.1 [13], using the same reference, that contained 184,119 single  
167 nucleotide polymorphism (SNP) variants. We also constructed a larger *Korn* tree using *Korn* genomes  
168 generated as part of other studies from Italy (n=25), Pakistan (n=5) and two isolates from WWTP in  
169 the East of England described previously [14] by mapping to the *Korn* isolate SPARK\_1635\_C1 from  
170 Italy. This generated a core alignment of 6,004,523 nucleotides with 24,659 polymorphisms. These  
171 trees were combined with metadata and output from Kleborate and visualised using Microreact  
172 v23.0.0 [15]. Distance matrices of isolates in each tree were generated using snp-dists  
173 (<https://github.com/tseemann/snp-dists>). Phylogenetic analysis of the *bla*<sub>OXA-48</sub> gene and *ybt* locus  
174 are described below.

## 175 Identification of resistance and virulence determinants

176 Genome assemblies produced using SPAdes 3.10.0 were assigned species and multilocus sequence  
177 type (in those species where schemes are available), as well as being screened for virulence and

178 resistance genes using Kleborate v0.4.0-beta (<https://github.com/katholt/Kleborate>). Recent  
179 phylogenetic analysis based on WGS data has revealed that the *Raoultella* species are unequivocally  
180 nested within the *Klebsiella* genus [16]; an observation further supported by the current data. We  
181 therefore follow Wyres *et al* [16] and refer to the '*Raoultella*' species *R. ornithinolytica* and *R.*  
182 *planticola* as '*Klebsiella*' *ornithinolytica* (Korn) and *K. planticola* (Kpla).

183 Abricate v0.9.8 (<https://github.com/tseemann/abricate>) was used for further screening for  
184 resistance genes in the ResFinder database (downloaded 29 April 2020) and virulence factors in the  
185 virulence factors database VFDB (downloaded 19 April 2020). We scored the presence or absence of  
186 genes in our genomes according to a threshold of >80% nucleotide identity and coverage. In  
187 addition, we searched for virulence factors with lower thresholds (>40% nucleotide identity and  
188 coverage). In the very small number of cases where 2 copies of the same gene were noted in a single  
189 genome we simply scored the gene as present.

190 In order to confirm the presence of the *bla*<sub>OXA-48</sub> gene and the associated plasmid, assemblies  
191 identified as harbouring this gene were screened using BLAST v2.9.0+ to identify homologous  
192 sequences carried on plasmid pOXA-48 ([17]; accession number, JN626286). The contigs were  
193 aligned with pOXA-48 and Tn1999 ([18]; accession no AY236073.2) using Clustal Omega v1.2.3 as  
194 implemented in Geneious Prime® v2020.1.1 (Biomatters, Ltd., Auckland, New Zealand). The  
195 alignment of representative contigs was visualised with Easyfig v2.2.2 [19]. Sequence reads of  
196 isolates harbouring *bla*<sub>OXA-48</sub> were mapped to pOXA-48 using Burrows–Wheeler Aligner v0.7.12 [20].  
197 and visualised in Tablet [21]. Read sets from the isolates and publicly available sequences of 21  
198 pOXA-48-like plasmids (described in Table S2) were mapped to pOXA-48 using Snippy v4.3.6  
199 (<https://github.com/tseemann/snippy>), giving an alignment of 61,881 nucleotides and 28 core single  
200 nucleotide variants. Where reads were available, the variants were confirmed by mapping to the  
201 reference (as above). An approximate maximum-likelihood phylogenetic tree using a GTR model  
202 was generated with FastTree v2.1.11 [11, 12].

203 The *ybt* locus encodes the siderophore and virulence factor yersiniabactin and is typically associated  
204 with an ICE (integrative conjugative element). The *ybt*-positive annotated genomes (n=33) were  
205 manually inspected to determine the location of the tRNA-*Asn* occupied site using Geneious Prime®.  
206 The contig containing the *ybt* locus was re-annotated with an in-house ICE*Kp*-*ybt* database using  
207 Geneious Prime®. The sequences of the genes in the *ybt*-locus (*ybtS*-*ybtX*-*ybtQ*-*ybtP*-*ybtA*-*irp2*-*irp1*-  
208 *ybtU*-*ybtT*-*ybtE*-*fyuA*) were extracted and concatenated. An alignment of the concatenated *ybt* locus  
209 was produced using MAFFT v7.450 [22] and a tree was generated using FastTree v2.1.11 [11, 12]  
210 with the GTR model. The *ybt* locus of *Kpne* NCTC11697 was used as reference to re-root the tree.  
211 Recombination events were identified using Gubbins v2.4.1 [23]. A Perl-based local version of  
212 ICEfinder [24] was used to detect potential ICEs. A tanglegram linking the core genome and *ybt* locus  
213 were generated using the “tanglegram” function from the “dendextend” package v1.13.4 in R v3.6.3  
214 (<https://www.r-project.org>).

215

## 216 **Plasmid detection and characterisation**

217 Plasmid replicons were identified using Abricate v0.9.8 with the PlasmidFinder database  
218 (downloaded 13 Jan 2020) based on a threshold of >80% nucleotide identity and coverage [25]. To  
219 determine the plasmid content of the isolates, we used MOB-suite [26] and mlplasmids v1.0.0 [27]  
220 to classify contigs as plasmid-borne or chromosomal. MOB-suite uses Mash distances to assign  
221 contigs to plasmids in a closed reference database. We used the default parameters that are already

222 optimised for Enterobacteriaceae plasmids. This approach identifies the accession number of the  
223 plasmid with the shortest Mash distance to a given set of contigs but, depending on the database,  
224 we recognise that substantial size or structural variation may still be present between the query  
225 contigs and the returned plasmid. In contrast, mlplasmids uses a machine learning tool to assign  
226 contigs as plasmid-borne or chromosomal and was run specifying *Kpne* as the species model, a  
227 minimum contig length of 1,000 bp, and a posterior probability threshold of 0.7. Only contigs that  
228 were consistently assigned as plasmid-borne or chromosomal by both MOB-suite and mlplasmids  
229 were accepted, cases where the results from these two approaches were discordant were assigned  
230 as ambiguous. We also carried out a clustering analysis to detect linkage between resistance genes,  
231 plasmids and sequence type (ST) using the pheatmap package in R v3.6.3. The NbClust function  
232 (method “ward.D2” and index “silhouette”) available in the RNbClust package (version 3.0) was used  
233 to evaluate an optimal number of clusters. The hierarchical clustering using the method “ward.D2”  
234 was computed by cutting the resulting trees specifying 15 clusters.

### 235 **Statistical analysis**

236 Box plots and Wilcoxon Rank Sum tests were carried out using R v4.0.2 (<https://cran.r-project.org/>).

237

### 238 **Results**

239 The phylogenetic tree, all metadata, as well as combined and parsed outputs from Kleborate,  
240 ResFinder, PlasmidFinder, mlplasmids, MOB-suite are freely available to explore and download via  
241 the Microreact project at <https://microreact.org/project/Wastewater>. A brief explanation to the  
242 metadata fields is given in supplementary note 1, and full instructions on how to use Microreact are  
243 available at <https://microreact.org/instructions>. The metadata is also available as an excel file (Table  
244 S1).

### 245 **Species diversity and distribution**

246 High quality genome assemblies were obtained for 95 isolates, 49 from the hospital wastewater, 45  
247 from the WWTP and 1 from the local river. A total of six species were isolated, but *Kpne* and *Korn*  
248 dominated the samples, together accounting for 88% of the isolates (Table 1). All six species were  
249 present in the hospital sample, but only three were present in the WWTP sample (*Kpne*, *Korn* and a  
250 single isolate of *K. variicola*; *Kvar*). Within the hospital sample, 19 were *Kpne* (39%) and 20 isolates  
251 were *Korn* (41%). In contrast, for the WWTP sample, 39 (87%) were *Kpne* and only 5 isolates (11%)  
252 were *Korn*. This was unexpected as *Kpne* is considered a major healthcare pathogen whilst *Korn* is  
253 considered a predominantly environmental species. Studies of hospital-acquired infection by  
254 *Klebsiella* species do not typically target *Korn*, hence the prevalence of this species in health-care  
255 settings may have been under-estimated. However, although a Fisher’s Exact Test confirmed that  
256 the WWTP sample was significantly enriched for *Kpne* over *Korn* compared to the hospital sample ( $P$   
257  $<0.0001$ ), the number of isolates sequenced is too small to draw firm conclusions on species  
258 distributions. Moreover, the samples were taken over a small temporal range (5 days), which  
259 renders the data vulnerable to transient clonal expansion.

260 The phylogenetic relationships between the species are shown in Figure 1. This confirms the close  
261 relatedness of the species corresponding to the *Kpne* species complex: *Kpne*, *Kvar* and *K.*  
262 *quasipneumoniae* subspecies *similipneumoniae* (*Kqps*). The two species previously assigned as  
263 ‘*Raoultella*’ (*Korn* and *Kpla*) are also related. The single isolate of *K. michigenensis* (*Kmic*) is more  
264 closely related to the ‘*Raoultella*’ group than to the *Kpne* species complex, which justifies the re-

265 inclusion of the '*Raoultella*' species within the *Klebsiella* genus as previously observed [16]. *Kmic*  
266 belongs to a third species complex with *K. grimontii* and *K. oxytoca*, which were not recovered in this  
267 study. The enrichment of *Kpne* within WWTP isolates (shown in blue) is also evident in Figure 1.  
268 Discussion of within species diversity and prevalent clonal lineages is given below and in  
269 supplementary material.

270

## 271 **The prevalence and distribution of resistance genes**

272 We used both ARG-Annot (via Kleborate) and ResFinder (via Abricate) in order to detect resistance  
273 genes in our data. The outputs from these tools were consistent, and available to explore via the  
274 Microreact project. The analysis below is primarily based on the more inclusive ResFinder data. We  
275 identified 58 resistance genes or gene variants, predicted to encode resistance to antibacterial drugs  
276 from the following 8 classes, where the number in brackets refer to gene variants rather than the  
277 number of isolates: Aminoglycoside (n=6), Beta-lactam (n=30), Chloramphenicol (n=1), Fosfomycin  
278 (n=7), Quinolones (n=5), Sulfonamide (n=3), Tetracycline (n=3), Trimethoprim (n=3). A minor caveat  
279 is that some of the genes assigned by this analysis as resistance genes are in fact intrinsic  
280 chromosomal genes present in the vast majority of *Klebsiella* strains, and may only confer resistance  
281 when highly expressed or when additional plasmid-borne duplicates are present. These genes  
282 include intrinsic *oqxA* and *oqxB* genes which encode efflux pumps and (unless highly expressed) only  
283 confer very low level resistance to fluoroquinolones [28, 29]. Other examples include *fosA*, which  
284 typically confers only low levels of resistance to fosfomycin, and *bla<sub>SHV-187</sub>* which confers intrinsic  
285 resistance to ampicillin and amoxicillin across all *Kpne* strains (Figure S1).

286 The median number of resistance genes per isolate (combining chromosomal and plasmid-borne)  
287 from the hospital wastewater is 9, whereas for the WWTP sample it is 4, and this difference is  
288 statistically significant by a Wilcoxon Rank Sum test ( $P < 0.001$ ; Figure 2A). The significant enrichment  
289 of resistance genes within the hospital wastewater holds true when only considering *Kpne* isolates,  
290 and therefore does not simply reflect the non-random distribution of species between sites  
291 ( $P < 0.001$ ; Figure 2B). As there is only one *Kpne* ST that is found in both sites (ST983), this difference  
292 is more likely due to differences in strain composition rather than to individual strains losing or  
293 gaining resistance genes according to which site they are located. This single species analysis was  
294 only possible for *Kpne* due to the low prevalence of *Korn* isolates from the WWTP influent.

295 Although there is no significant difference between *Kpne* and *Korn* in terms of the number of  
296 resistance genes identified by ResFinder per isolate ( $P = 0.059$ ; Figure S2), there is a surprising  
297 difference between these two species with respect to the carbapenemase gene *bla<sub>OXA-48</sub>*. Twenty-  
298 eight isolates over all species (29.5%) harboured this gene, and all of these except a single *Korn*  
299 isolate were recovered from the hospital wastewater. A total of 17 of the *Korn* isolates carry the  
300 *bla<sub>OXA-48</sub>* gene, accounting for 68% of the isolates from this species. In contrast, of the 59 *Kpne*  
301 isolates, only 2 (3.4%) carried this gene (7Rg and 8Rg), and these are clonally related thus have co-  
302 inherited this gene (these isolates differ by only 33 core SNPs and are marked with a red asterisk in  
303 Figure 3). Of the 11 isolates from species other than *Kpne* and *Korn*, 9 harboured *bla<sub>OXA-48</sub>*, the  
304 exceptions being one *Kvar* isolate from the WWTP and the single *Kmic* isolate (Figure 1). We  
305 emphasise that our culturing procedure did not select for non-susceptibility to carbapenems, thus  
306 the high frequency of *bla<sub>OXA-48</sub>* reflects a high abundance of this gene within the underlying  
307 community at the time of sampling.

## 308 **Characterisation of a pOXA-48-like plasmid**

309 We characterised the genetic context of *bla*<sub>OXA-48</sub> within the assemblies of the 28 isolates harbouring  
310 this gene. In 17/28 assemblies this gene is present on a conserved contig of approximately 62 kb.  
311 Alignments between these contigs revealed they share >99% sequence identity with each other and  
312 with the 63 kb plasmid pOXA-48 ([17]; accession number JN626286; Figure 4). This IncL conjugative  
313 plasmid (and minor variants) is the predominant source of *bla*<sub>OXA-48</sub> in Enterobacteriales worldwide  
314 [30]. pOXA-48 carries a composite transposon Tn1999, made up of *bla*<sub>OXA-48</sub>, *lysR* (encoding a helix-  
315 turn-helix type transcriptional regulatory protein) and two copies of IS1999. A common variant is  
316 Tn1999.2, which harbours IS1R between *bla*<sub>OXA-48</sub> and IS1999. Our 62 kb contigs included three of the  
317 four elements making up Tn1999 (Figure 4), but our assemblies failed to resolve the expected  
318 second copy of IS1999. Alignments with pOXA-48-like plasmids confirm that 8/17 of our contigs  
319 harbour Tn1999 (Figure 4 groups 1 and 3). The assemblies of the remaining 9/17 contigs do not  
320 extend far enough beyond *bla*<sub>OXA-48</sub> to distinguish between Tn1999 and Tn1999.2 (Figure 4 groups 2  
321 and 4), although we can be sure they are not Tn1999.3, .4 or .5 in which additional mobile elements  
322 are present between *bla*<sub>OXA-48</sub> and *lysR*, or within the *lysR* sequence [30]. In the absence of any  
323 evidence that our isolates do harbour Tn1999.2 we shall refer to them all as harbouring Tn1999. The  
324 transposon is inserted in the plasmid backbone in the same orientation as in pOXA-48 in 9/17 of  
325 these contigs (Figure 4, groups 1 and 4). Within the limitations of the short-read assemblies, the  
326 Tn1999 in our contigs are identical to each other at the nucleotide level, and differ from the  
327 reference sequence in pOXA-48 by 10 SNPs. The plasmid backbone (approx. 58 kb) is also highly  
328 conserved. Our contigs have two IS1 family transposase genes, not present in pOXA-48 (Figure 4),  
329 otherwise the identity is >99% throughout. Allowing for the presence of the additional IS1999, the  
330 size of our contigs (~62 kb) would be highly consistent with other pOXA-48-like plasmids [30].

331 In the remaining 11/28 *bla*<sub>OXA-48</sub> positive isolates, the gene is harboured on a short contig, up to 3.7  
332 kb. Mapping of reads from these isolates to pOXA-48 revealed that more than 99.8% of the plasmid  
333 is represented, although in all but one case the short-read assembled contig only carries *bla*<sub>OXA-48</sub> and  
334 *lysR* so we cannot determine the wider genetic context of the gene. In two of these isolates the *lysR*  
335 sequence is interrupted by an insertion sequence. *Korn* isolate 8RI harbours a fragment with  
336 homology to ISKpn26, an IS5 family transposase, whereas *Kpla* 6Rh contains a region with homology  
337 to a Tn3-like element Tn5403 family transposase. Multiple copies of these sequences are present in  
338 many of our isolates, as well as in many publicly available *Klebsiella* genomes and other  
339 Enterobacteriales, but they have not, to our knowledge, previously been shown to be associated  
340 with *bla*<sub>OXA-48</sub>.

341 Despite the potential for mobility, we found no evidence for Tn1999 or *bla*<sub>OXA-48</sub> transferring  
342 independently of a pOXA-48-like plasmid. Reads from all of our *bla*<sub>OXA-48</sub> positive isolates mapped to  
343 at least 99.8% of pOXA-48, and BLAST searches with the *bla*<sub>OXA-48</sub>, Tn1999 or the plasmid backbone  
344 only identified significant matches in the *bla*<sub>OXA-48</sub> positive isolates. An analysis of the *bla*<sub>OXA-48</sub>  
345 containing contigs with MOB-suite and mlplasmids v1.0.0 further supported the view that these  
346 contigs were of plasmid origin. MOB-recon assigned the contigs to plasmid cluster 681 and more  
347 specifically to plasmid accession number CP015075, a 63.5 kb pOXA-48-like plasmid pEC745\_OXA48  
348 isolated from *E. coli* ST131 [31]. Our contigs are more similar to this plasmid than to pOXA-48. The  
349 presence/absence of this plasmid was 100% consistent with the presence/absence of *bla*<sub>OXA-48</sub>.  
350 Hierarchical clustering analysis of predicted plasmids, resistance genes and replicon types further  
351 confirmed the association between *bla*<sub>OXA-48</sub>, replicon type IncL/M and a pOXA-48-like plasmid  
352 (Figures 5, S3).

353 Our data thus suggest that *bla*<sub>OXA-48</sub> has spread within and between species in the hospital  
354 wastewater community via the transfer of the pOXA-48 plasmid. Whereas most of the ~62 kb *bla*<sub>OXA-</sub>

355 <sup>48</sup> contigs differ by one or two SNPs, there are two pairs of isolates from different species in which  
356 the contigs are 100% identical, consistent with recent interspecies transfer (*Kpne* 8Rg / *Kvar* 9Rb,  
357 and *Korn* 9Ri / *Kpne* 6Rf). To examine whether there were single or multiple introductions of the  
358 pOXA-48 plasmid into this population, we constructed a phylogenetic tree to compare our isolates  
359 with 21 publicly available sequences of pOXA-48-like plasmids (Figure S4; Table S2). These publicly  
360 available plasmid sequences were from diverse geographic origins, multiple species and harbour  
361 *bla*<sub>OXA-48</sub> on either Tn1999 or the variant Tn1999.2. They include two pOXA-48-like plasmids  
362 associated with *Korn* isolates previously recovered from wastewater in the UK [14]. This analysis  
363 confirmed that the plasmid bearing *bla*<sub>OXA-48</sub> in our isolates is highly similar to those plasmids  
364 previously reported from global origins. Most plasmids on the tree are separated by only a single  
365 core SNP, confirming that this plasmid is very widespread and highly conserved. The plasmids  
366 harbouring *bla*<sub>OXA-48</sub> in our isolates are no more closely related to each other than they are to  
367 plasmids from global sources, hence it is not possible to deduce how many times this plasmid was  
368 introduced into our study community. A minor exception to the high degree of plasmid conservation  
369 is found in the two isolates 6Rbi (*Korn*, hospital wastewater) and 7Sd (*Korn*, WWTP); the pOXA-48  
370 plasmids in these strains are identical but separated from the other plasmids by a single core SNP  
371 (indicated by the red circle in Figure S4). As the host chromosomes of these two isolates differ by  
372 only 107 core SNPs (Figure 6), this congruence between plasmid and chromosomal phylogeny is  
373 likely to reflect common inheritance rather than horizontal transfer.

#### 374 **Summary of plasmid distribution across species and sites**

375 Having characterised the pOXA-48-like plasmid in our data, we used a combination of the outputs  
376 from MOB-suite, mlplasmids, PlasmidFinder and ResFinder to determine the plasmid and replicon  
377 profiles of all our isolates and, as far as possible, assign each resistance gene either to a specific  
378 plasmid or as chromosomal. The distribution of plasmids, replicon types and resistance genes over  
379 the whole dataset are shown in Figures S5, S6 and S1, respectively, and are available to explore on  
380 the Microreact project at <https://microreact.org/project/Wastewater> (see supplementary note 1).  
381 MOB-suite assigned the plasmid with accession number CP015075 as the closest hit to the *bla*<sub>OXA-48</sub>  
382 carrying pOXA-48 like plasmid in our data. Our data show this plasmid to be highly promiscuous,  
383 being present in 5 of the 6 species, the exception being the single isolate of *Kmic*. Out of a total of 80  
384 plasmids identified by MOB-suite from our data (representing 26 replicon types; Figure S5), 20  
385 carried at least one resistance gene (25%), only one other showed the same degree of cross-species  
386 distribution as the CP015075-like plasmid. This was a CP011607-like plasmid with replicon type  
387 Col440I, and this small (~5 kb) plasmid does not harbour any resistance genes in our data. Two other  
388 plasmids were detected in 5 species, three in four, three in three, 17 in two and 55 (68.8%) were  
389 restricted to a single species. An important caveat to these figures is that there is likely to be  
390 variation between plasmids that are placed in the same cluster by MOB-suite, and these differences  
391 may in turn impact on the ability of the plasmid to transfer between species.

392 Wilcoxon Rank Sum tests confirmed that the isolates from the hospital wastewater contain  
393 significantly more plasmids per isolate ( $P < 0.001$ ), and significantly more replicon types per isolate  
394 ( $P < 0.001$ ), than the isolates from the WWTP (Figure S7). As noted earlier, the hospital wastewater  
395 sample also contains significantly more resistance genes than the WWTP sample (Figure 2).  
396 Considering all 58 resistance gene variants across all 96 isolates, there were a total 665 resistance  
397 gene assignments attempted. In 374 cases (56.2%) the resistance gene was assigned as  
398 chromosomal, 205 assignments (30.8%) were plasmid-borne by both methods, 73 (11%) were  
399 ambiguous (ie assigned as plasmid-borne by only one of the two methods, and hence excluded), and  
400 13 (1.9%) were assigned as plasmid by both methods, but with no clear match in the MOB-suite

401 database ('unknown'). The resistance genes that were assigned plasmid-borne by both MOB-suite  
402 and mPlasmids were significantly enriched in the hospital wastewater sample ( $P < 0.001$ ), but there  
403 was no difference between the two sites with regards to chromosomal resistance genes (Figure 7).

404 To explore plasmid and resistance gene distribution within a finer sub-species phylogenetic context,  
405 we then considered each species in turn.

#### 406 **Plasmids, resistance genes and phylogeny of *K. ornithinolytica* (*Korn*)**

407 The distribution, according to source and phylogeny, of all 29 plasmids detected by MOB-suite  
408 (representing 16 replicon types) within the *Korn* isolates is given in Figure 6. Only 4 of these plasmids  
409 are associated with at least one resistance gene (13.8%). The distribution of replicon types is given in  
410 Figure S8. Nineteen of the 25 *Korn* isolates resolve into two clades, represented by 12 and 7  
411 isolates. All of the 19 isolates belonging to these clades were recovered from the hospital  
412 wastewater, whereas of the remaining 6 isolates only one was isolated from the hospital  
413 wastewater. Isolates within the larger clade differ between 42 and 136 SNPs, and within the smaller  
414 clade between 25-95 SNPs. These levels of diversity are within the maximum distance typically  
415 observed within single STs [32]. In order to place our *Korn* genomes within a wider phylogenetic  
416 context we rebuilt the tree with additional *Korn* genomes from Italy and Pakistan that were  
417 recovered from diverse sources and sequenced as part of other studies. We also included two *Korn*  
418 genomes recovered previously from UK wastewater and which harbour a pOXA-48-like plasmid  
419 ([14]; Figure S9). This revealed that the *Korn* isolates from the current study did not represent a  
420 monophyletic group, but are scattered across the tree indicating multiple introductions. However,  
421 none of these additional isolates clustered with either of the major two *Korn* lineages, which in turn  
422 points to subsequent local clonal expansion consistent with the low diversity within each of these  
423 clones.

424 The two major clones show distinct repertoires of plasmids and resistance genes (Figure 6), although  
425 this is less clear for replicon types (Figure S8). The larger clone is associated with a total of 13  
426 plasmids across all isolates, of which 5 are specific to this clone and only two of which carry  
427 resistance genes; the *bla*<sub>OXA-48</sub>-carrying CP015075-like plasmid, and the KT896499(pKPSH169)-like  
428 plasmid which carries the *qnrS2* gene encoding reduced susceptibility to quinolones. The original  
429 pKPSH169 plasmid was harboured by a *Kpne* isolate recovered from wastewater biosolids in Israel,  
430 and belongs to the widespread pKPN3-like family of small plasmids known to carry *qnrS* genes [33].  
431 Ten plasmids are detected among all isolates within the smaller clone, but again only two of these  
432 contain resistance genes; the *bla*<sub>OXA-48</sub>-carrying CP015075-like plasmid, and a KJ541070(pG5A4Y413)-  
433 like plasmid harbouring the  $\beta$ -lactamase *bla*<sub>MOX-3</sub> and *bla*<sub>OXA-10</sub> genes. The fourth resistance gene-  
434 bearing plasmid found in the *Korn* isolates is a KY798506-like plasmid that carries the *aac(3')-IIa*,  
435 *aac(6')-IIb*, *bla*<sub>OXA-1</sub> and *bla*<sub>SHV-12</sub> resistance genes. This plasmid is present in the pair of closely related  
436 *Korn* isolates (6Rbi and 7Sd) that also harbour a single SNP variant of the pOXA-48-like plasmid  
437 CP015075 (Figure S4). *bla*<sub>SHV-12</sub> is an important extended-spectrum beta-lactamase (ESBL) variant  
438 gene that is assigned as associated with the KY798506-like plasmid in strain 7Sd, but is not  
439 unambiguously assigned to this plasmid in isolate 6Rbi. The KY798506-like plasmid is also present  
440 within three isolates of *Kvar* ST454 (see below), and belongs to the pKpQIL-like family of plasmids  
441 that commonly carry *bla*<sub>KPC-2</sub> [34, 35]. An alignment of the KY798506 reference plasmid with the  
442 corresponding contigs in our data confirmed regions of high homology (Figure S10).

#### 443 **Plasmids, resistance genes and phylogeny of *K. pneumoniae* (*Kpne*)**

444 A total of 60 different plasmids and 19 replicon types were detected in 59 *Kpne* isolates using MOB-  
445 suite. The distribution of resistance genes and their associated plasmids is given in Figure 3, and the  
446 distribution of all plasmids and replicon types is given in Figures S11 and S12 respectively. Although  
447 the average number of plasmids per isolate is lower for *Kpne* (3.3) than for *Korn* (6), a higher  
448 proportion of the *Kpne* plasmids harbour at least one resistance gene (15/60; 25%) than the *Korn*  
449 plasmids (4/29; 13.8%). A higher proportion of the *Kpne* plasmids were present in only one isolate  
450 (26/60; 43%) than the *Korn* plasmids (7/29; 24.1%), consistent with a more diverse sample.

451 Kleborate was used to assign multilocus STs to the *Kpne* data. The most common ST is ST983, which  
452 is represented by 9 isolates, and these differ from each other by between 15 and 47 core SNPs,  
453 suggesting local clonal expansion. Eight of the 9 *Kpne* ST983 isolates are from the hospital  
454 wastewater, and one from the WWTP influent. A total of 10 different plasmids are observed within  
455 this clone, five of which carry resistance genes (Figures 3, S13). It is noteworthy that these five  
456 different resistance plasmids carry the same set, or a subset, of 9 resistance genes: the  
457 aminoglycoside resistance genes *aac(3)-IIa*, *aac(6')-Ib-cr*, *aph(3'')-Ib*, *aph(6)-Id*, in addition to  
458 *dfrA14*, *bla<sub>CTX-M-15</sub>*, *bla<sub>OXA-1</sub>*, *bla<sub>TEM-1</sub>* and *sul2*. The CP021953(AR\_0148)-like plasmid carries all these  
459 genes in three ST983 isolates (5Rk, 8Rc and 8Rhi), plasmid JX424423(pKDO1)-like carries all these  
460 genes in 5Rg (this plasmid is also present in a *Kpla* isolate where it harbours 11 resistance genes),  
461 and plasmid CP016925(pCTXM15\_DHQP1400954)-like contains all the genes except for *aac(3)-IIa* in  
462 5Rd (Figure S13).

463 The data therefore suggest that a suite of resistance genes are linked on a mobile element and have  
464 been co-transferred between different plasmids within the ST983 clone. This is supported by  
465 hierarchical clustering analysis, which confirmed the linkage of the resistance genes *bla<sub>CTX-M-15</sub>*,  
466 *bla<sub>TEM-1B</sub>*, *aph(3'')-Ib*, *sul2*, *dfrA14* and *aph(6)-Id* within *Kpne* ST983, but with multiple plasmids  
467 (Figure 5; cluster 2). Furthermore, comparison of the ST983 contigs with published data from South  
468 Africa [13] provides additional support that these genes are linked, mobile and have a global  
469 distribution (Figure S14) and more detailed analyses of the relevant contigs also point to the  
470 mobility of these genes (supplementary note 2). There are four *Kpne* STs (STs 35, 13, 17 and 584)  
471 that are each represented by 3 isolates (Figure 3). The plasmid and resistance gene profiles of these  
472 lineages are described in supplementary note 3.

#### 473 **Plasmids and resistance genes in other species**

474 In addition to the 59 *Kpne* isolates, we also recovered two other species corresponding to the *Kpne*  
475 species complex, *Kqps* (n=4) and *K. variicola* (*Kvar*) (n=4). All of these 8 isolates were recovered from  
476 hospital wastewater and harbour *bla<sub>OXA-48</sub>*, except one divergent *Kvar* isolate which was isolated  
477 from the WWTP and does not harbour *bla<sub>OXA-48</sub>*. The four isolates of *Kqps* all correspond to ST3590  
478 and harbour identical plasmid and resistance profiles. Three of the four *Kvar* isolates corresponded  
479 to ST454. Although this is not a clone of recognised clinical importance, all three ST454 isolates  
480 harbour a KY798506-like plasmid that was also found in *Korn* and belongs to the pKpQil-like family of  
481 plasmids as discussed above. Similar to the *Korn* isolates, this plasmid is also associated with the  
482 *bla<sub>SHV12</sub>* in *Kvar* ST454 isolates 8Rji and 5Rj, whereas this gene is assigned as chromosomal in *Kvar*  
483 ST454 isolate 9Rb. Finally, *Kpla* isolate 6Rf harbours plasmid a JX424423(pKDO1)-like plasmid with 11  
484 resistance genes, more than any other plasmid in the dataset. These are *aac(3)-IIa*, *aac(6')-Ib-cr*,  
485 *bla<sub>OXA-1</sub>*, *bla<sub>CTX-M-15</sub>*, *dfrA14*, *aph(3'')-Ib*, *aph(6)-Id*, *bla<sub>TEM</sub>*, *qnrB1*, *sul2*, *tet(A)*. This plasmid is also  
486 present in two *Kpne* isolates, including one ST983 isolate as previously noted, where it harbours  
487 subsets of nine and six of these genes.

#### 488 **Characterisation of virulence factors**

489 Kleborate revealed that 33 of the isolates contained the major virulence factor *ybt* that encodes the  
490 siderophore yersiniabactin. This locus was detected in all 25 *Korn* isolates and in each case was  
491 assigned an “unknown” type. We note that the *ybt* locus in *Korn* is chromosomally located close to  
492 an tRNA-*Asn* site, with no evidence for an associated ICE, and is phylogenetically distinct from the  
493 *ybt* locus in *Kpne* (Figure S15). A tanglegram linking the *ybt*-based and core genome-based  
494 phylogenies shows that different *ybt* variants match the different core genome lineages in *Korn*,  
495 suggesting a single acquisition of the *ybt* locus into this species (Figure S16), however, the *Korn*  
496 phylogeny lacks the resolving power to show this conclusively.

497 A total of 8 *Kpne* isolates harbour a yersiniabactin locus, 4 from the hospital wastewater, 3 from the  
498 WWTP sample and the single isolate from the river, and these correspond to 4 unique STs. The three  
499 *Kpne* ST13 isolates are all ybST21 (*ybt* 10; ICE*Kp*4). The two highly related ST35 isolates (River\_C and  
500 7Sl) harboured a novel 2LV of ybST183 (*ybt* 9; ICE*Kp*3), whilst the third ST35 isolate (8Sd) harboured  
501 ybST10 (*ybt* 5; ICE*Kp*6). A single locus variant of *Kpne* ST25 from the hospital wastewater (5Ra)  
502 harboured a 1LV of ybST63 (*ybt* 6; ICE*Kp*5) and finally an isolate of *Kpne* ST1536 was isolated (7Sc)  
503 from the WWTP sample harbouring a 2LV of ybST 209 (*ybt* 9; ICE*Kp*3). We confirmed the presence  
504 of the *ybt* locus using the vfdb database through ABRicate.

505 Kleborate and ABRicate also revealed the absence of type I or III *Klebsiella* fimbriae (although *fim*  
506 genes are present), and the presence of the *astA* gene in 3 *Korn* isolates (6Rbi, 7Sa, 7Sd) that  
507 encodes a heat-stable enterotoxin 1. We note that the *astA* gene is embedded in an IS256-family  
508 transposon, and a BLASTP search suggested that the closest *astA*-encoded protein (from strain 6Rbi),  
509 named EAST1, is from *Edwardsiella ictalurid* (100% coverage, 77.14% identity; data not shown).

510

## 511 **Discussion**

512 The acquisition of multiple antibiotic resistance genes by *Klebsiella* spp. accounts for a significant  
513 public health burden, particularly in health care settings. Here we compared *Klebsiella* spp. isolates  
514 from the wastewater of a large hospital in South West England with those from the influent to a  
515 WWTP serving the hospital. We targeted *Klebsiella* spp. isolates through selective culturing, but we  
516 did not actively enrich for antibiotic resistance (other than for ampicillin), nor for specific *Klebsiella*  
517 species. We note marked differences in resistance profile and species composition between the two  
518 sites which suggests that the signal from hospital wastewater is markedly diluted once it has reached  
519 the WWTP [36]. However, it remains likely that bacteria from the hospital are still present in the  
520 WWTP influent, and possibly also the effluent, albeit at a low frequency [14]. In support of this, the  
521 WWTP sample contained a single *Korn* isolate (7Sd) that carries both a pOXA-48-like plasmid  
522 (harbouring *bla*<sub>oxa48</sub>) and a pKpQIL-D2-like plasmid (harbouring *bla*<sub>SHV12</sub>). Although we cannot rule out  
523 the possibility that this isolate derived from the community rather than the hospital, isolate 7Sd is  
524 clonally related to the hospital wastewater *Korn* isolate 6Rbi, differing by only 107 core SNPs, and  
525 both 7Sd and 6Rbi possess a variant pOXA-48 plasmid containing a unique SNP. This exception aside,  
526 the prevalence of plasmid-borne resistance genes is significantly greater within the hospital  
527 wastewater than the WWTP influent, which again is consistent with previous studies examining a  
528 range of different hosts and including hospital associated isolates [37]. In contrast, we find no  
529 evidence for a difference in the prevalence of chromosomal resistance genes, indicating that these  
530 are commonly core genes in *Klebsiella* spp. [38].

531 Whereas both *Kpne* and *Korn* are present in the hospital wastewater at equal abundances, and four  
532 other species are also present at this site, the WWTP sample is overwhelmingly dominated by a

533 single species, *Kpne*. As *Kpne* is health-care associated, and *Korn* is considered an environmental  
534 species, their relative abundances at either site is the opposite of that expected. Moreover, the  
535 WWTP sample also represents a much more heterogeneous mixture of inputs from the surrounding  
536 community, thus would be expected to contain a higher species diversity. The bulk of the WWTP  
537 influent derives from domestic, rather than industrial, sources. Thus the high prevalence of *Kpne* in  
538 this sample presumably reflects, at least in part, a high rate of asymptomatic carriage of *Kpne* in the  
539 local community. We note that nursing homes in particular have been implicated as a major  
540 reservoir of ESBL-producing *E. coli* and *Kpne* [39].

541 Our data reveal a high abundance of a 63 kb IncL/M pOXA-48-like plasmid harbouring the  
542 carbapenemase gene *bla*<sub>OXA-48</sub>. This gene encodes the OXA-48 class D  $\beta$ -lactamase that hydrolyses  
543 penicillins at a high level and carbapenems at a low level. This enzyme confers a high level of  
544 resistance to imipenem [40] but is ineffective against cephalosporins [41]. The pOXA-48 plasmid is  
545 almost exclusively present in the hospital wastewater, with the *Korn* WWTP isolate 7Sd being the  
546 only exception. The pOXA-48 plasmid has disseminated worldwide, and has previously been  
547 associated with *Korn* isolates from sewage in the UK [14]. Although minor variants have been  
548 described [30], it appears to be highly stable [42]. This plasmid has also been observed to freely  
549 transfer between species within the *Enterobacteriaceae* family [14], and has a very low fitness  
550 burden [43]. These characteristics are evident in our data. Even without selective culturing, the  
551 pOXA-48-like plasmid is present in the majority of isolates of 4 species within the hospital  
552 wastewater (*Korn*, *Kpla*, *Kvar* and *Kqps*), with the notable exception being that only 2 clonally related  
553 isolates of *Kpne* carry this plasmid. The pOXA-48-like plasmid present in our data is highly related to  
554 publicly available sequences from diverse geographic origins, meaning it is not possible to infer how  
555 many times the local community has acquired this plasmid. Caution should thus be exercised before  
556 inferring local epidemiological spread of a pOXA-48-like plasmid from a single source.

557 In addition to the high abundance of plasmid-borne *bla*<sub>OXA-48</sub>, we note multiple plasmids that harbour  
558 clinically important ESBL genes. Cases where these plasmids co-reside with the pOXA-48-like plasmid  
559 (eg *Kpla* isolate 6Rf and *Korn* isolate 7Sd) are likely to present particular therapeutic challenges due  
560 to resistance to both cefpodoxime and meropenem. Two ESBL-bearing plasmids are present in  
561 multiple species; first, a *bla*<sub>SHV-12</sub> carrying KY798506(pKpQIL-D2)-like plasmid is present in the WWTP  
562 *Korn* isolate 7Sd and two hospital wastewater *Kvar* ST454 isolates 8Rji and 5Rj. This pKpQIL-like  
563 plasmid commonly carries the key carbapenemase gene *bla*<sub>KPC-2</sub>, and is facilitating the spread of this  
564 gene in the UK [34] and globally [43]. Although we did not detect the *bla*<sub>KPC-2</sub> gene in our data, we did  
565 observe a plasmid with high homology to the KY798506 reference plasmid that is known to carry this  
566 carbapenemase gene. Whilst the presence of this plasmid might potentially increase the risk of the  
567 acquisition and spread of *bla*<sub>KPC-2</sub> within this population it is currently not possible to speculate  
568 further on the public health relevance of this finding. The second ESBL-plasmid in multiple species is  
569 a JX424423(pKDO1)-like plasmid, which carries a *bla*<sub>CTX-M-15</sub> gene in a *Kpne* ST983 isolates and *Kpla*  
570 isolate 6Rf. In the latter case, this plasmid also harbours an additional 10 resistance genes and co-  
571 resides in isolate 6Rf with the pOXA-48-like plasmid. Thus both *Korn* and *Kpla* isolates can harbour  
572 multidrug resistance plasmids in the environment, and improved diagnostics are required to  
573 improve the reporting of serious infections caused by these species [44, 45].

574 The *bla*<sub>CTX-M-15</sub> gene is found associated with other plasmids in different *Kpne* isolates, including two  
575 highly related isolates of *Kpne* ST35 (7SI and River\_C) isolated from the WWTP and river respectively  
576 (supplementary note 3). This finding suggests that this clinically relevant clone, which also harbours  
577 a *yersiniabactin* virulence locus in our data, is circulating within the wider environment. The *bla*<sub>CTX-M-15</sub>  
578 gene is also associated with all nine isolates of *Kpne* ST983. This clone is associated with a suite of

579 linked resistance genes, including *bla*<sub>CTX-M-15</sub>, that co-mobilise between the different plasmids  
580 associated with this clone. Comparison with published data from an ST983 isolate from South Africa  
581 [13] suggests this association is stable on a global scale (Figure S14; supplementary note 2). This  
582 observation highlights that epidemiological surveillance should not only incorporate strains and  
583 plasmids, but should also consider mobile transposable elements that can independently transfer  
584 between them. Plasmid-borne transposons harbouring resistance genes have been noted to exhibit  
585 varying degrees of autonomy in *Kpne* [42], suggesting that the epidemiologically most relevant unit  
586 of mobility will vary between different species, strains, plasmids and resistance genes [46].

587 Although plasmids can be maintained even in the absence of the relevant antibiotics[47], the key  
588 observation that plasmid-borne resistance genes are enriched in the hospital wastewater sample  
589 points to selection pressures resulting from antibiotic exposure. However, it is unclear as to where  
590 this selection is predominantly operating. There have been a number of studies comparing  
591 wastewater and local clinical samples, and it is reasonably assumed that the microbial composition  
592 of hospital wastewater closely mirrors that of the hospital itself [14, 48-50]. However, an alternative  
593 is that resistance is both acquired and maintained directly within drain-associated biofilms, possibly  
594 driven by sub-lethal concentrations of antibiotics in these environments. In the absence of  
595 comparative data from the hospital itself, or on the concentration of carbapenems and other beta-  
596 lactam antibiotics within the wastewater, it is currently not possible to argue strongly in favour of  
597 one scenario over the other. Parallel sampling of hospital wastewater and patients over time would  
598 help to resolve this question.

599 This study has important practical implications regarding the public-health impact of *Klebsiella*  
600 species other than *Kpne*, and in particular *Korn* and other species corresponding to the *Raoultella*  
601 group. These species pose a risk both as emerging pathogens [45], but also as a potential reservoir  
602 for resistance determinants that can be readily transferred between species [51]. There are  
603 numerous reports of species of the *Raoultella* group harbouring carbapenemase genes, including  
604 those encoding OXA-48-like, VIM, KPC and NDM type enzymes in health-care, community and  
605 environmental settings [52-54]. Moreover, *bla*<sub>OXA-48</sub> specifically has been recognised as an increasing  
606 problem in the UK [55] and a major cause of hospital outbreaks [56, 57]. *Korn* isolates harbouring a  
607 pOXA-48 like plasmid have been previously reported from wastewater in the UK [14], although it is  
608 not possible to show that these plasmids are epidemiologically linked to those in the current study.

609 The pathogenic potential of *Korn*, and the putative virulence factors in this species, have not been  
610 widely studied. Our data confirm the presence of a chromosomally encoded yersiniabactin (*ybt*)  
611 locus, which is a major virulence factor for pulmonary infection in *Kpne* [58]. In *Kpne*, the *ybt* locus is  
612 typically located within an integrative conjugative element (ICE*Kp*). In contrast, in *Korn* the *ybt* locus  
613 is located in the chromosome next to a tRNA-*Asn* site but with no identifiable integrase gene [59].  
614 We show that the *Korn ybt* variant is phylogenetically distinct, but its role in the virulence of this  
615 species is yet to be determined. Additionally, we also found a homologue of the *astA* gene  
616 embedded in an IS256-family transposon in 3 *Korn* isolates, two of which also contain the pOXA-48-  
617 like plasmid and the pKpQIL-like plasmid that commonly carries *bla*<sub>KPC-2</sub>. The *astA* gene encodes for a  
618 heat-stable enterotoxin 1 (EAST1) in *E. coli* (usually EAEC or ETEC; [60]) and it has been described in  
619 enteropathogenic *Kpne* [61]. However, to the best of our knowledge, it has never been found in *Korn*  
620 (supplementary note 3). The relevance of this gene for the pathogenicity of *Korn* also remains to be  
621 elucidated, but it further raises its pathogenic potential.

622 In conclusion, our data reveal a high abundance of a pOXA-48-like plasmid in hospital wastewater in  
623 multiple *Klebsiella* species, and in particular within *Korn*. This plasmid was detected at a much lower

624 frequency in the influent to the WWTP serving the hospital. These data warrant close surveillance  
625 both of this plasmid and of *Korn* and related species.

626

### 627 **Authors and contributors**

628 EJF and BKH conceived the study. MJG and NC carried out the bioinformatics analyses, with input  
629 from HAT, JC and SD. Sampling was carried out by KJ, AK and DK with logistical support from RB, RS  
630 and TC. The microbiology was carried out by MJG, and the sequencing was managed by MJG, with  
631 additional data supplied by SH. The paper was written by EJF, MJG, NC, MBA, BKH, SD, HAT and JC.

### 632 **Conflicts of interest**

633 No conflicts of interest to declare.

### 634 **Funding information**

635 EJF, MJG, NC, PD and MA are funded by MRC project awarded to MA (OH-DART MR/S004769/1). EJF,  
636 HAT and JC are funded by JPI-AMR project SpARK awarded to EJF (MR/R00241X/1). SH is funded by  
637 the Schlumberger Foundation. BKH is funded by Wessex Water and EPSRC IAA (grant no.  
638 EP/R51164X/1) and NERC (grant no. 2109393).

650

651 Figure 1. Approximate maximum likelihood phylogenetic tree of the 95 isolates analysed in this study  
652 constructed using an alignment of 184,671 core SNPs. Species, source of each isolate and presence  
653 of carbapenemase resistance gene *bla*<sub>OXA-48</sub> are indicated. The tree and all metadata discussed can  
654 be accessed at <https://microreact.org/project/Wastewater>

655 Figure 2. Comparison of number of resistance genes identified using Abricate with the Resfinder  
656 database from the hospital wastewater and WWTP influent in (A) all isolates and (B) *Kpne* only.

657 Figure 3. Approximate maximum likelihood phylogenetic tree of the 59 *Kpne* isolates in this study  
658 isolated from the hospital wastewater, the WWTP influent and the river. The presence of plasmids  
659 identified by MOB-suite and listed by accession number, and of resistance genes identified using  
660 Abricate with the ResFinder database, are shown. STs are indicated. Only plasmids associated with  
661 resistance genes are included. The *Kpne* isolates 7Rg and 8Rg carry the pOXA-48 plasmid and are  
662 marked with a red asterisk.

663 Figure 4. Alignment of pOXA-48 ([17]; accession JN626286) and representative contigs from our  
664 isolates harbouring *bla*<sub>OXA-48</sub>. Arrows represent ORFs; *bla*<sub>OXA-48</sub> is shown in green and insertion  
665 sequences in red.

666 Figure 5. Simplified hierarchical clustering of predicted plasmid, resistance genes and replicon types  
667 in 95 isolates. Green refers to absence and pink to presence. For the complete hierarchical clustering  
668 see Figure S3.

669 Figure 6. Approximate maximum likelihood phylogenetic tree of the 25 *Korn* isolates in this study  
670 isolated from the hospital wastewater and WWTP influent. The presence of plasmids identified by  
671 MOB-suite and listed by accession number, and of resistance genes identified using Abricate with  
672 the ResFinder database, are shown. Plasmids associated with resistance genes are marked with an  
673 asterisk.

674 Figure 7. Frequency of resistance genes identified as (A) plasmid-borne and (B) chromosomal in  
675 isolates from the hospital wastewater and WWTP influent. Contigs harbouring resistance genes were  
676 characterised as plasmid or chromosomal using MOB-suite and mlplasmids; plasmid numbers  
677 assigned by MOB-suite were used to determine number of plasmids per isolate.

**Supplementary note 1 - Analysing the data via the microreact project at:**

<https://microreact.org/project/Wastewater>

Columns B - CX include output from Kleborate v0.4.0-beta, including species, MLST, virulence loci and antimicrobial resistance genes. Column CY lists the number of resistance genes identified in the isolates using Abricate v0.9.8 with the ResFinder database (downloaded 29 April 2020) using the threshold of >80 % nucleotide identity and coverage. The locations of these genes are detailed in columns CZ - FE, using output from MOB-suite and mlplasmids v1.0.0; 'chromosomal', 'ambiguous' (MOB-suite and mlplasmids predictions were discordant) or plasmid (when MOB-suite and mlplasmids both called 'plasmid', the accession number returned by MOB-suite is shown, or unknown in the case of novel plasmids). Columns FF - GE show replicon types identified using Abricate with the PlasmidFinder database (downloaded 13 Jan 2020) with a threshold of >80 % nucleotide identity and coverage. Columns GF - JG are presence ('1')/ absence ('-') of plasmids identified by MOB-suite identified by accession number (as above). Columns JH and JI show the number of virulence factors identified using Abricate with the virulence factors database (downloaded 19 April 2020) with thresholds of both >80 and >40 % nucleotide identity and coverage respectively. Columns JJ - NG show the presence of these virulence factors in the isolates as identified using thresholds of >40 % ('40') or >80 % ('80') nucleotide identity and coverage. Detailed instructions on how to use microreact are available at <https://microreact.org/instructions>.

**Supplementary note 2 - linked resistance genes on multiple plasmids in *Kpne* ST983**

In all nine ST983 isolates, the resistance genes *bla*<sub>CTX-M-15</sub>, *bla*<sub>TEM-1B</sub>, *aph(3'')*-*lb*, *sul2* and *aph(6)*-*ld* genes are on homologous contigs of 9 - 14 kb, which also harbour genes for IS1380 family transposase *ISEcp1* and transposon Tn3 resolvase. In the longer contigs these are flanked by an IS110 family transposase IS5075 and Tn3 family transposase Tn2. The resistance genes *aac(6')*-*lb-cr* and *bla*<sub>OXA-1</sub> are on another homologous contig with a gene encoding chloramphenicol acetyltransferase in all isolates, and also carries *dfrA14* in one isolate (5Rd). Resistance gene *aac(3)*-*IIa* is on a homologous contig in eight of the isolates, with an IS3 family transposase IS*Kpn11* and *tmrB* which encodes a tunicamycin resistance protein. Similarly, *dfrA14* is on a homologous contig in these eight isolates, alongside an IS6 family transposase IS6100 and flanked in the longer contigs by IS6 family transposase IS26. When aligned to CP021953 and JX424423, two of the resistance plasmids predicted by MOB-suite to harbour all of these resistance genes in four of these isolates, all of the contigs from all of the ST983 isolates align to the plasmid over an approximately 30 kb region, interspersed with insertion sequences (data not shown). These arrangements likely explain the mobility of these resistance genes. The ST983 isolates in a previous study from South Africa [1] show a similar profile of resistance genes with those in the present study (*aph(6')*-*ld*, *aph(3'')*-*lb*, *bla*<sub>TEM-1B</sub>, *bla*<sub>SHV-38</sub>, *bla*<sub>SHV-168</sub>, *bla*<sub>CTX-M-15</sub>, *qnrB6*, *oqxA*, *oqxB*, *fosA*, *sul2*, *tet(A)*, *tet(C)*, *dfrA14*, *qnrB1*). Phylogenetic analysis confirmed the close relatedness between the ST983 reported from South Africa and those in the current study (Figure S14).

### Supplementary note 3 – Other *Kpne* lineages

*Kpne* ST35 is a global multidrug-resistant clone [1]. Two isolates of ST35 were recovered from the WWTP (7Sl, 8Sd) and one from the river (River\_C). These two isolates have identical plasmid and resistance gene profiles, and differ by 80 core SNPs over the alignment of 5,100,720 nucleotides. Both isolates harbour a single NC\_021231\_00058-like plasmid, which contains 6 resistance genes (*aac(3′)-IIa*, *aac(6′)-Ib-cr*, *bla<sub>OXA-1</sub>*, *bla<sub>CTX-M-15</sub>*, *dfrA14* and *qnrB1*; Figure 3), possess the same two replicon types (IncFII\_1\_pKP91 and IncFIB(K)\_Kpn3; Figure S12), the same four chromosomal resistance genes *oqxA*, *oqxB*, *fosA6* and *bla<sub>SHV-33</sub>* (Figure 3) and the virulence factor yersiniabactin (type ybt9; ICEKp3; as discussed below). The high identity between these two isolates is striking, given that one isolate was from the WWTP influent, and the other sampled directly from the river approximately 8 km upstream from the WWTP and 3 months earlier. This suggests that this multidrug-resistant clone is stable and relatively abundant in the local aquatic environment. The third ST35 isolate, 8Sd from the WWTP, is slightly divergent on the tree and exhibits a different plasmid and resistance gene profile.

*Kpne* ST13 is also a globally disseminated clone of clinical importance [2, 3, 4, 5]. This ST was represented by 3 hospital wastewater isolates, each of which contains two plasmids, a CP000823-like plasmid (which does not carry any resistance genes) and a CP021856(tig00000001\_pilon)-like plasmid, which harbours *ant(3′′)-Ia*, *dfrA1* and *sul1*. All three ST13 isolates possess the chromosomal resistance genes *oqxA*, *oqxB*, *fosA6* and *bla<sub>SHV-101</sub>*. Similarly, ST17 has been detected from global sources and is known to harbour multiple resistance genes [6, 7]. ST17 was also represented by 3 hospital isolates which show more heterogeneous plasmid and resistance profiles; a total of 5 plasmids were detected within these 3 isolates, but 4 of these were only present in only one isolate. Only a single plasmid-borne resistance gene was detected in ST17, *tet(D)*, but 7 chromosomal genes were noted. Finally, ST584 was assigned to three isolates from the WWTP sample. One of these isolates, 5Sf, harbours 5 plasmids including a JX843238(pTOR\_02)-like plasmid [8] that carries *catA1* encoding resistance to chloramphenicol (the only unambiguous example of the presence of this gene on a plasmid in our data) and *sul1* genes. ST584 is not recognised as clinically significant, and is most notable for being recovered at high prevalence from wild boar and barbary macaques in Algeria [9].

**Figure S1.** Approximate maximum likelihood phylogenetic tree (midpoint rooted) of the 95 isolates analysed in this study constructed using an alignment of 184,671 core SNPs. Species and source of each isolate are indicated, with the location of resistance genes identified using Abricate with the Resfinder database. Contigs harbouring the resistance genes were classified as chromosomal or plasmid using MOB-suite and mPlasmids; contigs classified as plasmid by one method and chromosomal by another are marked as ‘ambiguous’. Where both methods assigned a contig to plasmid origin, the accession number of the plasmid as reported by MOB-suite is shown. Contigs assigned as plasmids but without a match to the database are assigned as “unknown”.

### Distribution of Resistance Genes Between Species

**Figure S2.** Distribution of resistance genes identified using Abricate with the Resfinder database between *Korn* and *Kpne*; not significantly different by a Wilcoxon test ( $p = 0.059$ ).

Figure S3. Complete hierarchical clustering analysis (ward.D2) of predicted plasmids, resistance genes and replicon types in 95 isolates. Green refers to absence and pink to presence.

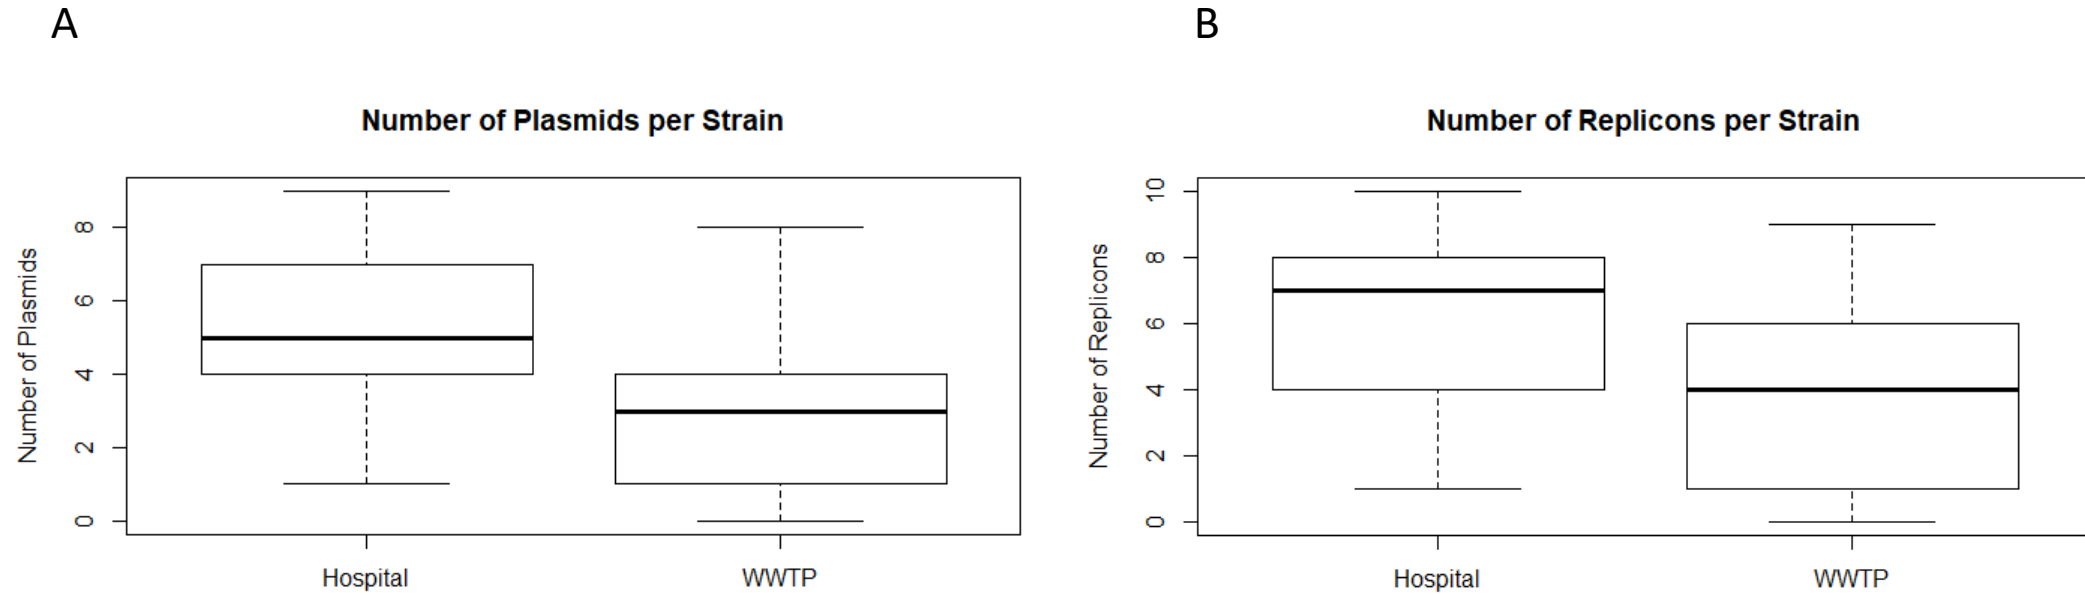

**Figure S5.** Approximate maximum likelihood phylogenetic tree (midpoint rooted) of the 95 isolates analysed in this study constructed using an alignment of 184,671 core SNPs. Species, source of each isolate and presence of plasmids identified using MOB-suite are indicated. A red asterisk indicates plasmids associated with resistance genes.

**Figure S6.** Approximate maximum likelihood phylogenetic tree (midpoint rooted) of the 95 isolates analysed in this study constructed using an alignment of 184,671 core SNPs. Species, source of each isolate and presence of replicon types identified using Abricate with the PlasmidFinder database are indicated.

**Figure S7.** Comparison of isolates from hospital drain and WWTP influent. (A) Number of plasmids as determined using MOB-suite; those that also not confirmed as plasmid by mlplasmids were classed as ambiguous, (B) number of replicon types identified by Abricate using the PlasmidFinder database. Wilcoxon test shows a significant difference in both cases.

**Figure S8.** Approximate maximum likelihood phylogenetic tree (midpoint rooted) of the 25 *Korn* isolates in this study isolated from the hospital drain and WWTP influent showing the presence of replicon types identified using Abricate with the PlasmidFinder database.

**Figure S9.** Approximate maximum likelihood phylogenetic tree (midpoint rooted) of the 25 *Korn* isolates from this study with isolates from WWTP in the East of England (n=2; Ludden *et al.*, 2017) and unpublished sequences of isolates from Italy (n=25) and Pakistan (n=5). Isolates were aligned to SPARK\_1625\_C1 from Italy; the tree was constructed using an alignment of 6,004,523 core SNPs. The source of each isolate is indicated.

**Figure S10.** Alignment of the GU595196 and KY798506 reference plasmids with the contigs identified in our data as KY798506-like. In red are the *bla*<sub>KPC</sub> genes, in grey the *bla*<sub>TEM</sub> and in blue the *bla*<sub>SHV</sub>.

**Figure S11.** Approximate maximum likelihood phylogenetic tree (midpoint rooted) of the 59 *Kpne* isolates in this study isolated from the hospital wastewater, WWTP influent and river showing ST and the presence of plasmids as identified by MOB-suite. Contigs were also analysed using miplasmids and any that were not identified as plasmid by both methods were omitted from this data. Plasmids associated with resistance genes are marked with a red asterisk.

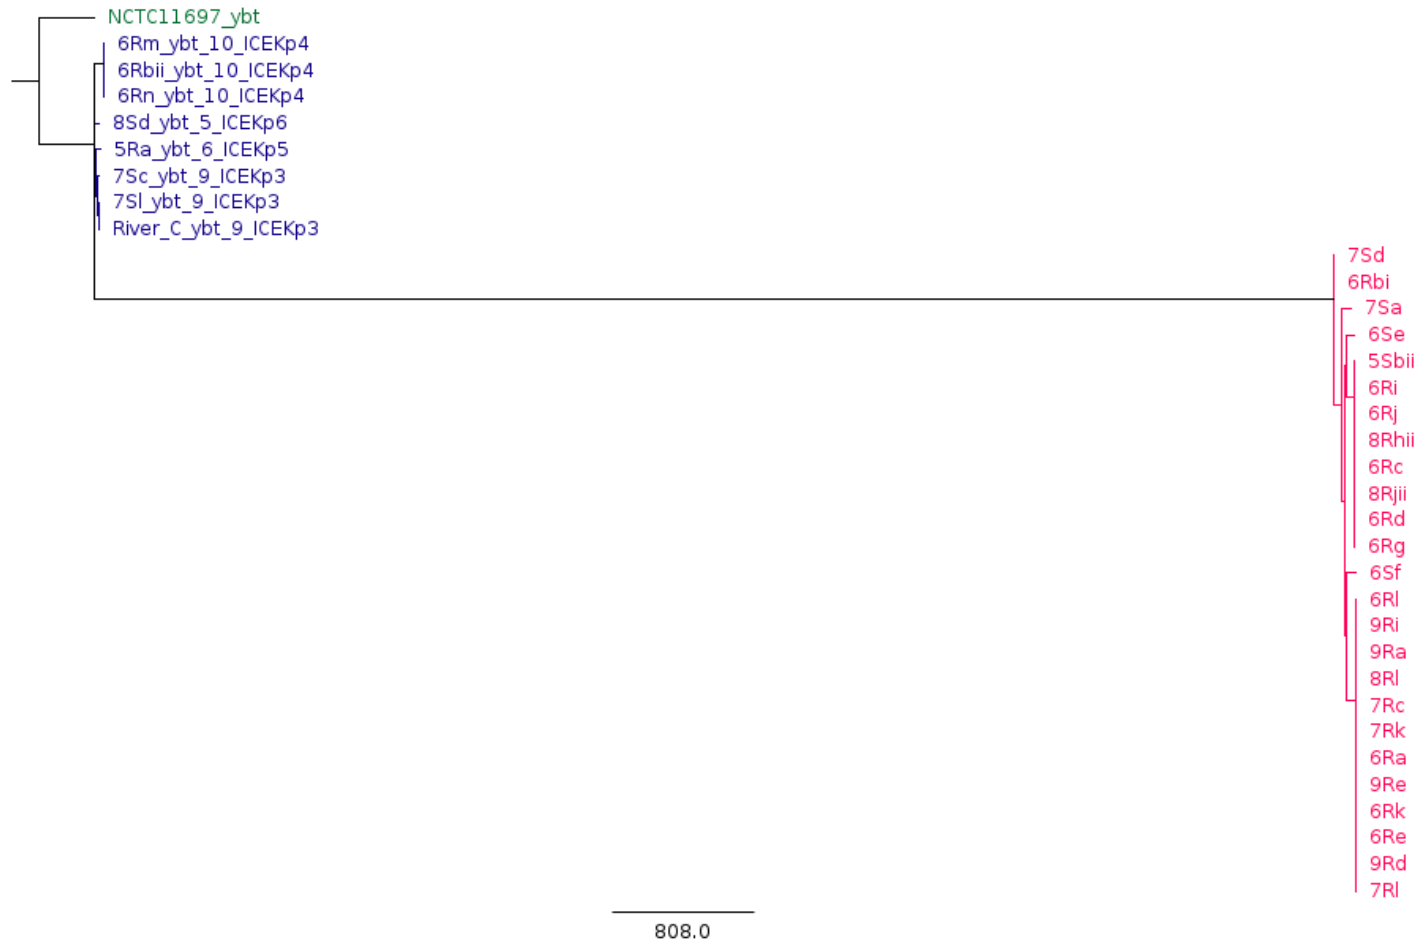

**Figure S12.** Approximate maximum likelihood phylogenetic tree (midpoint rooted) of the 59 *Kpne* isolates in this study isolated from the hospital drain, WWTP influent and river showing ST and the presence of replicon types identified using Abricate with the PlasmidFinder database.

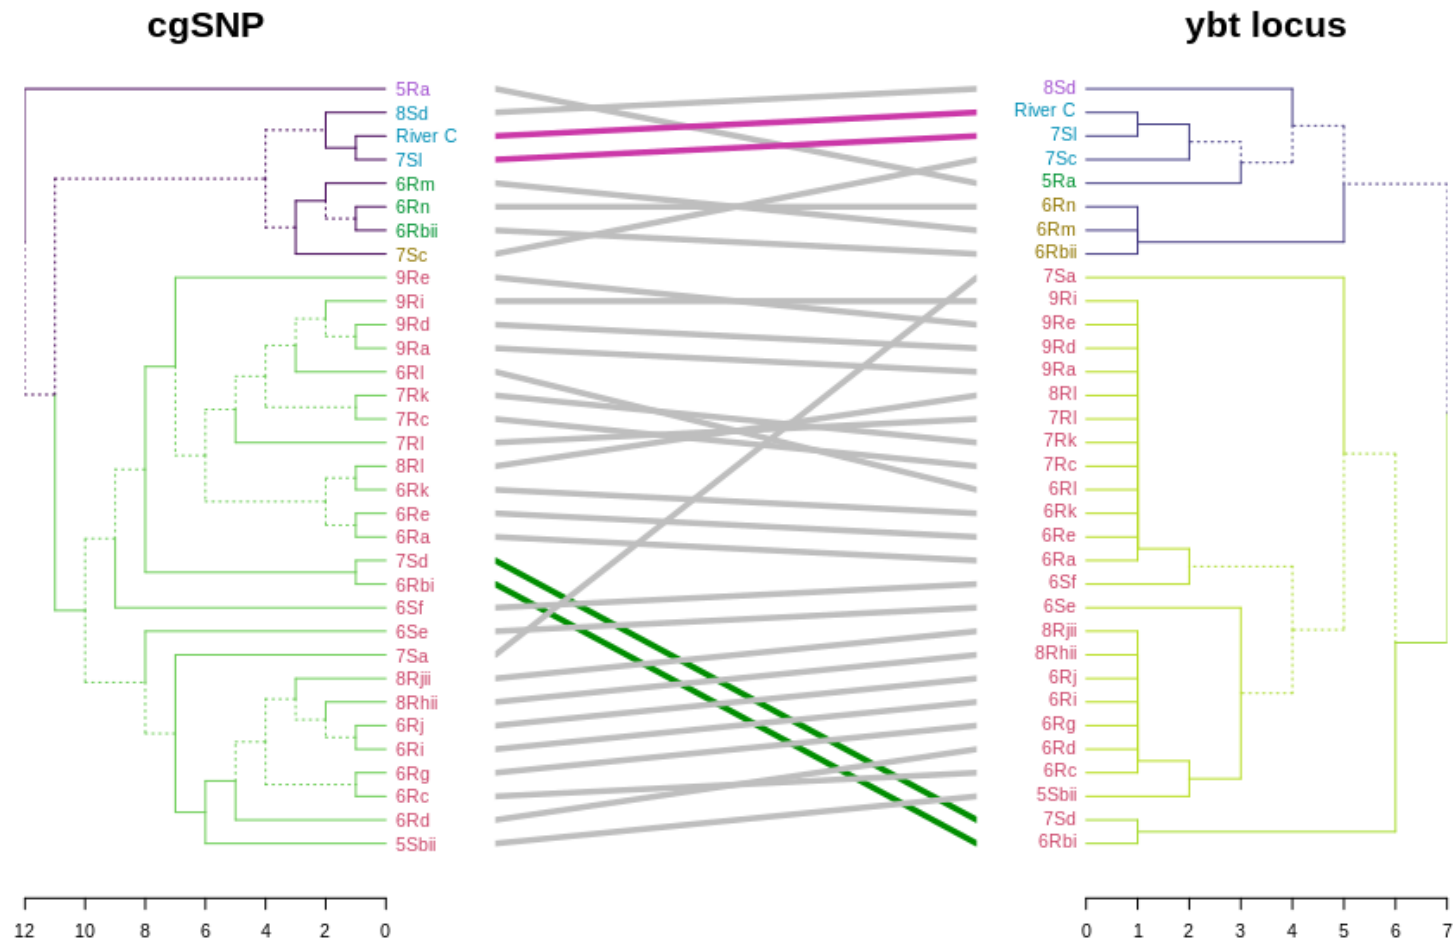

**Figure S13.** Approximate maximum likelihood phylogenetic tree (midpoint rooted) of the 9 *Kpne* ST983 isolates in this study isolated from the hospital drain and WWTP influent. The presence of plasmids identified using MOB-suite and mlplasmids, listed by accession number, is shown. The location of resistance genes (plasmid accession number / chromosomal / ambiguous) is shown; ambiguous was assigned to contigs when results from MOB-suite and mlplasmids did not agree. Plasmids associated with resistance genes are marked with an asterisk.

**Figure S14.** Approximate maximum likelihood phylogenetic tree (midpoint rooted) of the 59 *Kpne* isolates in this study with ED01500733 (ST983) from South Africa (accession number NZ\_POWS00000000.1). The South African ST983 isolate differed from the ST983 isolates in the current study by between 180 and 208 core SNPs.

**Figure S15.** Phylogenetic reconstruction of the *ybt* locus identified in our samples (n=33). Blue leaves correspond to *Kpne* isolates and pink to *Korn*.

**Figure S16.** Tanglegram linking the phylogenetic trees constructed using SNPs in the core genome (Left) and the *ybt* locus (Right). Both trees are midpoint rooted and include 33 isolates. The purple branches include *Kpne* *ybt*-positive isolates, while the green branches include *Korn* *ybt*-positive isolates. Lines have been drawn between tips in the trees representing the same isolate, while the tree branches were sorted to minimize the number of overlapping lines required. The lines are coloured by the leaves that are common in subtrees of both trees. The lines of the leaves that are not common in subtrees of both trees were left in grey. The leaves are coloured according to the maximum number of matching clusters the trees contain ( $k=5$ ).
