## Statement of Copyright

The copyright of this thesis rests with the author. No quotation from it should be published without his written consent and information derived from it should be acknowledged.

## Declaration

The work described in this thesis was carried out in the Department of Chemistry at the University of Durham between October 1998 and September 01. All the work was carried out by the author unless otherwise stated, and has not previously been submitted for a degree at this or any other university.

## ACKNOWLEDMENTS

I would like to express my heartfelt thanks to the people who have been involved in the completion of this work.

Firstly, I would like to thank my supervisor Prof. Martin Bryce for his help, his constant encouragements and for giving me the opportunity to come and work in Durham.

Prof. Dominique Lorcy, who wisely advised me to join Martin Bryce's group.
Dr. Slimane Dahaoui and Dr. Andrei Batsanov for performing the X-ray crystallographic analyses. Dr. Paul Hazendonk for the NMR study performed at various temperatures. Prof. Alan Kenwright, Ian McKeag, and Catherine Heffernan for their useful help on NMR spectroscopy matters. Dr. Mike Jones and Lara Turner for Mass spectroscopy service, and Jarka Dostal for elemental analyses.

Dr. Dmitrii Perepichka for his precious computer skills and his help in modelling studies and Dr. Thierry Le Gall for his advice in electrochemistry studies.

Thanks to the University of Durham and I.C.I for financial support.

Finally, thanks to my family for their support over the years.

## ABSTRACT

# Anthracenediylidene Derivatives: Control of Molecular and Supramolecular Architecture 

Nicolas Denis Jean-Michel GODBERT

University of Durham (October 2001)

In the context of new $\pi$-donor molecules, extended tetrathiafulvalenes have been widely studies for their use as components of electronically conductive charge-transfer materials. In contrast with the planar $\pi$-systems, we have focused our attention on extended tetrathiafulvalenes containing a conjugated anthracenyl spacer (anthracenediylidene derivatives). These TTF derivatives adopt a saddle-shaped conformation in the neutral state and a drastic change of conformation occurs upon oxidation to the dication species. Our main objective was to investigate the molecular and supramolecular architecture of these compounds. At the molecular scale, we synthesised cyclophanes by bridging the preformed anthracene tetrathiafulvalene system and studied their redox properties and crystal packing. We developed the chemistry of anthracenediylidene derivatives in order to direct the supramolecular architecture by secondary interactions (hydrogen-bonding, $\pi-\pi$ stacking). Finally, we also investigated the incorporation of anthracenediylidene units inside dendritic structures in order to study the highly charged species formed upon oxidation.

## INTRODUCTION

## \&

## BIBLIOGRAPHIC BACKGROUND

### 1.1 Tetrathiafulvalene: Description and Properties.

During the last thirty years, the $\pi$-electron donor molecule tetrathiafulvalene (TTF) and its derivatives have been central to the development of organic metals and organic superconductors. It was in 1970 that Wudl et al. ${ }^{1}$ reported the synthesis of TTF (1) for the first time.

1

TTF is a non-aromatic, planar molecule with $14 \pi$ electrons. The oxidation of TTF occurs sequentially in two reversible steps, forming first at low potential the radical cation species which can be further oxidised into the dication species $\left(\mathrm{E}_{1}^{1 / 2}=0.34 \mathrm{~V} ; \mathrm{E}_{2}^{1 / 2}=0.78 \mathrm{~V}\right.$ vs. $\mathrm{Ag} / \mathrm{AgCl}$ in acetonitrile (Figure 1.1).

Potential, V
Figure 1.1. Cyclic voltammogram of $\operatorname{TTF}(1)$ in acetonitrile vs. $\mathrm{Ag} / \mathrm{AgCl}$.

The TTF cation radical and dication species are thermodynamically very stable due to a contribution from $6 \pi$ electron heteroaromaticity of the 1,3-dithiolium ring (Figure 1.2). By treating a carbon tetrachloride solution of TTF with one equivalent of chlorine gas, the formation of a stable purple radical cation can be observed. An excess of chlorine yields the stable yellow dication.

Non-Aromatic Aromatic Non-Aromatic Aromatic Aromatic
Figure 1.2. Stabilisation of TTF radical cation and dication species.

In 1973, the first "organic metal" tetrathiafulvalene-tetracyano-p-quinodinemethane (TTF-TCNQ) was discovered. ${ }^{2,3}$ This crystalline material is composed of segregated stacks of $\pi$-donor TTF (1) and $\pi$-acceptor TCNQ.(2). TCNQ can be reduced sequentially in two reversible steps to give first the radical anion and then the dianion. The short interplanar distances which allow significant interactions between $\pi$-molecular orbitals of neighbours and a partial charge-transfer from donor to acceptor result in a highly anisotropic conductivity along the stacking axis (Figure 1.3). The degree of charge transfer is partial $\delta=0.59$, calculated by diffuse X-ray scattering techniques and infrared spectroscopy ( $\delta=0$, corresponds to a neutral complex, $\delta=1$ corresponds to a ionic complex where the charge transfer is total). The conductivity is, therefore, due to the presence of mixed valence species inside the crystalline structure, neutral species of the donor TTF (D), of the
acceptor TCNQ (A), radical cation species of TTF ( $\mathrm{D}^{+\bullet}$ ) and radical anion species of $\operatorname{TCNQ}\left(\mathrm{A}^{-\bullet}\right)$.

Figure 1.3. X-Ray crystal structure of the first organic metal TTF-TCNQ.

Since the discovery of this organic metal, a large amount of work has been carried out in order to improve the conductivities of salts and charge transfer complexes (CT) of TTF derivatives. However, interest in TTF goes beyond the field of conducting materials to include its role as an important building block in supramolecular chemistry (oligomers, polymers, or dendrimers), crystal engineering (ferromagnets, intramolecular donoracceptor systems or molecular switches), non linear optics studies (in association with fullerene core and electron-withdrawing substituents), liquid crystalline materials and Langmuir-Blodgett (LB) films. Thus, during the last ten years, many aspects of the synthesis and properties of tetrathiafulvalenes have been reviewed (Table 1.1).

### 1.2 Towards Increasing Dimensionality.

A key factor that has challenged many synthetic chemists is an increase in the dimensionality of the material. ${ }^{6}$ Several approaches have been extensively considered and can be classified in three categories.

### 1.2.1 Introduction of Selenium or Tellurium Atoms.

By replacing sulfur atoms of TTF by chalcogens with more diffuse orbitals like selenium or tellurium, the intermolecular $\pi$ molecular orbital overlap has been improved. Both tetraselenafulvalene (TSF) and tetratellurafulvalene (TTeF) form charge transfer complexes with TCNQ of higher conductivity ( $800 \mathrm{~S} \mathrm{~cm}^{-1}$ and $1200 \mathrm{~S} \mathrm{~cm}^{-1}$, respectively) than the complex TTF-TCNQ $\left(500 \mathrm{~S} \mathrm{~cm}^{-1}\right) .{ }^{22}$ An illustration of this strategy is the first organic superconductor (TMTSF) ${ }_{2} \mathrm{PF}_{6}$ reported in 1981 by Bechgaard et al. ${ }^{23}$ The overlap of selenium $\pi$-orbitals along the stacks allows conduction with a band width of $c a .1 \mathrm{eV}$. (Figure 1.4)
 3 (TSF)

4 (TTeF)

5 (TMTSF)

Figure 1.4. X -Ray crystal structure of $(\mathrm{TMTSF})_{2}{ }^{+\bullet} \mathrm{PF}_{6}{ }^{-}$.

### 1.2.2 Addition of Functionality.

The introduction of electron donating substituents such as alkylthio groups raise the highest occupied molecular orbital (HOMO) energy levels of the resultant system. This approach led to the syntheses of salts of BEDT-TTF (6), for which a record of superconductivity up to $c a .12 \mathrm{~K}$ at ambient pressure was obtained [eg. (BEDTTTF $\left.)_{2} \mathrm{Cu}\left[\mathrm{N}(\mathrm{CN})_{2}\right] \mathrm{Br}\right] .{ }^{24,25}$

6 (BEDT-TTF)

Also the introduction of other functional groups around the TTF core has been widely studied, mainly for the purpose of increasing crystal order (by $\pi$ - $\pi$-interactions of aryl groups or hydrogen bonds of hydroxyl or amino derivatives for example) and improving the conductivity of obtained salts. The chemistry of TTF is now well developed by adding functional groups before coupling the two 1,3-dithiole units, or after coupling, by lithiation and trapping of the lithiated species of TTF. 8,26

### 1.2.3 Spatial Expansion.

The spatial extension of the donor molecule can be achieved by replacing the central double bond by a conjugated spacer, which will stabilize multicationic states (by minimizing Coulombic repulsion between the positively charged 1,3-dithiolium rings), and may also enhance intermolecular and interstack interactions. In this area, a multitude of systems have been studied throughout the last thirty years. Widely studied systems are those which are elongated by conjugated double bonds (7, 8), ${ }^{27,28}$ the incorporation of
heterocycles $(9,10),{ }^{29-32}$ and possess larger quinonoidal cores (11-15). ${ }^{33-36}$ All these $\pi$ extended tetrathiafulvalenes present different properties and offer a wide variety of $\pi$ donors for the construction of new organic materials.

12

$13 R_{1}=H, M e, S M e$

A recent strategy for increasing the dimensionality involves the synthesis of nonplanar TTF derivatives. To attain efficient intermolecular interactions and optimum stackings to form conducting CT complexes, the general trend was to design planar TTF analogues. However, the study of non-planar TTF derivatives is in constant progress and some CT complexes of them present comparable conductivity to CT complexes derived from related planar molecules. ${ }^{37}$ Moreover, upon oxidation a remarkable change of conformation can occur leading to a completely different structure for the charged species compared with its neutral form. It is in this context that 9,10-bis-(1,3-dithiol-2-ylidene)-9,10-dihydroanthracene derivatives (anthracene-TTF or anthracenediylidene derivatives)
(13) first attracted our attention. Derivatives of 13 have been widely studied in our group due to their unusual redox and structural properties.

### 1.3 Anthracenediylidene Derivatives.

### 1.3.1 Synthesis of Anthracene-TTF Derivatives.

The first anthracenediylidene derivative, namely 9,10-bis-(1,3-benzodithiol-2-ylidene)-9,10-dihydroanthracene (17) was synthesised by Akiba et al. ${ }^{38}$ using a double Horner-Wadsworth-Emmons reaction of the phosphonate ester reagent 16 with anthraquinone in $78 \%$ yield (Scheme 1.1).

Scheme 1.1. Synthesis of dibenzo-anthracene-TTF (17).

Following this scheme, using appropriate phosphonate reagents, symmetrical anthracenediylidene have been synthesised in order to form charge transfer complexes (18a-c $)^{36,39,40}$ and study the electrochemistry by increasing the solubility of the system $(19,20) .{ }^{41,42}$

18 a R = H
b $R=M e$
c $\mathrm{R}=\mathrm{SMe}$

Unsymmetrical derivatives have been synthesised following a two step methodology ${ }^{41,43}$. First, the reaction of anthrone (21) with 1,3 -dithiolium cations (22a,b) afforded quinones 23a,b. A Horner-Wadsworth-Emmons reaction using phosphonates 24a-d on these quinones, allowed then the formation of unsymmetrical anthracenediylidenes 25a-d (Scheme 1.2).

$$
\begin{aligned}
& \text { i) } \mathrm{nBuLi} \text { or } \mathrm{LDA}
\end{aligned}
$$

Scheme 1.2. Synthesis of unsymmetrical anthracene-TTF derivatives.

With the aim of using anthracenediylidene systems as building blocks in materials and supramolecular chemistry, functionalisation was performed using lithiation and trapping of the resulting lithiated species with selected electrophiles. To circumvent a problem of precipitation of the lithiated species at low temperature, and to ensure that monolithiation occured, the trimethyl derivative (25b) was considered as the best solution ${ }^{41}$ (Scheme 1.3). Using methylchloroformate as a trapping agent proved to be a very efficient way to obtain the methylester derivative 26 ( $83 \%$ yield). Sulfur insertion followed by addition of benzoyl chloride, gave the thioester derivative 27 ( $53 \%$ yield) which is a convenient precursor of other mono-functionalised derivatives $(30,31)$.

Scheme 1.3. Synthesis of mono-functionalised anthracene-TTF derivatives.

### 1.3.2 Molecular Structure of Anthracenediylidene System.

### 1.3.2.1 Neutral State.

The crystal structure of the tetramethyl derivative 18b, reported by Bryce et al. revealed for the first time, the saddle shaped conformation of the anthracene-TTF system ${ }^{45}$ (Figure 1.5a). The central quinonoid ring is severely distorted into a boat conformation.

Theoretical calculations have been performed on this system by Martín, Ortí et al. establishing that steric hindrance between the sulfur atoms and the hydrogen atoms in peri-
positions of the anthraquinoid system causes the molecule to adopt this saddle shaped conformation. ${ }^{35}$
.Thus, derivatives such as 12 in which the repulsive $\mathrm{S} \cdots \mathrm{H}$ contacts are replaced by attractive $\mathrm{N} \cdots \mathrm{S}$ contacts, have been studied by Yamashita et al and are completely planar, as. expected ${ }^{44}$ (Figure 1.5b). Although the conductivity for such compounds is relatively high at room temperature as a single component $\left(3.7 \times 10^{-3} \mathrm{~S} \mathrm{~cm}^{-1}\right)$, no organic metals or CT complexes have been reported, probably for solubility reasons.

(a)

(b)

Figure 1.5. X-ray crystal structures of $\mathbf{1 8 b}$ (a) and 12 (b).

The typical crystal packing of the neutral form of anthracene-TTFs is shown by the methylester derivative 26, where dimers are formed (Figure 1.6). The 1,3-dithiole moieties contact face to face at the usual van der Waals distances. Solvent molecules can occupy cavities between the pairs. Therefore, the dithiole-dithiole interactions preclude efficient extended stacking in the crystal. ${ }^{41}$

Figure 1.6. Crystal packing of $\mathbf{2 6}$ as $\mathrm{CDCl}_{3}$ solvate.

### 1.3.2.2 Dicationic State.

The oxidation of anthracenediylidene derivatives occurs in a single two-electron wave leading to the formation of a thermodynamically stable dication $\left(\mathrm{E}^{0 \mathrm{x}} c a .0 .3 \mathrm{~V}\right.$ vs. $\mathrm{Ag} / \mathrm{AgCl}$ in acetonitrile). During oxidation a dramatic change of conformation of the molecule takes place. The saddle shape of the neutral anthracenediylidene derivative is flattened, the central anthracene ring becomes planar and aromatic whilst the two 1,3dithiolium rings twist orthogonally to this plane (Figure 1.7b).

(a)

(b)

(c)

Figure 1.7. Crystal Structure of $\mathbf{1 8 b}^{\mathbf{2 +}}$ (b) and Crystal packing of 1:4 complex $18 \mathrm{~b}^{2+}\left[(\mathrm{TCNQ})_{4}\right]^{2-}$ (c).

Evidence of the dicationic structure in the solid state was first obtained by X-ray crystallography of the charge transfer complex which formed by mixing the tetramethyl derivative 18b with $\mathrm{TCNQ}^{45}$ (Figure 1.7c).

The complex of $\mathbf{1 8 b}$ with TCNQ (ratio 1:4) is highly conductive $\left(\sigma_{300}=60 \mathrm{~S} \mathrm{~cm}^{-1}\right)$, paramagnetic and was the first semimetallic TCNQ complex formed by a TTF-type donor that adopts such a non planar conformation. Other non planar TTF analogues (32) have been recently reported which also show a dramatic change of conformation upon oxidation ${ }^{27}$ (Figure 1.8). However, the derived cation radical salts with $\mathrm{PF}_{6}{ }^{-}$and $\mathrm{Au}(\mathrm{CN})_{2}{ }^{-}$ have a 1:1 stoichiometry and, therefore, show semiconductivity behaviour ( $\sigma_{300 K}=3.10^{-6} \mathrm{~S} \mathrm{~cm}^{-1}$ and $\sigma_{300 \mathrm{~K}}=10^{-2} \mathrm{~S} \mathrm{~cm}^{-1}$, respectively).

Figure 1.8. Crystal structures of 32 (a) and $\mathbf{3 2}\left(\mathrm{PF}_{6}\right)$ (b) (top: structure of the donor molecule, bottom: crystal packing of $32\left(\mathrm{PF}_{6}\right)$.

### 1.3.3 Electrochemistry of Anthracene-TTF Derivatives.

### 1.3.3.1 Cyclic Voltammetry Studies of Anthracenediylidene Derivatives.

The electrochemistry of anthracenediylidene derivatives is influenced by this change of conformation upon oxidation. The characteristic voltammogram obtained for these compounds comprises a single, quasi-reversible two-electron wave (Figure 1.9a). The delay observed on the reduction which makes the system quasi-reversible, is correlated to the high stability of the dication species, which are fully aromatic, and also to the change of conformation that the dication species have to undergo to return to their neutral form. This effect is even more pronounced at low temperature, showing a complete irreversibility at $-70^{\circ} \mathrm{C}$ for compound 19 in DCM. ${ }^{42}$

Figure 1.9. Cyclic voltammograms of 18 b (a) and of 19 at various temperature (b). (Experimental conditions: Pt electrode, in DCM, electrolyte: $\mathrm{Bu}_{4} \mathrm{NPF}_{6} 0.1 \mathrm{M}$ )

Temperature-dependent studies performed on compound 19 also allowed the observation of a second reversible one-electron wave and a third irreversible one-electron wave, leading to the formation of trication radical species and tetracation species, respectively, corresponding to the oxidation of the anthracene system (Figure 1.9b).

As for tetrathiafulvalene ${ }^{46}$, oxidation potentials of anthracenediylidene derivatives can be finely tuned by attachment of electron donating or electron withdrawing substituents. The general trend is that an anodically shifted oxidation wave is observed for an electron withdrawing substituent. ${ }^{41}$

### 1.3.3.2 Radical Cation Form of Anthracene-TTF.

Calculations have been performed on compound 18 a , its radical cation form $18 \mathbf{a}^{+\boldsymbol{}}$ and its dication form $1 \mathbf{1 8}^{\mathbf{2 +}}$, in order to explain the electrochemical behaviour of anthracenediylidene derivatives. ${ }^{47}$ Oxidation mainly affects the central quinonoid ring and the dithiole units on which the highest occupied molecular orbital (HOMO) (i.e. the orbital from which electrons are removed) is mostly located (Figure 1.10). ${ }^{35}$

Figure 1.10 Atomic orbital composition and energy of the HOMO of 18a.

The aromatisation of the anthracene moiety and the dithiole rings during the oxidation process has important consequences for the conformation adopted by the molecule. The radical cation remains significantly distorted from planarity and retains the saddle shaped structure of the neutral form. The dication, comprising three aromatic units (the anthracene moiety and the two dithiolium rings), loses the saddle shape to adopt a planar conformation in which the two dithiolium rings twist perpendicularly to the planar anthracene core, as observed by X-ray analysis ${ }^{45}$ (Figure 1.11).

Figure 1.11 Minimum-energy conformation calculated for $18 \mathrm{a}, 18 \mathrm{a}^{+\boldsymbol{}}$, and $18^{\mathbf{2 +}}$.

This distorted conformation of the radical cation implies its instability with respect to the dication, thus explaining the anodic shift of the first oxidation potential and its coalescence with the second oxidation potential to give the two-electron wave observed by electrochemical studies, which is in contrast to TTF which shows two separated oneelectron waves for the radical cation and the dication species.

However, observation of the elusive $\pi$-radical cation species of compound 18 c has been achieved by photolytic generation, allowing its characterisation by UV-Vis and Raman spectroscopy. ${ }^{48}$ Photolysis of a degassed solution of $\mathbf{1 8 c}$ led to the formation of the
radical cation species $18 \mathbf{c}^{+\boldsymbol{}}$, which was shown to disproportionate to give the dication species $18 \mathbf{c}^{\mathbf{2 +}}$. In aerated solutions, the photodegradation product observed is the ketone 23c the mechanism of formation of which remains uncertain (Figure 1.12).

Figure 1.12 Ground state Raman spectrum of $\mathbf{1 8 c}$ recorded at 630 nm , and time resolved resonance Raman spectrum of $\mathbf{1 8 \mathbf { c } ^ { + \boldsymbol { } }}$ recorded by using 266 nm pump and 630 nm probe: time delays are indicated.

### 1.3.3.3 Intramolecular Electronic Interaction Studies.

Several diads containing anthracenediylidene derivatives linked by a $\sigma$ bond to different donor moieties have been synthesised for the study of intramolecular electronic interactions. Thus, dimeric systems (33a-c), donor-donor diads with ferrocenyl moieties (34, 35a, 36a-c) or with TTF moieties (35b, 37a-c) have been recently reported.

$\mathrm{D}=\hat{\theta} \mathrm{Fe} \theta$

The electrochemistry of compound $34^{49}$ is composed of waves from the two redox systems, namely anthracene-TTF and ferrocene. The oxidation of the anthracenediylidene moiety to yield the dication occurs first as the characteristic single, two-electron, quasireversible wave $\left(E_{1}{ }^{0 x}=0.59 \mathrm{~V}\right.$ in DCM$)$. The second oxidation of the ferrocene moiety occurs as a clean reversible wave $\left(E_{2}{ }^{0 x}=0.67 \mathrm{~V}\right.$ in DCM$)$ to lead to the formation of the trication species. As expected, since the two redox moieties are not conjugated for this molecule, no intramolecular electronic interactions have been observed, the two redoxmoieties acting independently. Similarly, compounds $\mathbf{3 5 a}$ and $\mathbf{3 5 b}{ }^{50}$ with an ester linkage
and compound 33 with an oxygen atom link, display independent redox units. Consequently, compound 33 shows a single four-electron quasi-reversible wave ${ }^{51}$, with both anthracenediylidene units being oxidised at the same time under a range of different experimental conditions eg. varying temperature, solvent and scan-rate. However, for compounds $36^{52}$ and $37^{53}$, in which the connection occurs through a conjugating double bond, intramolecular electronic interactions have been observed by electrochemistry and confirmed by UV-Vis spectroscopic analysis and semiempirical calculations. Therefore, for compound 37 , the oxidation of the ferrocene moiety is delayed (i.e. more difficult) showing an inductive effect from the positively charged dicationic state of the anthracenediylidene moiety.

### 1.3.3.4 Metal Ion Recognition Properties.

In order to investigate metal recognition properties, Bryce et al. ${ }^{54}$ recently reported the synthesis of $\mathrm{O}_{4} \mathrm{~S}_{2}$-crown annulated derivatives of the anthracenediylidene system. The unique combination of structural and redox properties of anthracenediylidene derivatives gives to the mono-crown system 38 a high selectivity toward silver and sodium ions. The complexation of the metal ion to the crown unit has been followed by UV/Vis spectroscopy and cyclic voltammetry. In the presence of metal cations, the first oxidation peak ( $E_{1}{ }^{\mathrm{ox}}$ ) observed for compound $\mathbf{3 8}$ is shifted more significantly for silver and sodium ions; while the second oxidation peak ( $E_{2}{ }^{\mathrm{ox}}$, due to the anthracene moiety) remained essentially unchanged, consistent with expulsion of the metal cation from the ionophore prior to the second oxidation wave (Figure 1.13). Saturation is achieved for ca. 10 equivalents of metal ions which makes possible the use of compound 33 as a highly sensitive and efficient voltammetric sensor of silver and sodium ions.

### 1.3.4 Donor-Acceptor Complexes.

In the development of optoelectronic devices, the synthesis of new organic molecules with delocalised $\pi$-electron systems bearing both electron donor and electron acceptor moieties within the same molecule has become a very active research area. These donoracceptor molecules are very attractive for their potential uses in nonlinear optics, molecular electronics, artificial photosynthetic models and solvatochromic effects. Anthracenediylidene derivatives are of a particular interest in this area since the oxidised species are stabilised by aromatisation of the anthracene ring.

High molecular hyperpolarizabilities can be obtained for molecules in which the donor and the acceptor are linked through a $\pi$-conjugated spacer allowing an intramolecular charge transfer. Respecting this key factor, in a search of new chromophores, compounds 39a-c and 40a-c have been reported as efficient NLO chromophores possessing relatively high second order optical nonlinearity $\left(\mu \beta_{0} c a\right.$. $150.10^{-48}$ esu for 39 a-c and $\mu \beta_{0} c a .300 \cdot 10^{-48}$ esu for 40a-c). ${ }^{55}$

b: $R=S \mathrm{SCH}_{3}$
c: $R-\mathrm{R}=\mathrm{SCH}_{2} \mathrm{CH}_{2} \mathrm{~S}$
$40 n=1$

In a search for new compounds exhibiting a long-lived charge separated state, [60]fullerene has been covalently attached to anthracene-TTF derivatives using various linkers, such as pyrrolidine rings $(\mathbf{4 1}, \mathbf{4 2}, 44)$, and cycloaddition using diazo compounds (43). These compounds show electroactivity of both the donor and the acceptor moieties exhibiting a two-electron oxidation wave corresponding to the oxidation of the anthracenediylidene moiety, and the four cathodically shifted one-electron reduction waves corresponding to the first four reductions of the $\mathrm{C}_{60}$ moiety. Electronic interactions in the solid state were confirmed by magnetic susceptibility $\left(\chi_{\mathrm{m}}\right)$. Compounds 41a-c ( $\chi_{\mathrm{m}}$ ca. $2.10^{-3}$ emu mol-1) show, therefore, paramagnetic behaviour. ${ }^{56}$ Photoexcitation of these diads activates an intramolecular electron-transfer from the singlet excited-state of the fullerene moiety to the donor leading to long-lived separated-charged states, characterised as being the radical anion of the $\mathrm{C}_{60}$ moiety and the radical cation of the anthracene-TTF (TTFAQ) moiety ( $\mathrm{C}_{60}$ - $\left.^{-}-\mathrm{TTFAQ}^{+\bullet}\right) .5$ The unusual geometry of anthracenediylidene
derivatives has a strong impact on the stabilisation of the charge-separated state, which for these compounds has a relative long life (several hundred nanoseconds in deoxygenated solvent). 58 In addition to the gain of aromaticity of the 1,3 -dithiole units, the aromatisation of the anthracene ring occurs upon oxidation leading to larger aromatic stabilisation energy, which seems to be a key feature for obtaining strong stabilisation of photolytically generated radical pairs in $\mathrm{C}_{60}$ diads, ${ }^{59}$ thus enabling the transformation of the photon energy into chemical energy, paving the way for the use of anthracenediylidene derivatives as appropriate materials for photovoltaic applications. ${ }^{47}$

### 1.4 Conclusion.

Anthracenediylidene derivatives are interesting electron donors which possess an unusual saddle-shaped conformation which imparts special properties to the system. These donors are easily oxidised to the dication species. Upon oxidation, the conformation changes dramatically leading to the loss of the cavity of the neutral structure. Chemical functionalisation is easily performed which allows access to a wide variety of substituted derivatives. We, therefore, decided to investigate the molecular and supramolecular architecture of this class of compounds. At the molecular scale, we targeted the synthesis of cyclophane derivatives by bridging the preformed anthracene tetrathiafulvalene system with a view to studying their redox properties and crystal packing, perhaps even observing the stabilisation of the cation-radical species. We also aimed to develop the chemistry of anthracenediylidene derivatives in order to direct the supramolecular architecture by secondary interactions ( $\pi-\pi$ stacking, hydrogen-bonding). Finally, we considered it of interest to study the incorporation of anthracenediylidene units into dendritic structures in order to obtain dendrimers which can form highly oxidised states.

## Chapter Two

## Secondary Interactions:

## Towards Increased Supramolecular

## Order in the Solid State.

### 2.1 Intermolecular Hydrogen Bonding.

As we have already mentioned in the preceding chapter, tetrathiafulvalene (TTF) is a $\pi$-electron donor, which readily forms conductive charge transfer salts or organic metals with $\pi$-electron acceptors like TCNQ. To increase the conductivity of these materials, organic chemists have synthesised tetrathiafulvalene derivatives bearing different functional groups with the purpose of increasing their intermolecular interactions to gain control over their solid state architecture. Crystal structures of organic solids are governed by a delicate balance between several weak interactions such as electrostatic forces, Van der Waals interactions, hydrogen bonding and $\pi-\pi$ stacks. ${ }^{1}$ Consequently, changing the strength of one of these interactions can result in a complete change of structure.

### 2.1.1 Hydrogen-bonded networks in tetrathiafulvalene derivatives.

The first observation of strong hydrogen bonding within the crystal structure of TTF derivatives was realised fortuitously by analysing crystals of BEDT-TTF (6) chargetransfer salts containing water molecules [eg. (BEDT-TTF) $\left.{ }_{3} \mathrm{Cl}_{2} \cdot 2 \mathrm{H}_{2} \mathrm{O}\right)$ ]. The stacks of BEDT-TTF molecules are connected by hydrogen bonds to $\mathrm{Cl}_{4}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}$ units (Figure 2.1). It was the first superconducting hydrate salt to be reported. ${ }^{2}$

Figure 2.1 Crystal structure of (BEDT-TTF) ${ }_{3} \mathrm{Cl}_{2} 2 \mathrm{H}_{2} \mathrm{O}$. (in black: chloride anions)

A wide variety of functionalised TTFs bearing substituents that can participate in intermolecular hydrogen bonding (hydroxy, amido, thioamido, etc.) have been synthesised. ${ }^{3-5}$ Often, the increase of intermolecular forces results in very low solubility of the molecules, thereby hindering studies on crystal growth. However, hydroxyfunctionalised TTF derivatives, such as compounds 45 and $46^{6}$ have been successfully characterised and present a remarkable network of hydrogen bonding, which, controls together with $\pi$ - $\pi$ stacking of the TTF cores, the architecture of their crystal structures (Figure 2.2).

Figure 2.2 Crystal structures of $\mathbf{4 5} 2 \mathrm{MeOH}$ (a), and of $\mathbf{4 6}$ (b)

Anthracenediylidene derivatives, as we mentioned in the preceding chapter, possess a saddle shaped conformation in the neutral state. The crystal structures of most of these systems comprises dimers, in which one molecule engulfs the dithiole moiety of another (Figure 1.6 p.14). The dithiole-dithiole interaction, which occurs inside these dimers, prevents efficient stacking in the crystal. We recognised that it could be possible to modify the intermolecular interactions by adding to the structure some secondary interactions such as hydrogen bonding by hydroxyl groups. We, therefore, decided to synthesise the monoand di-hydroxymethyl derivative of the anthracenediylidene system. We also recognised that these functionalised derivatives could be useful building blocks for more elaborate systems, by reactions of the hydroxy group(s).

### 2.1.2 Hydroxymethyl anthracenediylidene derivative.

### 2.1.2.1 Synthesis.

Ester 26 was synthesised following the literature procedure ${ }^{7}$ from the trimethyl anthracenediylidene derivative $\mathbf{2 5 b}$ by lithiation followed by trapping of the lithiated species by methyl chloroformate. The synthesis shown in Scheme 2.1 has been scaled up, with modifications to obtain 20 g of $\mathbf{2 5 b}$. The problematic step on a large scale is the Horner-Wadsworth-Emmons reaction for which the solubility of the ketones is very important. The reaction needs a rigorously anhydrous media maintained at $-78^{\circ} \mathrm{C}$ during the addition of all the ketone $\mathbf{2 3} \mathbf{b}$ to the ylide of $\mathbf{2 4}$; a cannula was used to transfer dropwise the ketone to the reaction mixture under nitrogen. The ketone 23 b was dissolved in hot dry THF, and heating was maintained during the transfer via the cannula, while the reaction mixture containing the phosphonate $\mathbf{2 4 c}$ dissolved in dry THF with 1.1 equivalent of LDA was maintained at $-78^{\circ} \mathrm{C}$. Using this procedure, compound $\mathbf{2 5 b}$ ( 20 g batch) was obtained in $70 \%$ yield.

Scheme 2.1 Synthesis of trimethyl-anthracenediylidene derivative 25b.

The preparation of the hydroxymethyl anthracenediylidene derivative (47) was performed by reduction of the corresponding ester (26) by lithium aluminium hydride in THF (Scheme 2.2) in a very high yield.

Scheme 2.2 Synthesis of hydroxymethyl anthracenediylidene derivative 47.

Unfortunately, the lithiation of compound $\mathbf{2 5 b}$ is not a quantitative reaction. Separation of the starting material and the product 26 was achieved by silica gel chromatography, using $D C M / h e x a n e s(1: 2 \mathrm{v} / \mathrm{v})$ for the best separation, in which the compounds have low solubility. This solubility problem prevented the scale up of the reaction beyond 5 g of $\mathbf{2 5 b}$. However, if the alcohol $\mathbf{4 7}$ is the desired product, it is possible to circumvent this problem by using the crude product obtained by the lithiation reaction (composed of a mixture of $\mathbf{2 5 b}$ and $\mathbf{2 6}$ ) directly in the reduction by lithium aluminium hydride. This second step being almost quantitative, the crude product comprising $\mathbf{2 5 b}$ and 47, is easier to purify, by chromatography in pure DCM, in which the compounds are readily soluble. This method allowed the synthesis of 15 g of 47 with an overall yield of $70 \%$ from 25b.

### 2.1.2.2 Dynamic NMR studies.

${ }^{1} \mathrm{H}$ NMR studies performed on 47 , showed a difference in chemical shift for the two protons $\mathbf{H}_{\mathbf{a}}$ and $\mathbf{H}_{\mathbf{b}}$ in the $\alpha$-position to the hydroxyl group (Figure 2.3). This is observed at $20^{\circ} \mathrm{C}$ in $d_{\sigma}$ - DMSO, giving a four-line AB system $\left(\mathrm{J}_{\mathrm{AB}}=c a .13 \mathrm{~Hz}\right)$.

Figure $2.3^{1} \mathrm{H}$ NMR spectrum of $\mathbf{H}_{\mathbf{a}}$ and $\mathbf{H}_{\mathbf{b}}$ of $\mathbf{4 7}$ in $\left(\mathrm{CD}_{3}\right)_{2} \mathrm{SO}$ at $20^{\circ} \mathrm{C}$.

This observation leads to a significant conclusion. The only possibility to observe this four line AB-system is in the case of $\mathbf{H}_{\mathrm{a}}$ and $\mathbf{H}_{\mathrm{b}}$ being diastereotopic, which directly implies that the molecule is not planar in solution. Therefore, we suggest that the molecule exists as the two conformers A and B, which interconvert slowly (by boat-boat flipping of the central ring) on the NMR timescale at this temperature (Figure 2.4b). By increasing the temperature, the interconversion is faster and $\mathbf{H}_{\mathbf{a}}$ and $\mathbf{H}_{b}$ are no longer differentiated. At $80^{\circ} \mathrm{C}$ (Figure 2.4a), the four lines have coalesced, the interconversion between form A and form $B$ is fast enough to observe on the NMR timescale for this temperature the average planar conformation via which the two forms are interconverting.

(a)

(b)

Figure 2.4 (a) ${ }^{1} \mathrm{H}$ NMR spectra of $\mathbf{H}_{\mathrm{a}}$ and $\mathbf{H}_{\mathrm{b}}$ of 47 in $\left(\mathrm{CD}_{3}\right)_{2} \mathrm{SO}$ at $20^{\circ} \mathrm{C}$ and $80^{\circ} \mathrm{C}$; (b) Proposed conformations of 47 in solution.

Rate exchange measurements between the two conformations of compound 47 were carried out by Dr P. Hazendonk. Comparing the experimental data for the variation of the chemical shift of the AB system coalescing to the singlet with temperature and simulation of this process, the Eyring relationship gave an activation enthalpy, $\Delta H^{\ddagger}=75.3 \mathrm{~kJ} / \mathrm{mol}$, and an activation entropy $\Delta S^{\ddagger}=11.5 \mathrm{~J} / \mathrm{mol} \mathrm{K}$. The error in $\Delta S^{\ddagger}$ is too large for reliable interpretation, requiring further studies to reduce the interpolation error in the Eyring plot. This is currently under investigation. (See also Appendix One for more details about the determination of the activation enthalpy $\Delta H^{\ddagger}$ and the activation entropy $\Delta S^{\ddagger}$ of the system).

### 2.1.2.3 Crystal Structure.

Single crystals of 47 suitable for X-ray analysis were obtained by recrystallisation from dichloromethane/hexanes. Each molecule adopts the characteristic saddle shaped conformation of anthracenediylidene derivatives ${ }^{7}$ (See also Chapter One). The packing motif is also similar to that displayed by the precursor methyl ester 26 , constituted by pseudo dimers of molecules, related by an inversion centre and mutually engulfing each other by interactions between the dithiole rings. Hydrogen bonds are present between the dimers but seem not to be strong enough to modify the packing in any significant way (Figure 2.5).

Figure 2.5 Crystal packing of 47 showing possible contacts between disordered O atoms. Hydrogen atoms have been omitted for clarity.

### 2.1.3 Dihydroxymethyl anthracenediylidene derivative.

### 2.1.3.1 Synthesis.

Following the Scheme used to obtain the monohydroxymethyl derivative 47, we synthesised the dimethyl derivative 48 as described in the literature. ${ }^{8}$ Lithiation of 48 by lithium diisopropylamide (LDA) followed by in situ trapping of the lithiated species with methylchloroformate gave a mixture of the mono-and diester derivatives 49 and 50. LDA being a strong nucleophilic base cannot be used in excess for this reaction, as it would react with the ester formed. Using independently one or two equivalents of LDA, the mono-ester derivative 49 was always the major product of the reaction with an optimised yield of $32 \%$ when using 1.1 equivalent of LDA (Scheme 2.3).

49 (32\%)
50 (3\%)

Scheme 2.3 Lithiation of 48 using Lithium diisopropylamide (LDA).

We, therefore, decided to use lithium bis(trimethylsilyl)amide (LHMDS) for the lithiation of 48. LHMDS is a strong base, equivalent to LDA, but possessing sterically encumbered silyl groups, which decrease the nucleophilicity of the nitrogen atom. Therefore an excess of LHMDS can be used for the lithiation of 48. Indeed, with 4 equivalents of LHMDS used to form the lithiated species of 48 followed by addition of methylchloroformate, the diester 50 was obtained in an optimised yield of $96 \%$ (Scheme 2.4).

Reduction of diester 50 was performed using lithium aluminium hydride to yield to the dihydroxymethyl derivative 51 in an almost quantitative yield.

Scheme 2.4 Synthesis of dihydroxymethyl derivative 51.

### 2.1.3.2 Crystal Structure.

Single crystals of $\mathbf{5 1}$ suitable for X-ray crystallographic studies have been obtained by recrystallisation from dissolution of the compound in dichloromethane and adding methanol. Like the monohydroxymethyl derivative 47, each molecule adopts the characteristic saddle shaped conformation. The packing motif is also similar, and the presence of the two hydroxyl groups does not modify the structure nor the continuity of the hydrogen bonding chain linking the dimers (Figure 2.6). It seems likely that methyl and hydroxymethyl groups form hydrophobic and hydrophilic clusters, respectively, inside the structure directed by the strong dithiole---dithiole ring interactions.

Figure 2.6 Crystal packing of $\mathbf{5 1}$ showing possible contacts between disordered O atoms.

### 2.1.4 Conclusion

We developed the synthesis of the mono and di-hydroxymethyl derivatives of the anthracenediylidene system. The NMR study of the monohydroxymethyl 47 allowed the observation for the first time of the saddle shaped conformation of this class of extendedTTF in solution as observed in X-ray crystallography ${ }^{9}$ and predicted by theoretical calculations. ${ }^{10}$ Hydrogen bonds are present inside the crystalline structures as expected. Even if the molecules are linked by a chain of hydrogen bonds, $\mathrm{RO}-\mathrm{H} \cdots \mathrm{O}(\mathrm{R})-\mathrm{H} \cdots \mathrm{O}(\mathrm{R})-\mathrm{H}$, such as exist in the crystals of higher alcohols, the presence of the pseudo-dimeric packing motif prevents its continuity and its order; and, therefore, is evidence of the high stability of this motif. Attempts to synthesise tetrahydroxymethyl derivatives of the system failed, the compounds obtained being insoluble in any solvents. We, therefore, orientated our research towards other secondary interactions such as secondary $\pi-\pi$ interactions of aromatic ester derivatives.

### 2.2 Secondary $\pi-\pi$ interactions.

Aromatic interactions are weaker, less well-defined interactions with respect to hydrogen bonds, however, the surface area of intermolecular contact is larger, so van der Waals interactions are much more important and a vast range of different functional groups can be involved. ${ }^{11}$

In order to study secondary $\pi-\pi$ interactions, we synthesised a new series of aromatic esters derived from the hydroxymethyl derivative 47 . Esterifications of 47 were performed under $\mathrm{N}_{2}$ in dichloromethane at room temperature, using triethylamine as catalytic base, and the appropriate acid chloride (Scheme 2.5). Reaction of 47 with benzoyl chloride and 2-naphthaloyl chloride gave the corresponding ester derivatives 52 ( $99 \%$ yield) and 53 ( $67 \%$ yield).

47

$\mathrm{Et}_{3} \mathrm{~N}$

52 (99\%)

53 (67\%)

Scheme 2.5 Synthesis of benzoyl ester derivative (52) and 2-naphthaloyl ester derivative (53).

Both compounds 52 and - 53 were recrystallised by dissolution in hot dichloromethane adding hexanes before cooling to room temperature. The crystal structures of 52 and $53 \cdot \mathrm{CH}_{2} \mathrm{Cl}_{2}$ (Figure 2.7) present the characteristic saddle shaped conformation of anthracenediylidene derivatives.

Figure 2.7 Crystal structures of benzoyl ester derivative 52 (a) and 2-naphtaloyl ester derivative 53 (b)

We can notice for the benzoyl ester derivative 52, the slightly different orientations of the two dithiole rings (Figure 2.7a). Moreover, comparing with their precursor 47, the folding of the saddle increases with the size of the substituents, which can be observed by comparing the angles representative of this structure $\left(\varphi, \delta_{1}, \delta_{2}, \theta\right)$ (Figure 2.8).

|  | Dihedral angles ( ${ }^{\circ}$ ) |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | 47 | 50 | 51 | 52 | 53 |  |
|  | $\varphi$ | 37.3 | 37.4 | 37.4 | 41.4 | 39.7 | 38.1 |
|  | $\delta_{1}$ | 6.1 | 16.7 | 9.0 | 16.7 | 11.3 | 14.9 |
|  | $\delta_{2}$ | 9.9 | 8.7 | 6.2 | 9.9 | 6.3 | 8.4 |
|  | $\theta$ | 89.4 | 100.2 | 91.3 | 89.4 | 72.9 | 77.5 |

$\varphi$ represents the folding of the anthracenediylidene moiety along $\mathrm{C}(9) \cdots \mathrm{C}(10)$ vector.
$\delta_{1}, \delta_{2}$ represent the folding of the dithiole rings along $S(1) \cdots S(2)$ and $S(3) \cdots S(4)$ vectors, respectively.
$\theta$ is the dihedral angle of the outlying planar $(\mathrm{S}(1)-\mathrm{C}(16)-\mathrm{C}(17)-\mathrm{S}(2))$ and $(\mathrm{S}(3)-\mathrm{C}(21)-\mathrm{C}(22)-$ $S(4)$ ).

Figure 2.8 Comparative study of the molecular folding of compounds $47,50,51,52$, and 53.

For compound 53, two series of data are given, two different molecules existing in its crystal structure.

The packing motif of these ester derivatives is similar to their precursor. Each compound displays pseudo dimers formed by the intermolecular interactions of two dithiole rings, which engulf each other. This motif ensures the most dense packing and to conform to it, molecular folding is increased and twisting can occur, which is the case for the benzoyl ester derivative (52) for which the two dithiole rings have slightly different orientations. Contrary to our initial hypothesis, secondary $\pi-\pi$ interactions do not occur nor is the dithiole rings interaction broken. There is possible intramolecular charge transfer inside the dimers as the electron-rich dithiole moiety (D) lies in proximity to the electronpoor benzoyl group (A) of the other molecule. The shortest contact between $\mathrm{D}--\mathrm{A}$ is
$3.53 \AA$ for 52, however the donor and acceptor moieties are nearly parallel (interplanar angle $10^{\circ}$ ) and have anti-orientations, thus limiting their overlap. The crystal structure of 52 thus displays oligomeric stacks of 4 layers ADDA but does not contain infinite stacks (Figure 2.9).

(a)

(b)

Figure 2.9 Intramolecular charge transfer ADDA (a) and Crystal packing (b) for the benzoyl ester 52 (Hydrogen atoms have been omitted for clarity).

For the naphthaloyl ester derivative 53, the conditions of intramolecular charge transfer are more favourable. Each naphthaloyl group is sandwiched between two dithiole groups, one belonging to the other molecule of the same dimer and the other belonging to a different dimer. The donor and acceptor moieties are practically parallel (interplanar angles $0.4^{\circ}$ and $3.6^{\circ}$ ), the contacts between them are between $3.41 \AA$ and $3.67 \AA$, which are close to the sum of the van der Waals' radii ( $3.61 \AA$ ). The crystal structure of 53 thus displays oligomeric stacks of 6 layers DADDAD but does not contain infinite stacks (Figure 2.10).

Figure 2.10 Intramolecular charge transfer DADDAD (a) and crystal packing of the naphtaloyl ester 53 (Hydrogen atoms have been omitted for clarity).

In order to increase this interaction between donor and acceptor moieties inside the crystal structure of anthracenediylidene derivatives, we synthesised the ester 54 bearing an anthraquinone acceptor moiety (55). (Scheme 2.6)

47

Scheme 2.6 Synthesis of anthraquinoyl ester derivative (54).

Recrystallisations in different solvents and mixtures of solvent did not give crystals, which were suitable for X-ray analysis. However, the black-green colour of the crystalline powder of 54 is characteristic of charge transfer interactions in the solid state, which are not present in solution. UV-Vis spectra in solution do not show any characteristic band for charge transfer in solutions (DCM or acetonitrile) for a range of concentrations ( $10^{-6}$ to $\left.10^{-4} \mathrm{M}\right)$ and solutions of 54 are always yellow. However, the UV-Vis spectrum recorded on the solid state, shows the characteristic charge transfer band present at $\lambda_{\max }=550-750$ nm (Figure 2.11).
(n)

Figure 2.11 UV-Vis spectra on solid state of compounds $\mathbf{2 5 b}(-)$ and $54(-)$.

### 2.3 Solution Electrochemical Studies.

Solution electrochemical data for the new anthracenediylidene derivatives presented in this chapter are consistent with their substitution patterns (Table 2.1). As for TTF derivatives, the general trend is that electron withdrawing substituents result in a positive shift (i.e. more difficult to oxidise) and electron-donating groups in a negative shift (easier to oxidise).

| Compound | $E_{\text {pa }}^{\text {Ox }} / \mathrm{V}$ | $E_{\text {pc }}^{\text {Ox }} / \mathrm{V}$ | $\Delta E / \mathrm{V}$ |  |
| :---: | :---: | :---: | :---: | :---: |
| 25b | 0.40 | 0.18 | 0.22 | 1 |
| 26 | 0.51 | 0.18 | 0.33 | - |
| 47 | 0.39 | 0.05 | 0.34 | $\mathrm{R}_{1}=\mathrm{Me} ; \mathrm{R}_{2}=\mathrm{H}: 25 \mathrm{~b}$ |
| 48 | 0.38 | 0.16 | 0.22 | $\mathrm{R}_{1}=\mathrm{Me} ; \mathrm{R}_{2}=\mathrm{CO}_{2} \mathrm{Me}: 26$ |
| 49 | 0.52 | 0.25 | 0.27 | $\mathrm{R}_{1}=\mathrm{Me} ; \mathrm{R}_{2}=\mathrm{CH}_{2} \mathrm{OH}: 47$ |
| 50 | 0.60 | 0.29 | 0.31 | $\mathrm{R}_{1}=\mathrm{H} ; \mathrm{R}_{2}=\mathrm{CO}_{2} \mathrm{Me}: 49$ |
| 51 | 0.35 | 0.20 | 0.15 | $\mathrm{R}_{1}, \mathrm{R}_{2}=\mathrm{CO}_{2} \mathrm{Me}: 50$ |
| 52 | 0.45 | 0.14 | 0.31 | $\mathrm{R}_{1}, \mathrm{R}_{2}=\mathrm{CH}_{2} \mathrm{OH}: 51$ |
| 53 | 0.46 | 0.06 | 0.40 | $\mathrm{R}_{1}=\mathrm{Me} ; \mathrm{R}_{2}=\mathrm{CH}_{2} \mathrm{O}_{2} \mathrm{CNaph}: 53$ |
| 54 | 0.46 | 0.16 | 0.30 | $\mathrm{R}_{1}=\mathrm{Me} ; \mathrm{R}_{2}=\mathrm{CH}_{2} \mathrm{O}_{2}$ CAnthraquinone : 54 |
| 29 | 0.52 | 0.24 | 0.28 | $\mathrm{R}_{1}=\mathrm{Me}, \mathrm{R}_{2}=\mathrm{CHO}$ |

Table 2.1 Cyclic voltammetric data. $\Delta E=E_{\mathrm{pa}}^{\mathrm{Ox}}-E_{\mathrm{pc}}^{\mathrm{Ox}}$
$E_{\mathrm{pa}}^{\mathrm{Ox}}$ is the oxidation peak potential on the first anodic scan;
$E_{\mathrm{pc}}^{\mathrm{Ox}}$ is the coupled reduction peak potential on the cathodic scan.
[Experimental conditions: Dichloromethane/Acetonitrile ( $2: 1 \mathrm{v} / \mathrm{v}$ ), Pt electrode, versus $\mathrm{Ag} / \mathrm{AgCl}$, electrolyte $\mathrm{Bu}_{4} \mathrm{~N}^{+} \mathrm{ClO}_{4}{ }^{-}(0.1 \mathrm{M}), 20^{\circ} \mathrm{C}$, scan rate $100 \mathrm{mV} \mathrm{s}^{-1}$.]

Thus, ester substituents of compounds $\mathbf{2 6}, \mathbf{4 9}, 50$ result in a positive shift of the quasi-reversible, two-electron wave characteristic of the system (See also Chapter One). In particular, we can observe the effect of one ester group and the cumulative effect of two ester groups on the system, which respectively increase the oxidation potential by ca. 120 mV and 220 mV . Hydroxymethyl groups, being very weak electron donating substituents, result in a small negative shift ( $c a .10-20 \mathrm{mV}$ ), which can be observed by comparing the oxidation potentials of 47 with $\mathbf{2 5 b}$. The cumulative effect of two hydroxymethyl groups is seen by comparing the oxidation potentials of 51 with 48 ( 30 mV ). For the esters $\mathbf{5 2 , 5 3}$ and 54 (TTFAQ- $\mathrm{CH}_{2} \mathrm{O}_{2} \mathrm{CR}$ ), the oxidation potentials are shifted by $c a .60 \mathrm{mV}$ which is consistent with the ester functions being further removed from the anthracenediylidene moiety (TTFAQ) than for the previous esters 26, 49 and $50\left(T T F A Q-\mathrm{CO}_{2} \mathrm{R}\right)$.

Electrochemical data are really dependent upon the experimental conditions (solvent, nature and concentration of electrolyte, temperature, humidity...) and also depend on the solubility of the compound and its oxidised species, therefore, puzzling unexplained variations in $\Delta E$ for compounds $51(150 \mathrm{mV})$ and $53(400 \mathrm{mV})$ have been observed and might be only due to solubility problems. However, similar unexplained results have already been noted by Martín et al. for dimeric compounds of anthracene-TTF derivatives. ${ }^{12}$

The cyclic voltammogram of compound 54 displays clean amphoteric redox behaviour; upon reduction we observe the two one-electron waves of the anthraquinone moiety, and upon oxidation the two-electron wave characteristic of anthracene-TTF derivatives (Figure 2.12), and, as expected for non conjugated donor-acceptor compounds (see Chapter One), no interaction between the donor and the acceptor moieties is evident from the CV.

Figure 2.12 Cyclic voltammogram of 54.
[Experimental conditions: Pt electrode, in $\mathrm{DCM} /$ Acetonitrile ( $2: 1$ ), $\mathrm{Bu}_{4} \mathrm{~N}^{+} \mathrm{ClO}_{4}{ }^{-}$( 0.1 M ), $\left.20^{\circ} \mathrm{C}\right]$

### 2.4 Conclusion.

Through the synthesis and the study of these new anthracenediylidene derivatives, bearing hydroxyl or ester substituents, we have shown that the anthracenediylidene system possesses a saddle shape conformation in solution and in the solid state in a wide range of derivatives. Moreover, the crystallographic studies suggest a certain flexibility of the structure, the folding increasing with the size of the substituents. In the solid state, the main interaction which predominates, and consequently directs the architecture of the crystal, is the dithiole rings interactions. Therefore, pseudo dimers are formed preventing efficient packing in the crystal. These results led us to consider the possibility of incorporating the anthracenediylidene moiety into cyclophane structures, which would possess interesting solid state structures and also should possess unusual electrochemical properties. The availability in large quantities of the hydroxymethyl derivative 47, also allows us to consider its incorporation into dendritic macromolecules leading to the synthesis of highly charged redox dendrimers.

## Chapter Three

## Redox Active Cyclophanes:

## Constraining the

Molecular Architecture.

### 3.1 Tetrathiafulvalene Cyclophanes.

### 3.1.1 Synthesis and Characterisation.

The incorporation of tetrathiafulvalene moieties into cyclophane structures was proposed by Staab et al. as a possible route to intramolecular charge transfer macrocycles containing both donor and acceptor moieties, with the aim of controlling the crystal structure of derived organic conductors. To illustrate the strategy employed, compounds 56a,b (tetrathiafulvalenocyclophanes) ${ }^{1}$ were synthesised via cyclisation by intramolecular coupling of the bis(1,3-dithiolium tetrafluoroborate) precursors 55a,b (Scheme 3.1). For $57 \mathrm{a}, \mathrm{b}$ with a shorter spacer between the two dithiolium rings, intermolecular coupling was observed to yield compounds $\mathbf{5 8 a}, \mathbf{b}$ (tetrathiafulvalenophanes) ${ }^{2}$ (Scheme 3.2).

Scheme 3.1 Synthesis of tetrathiafulvalenocyclophanes 56a,b.

Scheme 3.2 Synthesis of tetrathiafulvalenophanes 58a,b.

From this first synthesis of cyclophanes containing TTF moieties, we can notice the difficulty of controlling the selectivity of the coupling, which yield to mixtures of cis and trans isomers, which can in some cases be separated by consecutive fractional crystallisations. However, pure isomers are gradually converted into isomeric mixtures. This isomerisation is promoted by traces of acid, as reported by Robert et al. based on the isomerisation of compound 59a (Scheme 3.3). The isomerisation of pure trans 59a into a mixture of cis 59b and trans 59a was followed by ${ }^{1} \mathrm{H}$ NMR spectroscopy, e.g. in commercially available deuterated chloroform. ${ }^{3}$

Scheme 3.3 Isomerisation of trans 59a in acidic media.

Isomerisation of TTF cyclophanes can also occur upon oxidation. This is observed for example, with compounds 60a and 61a in the trans configuration. ${ }^{4}$ The long bridging chain allowed the synthesis of the trans isomers only. Their oxidised cation radical species, isolated by electrocrystallisation as a salts $\left(60 b^{+\bullet}\right)_{2}\left[\operatorname{Re}_{6} \mathrm{~S}_{6} \mathrm{Cl}_{8}\right]^{2-} 2 \mathrm{CH}_{3} \mathrm{CN}$ and $(61 \mathrm{~b})_{2}{ }^{+\bullet}\left[\mathrm{Re}_{6} \mathrm{~S}_{5} \mathrm{Cl}_{9}\right]^{-}$were analysed by X-ray crystallography confirming their cis configuration (Figure 3.1). Cyclic voltammetry data are conșistent with an EC mechanism ( $\mathrm{EC}=$ electron transfer with subsequent chemical reaction) leading to the formation and the observation of cis 60b and cis 61b after the second scan.

Figure 3.1 Crystal structures of $\mathbf{6 0 a}, \mathbf{6 0 b}^{+\boldsymbol{}}, \mathbf{6 1 a}$ and $\mathbf{6 1 b ^ { + \boldsymbol { } }}$.

Upon oxidation a dimerisation process can also occur. Electrolysis of cyclophane 62a-c resulted in the formation of the dimer 63a-c identified for 63b by X-ray analysis (Figure 3.2). Cyclic voltammetry data are also consistent with an EC mechanism. The breakdown of ring strain during the transformation of 62a-c to 63a-c can be considered as the driving force for the ring-enlarging dimerisation, even though the exact mechanism of the dimerisation process is unknown. ${ }^{5}$

(a)

Figure 3.2 Dimerisation of 62a-c into 63a-c upon oxidation (a), Crystal structure of 63b (b).

### 3.1.2 Electrochemistry of tetrathiafulvalenophanes.

TTF is an electron rich donor, with the HOMO mainly localised on the central $\mathrm{S}_{2} \mathrm{C}=\mathrm{CS}_{2}$ moiety. In tetrathiafulvalenophane derivatives, the TTF moiety is often non planar due to steric constraints. Therefore, the folding of the dithiole rings disrupts the extended $\pi$-system and enhances this localisation still further. Consequently, the oxidation potentials of strongly distorted bridged TTF derivatives are shifted positively (i.e. they are harder to oxidise) compared to their parent planar analogues.

However, in systems containing several TTF units, intramolecular stabilisation of cation radical species can occur. Double-bridge TTF cyclophanes were synthesised by dimeric coupling of the bis-dithiole-2-one 64 followed by decarboxylation leading to the formation of all the possible isomers 65 a-d (Scheme 3.4). ${ }^{6}$

64

$\xrightarrow{\text { i) } \mathrm{P}(\mathrm{OMe})_{3}}$

65c

65d

Scheme 3.4 Synthesis of TTF cyclophanes 65a-d.

Repeated fractional recrystallisations allowed the separation of isomers 65a-c. These pure isomers were gradually converted into isomeric mixture in solution due to traces amounts of acid. The cyclic voltammetry of the isomer 65b in benzonitrile showed two reversible one-electron waves $\left(E_{1}^{1 / 2}=0.41 \mathrm{~V} ; E_{2}^{1 / 2}=0.56 \mathrm{~V} \mathrm{vs} . \mathrm{Ag} / \mathrm{AgCl}\right)$ followed by one quasi-reversible two-electron wave $\left(\mathrm{E}_{3}^{1 / 2}=0.83 \mathrm{~V}\right)$. In the same conditions, compound 66 used as a non-bridged reference displayed two reversible one-electron waves ( $E_{1}{ }^{1 / 2}=0.45$ V and $\left.E_{2}^{1 / 2}=0.80 \mathrm{~V}\right)$.

66
The first oxidation wave of compound $\mathbf{6 5 b}$ is ascribed to the formation of the cation radical of one TTF unit. The fact that this oxidation occurs at a lower potential than for the non-bridged reference 66, is good evidence of intramolecular interactions. The cation radical is, therefore, stabilised by the unoxidised TTF unit sharing electron density with the cationic species. The formation of the dicationic species occurs at higher potential due to Coulombic repulsion between the charged TTF units. Electrocrystallisation of 65b allowed the formation of a radical cation salt of 3:4 donor to anion stoichiometry with
$\mathrm{ClO}_{4}^{-}$. X-Ray analysis identified the donor as being 65 d the most compact isomer obtained by isomerisation of the radical cation species of $\mathbf{6 5 b}$. Crystal structures of $\mathbf{6 5 d ^ { + \boldsymbol { } }}$ and $65 \mathrm{~d}^{2+}$ (Figure 3.3) provided a clear observation of the intramolecular interaction (interplanar distance of $3.4 \AA$, sum of van der Waals radii for $S \cdots \mathrm{~S}$ close contact $3.60 \AA^{7}$ ) and the Coulombic repulsion effect. ${ }^{8}$

Figure 3.3 Crystal structures of $\mathbf{6 5 d ^ { + \boldsymbol { * } }}$ (a) and $\mathbf{6 5 d ^ { 2 + }}$ (b).

### 3.1.3 Conclusion

The incorporation of electroactive components into macrocyclic assemblies is currently a challenge in the field of organic materials chemistry, enabling studies of intramolecular charge transfer. For their unusual electrochemical properties, the design of cyclophanes containing TTF moieties is important for research into new redox components. However, as we noted above, the formation of isomers either during their synthesis or subsequently in the presence of traces of acids or by oxidation raise problems of controlling the final structure of such cyclophanes. Therefore, we decided to investigate the properties of cyclophanes containing anthracenediylidene derivatives, which already present a preformed cavity and for which isomerisation has not been observed.

### 3.2 Anthracenediylidene Cyclophanes.

### 3.2.1 First Bridged Extended Tetrathiafulvalene Derivatives.

The first extended tetrathiafulvalene derivatives incorporated in cyclophane structures ( $\mathbf{6 8 a , b}$ and 71) were reported in 1995 by Lorcy et al. ${ }^{9}$, synthesised from the bis(2-piperidino-4-alkylthio-1,3-dithiolium) salts 67 (Scheme 3.5).

 68 a $n=10$ b $\mathrm{n}=12$

69
$\mathrm{NaI}, \mathrm{P}(\mathrm{OEt})_{3}$

70

Scheme 3.5 Synthesis of extended tetrathiafulvalenophanes $68 a, b$ and 71.

Contrary to the case of TTF cyclophanes for which a long bridging chain allows the formation of trans cyclophanes, the increased spatial extension imposed the cis conformation in compounds $\mathbf{6 8 a}, \mathbf{b}$ and 71 . However, their electrochemical properties are similar to their non-bridged analogues as expected for such long chains.

Recently, Bryce et al. investigated the reactivity of shorter chain analogues of compound 70 ( $\mathbf{7 1 a , b}$ ) on anthraquinone, to synthesise by a 2 -fold Horner-Wadsworth Emmons olefination reaction, the first bridged anthracenediylidene derivatives (72a,b) ${ }^{10}$ (Scheme 3.6).

Scheme 3.6 Synthesis of anthracenediylidene cyclophanes 72a,b.

Both compounds 72a and 72b gave single crystals suitable for X-ray analysis, which confirmed their cis configurations (Figure 3.4).

Figure 3.4 Crystal structures of anthracenediylidene cyclophanes 72a (a) and 72b (b)

The bridge aggravates the U-bend of the anthracenediylidene system reducing the size of the internal cavity. The dihedral angle between the two dithiole rings is reduced from $77^{\circ}$ (non-bridged analogue ${ }^{11}$ ) to $54^{\circ}$ and $46^{\circ}$ for the two polymorphic forms obtained for $\mathbf{7 2 a}$, and to $35^{\circ}$ for $\mathbf{7 2 b}$.

The solution electrochemistry of compounds $\mathbf{7 2 a , b}$ was studied by cyclic voltammetry and differential pulse voltammetry. Both compounds display in acetonitrile an irreversible two-electron oxidation wave $\left(E_{1}{ }^{0 x}=0.69 \mathrm{~V}\right)$ followed by a second oxidation wave $\left(E_{2}{ }^{\mathrm{ox}}=1.0 \mathrm{~V}\right)$, which has been attributed to new electrochemical species formed by the decomposition of the oxidised forms of 72a,b.

We decided, therefore, to investigate a more versatile approach to form anthracenediylidene cyclophanes, with the aim of developing a method, which would allow the incorporation of different bridging spacers. Based on the existence of the saddle shaped conformation of anthracenediylidene derivatives, favourable for intramolecular bridging, we decided to synthesise the dimethylanthracene-TTF derivative 74 and develop. its chemistry to build new cyclophane derivatives (Scheme 3.7). The overall aim was to study the effect of various spacers on the electrochemical and structural properties of the cyclophanes, perhaps even to stabilise the cation radical species of the anthracenediylidene system.

Scheme 3.7 New synthetic strategy towards anthracenediylidene cyclophanes.

### 3.2.2 New Bridged Anthracenediylidene Derivatives.

### 3.2.2.1 Synthetic Route.

Compound 74 was synthesised via a 2 -fold Horner-Wadsworth Emmons olefination reaction of anthraquinone with the anion of 4-methyl-1,3-dithiole-2-phosphonate 73 prepared beforehand following the literature procedure ${ }^{12}$ (Scheme 3.8).

Scheme 3.8 Synthesis of a 50:50 mixture of $E / Z$ isomers of 74 .

Compound 74 was obtained in $73 \%$ yield as a mixture of inseparable $E / Z$ isomers. Deprotonation of $\mathbf{7 4}$ using lithium diisopropylamide (LDA) and trapping of the resulting dianion with methylchloroformate afforded diester derivative $(E / Z) 75$ a in $61 \%$ yield after separation by chromatography from unchanged 74 and monoester derivative $(E / Z) 75 \mathrm{~b}$. Diester 75a was reduced with lithium aluminium hydride to give the dialcohol derivative (E/Z) 76 in $82 \%$ yield (Scheme 3.9).

Scheme 3.9 Synthesis of ( $E / Z$ ) dihydroxymethyl derivative 76.

The dihydroxymethyl derivative ( $E / Z$ ) 76 was used as the precursor for synthesising new cyclophane derivatives, by diester forming macrocyclisation. We studied the dicarbonyl chloride derivatives 77a-f to provide a variety of spacer units in the bridging group. Reactions were performed in high dilution conditions in order to favour cyclisation to the detriment of polymerisation, using triethylamine as catalytic base. Thus, cyclophanes 78a ( $11 \%$ yield), 78 b ( $8 \%$ yield), 78 c ( $14 \%$ yield) and 78 ( $15 \%$ yield) were obtained arising from bridging of the $Z$ isomer of 76 (Scheme 3.10), separated by chromatography from intractable material, presumably of oligomeric or polymeric nature.

$77 e$

$77 f$

Scheme 3.10 Synthesis of anthracenediylidene cyclophane 78a-d.

No cyclophane was obtained from the reactions involving 77e and 77f, due probably to steric encumbrance and too short distances between the acid chloride functions (Table 3.1) compared with the other diacid chlorides used.

Table 3.1 Compared distances $\left(\mathrm{d}_{1}\right)$ between carbon atoms of the carbonyl functions of the diacid chlorides 77a-f and distances ( $\mathrm{d}_{2}$ ) between the oxygen atoms of the hydroxyl functions of $(\boldsymbol{Z}) 76$ and $(E) 76$. All distances have been obtained from modelling studies using hyperchem (See Appendix Two).

All the cyclophanes 78a-d were recrystallised from dichloromethane/hexanes forming single crystals suitable for X -ray analysis, which confirmed their cis configuration.

The small difference of the distances between the oxygen atoms of the hydroxyl functions of $(Z) 76(10.57 \AA)$ and $(E) 76(10.99 \AA)$ does not explain the puzzling unique formation of the cis configuration of the cyclophanes. On no occasion was the corresponding trans-bridged cyclophane observed.

Initial evidence to support the cyclophane structures 78a-d came from ${ }^{1} \mathrm{H}$ NMR studies. In particular, the large difference in chemical shift between the two diastereotopic protons $\mathrm{H}_{\mathrm{a}}$ and $\mathrm{H}_{\mathrm{b}}$ was indicative of the conformational rigidity of their structures (Table 3.2).

Table 3.2 Chemical shift of the diastereotopic protons $\mathrm{H}_{\mathrm{a}}$ and $\mathrm{H}_{\mathrm{b}} .{ }^{1} \mathrm{H}$ NMR recorded in $\mathrm{CDCl}_{3}$.

A NOESY spectrum (long distance coupling) of the cyclophanes was recorded, identified $\mathrm{H}_{\mathrm{a}}$ as being closer to the methyl group (Figure 3.5).

Figure 3.5 NOESY spectrum of cyclophane 78a recorded in $\mathrm{CDCl}_{3}$.

### 3.2.2.2 Molecular Structures of New Cyclophanes.

All cyclophanes 78a-d have been recrystallised forming single crystals suitable for X-ray analysis. Simultaneously, molecular modelling studies of the cyclophanes have been performed for comparison with the crystal structures (See Appendix Two for details of these calculations).

The asymmetric unit of 78a comprises two molecules of slightly different conformations, forming dimers wherein a methyl group of each molecule is inserted into the intramolecular cavity of another (Figure 3.6). In both molecules, the bridging benzene ring suffers a boat like distortion (distortion of the plane formed by the ring of $3^{\circ}$ ), which clearly indicates the steric strain of these structures (Figure 3.7).

Figure 3.6 Crystal structure of dimers of 78a.

(a)
(b)

Figure 3.7 Crystal structure (a) and molecular structure obtained by modelling studies (b) of 78a.

Cyclophane 78b crystallises as a $1: 1$ solvate with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$; the solvent molecule is disordered equally between the two positions. The bridging thiophene ring is planar, the carboxyl groups are inclined to its plane by $6^{\circ}$ and $8^{\circ}$. The oxygen atoms of the carbonyl functions adopt a syn orientation with respect to each other and to the sulfur atom of the thiophene ring, resulting in intramolecular noncovalent distances of ca. $2.7 \AA$ (Figure 3.8).

(a)

(b)

Figure 3.8 Crystal structure (a) and molecular structure obtained by modelling studies (b) of 78 b .

The asymmetric unit of 78c comprises two molecules, one showing no disorder, while in the other one, the entire ferrocenyl moiety is disordered between two conformations, related by turning the ferrocenyl moiety upside-down. Thus the two conformations are roughly mirror images of each other and either can be identified with the molecule showing no disorder. In all cases, the carboxyl groups are almost coplanar with the cyclopentadienyl rings (Figure 3.9).

(a)

(b)

Figure 3.9 Crystal structure (a) and molecular structure obtained by modelling studies (b) of 78 c .

Compound 78d crystallises as a $1: 3$ solvate with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$; two molecules of solvent lie inside the molecular cavity of $\mathbf{7 8 d}$ and are intensely disordered, the third one is situated in the intermolecular space and is ordered. The two bridging benzene rings form a dihedral angle of $73^{\circ}$, while the carboxyl groups at each ring deviate slightly (by $8^{\circ}$ and $5^{\circ}$ ) from the ring plane (Figure 3.10).

(a)

(b)

Figure 3.10 Crystal structure (a) and molecular structure obtained by modelling studies (b) of 78 d .

The molecular conformations of 78a-d are similar to all previous anthracenediylidene derivatives studied. The anthracene moiety is folded along $\mathrm{C}(9) \cdots \mathrm{C}(10)$ vector by an angle $\varphi$ (Table 3.3); the bis(dithiolene)quinone system is U-shaped through folding of both dithiole rings by the angles $\boldsymbol{\delta}_{\mathbf{1}}$ and $\boldsymbol{\delta}_{\mathbf{2}}$ along $S(1) \cdots S(2)$ and $S(3) \cdots S(4)$ vectors respectively; giving to the structure its saddle shaped conformation. A measure of the overall bending is given by the dihedral angle $\theta$ between the $S(1) \mathrm{C}(16) \mathrm{C}(17) \mathrm{S}(2)$ and $S(3) C(21) C(22) S(4)$ planes, which shows a direct linear correlation with the length of the bridge, as defined by the intramolecular distances $\mathrm{O}(1) \cdots(2)\left(\mathbf{d}_{1}\right)$ and $\mathrm{C}(18) \cdots \mathrm{C}(23)\left(\mathbf{d}_{2}\right)$.

The bridges in all the compounds are flexible, so the actual molecular conformation is a compromise between steric demands of the bridge and the saddle moiety, strongly influenced by the crystal packing. Comparing the data obtained from the crystal structures with those obtained by molecular modelling, the influence of intermolecular interactions in the solid state can be seen by the slightly different conformations. Calculations have been realised in vacuum, whilst in the solid state the presence of solvent molecules (78b and 78d) or interactions between molecules forming dimers (78a) can occur affecting the shape of the overall structure. However, molecular modelling appears to be an useful tool for visualising the molecular conformation, especially in the cases when crystals have not been obtained $\left((E) \mathbf{7 6}, 7 \mathbf{6}^{\mathbf{2 +}}, \mathbf{7 8 a ^ { 2 + }}, \mathbf{7 8} \mathrm{b}^{\mathbf{2 +}}\right)$. The flexibility of the structures is manifest in the crystals by the presence of different molecules inside the asymmetric unit (78a and 78c) which differ by their bending angles ( $\varphi$ and $\theta$ ). Nonbridged anthracenediylidene derivatives display a $\theta$ of $73-101^{\circ}$, hence only the bridges with $\mathbf{d}_{\mathbf{2}}$ smaller than $9.5 \AA$ can be said to increase the U-bend, which is not the case for the longest bridge 78d. It is noteworthy that the overall folding represented by the angle $\varphi$ is not affected systematically by the length of the bridges. The dithiole ring folding ( $\boldsymbol{\delta}_{1}$ and $\boldsymbol{\delta}_{2}$ ) generally increases with the shortening of the bridge, but the correlation is poor, as other degrees of conformational freedom also contribute to the accumulated U-bend.

Crystallisations under iodine vapours of all the bridged derivatives (78a-d) have been performed but only in the case of 78 d were crystals of $78 \mathrm{~d}^{2+}\left(\mathrm{I}_{3}{ }^{-}\right)_{2}{ }^{( }\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right)_{2.25}$ suitable for X-ray analysis obtained (Figure 3.11). The asymmetric unit of the triiodide salt of $78 \mathbf{d}$ comprises 2.25 molecules of dichloromethane. One independent solvent molecule fits into the intramolecular cavity and is ordered, one occupies an intermolecular cavity and
displays chaotic disorder (approximated by three orientations), and another is disordered around an inversion centre and has a nonstoichiometric occupancy (estimated as 0.25 per asymmetric unit). The $\mathbf{7 8 d ^ { 2 + }}$ dication shows a drastic change of conformation and bond lengths compared to the neutral molecule, similar to those observed for nonbridged systems (Cf. Chapter One). Both dithiolium rings are planar with the bonding pattern indicative of one positive charge on each, while the anthracene moiety is essentially aromatic. However, the bridge imposes significant distortions. Nonbridged dications have rigorously planar anthracene moieties and the dithiolium rings are coplanar to each other and nearly perpendicular to the latter. In $78 \mathbf{d}^{2+}$, the anthracene moiety displays a small folding of $6^{\circ}$. Both dithiolium rings deviate by ca. $20^{\circ}$ from the normality to the anthracene moiety and form a dihedral angle of $163^{\circ}$ between them. The conformation of the bridge is basically the same as in the neutral 78d, the benzene rings forming a dihedral angle of $74^{\circ}$; its overall length increases by 6 or $7 \%$.

(a)

(b)

Figure 3.11 Crystal structure (a) and molecular structure obtained by modelling studies (b) of $78 \mathrm{~d}^{2+}$.

In order to visualise the effect of shorter bridges on the molecular structures of the dicationic state, molecular modelling has been performed on $\mathbf{7 8 a ^ { 2 + }}$ and $\mathbf{7 8 b ^ { 2 + }}$ (Figure 3.12). Their molecular conformations are similar to their neutral analogues. Contrary to the dication of 78d, no dramatic change of conformation between the neutral and oxidised states is observed. For both molecules, the saddle shape is still present although less pronounced. The two dithiolium rings are both twisted by $70.8^{\circ}$ for $78 \mathrm{a}^{2+}$ and $68.6^{\circ}$ for $78 \mathrm{~b}^{2+}$ (compared to $90^{\circ}$ for nonbridged derivatives), the bridge preventing them twisting perpendicularly to the anthracene moiety, and they form a dihedral angle ( $\theta$ ) between each other of $47.6^{\circ}$ and $57.7^{\circ}$ for the two compounds respectively, which for 78 b is very close to its neutral form $\left(58.8^{\circ}\right)$. For both compounds, the folding of the anthracene moiety is less pronounced but still present ( $\varphi$ equal to $25.5^{\circ}$ and $27^{\circ}$ for $78 \mathrm{a}^{\mathbf{2 +}}$ and $78 \mathrm{~b}^{2+}$ respectively). The short bridges seem to prevent the system undergoing a change of conformation keeping the dication structures close to their neutral forms (Table 3.3).

$\rho$ is the folding along the $\mathrm{C}(9) \cdots \mathrm{C}(10)$ vector.
$\boldsymbol{\delta}_{1}$ is the folding along $S(1) \cdots S(2)$ vector. $\boldsymbol{\delta}_{2}$ is the folding along $S(3) \cdots S(4)$ vector.
$\theta$ is the dihedral angle between the $S(1) C(16) C(17) S(2)$ and $S(3) C(21) C(22) S(4)$ planes.
$\mathbf{d}_{1}$ is the intramolecular $\mathrm{O}(1) \cdots \mathrm{O}(2)$ distance. $\mathbf{d}_{2}$ is the intramolecular $\mathrm{C}(18) \cdots \mathrm{C}(23)$ distance.
NB: For 78a and 78c two different molecules are present in their crystal structures.

Table 3.3 Dihedral angles and intramolecular distances in the crystal structure and calculated from modelling studies (See Appendix $T w o$ ) for compounds 76, 78a-d, 76 ${ }^{2+}$, $78 \mathrm{a}^{2+}, 78 \mathrm{~b}^{2+}$ and $78 \mathrm{~d}^{2+}$.

### 3.2.2.2 Electrochemical Studies.

In order to study the electrochemical behaviour of the cyclophanes, cyclic voltammetry studies have been performed on all the bridged systems (78a-d) and compared with the redox properties of the model non-bridged compound 52 (see also Chapter Two), and the precursors of the bridged systems (74, 75a-b and 76). The results obtained reveal some very interesting trends (Table 3.4).

|  | $E_{\text {pa }}^{\text {Ox }} / \mathrm{V}$ | $E_{\mathrm{pc}}^{\mathrm{Ox}} / \mathrm{V}$ | $\Delta E / \mathrm{V}$ |  |
| :---: | :---: | :---: | :---: | :---: |
| 52 | 0.41 (2e) | 0.12 | 0.29 |  |
| (E/Z) 74 | 0.36 (2e) | 0.13 | 0.23 |  |
| (E/Z) 75a | 0.61 (2e) | 0.26 | 0.35 |  |
| (E/Z) 75b | 0.53 (2e) | 0.22 | 0.31 |  |
| (E/Z) 76 | 0.36 (2e) | 0.08 | 0.28 | $\mathrm{C}_{5}$ |
| 78a | 0.70 (2e) | 0.63 | 0.07 | - |
| 78b | 0.70 (2e) | 0.66 | 0.04 | $\mathrm{R}_{1}, \mathrm{R}_{2}=\mathrm{CO}_{2} \mathrm{Me}(\mathrm{E} / Z) 75 \mathrm{a}$ |
| 78c | 0.72 (2e)/1.08 (1e) | $0.96 / 0.60$ | $0.12 / 0.12$ | $\mathrm{R}_{1}, \mathrm{R}_{2}=\mathrm{CH}_{2} \mathrm{OH}$ (E/Z) 76 |
| 78d | 0.47 (2e) | 0.28 | 0.19 |  |

Table 3.4 Cyclic voltammetric data. $\Delta E=E_{\mathrm{pa}}^{\mathrm{Ox}}-E_{\mathrm{pc}}^{\mathrm{Ox}}$
$E_{\mathrm{pa}}^{\mathrm{Ox}}$ is the oxidation peak potential on the first anodic scan;
$E_{\mathrm{pc}}^{\mathrm{Ox}}$ is the coupled reduction peak potential on the cathodic scan.
(Experimental conditions: Acetonitrile, Pt electrode, versus $\mathrm{Ag} / \mathrm{AgCl}$, electrolyte $\mathrm{Bu}_{4} \mathrm{~N}^{+} \mathrm{PF}_{6}{ }^{-}(0.1 \mathrm{M}), 20^{\circ} \mathrm{C}$, scan rate $100 \mathrm{mV} \mathrm{s}^{-1}$.)

Comparing the non-bridged systems 74-76, a notable feature, as we discussed in Chapter Two, is that the electron withdrawing ester substituents result in a significant positive shift of the quasi-reversible two-electron redox wave, which is consistent with mesomeric conjugation ( 170 mV for $\mathbf{7 5 b}$ bearing one ester function and 250 mV for $\mathbf{7 5 a}$ bearing two ester functions compare to the unsubstituted precursor 74).

Comparing the bridged systems 78a-d with the model compound 52 , the oxidation potential ( $\mathrm{E}_{\mathrm{pa}}^{\mathrm{ox}}$ ) is raised significantly (by ca. 300 mV ) for 78a-c but only slightly (by 60 mV ) for 78d. This is consistent with the shorter bridges of 78a-c hindering the marked conformational change, which accompanies oxidation to the dication. As we observed previously by molecular modelling for $\mathbf{7 8} a^{\mathbf{2 +}}$ and $\mathbf{7 8} \mathrm{b}^{\mathbf{2 +}}$, their molecular structures are expected to be close to the structure of their neutral forms, the saddle shaped conformation being still present. Another striking feature of these data is a sequential reduction in the value of $\Delta \mathrm{E}$, which corresponds to an increased reversibility of the oxidation process as the bridge is progressively shortened. $\Delta \mathrm{E}$ is reduced to only 70 and 40 mV for compounds 78 a and 78 b , respectively, compared to the typical values of quasi-reversibility in the range 230-350 mV for non-bridged derivatives (Table 3.4). This reflects the reduced stability of the twisted dication structure within the steric constraints of the smaller cyclophanes. Moreover, the stability of the dicationic species for non-bridged compounds is increased by the gain in aromaticity of the planar anthracene moiety, which is not the case for the smaller cyclophanes; as we observed by molecular modelling of 78 a and 78 b , the anthracene moiety being still folded. This feature is, therefore, less pronounced for 78d, which displays redox behaviour close to the nonbridged model 52, consistent with the molecular structure of the dicationic species $78 \mathrm{~d}^{2+}$ which is closer to the dicationic structure of nonbridged derivatives (Figure 3.13).

Figure 3.13 Cyclic voltammograms of 52, 78a, 78d (under the conditions stated in Table 3.4)

The cyclic voltammetry of the ferrocenyl bridge 78c reveals an additional, quasireversible, one-electron oxidation wave at $\mathrm{E}^{0 \mathrm{x}}{ }_{\mathrm{pa}} 1.08 \mathrm{~V}$, arising from the ferrocene/ferrocenium redox couple, which also corresponds to the formation of the $78 \mathrm{c}^{3+}$ species (Figure 3.14). The smaller current associated with this second wave is also consistent with the primary oxidation wave of these cyclophanes being a two electron process, which has been also confirmed by ${ }^{1} \mathrm{H}$ NMR studies of the oxidised species (Figure 3.15). The positive shift for the ferrocene oxidation wave in 78c, compared to standard diester derivatives of ferrocene $\left(79, \mathrm{E}^{1 / 2} 0.972 \mathrm{~V} \text { vs } \mathrm{Ag} / \mathrm{AgCl} \text { in } \mathrm{CH}_{2} \mathrm{Cl}_{2}\right)^{13}$ is explained by intramolecular Coulombic repulsion between the ferrocenium and the dithiolium cations, together with steric constraints of the bridge.

78c

79

Figure 3.14 Cyclic voltammogram of 78c (under the conditions stated in Table 3.4).

In order to provide additional evidence that the oxidation of all the bridged systems gave their corresponding dication species, to the exclusion of the formation of cation radical species, as was clearly suggested by the electrochemical studies, ${ }^{1}$ H NMR spectra of the oxidised species have been recorded. For example, ${ }^{'} \mathrm{H}$ NMR spectra of 78a in $\mathrm{CD}_{3} \mathrm{CN}$ before and after addition of iodine (Figure 3.15), resulted in a clean change in the spectrum consistent with complete conversion to the dication salt $78 \mathrm{a}^{2+}\left(\mathrm{I}_{3}{ }^{-}\right)_{2}$ (No broadening was observed which would imply the presence of radicals). New peaks are present at $\delta 5.86(4 \mathrm{H})$ and $2.93(6 \mathrm{H}, \mathrm{Me})$, replacing those at $4.70\left(2 \mathrm{H}, \mathrm{H}_{\mathrm{a}}\right), 5.64\left(2 \mathrm{H}, \mathrm{H}_{\mathrm{b}}\right)$ and $2.07(6 \mathrm{H}, \mathrm{Me})$ obtained for 78 a in $\mathrm{CD}_{3} \mathrm{CN}$. This deshielding effect is characteristic of the positive charge on each dithiolium ring. Protons $\mathrm{H}_{\mathrm{a}}$ and $\mathrm{H}_{\mathrm{b}}$ are no longer differentiable in the spectrum of the oxidised $\mathbf{7 8} \mathbf{a}^{2+}$, consistent with a twist of the dithiole rings
occurring during oxidation which places these two protons in the similar magnetic environment, in a more symmetrical position at a distance more analogous to the methyl group, compared with the neutral form where $\mathrm{H}_{\mathrm{a}}$ is pointing towards the inside of the cavity, nearer to the methyl group than $\mathrm{H}_{\mathrm{b}}$ pointing outside the cavity (Figure 3.15 and also Figure 3.5).

Figure 3.15 Molecular modellings and ${ }^{1} \mathrm{H}$ NMR spectra in $d_{3}$-acetonitrile for 78 a (a) and $78 \mathrm{a}^{2+}$ (b). Residual solvent peaks (at $\delta 1.93 \mathrm{ppm}$ for acetonitrile and at $\delta 2.15 \mathrm{ppm}$ for water) have been removed for more clarity.

### 3.3 Conclusion.

Anthracenediylidene derivatives are outstanding compounds, which exhibit a saddle shaped conformation thus presenting a semi cavity. We have developed a new strategy based on the flexibility of this conformation, which has allowed the synthesis of new cyclophanes by bridging the preformed structure. Therefore, this strategy enables the use of different bridging spacers. Consequently, the size of the inner cavity can be controlled and the redox properties of the resulting cyclophanes can be finely tuned. The redox properties of the bridged systems are unique and depend on the size of the bridge used. Nevertheless, this single bridging is not sufficient to stabilise the radical cation, which has not been observed throughout this study. Even for the smallest bridged system (thienyl bridge 78b), the structure still possess enough freedom to twist during oxidation which seems to be the key factor in the formation of the dication (theoretical studies, as we discuss in Chapter One, having postulated that the radical cation conformation would be very close to the neutral structure). However, this study has paved the way to the synthesis of new cyclophanes including doubly-bridged systems ${ }^{\dagger}$, which should exhibit remarkable redox properties and opened the door to the study of redox-controlled molecular recognition within related cyclophane cavities.

## Chapter Four

## Dendritic Macromolecules:

## Towards Supramolecular Architecture.

### 4.1 Redox-Active Dendrimers.

Dendrimers are a relatively new class of macromolecule. These materials comprise a multifunctionalised core, from which radiate repeating layers of monomers with a branch occurring at each monomer unit (Figure 4.1). Dendrimers attract considerable attention for their well-defined, three-dimensional frameworks in which functional groups can be placed in predetermined positions thereby imparting special properties to the molecules.

Figure 4.1. A fifth generation dendritic structure.

The interest in dendrimers has blooming over the last decade; thus, partial aspects of the synthesis and properties of dendrimers have been reviewed (Table 4.1).

Table 4.1 Recent reviews on specific aspects of dendrimers.

Redox-active dendrimers comprising organomettalic groups (metallodendrimers) or redox-active molecules at the centre or on the periphery, are excellent candidates for use in practical applications such as new organic semiconductors, electron transfer mediators, new materials for energy conversion, new sensors and mimic molecules of biological redox processes

### 4.1.1 Metallodendrimers.

The three dimensional structure of dendrimers can influence the microenvironment around the electroactive centre and hence studies are focused on both the dendritic wedge effect on the electroactive core and the redox behaviour of multiple electroactive sites on the higher generation dendrimer surfaces. Recently, Majoral et al. ${ }^{11}$ studied the incorporation of ferrocene units at the core (83-87), within branches (88), and on the periphery (89) of phosphorous-containing dendrimers. A marked dendritic effect has been observed for this class of compounds. For 83-87 (Scheme 4.1), the ferrocenyl core is insulated as the generation is increased leading to almost electrochemically inactive molecules for $\mathbf{8 6}$ and $\mathbf{8 7}$ (comprising 32 and 64 CHO end groups, respectively).

i) $81 \mid$ ii) 82

87
Scheme 4.1 Synthesis of phosphorous containing dendrimers 83-87 comprising a ferrocenyl core.

Dendrimer 88 having three consecutive ferrocene layers within the branches displays two sequential redox processes. Both inner layers are oxidised at the same potential, the outer layer needed a higher potential for oxidation due to the presence of the electronwithdrawing formyl groups $\left(\mathrm{E}_{1}^{1 / 2}=0.66 \mathrm{~V}, E_{2}^{1 / 2}=0.80 \mathrm{~V} \mathrm{vs}\right.$. SCE in THF/acetone 2:1 $\mathrm{v} / \mathrm{v})$. This behaviour indicates that electronic effects have a greater importance than the localisation upon the oxidation process.

Finally, the largest dendritic ferrocenyl derivative 89 comprising theoretically 1536 ferrocenyl groups on its periphery has been studied by cyclic voltammetry and displays one oxidation wave corresponding to the oxidation of all the ferrocenyl units at the same potential (theoretical number of transferred electrons 1532, consistent for a such large molecule which can easily be adsorbed at the surface of the electrode and therefore modify the measurement of transferred electrons).

The multiferrocenium derivatives obtained from exhaustive electrolysis of 89, which deposit onto the Pt electrode surface, formed conducting films. Cuadrado et al. ${ }^{12}$ studied the immobilisation of silicon based ferrocenyl dendrimer such as compounds 90 93 on electrode surfaces and obtained successfully modified electrodes which were used as amperometric biosensors. ${ }^{13}$

Ferrocenyl dendrimers 90-93 act in this process as electron mediating species in dendrimer/glucose-oxidase/carbon paste electrodes. Cyclic voltammograms of these carbon paste electrodes showed that the addition of glucose leads to the enhancement of the oxidation current and decrease of the cathodic peak indicative of a the enzymedependent catalytic reduction of the ferricinium cations (Figure 4.2).

Figure 4.2 Cyclic voltammograms for dendrimer 93/glucose oxidase/carbon paste electrode with no glucose present (----) and with 0.1 M glucose (-) (a), Variation of the steady-state current of the dendrimer/glucose oxidase/carbon paste electrodes with glucose concentration for dendrimers 90-93 (b)

For their high redox stability, ferrocenyl dendrimers can also be considered as molecular batteries, electron sponges or electron reservoirs, which might find applications in molecular-electronic devices. ${ }^{14,15}$

Among the more studied redox systems incorporated in dendritic structures, metalloporphyrin dendrimers such as compounds 94-96 have been designed in attempts to mimic the properties of heme proteins and chlorophylls. ${ }^{16,17 .}$

Dendrimers 94-96 are water-soluble compounds and model studies suggest their use as mimic to heme-containing proteins such as cytochrome $c$ (Figure 4.3).

Cytochrome $c$

Figure 4.3 Computer-generated model of the dendritic zinc porphyrin 94 and X-ray crystal structure of cytochrome $c$ (bonita).

Electrochemical studies on dendritic Zn or Fe porphyrins such as $94-96$ are very dependent on generation, in particular, the polarity of the pendant arms strongly influences the redox potential of electrochemical reactions at the porphyrin core. For dendrimer 96 , the potential of the $\mathrm{Fe}^{2+} / \mathrm{Fe}^{3+}$ couple in water was raised by ca. 300 mV compare to lower generation systems. This is consistent with the dense packing of higher generation preventing solvation of the core, which destabilises the $\mathrm{Fe}^{3+}$ state. This observation is similar to the electron transfer proteins such as cytochrome $c$, for which the oxidation potential of the $\mathrm{Fe}^{2+} / \mathrm{Fe}^{3+}$ couple in aqueous solution is raised of $300-400 \mathrm{mV}$ compare to similar heme proteins which lack of hydrophobic peptide shell.

Porphyrin dendrimers have also been studied for the mimicry of natural oxidation catalysts, in particular heme-based oxygenases. Manganese porphyrins carrying oxidatively robust poly(phenyl ester) dendrons such as compound 97 were reported by Moore et al. ${ }^{18,19}$ and were found to catalyse the shape-selective epoxidation of alkenes when iodosobenzene was used as the oxidizing agent (Figure 4.4). The shape-selectivity of the epoxidation is due to the structure of the dendrimer, which has been studied by molecular modelling showing that the top access is completely blocked but the side-access to the putative metal oxo intermediate is available with an entrance opening of $7 \AA$ (Figure 4. 5).

Figure 4.4 Shape-selective olefin epoxidation using dendrimer 97 with a manganese (III) porphyrin core as catalyst.

Figure 4.5. Molecular models of 97. Top view (a), showing the sterically crowded top access, and side view (b) showing the pocket of $7 \AA$.

Other metallic redox active moieties have been incorporated into dendritic structures, on their periphery or inside their framework such as ruthenium(II)bis(terpyridiyl) complex ${ }^{20}$, metal(bipyridyl) ${ }^{21,22}$ and iron-sulfur cluster ${ }^{23}$ in the search for new applications such as described previously for ferrocenyl and metalloporphyrins dendrimers.

### 4.1.2 Tetrathiafulvalene Dendritic Structures.

The first dendrimers incorporating tetrathiafulvalene units (98-101) were synthesised using a convergent strategy based on a repetitive coupling/deprotection sequence using 4-(hydroxymethyl)-TTF as the starting monomer. ${ }^{24,25}$

Several problems emerged as a result. These dendrimers have limited solubility in most organic solvents and higher generation dendrimers must be kept a low temperature to prevent decomposition due to instability.

Other dendrimers containing a lipophilic linker such as 102, which comprises 21 TTF units, were synthesised in order to improve the solubility and increase the flexibility of the macrostructure, which should facilitate interactions between the TTF units. ${ }^{26,27}$

All of these dendrimers exhibit two redox couples corresponding to the TTF cation radical and TTF dication species. All the TTF units are independent, no interference was observed during the oxidation. As the number of TTF units increases, the first and second redox waves tend to broaden and sharpen, respectively, probably due to the adsorption or precipitation on the Pt electrode. Dendrimers 98-101 form charge transfer complexes with iodine, analysed by UV-Vis spectroscopy showing two absorption bands in the 516-590 nm and $810-836 \mathrm{~nm}$ regions assignable to isolated TTF cation radicals and cation radical dimers, respectively. The absorption in the lower energy band decreased with increasing dilution, indicating that the dimers form intermolecularly and the oxidised dendrimers selfassociate in solution. For dendrimer 102, a spectroelectrochemistry study upon oxidation at 0.7 V showed the two absorption bands of isolated (non-interacting) TTF cation radical (425 nm), and interacting TTF cation radical dimers ( 800 nm ). Even at very low concentration, both bands are always present, indicating of their intramolecular nature, which is a consequence of the flexibility of the oxyethylene chains.

In a search for optoelectonic properties, compounds containing a phthalocyanine core surrounding by TTF units ${ }^{28}$ such as compound 103 and dendrimers comprising anthraquinone and TTF units, ${ }^{29}$ e.g compound 104 have been successfully synthesised.

Compound 103, in which both phthalocyanine and TTF units are liable to selfassemble by face-to face $\pi$ - $\pi$ stacking, displays supramolecular aggregations depending on the solvent properties. Quenching of the fluorescence in dendrimer 103 is ascribed to rapid intramolecular electron transfer between the excited singlet state of the phthalocyanine core and a peripheral neutral TTF unit acting as an electron donor group.

Dendrimer 104 comprising 8 TTF units ( $\pi$-donors) and 4 anthraquinone units ( $\pi$ acceptors) exhibits clean amphoteric redox behaviour with reversible charged states switching between $104^{+16}, 104^{+8}, 104,104^{-4}$, and $104^{-8}$ and intramolecular charge transfer interaction have been observed by UV-Vis spectroscopy.

Other dendrimers containing redox active organic moieties such as bipyridiium ${ }^{30}$, fullerenes ${ }^{31}$, naphthalene diimides ${ }^{32}$, phenothiazines ${ }^{33}$ have been synthesised, all presenting specific properties due to their unique structures.

### 4.2.1 Preliminary Studies of oligomers.

We first evaluated the possibility of forming dendrimers comprising anthracenediylidene derivatives units at peripheral sites, by synthesising dimer 105 and trimer 106 by reaction of 47 with 1,4-benzenedicarbonyl chloride and 1,3,5-benzene tricarbonyl chloride, respectively (Scheme 4.2).

Scheme 4.2 Synthesis of diemr 105 and trimer 106.

The only previous multi anthracene-TTF derivatives reported in the literature are structurally very different, linked by an oxygen atom bridge between the anthracene units synthesised directly from the corresponding bis (anthraquinone) precursor. ${ }^{35}$

Probably due to mixture of conformers, since each anthracene-TTF unit adopts two possible conformations (Cf. Chapter Two), crystals of dimer 105 and trimer 106 have not been obtained.

Electrochemical data for the dimer 105 and the trimer 106 are consistent with each donor unit acting independently. Dimer 105 displays a four-electron wave related to the formation of the tetracation species, whilst trimer 106 displays a six-electron wave corresponding to the formation of the hexacation species. A comparison with benzyl ester derivative 52 reveals that the oxidation potential are not significantly changed within the series, although it seams that it becomes slightly harder to oxidise in the sequence monomer (52), dimer (105) amd trimer (106) (Table 4.2)

| Compound | $E_{\mathrm{pa}}^{\mathrm{Ox}} / \mathrm{V}$ | $E_{\mathrm{pc}}^{\mathrm{Ox}} / \mathrm{V}$ | $\Delta E / \mathrm{V}$ |
| :---: | :---: | :---: | :---: |
| $\mathbf{5 2}$ | $0.45(2 \mathrm{e})$ | 0.21 | 0.24 |
| $\mathbf{1 0 5}$ | $0.47(4 \mathrm{e})$ | 0.12 | 0.35 |
| $\mathbf{1 0 6}$ | $0.49(6 \mathrm{e})$ | 0.19 | 0.30 |

Table 4.2 Cyclic voltammetric data. $\Delta E=E_{\mathrm{pa}}^{\mathrm{Ox}}-E_{\mathrm{pc}}^{\mathrm{Ox}}$
$E_{\mathrm{pa}}^{\mathrm{Ox}}$ is the oxidation peak potential on the first anodic scan;
$E_{\mathrm{pc}}^{\mathrm{Ox}}$ is the coupled reduction peak potential on the cathodic scan.
[Experimental conditions: Dichloromethane, Pt electrode, versus $\mathrm{Ag} / \mathrm{AgCl}$, electrolyte $\mathrm{Bu}_{4} \mathrm{~N}^{+} \mathrm{ClO}_{4}{ }^{-}(0.1 \mathrm{M}), 20^{\circ} \mathrm{C}$, scan rate $100 \mathrm{mV} \mathrm{s}^{-1}$.]

Trimer 106 can be considered as a generation zero dendrimer, therefore these preliminary results on oligomers of anthracenediylidene derivatives pave the way for the incorporation of this $\pi$-system into dendritic structures, which should possess well-defined redox behaviour.

### 4.2.2 Polyester dendrimers.

The first dendrimer containing anthracene-TTF units was obtained following Miller's methodology by reacting 47 with the silyl-protected diacid chloride 107,34 using triethylamine as base in dichloromethane to afford the first dendron wedge 108 (97\% yield) comprising two units of anthracene-TTF. Deprotection of 108 by tetra-nbutylammonium fluoride (TBAF) afforded the dendron wedge 109 almost quantitatively. By analogy with the synthesis of trimer 106, dendrimer 110 comprising six anthraceneTTF units was obtained by reacting 109 with 1,3,5-benzenetricarbonyl chloride (Scheme 4.3).

47

$$
\left.\begin{array}{l}
108(97 \%) R=\mathrm{SiMe}_{2} \mathrm{Bu}^{\mathrm{t}} \\
109(99 \%) \mathrm{R}=\mathrm{H}
\end{array}\right) \text { TBAF }
$$

Scheme 4.3 Synthesis of dendrimer 110 comprising 6 anthracene TTF units and ester linkages.

Similarly to the synthesis of the first dendron wedge 108, 109 reacted with the silylprotected diacid chloride 107 afforded dendron wedge 111 ( $72 \%$ yield) comprising 4 units of anthracene-TTF. However, repeated attempts to deprotect 111 unexpectedly led to the fragmentation of the molecule and essentially quantitative conversion back to the dendron wedge 109 (Scheme 4.4). Therefore, we were unable to synthesis higher generation analogues of dendrimer 110 by this strategy.

109

111

Scheme 4.4 Synthesis of dendron wedge 111 comprising 4 units of anthracene-TTF.

To.circumvent this problem, we decided to incorporate more robust ether linkages into the dendritic scaffold, using the convergent strategy developed by Fréchet for poly(arylether) systems. ${ }^{36}$

### 4.2.3 Polyether dendrimers.

The monohydroxymethyl anthracene-TTF derivative 47 was converted into the chloromethyl derivative 112 ( $95 \%$ yield) by treatment with triphenylphosphine in carbon tetrachloride. Compound 112 is easily decomposed in presence of acidic media and for this reason dichloromethane must be avoided during the purification by chromatography on silica gel, for which ethyl acetate appeared to be the best solvent. Two-fold reaction of 112 with 3,5-dihydroxybenzyl alcohol (113), using potassium carbonate as base, afforded the dendron wedge 114 in only $28 \%$ yield. The disappointing yield for this reaction is due
to the heterogeneous mixture and poor reactivity of the chloromethyl derivative 112. The dendron wedge 114 was converted into dendrimer 115 (57\%) by direct analogy with the preparation of dendrimer 110 (Scheme 4.5).

Scheme 4.5 Synthesis of dendrimer 115 comprising 6 anthracene TTF units and ether linkages.

Reaction of dendron wedge 114 with the silyl-protected diacid chloride 107 afforded dendron wedge 116 (65\%). Unlike 111 (Scheme 4.4), dendron wedge 116 was cleanly deprotected using tetra-n-butylammonium fluoride (TBAF) to yield the corresponding alcohol derivative 117 ( $70 \%$ yield). Three fold esterification of 117 with 1,3,5-benzenetricarbonyl chloride gave the dendrimer 118 ( $54 \%$ yield) (Scheme 4.0).

Scheme 4.6 Synthesis of dendrimer 118 comprising 12 anthracene TTF units and ether linkages.

Evidence for the synthesis of dendrimers 110,115 and 118 was first obtained by ${ }^{1} \mathrm{H}$ NMR spectra. Unlike for dendrimer 110 and 115 where the two methyl groups ( $\mathrm{Me}_{1}, \mathrm{Me}_{2}$ ) display different chemical shift (Figure 4.6); for dendrimer 118, they are no longer differentiable (Figure 4.7). This observation could be a result of intramolecular interactions inside dendrimer 118, which place the two methyl groups in a more analogous environment for which the nuclear magnetic properties are more similar.

Figure $4.6{ }^{1} \mathrm{H}$ NMR of dendrimer 110 in $\mathrm{CDCl}_{3}$.

Figure $4.7^{1} \mathrm{H}$ NMR of dendrimer 118 in $\mathrm{CDCl}_{3}$.

### 4.2.4 Electrochemical Studies.

Solution electrochemical data, obtained by cyclic voltammetry were performed in two different solvents (THF and Dichloromethane/Acetonitrile (2:1, v/v)), to compare the effect of solubility on the electrochemical behaviour of the dendrimers. A comparison of the model compound 52 (benzyl ester anthracene-TTF derivative) with the dendritic molecules 106, 110, 115 and 118 reveals some interesting trends (Table 4.3).

The benzoyl ester 52 shows the typical quasi-reversible two-electron redox wave from neutral to dication species observed for anthracene-TTF derivatives (See Chapter One).

| Compound | THF |  |  | DCM/Acetonitrile (2:1 $/ \mathrm{v})$ |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | $E_{\mathrm{pa}}^{\mathrm{Ox}} / \mathrm{V}$ | $E_{\mathrm{pc}}^{\mathrm{Ox}} / \mathrm{V}$ | $\Delta E / \mathrm{V}$ | $E_{\mathrm{pa}}^{\mathrm{Ox}} / \mathrm{V}$ | $E_{\mathrm{pc}}^{\mathrm{Ox}} / \mathrm{V}$ | $\Delta E / \mathrm{V}$ |
| $\mathbf{5 2}$ | $0.60(2 \mathrm{e})$ | 0.18 | 0.42 | $0.46(2 \mathrm{e})$ | 0.16 | 0.30 |
| $\mathbf{1 0 6}$ | $0.62(6 \mathrm{e})$ | 0.16 | 0.46 | n.d. | $\mathrm{n} . \mathrm{d}$ | $\mathrm{n} . \mathrm{d}$ |
| $\mathbf{1 1 0}$ | $0.66(12 \mathrm{e})$ | -0.13 | 0.79 | $0.51(12 \mathrm{e})$ | 0.11 | 0.40 |
| $\mathbf{1 1 5}$ | $0.64(12 \mathrm{e})$ | 0.02 | 0.62 | $0.54(12 \mathrm{e})$ | 0.08 | 0.46 |
| $\mathbf{1 1 8}$ | $0.61(24 \mathrm{e})$ | -0.54 | 1.15 | not soluble |  |  |

Table 4.3 Cyclic voltammetric data. (n.d. Non determined) $\Delta E=E_{\mathrm{pa}}^{\mathrm{Ox}}-E_{\mathrm{pc}}^{\mathrm{Ox}}$
$E_{\mathrm{pa}}^{\mathrm{Ox}}$ is the oxidation peak potential on the first anodic scan;
$E_{\mathrm{pc}}^{\mathrm{Ox}}$ is the coupled reduction peak potential on the cathodic scan.
[Experimental conditions: Pt electrode, versus $\mathrm{Ag} / \mathrm{AgCl}$, electrolyte $\mathrm{Bu}_{4} \mathrm{~N}^{+} \mathrm{PF}_{6}{ }^{-}(0.1 \mathrm{M})$, $20^{\circ} \mathrm{C}$, scan rate $100 \mathrm{mV} \mathrm{s}^{-1}$.]

The oxidation potential ( $E_{\text {pa }}^{0 \times}$ ) is almost identical for all the compounds [ca. 600 mV in THF and 500 mV in DCM/AcN (2:1 v/v)]. All anthracene-bis(dithiole) units are independent and oxidised at the same time. A broadening of the oxidation peak can be noticed as the generation is increasing. This feature has already been reported with certain other dendrimers containing redox moieties at the periphery. ${ }^{3}$

A striking feature of these data is the as the generation increases there is a decrease in the reversibility of the redox wave in THF leading to a complete electrochemical irreversibility for $118(\Delta E=1150 \mathrm{mV})$ (Figure 4.8).

Figure 4.8 Cyclic voltammograms of dendrimers 110, 115, 118 and benzyl ester derivative 52 in THF (under the conditions stated in Table 4.3).

However, in a mixture of DCM/AcN where the charged species are more soluble, this irreversibility is less pronounced (Figure 4.9).

Figure 4.9 Cyclic voltammograms of dendrimers $\mathbf{1 1 0}, \mathbf{1 1 5}, 118$ and benzyl ester derivative 52 in Dichloromethane/Acetonitrile ( $2: 1 \mathrm{v} / \mathrm{v}$ ) (under the conditions stated in Table 4.3).

This difference of reversibility in the two solvent systems studied is consistent with a precipitation of the charged species occurring on the surface of the Pt electrode in THF, which does not take place in $\mathrm{DCM} / \mathrm{MeCN}$. This is confirmed by the electrode being completely blocked after few scans around $E_{\text {pa }}^{0 x}$ for 110 and 118 in THF and the observation of deposition on the surface of the electrode. However the non-aligned stacking prevents their use as modified electrodes, cf. the ferrocenyl dendrimers reported recently by Astruc et al. ${ }^{14}$ and Cuadrado et al. ${ }^{12}$ which are useful in this regard. Consequently, the decrease of reversibility for 110 and 115 in $\mathrm{DCM} / \mathrm{MeCN}$ ( $\triangle \mathrm{E}$ increased by 100 mV and 160 mV , respectively) can be attributed to the dramatic change of conformation which must occur on reduction of the oxidised form of $10^{12+}$ and $15^{12+}$ back to their neutral form. This represents an interesting dendritic effect on the solution redox chemistry.

### 4.2.5 Chemical oxidation $v s$. Electrochemical oxidation.

Addition of iodine to a dichloromethane solution of dendrimers 110,115 and 118 gave red-purple precipitates of the iodide salts of $110^{\mathrm{n}+}, 115^{\mathrm{n+}}$ and $118^{\mathrm{n+}}$. These precipitates could be reduced back to the neutral species by adding sodium hydrosulfite and heating the mixture. The ${ }^{1} H$ NMR spectra recorded before oxidation and after reduction were identical, showing that the chemical redox processes in these dendrimers are reversible without any significant decomposition of the oxidised species. Evidence of complete oxidation to $110^{12+}$ was provided by ${ }^{1} \mathrm{H}$ NMR data in dry DMF (Figure 4.10) in which both the neutral and the oxidised species are soluble: in particular, the methyl and $\mathrm{CH}_{2}$ protons $\left(\mathrm{Me}_{1}, \mathrm{Me}_{2}\right.$ and $\left.\mathrm{H}_{\mathrm{d}}\right)$ shifted downfield from $\delta 2.19,1.88$ and 5.23 ppm to $\delta$
$3.36,3.10$ and 6.28 ppm , respectively, consistent with each unit being oxidised to the bis(1,3-dithiolium) cation, as shown previously in monomeric derivatives (Cf. Chapter Three). No paramagnetic broadening of the NMR spectra were observed, confirming that no cation radical species derived from 110 were present.

Figure $4.10{ }^{1} \mathrm{H}$ NMR spectra in $\mathrm{d}_{7}$-DMF of dendrimers 110 and $110^{12+}$ (obtained by adding iodine into the NMR tube).

### 4.2.6 UV-Vis Spectroscopy.

UV-VIS spectra of dendrimers 110,115 and 118 were obtained in dichloromethane solutions. The benzoyl ester 52 was employed as a model compound, which shows the two characteristic absorption bands at $\lambda_{\max }=368 \mathrm{~nm}$ and $\lambda_{\max }=436 \mathrm{~nm}$ for anthracenebis(ditiole). ${ }^{37}$ UV-VIS spectra of compound $\mathbf{5 2}$ were recorded for a range of concentration varying from C to 20 xC (where $\mathrm{C}=6.31 \times 10^{-6} \mathrm{M}$ ). The absorbance at $\lambda_{\max }=368 \mathrm{~nm}$ and $\lambda_{\max }=436 \mathrm{~nm}$ is a linear function of the concentration (Figure 4.11).

(a)

Figure 4.11 UV-Vis spectra of 52 at varying concentrations $C$ to 20 C (a), linear variation of absorbance as a function of the concentration of compound 52 for the two wavelenght of maximum of absorbance: $\lambda=368 \mathrm{~nm}$ and $\lambda=436 \mathrm{~nm}(\mathrm{~b})$ with $\mathrm{C}=6.31 \times 10^{-6} \mathrm{M}$.

UV-VIS spectra of dendrimers 110,115 and 118 were recorded at the same concentration $\mathrm{C}=6.31 \times 10^{-6} \mathrm{M}$. The spectra obtained for 110 and 115 (curves II and III respectively) are equivalent to a 6 xC spectrum of 52 , and for 118 (curve I), equivalent to a 12xC spectrum of 52 (Figure 4.12). Consequently, the extinction coefficient of each dendrimer corresponds to the extinction coefficient of one chromophore unit multiplied by
the number of units in the dendrimer. This confirms that each chromophore unit is acting independently, with no dendritic effect observed in the optical spectra. Therefore, this spectroscopic technique could also be used to quantify the number of units present for a new dendrimer.

(a)
(b)

Figure 4.12 UV-Vis spectra of $\mathbf{5 2}$ (at varying concentration C to 20 C , blue curves), dendrimers 110 (concentration C, red curve II), dendrimer 115 (concentration C , red curve III) and dendrimer 118 (concentration C , red curve I ); $\mathrm{C}=6.31 \times 10^{-6} \mathrm{M}$ in dichloromethane (a). Correlation of the maxima of absorption for dendrimers 110, 115 and 118 at concentration C (red points) to the linear variation of absorbance as a function of the concentration of compound 52 (b).

### 4.2.7 Modelling Studies.

In order to visualise the change in conformation occurring during oxidation, molecular modelling studies were performed on dendrimers 110, 118 and their oxidised form $110^{12+}$ and $118^{24+}$ by molecular mechanics.

In the precedent Chapter, we performed the energy minimisation of the anthracenebis(dithiole) unit in the neutral state with the dihydroxymethyl derivatives $(\boldsymbol{E})$ and ( $\boldsymbol{Z}$ ) 76 (See also Appendix Two), showing the most favourable saddle-shape conformation which is in agreement with X-ray crystal structures ${ }^{37-39}$ and theoretical calculations ${ }^{40}$ reported in the literature for monomeric derivatives.

Energy minimisation of the core was then performed before the addition of the energy-minimised units at its periphery. Geometry optimisation of the dendrimers 110 was then calculated. The energy-minimised conformation of $110^{12+}$ was obtained by setting to the energy-minimised conformation of 110 (Figure 4.13), a positive charge on the $C(2)$ atom of each dithiole ring (i.e. 12 positive charges in total). The structure obtained for $10^{12+}$ (Figure 4.14) shows that each unit adopts the characteristic dicationic shape wherein the anthracene moiety is planar with the two dithiole units perpendicular to it, which is in accord with theoretical calculations and X-ray crystal structures (Cf. Chapter One). It also complies with a maximum space expansion between the units arisen from Coulombic repulsion between the positively charged dithiole rings. It should be noted that for the neutral form of dendrimer 110 other unsymmetrical local minima of comparable energy can be reached where $\pi-\pi$ interactions between the units occur. On the contrary, starting from different non-optimised geometries of $110^{12+}$, only one converged form was
observed, in which all the charged units are as far as possible one of each other. The presented structure of $\mathbf{1 1 0}$ ( 2 views) is therefore shown to help visualise the neutral structure and allow a good comparison between the shape of the neutral and oxidised forms of the dendrimer. The main feature of these structures is the average molecular diameter of their spherical shape, which is of $40 \AA$ for 110 and $46 \AA$ for $110^{12+}$. This is representative of the compact form of $\mathbf{1 1 0}$ imposed by the saddle-shape conformation of the units, compared to the more extended form of $\mathbf{1 1 0}{ }^{12+}$ imposed by the Coulombic repulsion.

Figure 4.13 Molecular model of dendrimer 110: perpendicular to the plane of the core benzene ring (a) and along the plane of this ring (b). Colour code: 9,10-bis(1,3-dithiole-2-ylidene)-9,10-dihydroanthracene system (dark blue); sulfur (yellow); oxygen (red); remaining carbon scaffold (light blue).

Figure 4.14 Molecular model of dendrimer $110^{12+}$
(views and colour codes as for Figure 4.13)

Modelling studies of dendrimer 118 , were performed similarly to the calculations performed for dendrimer $\mathbf{1 1 0}$. The proximity of the 12 units of dendrimer 118 leads to $\pi-\pi$ interactions between the units and consequently to several converged unsymmetrical structures, but also to a symmetrical one of lowest energy (Figure 4.15). The energyminimised structure of $\mathbf{1 1 8}^{\mathbf{2 4 +}}$ was obtained by setting a positive charge on each $\mathrm{c}(2)$ atom of each dithiole ring (i.e 24 positive charges in total), and like for $11 \mathbf{0}^{12+}$, only one converged structure of $\mathbf{1 1 8}^{\mathbf{2 4 +}}$ (Figure 4.16) was obtained due to Coulombic repulsion, placing the charged units with the maximum space expansion. The structural differences between the neutral and the oxidised forms of dendrimer 118 are even more pronounced especially due to the $\pi-\pi$ interactions occurring inside the dendritic structure. Consequently, dendrimer 118 presents a cylindrical shape (ca. $52 \AA \times 30 \AA$ ) and its oxidised form the expected spherical shape with an average molecular diameter of 61 A .

### 4.3 Conclusion.

We have successfully synthesised and extensively characterised the first dendrimers to incorporate the anthracene-bis(dithiole) system, with 3, 6 and 12 of these redox units at the periphery using a convergent methodology with aryl ester and aryl ether units in the branches, joined to a 1,3,5-benzene triester core. These macromolecules possess welldefined redox activity, and the two-electron oxidation of each of the redox units affords species with high charge:molecular weight ratio. The structural properties of the anthracenediylidene derivatives, which undergo a dramatic change of conformation upon oxidation impart to these dendrimers unique properties. 1 H NMR studies of dendrimer 118 suggest intramolecular interactions inside the dendritic structure between the units, which have been supported by molecular models. These interactions bestow to the dendrimer a more compact structure, which upon oxidation, due to Coulombic repulsion undergoes a global change of conformation simultaneously to the change of conformation of each unit. Consequently, the cavities inside the neutral and oxidised forms are completely different which opens the door to host-guest properties, which can be forecast for this class of nanoparticles. Charged organic nanoparticles of this type are also relevant to the miniaturisation of electronic materials. ${ }^{41}$ The dendritic wedges synthesised during the course of this work, which possess reactive alcohol substituents, are available in synthetically useful quantities and should be amenable to other synthetic transformations to yield dendronised polymers or new systems which undergo multi-electron charge-transfer processes.

## Chapter Five

## Experimental Details.

### 5.1 General Equipments and Procedures.

${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra were obtained on Oxford 200, Varian Unity 300 and Varian VXR 400 S spectrometers operating at $199.992\left({ }^{1} \mathrm{H}\right)$ and $50.293\left({ }^{13} \mathrm{C}\right), 299.908\left({ }^{1} \mathrm{H}\right)$ and $75.420\left({ }^{13} \mathrm{C}\right)$, and $400.0\left({ }^{1} \mathrm{H}\right)$ and $100.6\left({ }^{13} \mathrm{C}\right) \mathrm{MHz}$, respectively.

Mass spectra were recorded on a Micromass Autospec spectrometer operating at 70 eV .

MALDI TOF mass spectra were obtained on a Kratos IV instrument in the reflection mode, operating with irradiation from a nitrogen laser at 337 nm . The matrix was 2,5dihydroxybenzoic acid, and spectra were averaged over 100 pulses whilst scanning across the sample: peak half-widths were between 6-10 amus.

Infra-red spectra were recorded using KBr disks on a Perkin Elmer 1600 FTIR, spectrometer operated from a Grams Analyst 1600.

Electronic absorption spectra were obtained using a Perkin Elmer II UV-vis spectrophotometer operating with 1 mL quartz cells.

Melting points were obtained on a Philip Harris melting point apparatus and are uncorrected.

Cyclic voltammetric data were measured with iR compensation using a BAS CV50 electrochemical analyser. The experiments were carried out with 3 mL of a ca. $10^{-4} \mathrm{M}$ solution of the compound in dichloromethane containing 0.1 M tetrabutylammonium perchlorate as the electrolyte, at scan rate $100 \mathrm{mV} \mathrm{s}^{-1}$ (unless specified otherwise). The oxidation potentials were measured versus a platinum wire quasi-reference electrode and corrected versus decamethylferrocene/decamethylferrocenium ${ }^{+}$by adding decamethylferrocene to the studied solution after the experiment, and referenced versus $\mathrm{Ag} / \mathrm{AgCl}$.

Structures were modelled and optimised in the gas phase and without consideration of the counter ions using the MM+ program Hyperchem 5.0: Hyperchem, Inc., 1115 NW $4^{\text {th }}$ Street, Gainesville, FL 32601 (USA) (See Appendix Two).

Column chromatography was carried out using Merck silica gel (70-230 mesh) and solvents were distilled prior to use in column chromatography.

All reactions were performed under an inert atmosphere of nitrogen in pre-dried glassware.

### 5.2 Experimental Procedures for Chapter Two.

## 10-(4,5-Dimethyl-1,3-dithiol-2-ylidene)- 9,10-dihydro-9-(4-hydroxymethyl-5-

 methyl-1,3-dithiol-2-ylidene)anthracene (47):

47
To a stirred solution of 9-(4-methyloxycarbonyl-5-methyl-1,3-dithiol-2-ylidene)-10-(4',5'-dimethyl-1',3'-dithiol-2'-ylidene)-9,10-dihydroanthracene $\mathbf{2 6}^{1}$ ( $3.00 \mathrm{~g}, 6.25$ mmol ) in dry THF under $\mathrm{N}_{2}$ at $0^{\circ} \mathrm{C}$ was added dropwise lithium aluminium hydride (1.00 $\mathrm{g}, 26.38 \mathrm{mmol}$ ) and the resultant mixture was stirred for 1 h at $0^{\circ} \mathrm{C}$ and 2 h at room temperature. After adding dropwise wet sodium sulphate (in excess), the reaction mixture was stirred for 1 h , during which time the solution changed from green to orange. The reaction mixture was filtered through Celite. After evaporation, the residue was chromatographed on a silica column eluting with dichloromethane to afford 47 ( 2.55 g ,
$90 \%$ ). Recrystallisation, if required, may be achieved by dissolution in dichloromethane and addition of hexane. M.p. $>250^{\circ} \mathrm{C} .{ }^{1} \mathrm{H}$ NMR (DMSO- $\mathrm{d}_{6}$ ): $\delta=7.56-7.54(\mathrm{~m}, 4 \mathrm{H}) 7.34-$ $7.30(\mathrm{~m}, 4 \mathrm{H}) 4.20\left(\mathrm{dd}, J_{A B}=13 \mathrm{~Hz}, 2 \mathrm{H}\right) 1.95(\mathrm{~s}, 3 \mathrm{H}) 1.92(\mathrm{~s}, 6 \mathrm{H}) . \mathrm{IR}(\mathrm{KBr}): v=3400(b r$.$) ,$ 1514, 1512, 1452, 1446, 755, $644 \mathrm{~cm}^{-1}$. UV/Vis $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right): \lambda_{\max }(\log \varepsilon) 368(4.03), 436$ (4.30) nm. MS (EI): m/z (\%) 452 (100) $\left[\mathrm{M}^{+}\right] . \mathrm{C}_{24} \mathrm{H}_{20} \mathrm{OS}_{4}$ (452.7): calcd. C 63.68, H 4.45; found C 63.39, H 4.50.

9-(4-5-Dimethyl-1,3-dithiol-2-ylidene)-9,10-dihydro-10-(4-methoxycarbonyl-1,3-dithiol-2-ylidene)anthracene (49)

49
To a stirred solution of $48^{2}(0.5 \mathrm{~g}, 1.22 \mathrm{mmol})$ in dry THF ( 30 mL ), under $\mathrm{N}_{2}$, at $78^{\circ} \mathrm{C}$ was added lithium diisopropylamide monotetrahydrofuran (ca. 1.5 M in cyclohexane, $0.9 \mathrm{ml}, 1.35 \mathrm{mmol}$ ). The reaction mixture was stirred at $-78^{\circ} \mathrm{C}$ during 2 h . Methyl chloroformate ( $0.18 \mathrm{ml}, 2.44 \mathrm{mmol}$ ) was then added and the mixture was stirred and left to warm to $20^{\circ} \mathrm{C}$ overnight. Solvents were removed in vacuo and the residue was purified by chromatography on silica gel with DCM/Hexane ( $1: 1 \mathrm{v} / \mathrm{v}$ ) as eluent to afford $49(0.19 \mathrm{~g}$, $40 \%$ ) as an orange solid, separated from unchanged 48 and traces of 50 . M.p. $180-182^{\circ} \mathrm{C}$. ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta(\mathrm{ppm})=7.7-7.5(\mathrm{~m}, 4 \mathrm{H}), 7.4-7.2(\mathrm{~m}, 4 \mathrm{H}+1 \mathrm{H}), 3.79(\mathrm{~s}, 3 \mathrm{H}), 1.93(\mathrm{~s}$, $6 H) . \operatorname{IR}(\mathrm{KBr}): v=1712,1564,1517,1457,1445,1251,1056,754,674,643 \mathrm{~cm}^{-1} . \mathrm{UV} / \mathrm{Vis}$ $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right): \lambda_{\max }(\log \varepsilon) 360(4.08), 428$ (4.31) nm. MS (EI): m/z (\%) 466 (100) $\left[\mathrm{M}^{+}\right]$. $\mathrm{C}_{24} \mathrm{H}_{18} \mathrm{O}_{2} \mathrm{~S}_{4}$ (466.7): calcd. C 61.77, H 3.89; found C 62.07, H 4.09 .

10-[4,5-Di(methoxycarbonyl)-1,3-dithiol-2-ylidene]-9-(4-5-dimethyl-1,3-dithiol-

## 2-ylidene)-9,10-dihydroanthracene (50)

50
To a stirred solution of $48^{2}(210 \mathrm{mg}, 0.51 \mathrm{mmol})$ in dry THF ( 15 mL ), under $\mathrm{N}_{2}$, at $78^{\circ} \mathrm{C}$ was added lithium bis(trimethylsilyl)amide ( $c a .1 .06 \mathrm{M}$ in THF, $2 \mathrm{ml}, 2.04 \mathrm{mmol}$ ). The reaction mixture was stirred at $-78{ }^{\circ} \mathrm{C}$ during 2 h . Methyl chloroformate $(0.16 \mathrm{~mL}$, $2.04 \mathrm{mmol})$ was then added. Workup and purification as described above for 49, gave 50 $(0.26 \mathrm{~g}, 96 \%)$ as an orange-red solid. M.p. $>250{ }^{\circ} \mathrm{C} .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta(\mathrm{ppm})=7.7-7.6$ $(\mathrm{m}, 2 \mathrm{H}), 7.5-7.4(\mathrm{~m}, 2 \mathrm{H}), 7.3-7.2(\mathrm{~m}, 4 \mathrm{H}), 3.81(\mathrm{~s}, 6 \mathrm{H}), 1.93(\mathrm{~s}, 6 \mathrm{H}) . \mathrm{IR}(\mathrm{KBr}): v=1739$, $1718,1583,1512,1454,1444,1259,755,675,644 \mathrm{~cm}^{-1}$. UV/Vis $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right): \lambda_{\max }(\log \varepsilon) 356$ (4.19), 428 (4.40) nm. MS (EI): $\mathrm{m} / \mathrm{z}$ (\%) 524 (40) $\left[\mathrm{M}^{+}\right] . \mathrm{C}_{26} \mathrm{H}_{20} \mathrm{O}_{4} \mathrm{~S}_{4}$ (524.7): calcd. C 59.52, H 3.84 ; found C 59.26, H 3.79.

10-[4,5-Di(hydroxymethyl)-1,3-dithiol-2-ylidene]-9-(4-5-dimethyl-1,3-dithiol-2-ylidene)-9-10-dihydroanthracene (51)

51
Following the same procedure as for compound 47, compound 50 ( $200 \mathrm{mg}, 0.38$ $\mathrm{mmol})$ and lithium aluminium hydride ( $0.11 \mathrm{~g}, 3 \mathrm{mmol}$ ) afforded $51(180 \mathrm{mg}, 95 \%)$ as a orange solid. Recrystallisation from dichloromethane/methanol gave purple prisms
suitable for X-Ray analysis. M.p. $>250{ }^{\circ} \mathrm{C} .{ }^{1} \mathrm{H}$ NMR (DMSO- $\mathrm{d}_{6}$ ): $\delta(\mathrm{ppm})=7.6-7.5(\mathrm{~m}$, $4 \mathrm{H}) 7.4-7.3(\mathrm{~m}, 4 \mathrm{H}), 5.42\left(\mathrm{t}, \mathrm{J}_{O H, H}=5.5 \mathrm{~Hz}, 2 \mathrm{H}\right), 4.27\left(\mathrm{dd}, \mathrm{J}_{A B}=13.5 \mathrm{~Hz}, \mathrm{~J}_{H, O H}=5.5 \mathrm{~Hz}\right.$, $2 \mathrm{H}), 4.19\left(\mathrm{dd}, \mathrm{J}_{A B}=13.5 \mathrm{~Hz}, \mathrm{~J}_{H, O H}=5.5 \mathrm{~Hz}, 2 \mathrm{H}\right), 1.93(\mathrm{~s}, 6 \mathrm{H}) . \mathrm{IR}(\mathrm{KBr}): v=3400(b r$.$) ,$ $1519,1443,1279,755,675,644 \mathrm{~cm}^{-1} . \mathrm{UV} / \mathrm{Vis}\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right): \lambda_{\max }(\mathrm{log} \varepsilon) 364$ (4.14), 432 (4.40) nm. MS (EI): m/z (\%) 468 (49) [M $\left.{ }^{+}\right], 450(100) . \mathrm{C}_{24} \mathrm{H}_{20} \mathrm{O}_{2} \mathrm{~S}_{4}$ (468.7): calcd. ( +0.5 mol of $\mathrm{H}_{2} \mathrm{O}$ ) C 60.34, H 4.43; found C 60.22, H 4.26 .

## 10-(4,5-Dimethyl-1,3-dithiol-2-ylidene)-9,10-dihydro-9-(5-methyl-4-phenyl

 carbonyloxymethyl-1,3-dithiol-2-ylidene)anthracene (52)

52

To a stirred solution of alcohol $47(100 \mathrm{mg}, 0.22 \mathrm{mmol})$ in dry dichloromethane ( 10 mL ) under $\mathrm{N}_{2}$ at room temperature was added benzoyl chloride ( $26 \mu \mathrm{l}, 0.22 \mathrm{mmol}$ ) and triethylamine ( $61 \mu \mathrm{~L}, 0.44 \mathrm{mmol}$ ). The resultant mixture was stirred during 2 h . After evaporation, the residue was chromatographed on silica eluting with dichloromethane to give 52 as an orange powder ( $122 \mathrm{mg}, 99 \%$ ). An orange prism suitable for X -ray structural analysis was obtained by recrystallisation from dichloromethane. M.p. $228-231{ }^{\circ} \mathrm{C} .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta(\mathrm{ppm})=8.0(\mathrm{dd}, J=7 \mathrm{~Hz}, J=1 \mathrm{~Hz}, 2 \mathrm{H}) 7.6(\mathrm{~m}, 4 \mathrm{H}) 7.55(\mathrm{tt}, J=7.5 \mathrm{~Hz}$, $J=1 \mathrm{~Hz}, 1 \mathrm{H}) 7.4(\mathrm{dd}, J=7 \mathrm{~Hz}, J=7.5 \mathrm{~Hz}, 2 \mathrm{H}) 7.2(\mathrm{~m}, 4 \mathrm{H}) 5.04\left(\mathrm{~d}, \mathrm{~J}_{A B}=13 \mathrm{~Hz}, 1 \mathrm{H}\right) 5.01$ $\left(\mathrm{d}, \mathrm{J}_{A B}=13 \mathrm{~Hz}, 1 \mathrm{H}\right) 2.11(\mathrm{~s}, 3 \mathrm{H}) 1.92(\mathrm{~s}, 6 \mathrm{H}) . \mathrm{R}(\mathrm{KBr}): v=1724,1512,1456,1444$, 1262, $754,709 \mathrm{~cm}^{-1}$. UV/Vis $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right): \lambda_{\max }(\log \varepsilon) 368$ (4.15), 436 (4.41) nm. MS (EI): $\mathrm{m} / \mathrm{z}$ (\%) 556 (48) $\left[\mathrm{M}^{+}\right], 436$ (100). $\mathrm{C}_{31} \mathrm{H}_{24} \mathrm{O}_{2} \mathrm{~S}_{4}$ (556.8): calcd. C 66.65; H 4.21; found C 66.87; H 4.34.

10-(4,5-Dimethyl-1,3-dithiol-2-ylidene)-9,10-dihydro-9-(5-methyl-4-(2-naphthyl) carbonyloxymethyl-1,3-dithiol-2-ylidene)anthracene (53)

53
Following the same procedure as for compound 52 , alcohol 47 ( $52 \mathrm{mg}, 0.11 \mathrm{mmol}$ ), 2-naphthaloyl chloride ( $22 \mathrm{mg}, 0.11 \mathrm{mmol}$ ) and triethylamine ( $32 \mu \mathrm{~L}, 0.22 \mathrm{mmol}$ ) in dichloromethane ( 10 mL ) were stirred during 2 h , under $\mathrm{N}_{2}$, at room temperature. After evaporation and chromatography (dichloromethane as eluent), recrystallisation from dichloromethane/hexane gave 53 ( $47 \mathrm{mg}, 67 \%$ ) as orange prisms suitable for X-ray analysis. Mp: 176-178 ${ }^{\circ} \mathrm{C} .{ }^{1} \mathrm{H} \operatorname{NMR}\left(\mathrm{CDCl}_{3}\right): \delta(\mathrm{ppm})=8.60(\mathrm{~s}, 1 \mathrm{H}) 8.0-7.7(\mathrm{~m}, 4 \mathrm{H}) 7.6-$ $7.3(\mathrm{~m}, 6 \mathrm{H}) 7.2(\mathrm{~m}, 4 \mathrm{H}) 5.07(\mathrm{~d}, \mathrm{JAB}=13 \mathrm{~Hz}, 1 \mathrm{H}) 5.03\left(\mathrm{~d}, \mathrm{~J}_{\mathrm{AB}}=13 \mathrm{~Hz}, 1 \mathrm{H}\right) 2.12(\mathrm{~s}, 3 \mathrm{H})$ $1.87(\mathrm{~s}, 6 \mathrm{H}) . \mathrm{RR}(\mathrm{KBr}): 1716,15231456144412791192777755 \mathrm{~cm}^{-1}$. UV/Vis $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right)$ : $\lambda_{\max }(\log \varepsilon) 368$ (4.09), 436 (4.35) nm. MS (EI): $\mathrm{m} / \mathrm{z}(\%) 606$ (87) $\left[\mathrm{M}^{+}\right], 127$ (100). $\mathrm{C}_{35} \mathrm{H}_{26} \mathrm{O}_{2} \mathrm{~S}_{4}$ calcd. (+ 1 mole of $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ ) $\mathrm{C} 62.50, \mathrm{H} 4.08$; found C 62.33, H 3.98 .

9-(4-(2-Anthraquinoyl)-carbonyloxymethyl-5-methyl-1,3-dithiol-2-ylidene)-9,10-dihydro-10-(4,5-dimethyl-1,3-dithiol-2-ylidene)anthracene (54)

54

Following the same procedure as for compound 52, alcohol 47 ( $300 \mathrm{mg}, 0.66$ mmol ), anthraquinone-2-carbonyl chloride ( $180 \mathrm{mg}, 0.66 \mathrm{mmol}$ ) and triethylamine (192 $\mu \mathrm{L}, 1.32 \mathrm{mmol}$ ) in dichloromethane ( 30 mL ) were stirred during 2 h , under $\mathrm{N}_{2}$, at room temperature. After evaporation and chromatography (dichloromethane as eluent), recrystallisation from dichloromethane/hexane gave 54 ( $430 \mathrm{mg}, 96 \%$ ) as a black-green crystalline powder. Mp: 216-218 ${ }^{\circ} \mathrm{C} .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta(\mathrm{ppm})=8.95(\mathrm{~s}, \mathrm{lH}) 8.4-8.2(\mathrm{~m}$, 4H) 7.9-7.8 (m, 2H) 7.6-7.5 (m, 4H) 7.3-7.2 (m, 4H) $5.1(\mathrm{~s}, 2 \mathrm{H}) 2.15(\mathrm{~s}, 3 \mathrm{H}) 1.90(\mathrm{~s}, 6 \mathrm{H})$. IR (KBr): 1727, $167715941516144312681237755705 \mathrm{~cm}^{-1}$. UV/Vis $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right): \lambda_{\max }$ (loge) 368 (4.07), 436 (4.31) nm. MS (EI): $\mathrm{m} / \mathrm{z}(\%) 686(100)\left[\mathrm{M}^{+}\right] . \mathrm{C}_{39} \mathrm{H}_{26} \mathrm{O}_{4} \mathrm{~S}_{4}(686.89)$ HRMS: 686.0782 (calcd. 686.0714)

### 5.3 Experimental Procedures for Chapter Three.

## (E, Z)-9,10-Bis(4-methyl-1,3-dithiol-2-ylidene)-9,10-dihydroanthracene (74).

74 (E/Z)

Compound $73^{1}$ ( $5.11 \mathrm{~g}, 22.3 \mathrm{mmol}$ ) was dissolved in dry tetrahydrofuran ( 100 mL ), under $\mathrm{N}_{2}$, at $-78^{\circ} \mathrm{C}$ and a solution of lithium diisopropylamide $1.5 \mathrm{M}(16.4 \mathrm{~mL}, 24.6 \mathrm{mmol})$ was added dropwise. The mixture was stirred at $-78^{\circ} \mathrm{C}$ during 1 h then anthraquinone (2.32 $\mathrm{g}, 11 \mathrm{mmol}$ ) was added and the mixture was left to warm at room temperature overnight. After evaporation of solvent, the crude residue was chromatographed on a silica column
(eluent: dichloromethane/hexanes (1:1 v/v)) to afford $74(3.34 \mathrm{~g}, 73 \%)$ as a yellow solid. (The coproduct of the reaction is the monoWittig adduct which can be easily separated from 74 during chromatography). M.p. $239-240{ }^{\circ} \mathrm{C} .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta(\mathrm{ppm})=7.70-$ $7.64(\mathrm{~m}, 4 \mathrm{H}) 7.30-7.23(\mathrm{~m}, 4 \mathrm{H}) 5.82(\mathrm{dd}, J=1.5 \mathrm{~Hz}, 2 \mathrm{H}) 2.05(\mathrm{dd}, J=1.5 \mathrm{~Hz}, 6 \mathrm{H}) . \mathbb{R}$ $(\mathrm{KBr}): \nu=1518,1455,1441,1279,755,642 \mathrm{~cm}^{-1} . \mathrm{UV} / \mathrm{Vis}\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right): \lambda_{\max }(\log \varepsilon) 368$ (4.05), 432 (4.29) nm. MS (EI): $\mathrm{m} / \mathrm{z}(\%) 408$ (100) $\left[\mathrm{M}^{+}\right] . \mathrm{C}_{22} \mathrm{H}_{16} \mathrm{~S}_{4}(408.63)$ calcd. C 64.66, H 3.95; found C 64.83; H 4.02 .
(E,Z)-9,10-Bis[(4-methyloxycarbonyl-5-methyl)-1,3-dithiol-2-ylidene]-9,10dihydroanthracene (75a).

To a stirred solution of $74(3 \mathrm{~g}, 73.5 \mathrm{mmol})$ in dry tetrahydrofuran ( 250 mL ), under $\mathrm{N}_{2}$, at $-78^{\circ} \mathrm{C}$ was added dropwise a solution of lithium diisopropylamide $1.5 \mathrm{M}(10.8 \mathrm{~mL}$, 162 mmol ). The mixture was stirred at $-78^{\circ} \mathrm{C}$ during 2 h then methylchloroformate ( 3.42 $\mathrm{mL}, 440 \mathrm{mmol}$ ) was added. The mixture was left to warm at room temperature overnight. After evaporation of solvent in vacuo, the residue was chromatographed on a silica column (eluent dichloromethane/hexanes (1:3, then $1: 1 \mathrm{v} / \mathrm{v})$ ) to afford $75 \mathrm{a}(2.36 \mathrm{~g}, 61 \%)$ as a yellow solid. (The coproducts of the reaction are the monoester 75b and the unchanged 74 which can be easily separated from 75 a during chromatography). M.p. $152-154{ }^{\circ} \mathrm{C} .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta(\mathrm{ppm})=7.63-7.55(\mathrm{~m}, 4 \mathrm{H}) 7.33-7.25(\mathrm{~m}, 4 \mathrm{H}) 3.77(\mathrm{~s}, 6 \mathrm{H}) 2.38(\mathrm{~s}, 6 \mathrm{H})$. IR (KBr): $v=1716,1696,1585,1523,1445,1432,1292,1241,1062,755,644 \mathrm{~cm}^{-1}$.
(E,Z)-9-(4-Methyl-1,3-dithiol-2-ylidene)-10-[(4-methyloxycarbonyl-5-methyl)-

## 1,3-dithiol-2-ylidene]-9,10-dihydroanthracene (75b).

75b ( $E / Z$ )
Compound 75b was obtained as a side product of the preceding reaction and isolated during chromatography on silica gel (See experimental procedure for compound $\mathbf{7 5 a}$ ). M.p. $171-174{ }^{\circ} \mathrm{C} .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta(\mathrm{ppm})=7.7-7.5(\mathrm{~m}, 4 \mathrm{H}), 7.4-7.2(\mathrm{~m}, 4 \mathrm{H}), 5.85(\mathrm{~s}$, $1 \mathrm{H}), 3.77(\mathrm{~s}, 3 \mathrm{H}), 2.37(\mathrm{~s}, 3 \mathrm{H}) 2.05(\mathrm{~s}, 3 \mathrm{H}) . \mathrm{R}(\mathrm{KBr}): v=1712,1565,1515,1457,1445$, 1249, 1053, $754,643 \mathrm{~cm}^{-1}$. UV/Vis $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right): \lambda_{\max }(\log \varepsilon) 360(4.05), 428$ (4.33) nm. MS (EI): $\mathrm{m} / \mathrm{z}$ (\%) 466 (100) [ $\left.\mathrm{M}^{+}\right] . \mathrm{C}_{24} \mathrm{H}_{18} \mathrm{O}_{2} \mathrm{~S}_{4}$ (466.66): calcd. C 61.77, H 3.89 ; found C 62.04, H 3.92.
(E, Z)-9,10-Bis[(4-hydroxymethyl-5-methyl)-1,3-dithiol-2-ylidene]-9,10-dihydro anthracene (76).

$76(E / Z)$

Following the same procedure as for compound 47, 76 was obtained by reduction of $75 \mathrm{a}(2.0 \mathrm{~g}, 3.8 \mathrm{mmol})$, in dry THF ( 200 mL ) and lithium aluminium hydride ( $1.15 \mathrm{~g}, 30.4$ mmol ). The chromatography was achieved using ethyl acetate as eluent, to afford 76 (1.45 $\dot{\mathrm{g}}, 82 \%) . \mathrm{M} \cdot \mathrm{p}>250^{\circ} \mathrm{C} .{ }^{1} \mathrm{H} \operatorname{NMR}\left(\mathrm{CDCl}_{3}\right): \delta(\mathrm{ppm})=7.64-7.57(\mathrm{~m}, 4 \mathrm{H}) 7.31-7.28(\mathrm{~m}, 4 \mathrm{H})$ 4.38 (s, 4H) $2.00(\mathrm{~s}, 6 \mathrm{H}) . \mathbb{R}(\mathrm{KBr}): v=3407$ (br.), 1513, 1457, 1445, 1283, 997, 756, 675, $645 \mathrm{~cm}^{-1}$. UV/Vis $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right): \lambda_{\max }(\log \varepsilon) 368(4.09), 432(4.31) \mathrm{nm} . \mathrm{MS}(\mathrm{EI}): \mathrm{m} / \mathrm{z}(\%) .468$ (100) $\left[\mathrm{M}^{+}\right] . \mathrm{C}_{24} \mathrm{H}_{20} \mathrm{O}_{2} \mathrm{~S}_{4}(468.68)$ : calcd C, $61.50 ; \mathrm{H}, 4.30$; found $\mathrm{C}, 61.82 ; \mathrm{H}, 4.60$.

## Benzyl cyclophane (78a)

78a
To a solution of $76(300 \mathrm{mg}, 0.64 \mathrm{mmol})$, in dry dichloromethane $(300 \mathrm{~mL})$, were added 1,4-benzenedicarbonyl chloride ( $130 \mathrm{mg}, 0.64 \mathrm{mmol}$ ) and triethylamine ( 0.36 mL , 2.56 mmol ) and the mixture was stirred at $20^{\circ} \mathrm{C}$ for 2 h . After evaporation in vacuo, the residue was chromatographed on silica with dichloromethane as eluent to give 78a as a yellow solid. Recrystallisation from dichloromethane/hexanes afforded 78a ( $42 \mathrm{mg}, 11 \%$ ). Mp. ca. $250^{\circ} \mathrm{C}$ (decomp.). ${ }^{\mathrm{H}} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta(\mathrm{ppm})=7.88(\mathrm{~s}, 4 \mathrm{H}) 7.60-7.59(\mathrm{~m}, 2 \mathrm{H})$ 7.38-7.36(m, 2H) 7.34-7.32 (m, 2 H).7.26-7.2 (m, 2H) $5.70\left(\mathrm{~d}, 2 \mathrm{H}, \mathrm{J}=13 \mathrm{~Hz}, \mathrm{H}_{\mathrm{a}}\right) 4.43(\mathrm{~d}$, $\left.2 H, J=13 \mathrm{~Hz}, \mathrm{H}_{\mathrm{b}}\right) 2.05(\mathrm{~s}, 6 \mathrm{H}) . \mathrm{R}(\mathrm{KBr}): v=1725,1528,1457,1446,1261,1055,756$, $644 \mathrm{~cm}^{-1}$. UV/Vis $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right): \lambda_{\max }(\log \varepsilon) 356(4.17), 420(4.41) \mathrm{nm} . \mathrm{MS}(\mathrm{EI}): \mathrm{m} / \mathrm{z}(\%) 598$ (100) $\left[\mathrm{M}^{+}\right] . \mathrm{C}_{32} \mathrm{H}_{22} \mathrm{O}_{4} \mathrm{~S}_{4}(598.78$ ) calcd C, $64.19 ; \mathrm{H}, 3.70$; found $\mathrm{C}, 63.90 ; \mathrm{H}, 3.94$.

## Thienyl cyclophane (78b)

78b
Following the same procedure as for compound 78a, 78b was obtained by double esterification of $76(300 \mathrm{mg}, 0.64 \mathrm{mmol})$, in dry dichloromethane ( 300 mL ) with $1,3-$ thiophenedicarbonyl chloride ( $134 \mathrm{mg}, 0.64 \mathrm{mmol}$ ) and triethylamine $(0.36 \mathrm{~mL}, 2.56$ mmol). The chromatography was achieved using dichloromethane as eluent. Recrystallisation was achieved by dissolving 78b in dichloromethane and adding hexanes to afford 78b (32 mg, 8\%) as yellow crystals. Mp. ca. $200{ }^{\circ} \mathrm{C}$ (decomp.). ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta(\mathrm{ppm})=7.65(\mathrm{~s}, 2 \mathrm{H}) 7.53-7.49(\mathrm{~m}, 2 \mathrm{H}) 7.37-7.28(\mathrm{~m}, 6 \mathrm{H}) 5.12(\mathrm{~d}, 2 \mathrm{H}, J=13$ $\mathrm{Hz}, \mathrm{Ha}) 4.61(\mathrm{~d}, 2 \mathrm{H}, J=13 \mathrm{~Hz}, \mathrm{Hb}) 2.06(\mathrm{~s}, 6 \mathrm{H}) . \mathbb{R}(\mathrm{KBr}): v=1719,1528,1457,1446$, 1236, 1091, $756,646 \mathrm{~cm}^{-1}$. UV/Vis $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right): \lambda_{\max }(\log \varepsilon) 356$ (4.17), 420 (4.41) nm. MS (EI): $\mathrm{m} / \mathrm{z}(\%) 604(100)\left[\mathrm{M}^{+}\right] . \mathrm{C}_{30} \mathrm{H}_{20} \mathrm{O}_{4} \mathrm{~S}_{5}(604.81)$ HRMS: 604.00487 (calcd. 686.00497).

## Ferrocenyl cyclophane (78c)

Following the same procedure as for compound 78a, 78c was obtained by double esterification of 76 ( $300 \mathrm{mg}, 0.64 \mathrm{mmol}$ ), in dry dichloromethane ( 300 mL ) with $1,1^{\prime}$ ferrocenedicarbonyl chloride ${ }^{3}$ ( $184 \mathrm{mg}, 0.64 \mathrm{mmol}$ ) and triethylamine $(0.36 \mathrm{~mL}, 2.56$ mmol). The chromatography was achieved using dichloromethane as eluent, and recrystallisation was achieved from dichloromethane/hexanes to afford $78 \mathrm{c}(62 \mathrm{mg}, 14 \%)$ as yellow crystals. Mp. ca. $230{ }^{\circ} \mathrm{C}$ (decomp.). ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta(\mathrm{ppm})=7.50-7.48(\mathrm{~m}$, 2H) 7.39-7.37 (m, 4H) 7.29-7.27 (m, 2H) $4.87(\mathrm{~d}, \mathrm{~J}=13 \mathrm{~Hz}, 2 \mathrm{H}) 4.74-4.72(\mathrm{~m}, 4 \mathrm{H}) 4.71$ (d, $J=13 \mathrm{~Hz}, 2 \mathrm{H}) 4.60-4.58(\mathrm{~m}, 2 \mathrm{H}) 4.34-4.28(\mathrm{~m}, 4 \mathrm{H}) 2.07(\mathrm{~s}, 6 \mathrm{H}) . \mathrm{IR}(\mathrm{KBr}): v=1713$, $1458,1272,1183,1144,1,752 \mathrm{~cm}^{-1}$. UV/Vis $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right): \lambda_{\max }(\mathrm{l} \log \varepsilon) 356$ (4.13), 420 (4.28) $\mathrm{nm} . \mathrm{MS}(\mathrm{EI}): \mathrm{m} / \mathrm{z}$ (\%) 706 (21) $\left[\mathrm{M}^{+}\right] . \mathrm{C}_{36} \mathrm{H}_{26} \mathrm{FeO}_{4} \mathrm{~S}_{4}$ HRMS: 706.01316 (calcd. 706.01305).

## Oxobisphenyl cyclophane (78d)

78d
Following the same procedure as for compound 78a, 78d was obtained by double esterification of $76(300 \mathrm{mg}, 0.64 \mathrm{mmol})$, in dry dichloromethane ( 300 mL ) with $4,4^{\prime}$ oxybis(carbonyl chloride) ( $190 \mathrm{mg}, 0.64 \mathrm{mmol}$ ) and triethylamine ( $0.36 \mathrm{~mL}, 2.56 \mathrm{mmol}$ ). The chromatography was achieved using dichloromethane as eluent, and recrystallisation was achieved from dichloromethane/hexanes to afford 78 d ( $66 \mathrm{mg}, 15 \%$ ) as yellow crystals. M.p. 194-196 ${ }^{\circ} \mathrm{C} .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta(\mathrm{ppm})=7.9(\mathrm{~d}, \mathrm{~J}=7 \mathrm{~Hz}, 4 \mathrm{H}) 7.66-7.62$
$(\mathrm{m}, 4 \mathrm{H}) 7.29-7.26(\mathrm{~m}, 4 \mathrm{H}) 6.86(\mathrm{~d}, \mathrm{~J}=7 \mathrm{~Hz}, 4 \mathrm{H}) 5.37(\mathrm{~d}, \mathrm{~J}=13 \mathrm{~Hz}, 2 \mathrm{H}) 4.65(\mathrm{~d}, \mathrm{~J}=13$ $\mathrm{Hz}, 4 \mathrm{H}) 2.12(\mathrm{~s}, 6 \mathrm{H}) . \mathrm{IR}(\mathrm{KBr}): v=1720,1593,1518,1497,1457,1444,1260,1217$, $1091,1068,755,735,644 \mathrm{~cm}^{-1}$. UV/Vis $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right): \lambda_{\text {max }}(\log \varepsilon) 368(4.10), 440(4.38) \mathrm{nm}$. $\mathrm{C}_{38} \mathrm{H}_{26} \mathrm{O}_{5} \mathrm{~S}_{4}$ (690.87) HRMS: 690.07300 (calcd. 690.07307).

### 5.4 Experimental Procedures for Chapter Four.

Dimer 105.

105

To a stirred solution of alcohol $47(55 \mathrm{mg}, 0.12 \mathrm{mmol})$ in dry dichloromethane ( 10 mL ) under $\mathrm{N}_{2}$ at room temperature was added terephthaloyl chloride ( $12.4 \mathrm{mg}, 0.06 \mathrm{mmol}$ ) and triethylamine ( $34 \mu \mathrm{l}, 0.24 \mathrm{mmol}$ ). The resultant mixture was stirred during 2 h . After evaporation, the residue was chromatographed on silica eluting with dichloromethane to give 105 as an orange powder ( $122 \mathrm{mg}, 99 \%$ ). Mp: $250^{\circ} \mathrm{C}$ (darkening at $220^{\circ} \mathrm{C}$ ). ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta(\mathrm{ppm})=8.02(\mathrm{~s}, 4 \mathrm{H}) 7.5(\mathrm{~m}, 8 \mathrm{H}) 7.2(\mathrm{~m}, 8 \mathrm{H}) 4.96\left(\mathrm{~d}, \mathrm{~J}_{A B}=13 \mathrm{~Hz}, 2 \mathrm{H}\right), 4.92$ $\left(\mathrm{d}, \mathrm{J}_{A B}=13 \mathrm{~Hz}, 2 \mathrm{H}\right) 2.03(\mathrm{~s}, 6 \mathrm{H}) 1.82(\mathrm{~s}, 12 \mathrm{H}) . \mathrm{IR}(\mathrm{KBr}): v=1721,1520,1455,1444$, 1261, 1242, 1096, $755,644 \mathrm{~cm}^{-1}$. UV/Vis $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right): \lambda_{\max }(\log \varepsilon) 368$ (4.12), 436 (4.31) nm. MS (MALDI-TOF): $\mathrm{M}^{+}=1035 . \mathrm{C}_{56} \mathrm{H}_{42} \mathrm{O}_{4} \mathrm{~S}_{8}$ (1035.46) calcd. C $6 \dot{4} .96, \mathrm{H} 4.09$; found C 65.13, H 4.35.

Trimer 106

Following the same procedure as for compound 105,106 was obtained by triple esterification of 47 ( $80 \mathrm{mg}, 0.18 \mathrm{mmol}$ ), in dry dichloromethane ( 30 mL ) with 1,3;5benzenetricarbonyl trichloride ( $15.6 \mathrm{mg}, 0.06 \mathrm{mmol}$ ) and triethylamine ( $49 \mu \mathrm{~L}, 0.36 \mathrm{mmol}$ ). The chromatography was achieved using dichloromethane as eluent to afford 106 ( 70 mg , $78 \%)$ as an orange solid. $\mathrm{Mp}>250{ }^{\circ} \mathrm{C} .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta(\mathrm{ppm})=8.77(\mathrm{~s}, 3 \mathrm{H}) 7.5(\mathrm{~m}$, 12H) $7.2(\mathrm{~m}, 12 \mathrm{H}) 4.96(\mathrm{~m}, 6 \mathrm{H}) 2.02(\mathrm{~s}, 9 \mathrm{H}) 1.79(\mathrm{~s}, 18 \mathrm{H}) . \mathrm{IR}(\mathrm{KBr}): v=1734,1444$, 1223, $755,644 \mathrm{~cm}^{-1}$. UV/Vis $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right)$ : $\lambda_{\max }(\log \varepsilon) 368$ (4.05), 436 (4.31) nm. MS (MALDI-TOF): $\mathrm{M}^{+}=1514 . \mathrm{C}_{81} \mathrm{H}_{60} \mathrm{O}_{6} \mathrm{~S}_{12}$ (1514.13) calcd. (with 1 mol. of $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ ) C 61.59, H 3.91 ; found C 61.77, H 3.92.

## Dendron wedge 108.

To a stirred solution of alcohol $47(800 \mathrm{mg}, 1.77 \mathrm{mmol})$ in dry dichloromethane under $\mathrm{N}_{2}$ at room temperature was added dichloride $107^{4}(320 \mathrm{mg}, 0.885 \mathrm{mmol})$ and triethylamine ( $0.5 \mathrm{~mL}, 3.54 \mathrm{mmol}$ ). The resultant mixture was stirred overnight. After evaporation of the solvents in vacuo, the residue was purified by chromatography on silica gel eluting with dichloromethane to afford the $108(1.00 \mathrm{~g}, 97 \%)$ as an orange solid. Mp: $213-215^{\circ} \mathrm{C}, .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta(\mathrm{ppm})=8.26(\mathrm{~s}, 1 \mathrm{H}) 7.6(\mathrm{~m}, 10 \mathrm{H}) 7.2(\mathrm{~m}, 8 \mathrm{H}) 5.01(\mathrm{~s}, 4 \mathrm{H}) 2.09(\mathrm{~s}, 6 \mathrm{H})$ $1.88(\mathrm{~s}, 12 \mathrm{H}) 0.98(\mathrm{~s}, 9 \mathrm{H}) 0.20(\mathrm{~s}, 6 \mathrm{H})$. IR (KBr): $\mathrm{v}=1727,1521,1445,1219,755,675$, $644 \mathrm{~cm}^{-1}$. UV/Vis $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right): \lambda_{\max }(\mathrm{lg} \varepsilon) 368$ (4.33), 436 (4.58). MS (MALDI-TOF): $\mathrm{M}+=$ 1164. $\mathrm{C}_{62} \mathrm{H}_{56} \mathrm{O}_{5} \mathrm{~S}_{8} \mathrm{Si}(1164.17)$ : calcd. C 63.88, H 4.84; found C $63.76, \mathrm{H} 5.01$.

## Dendron wedge 119.

To a stirred solution of 108 ( $200 \mathrm{mg}, 0.17 \mathrm{mmol}$ ) in dry THF under $\mathrm{N}_{2}$ at room temperature was added tetrabutylammonium fluoride ( 1 M in $\mathrm{THF}, 0.17 \mathrm{~mL}, 0.17 \mathrm{mmol}$ ). The resultant mixture was stirred during 1 h . The solvents were removed by evaporation in vacuo and the residue was purified by chromatography on silica gel with dichloromethane containing $2 \%$ of methanol as eluent, to afford $109(178 \mathrm{mg}, 99 \%)$ as an orange solid. $\mathrm{Mp}>250{ }^{\circ} \mathrm{C} .{ }^{1} \mathrm{H} \operatorname{NMR}\left(\mathrm{CDCl}_{3}\right): \delta(\mathrm{ppm})=8.24(\mathrm{~s}, 1 \mathrm{H}) 7.6(\mathrm{~m}, 10 \mathrm{H}) 7.2(\mathrm{~m}, 8 \mathrm{H}) 5.01(\mathrm{~s}$, 4H) $2.09(\mathrm{~s}, 6 \mathrm{H}) 1.89(\mathrm{~s}, 12 \mathrm{H})$. IR (KBr): $v=3500$ (br.), 1727, 1521, 1445, 1219, 755, 675, $645 \mathrm{~cm}^{-1}$. UV/Vis $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right): \lambda_{\max }(\mathrm{lg} \varepsilon) 368$ (4.39), 436 (4.63). MS (MALDI-TOF): $\mathrm{M}+=$ 1050. $\mathrm{C}_{56} \mathrm{H}_{42} \mathrm{O}_{5} \mathrm{~S}_{8}$, (1051.46): calcd. C 63.97, H 4.03; found C 63.72 , H 4.04.

## Dendrimer 110.

110

By analogy with the preparation of 108 , alcohol 109 ( $100 \mathrm{mg}, 0.1 \mathrm{mmol}$ ), 1,3,5benzenetricarbonyl trichloride ( $8.4 \mathrm{mg}, 0.033 \mathrm{mmol}$ ) and triethylamine ( $26 \mu \mathrm{l}, 0.2 \mathrm{mmol}$ ) in dry dichloromethane $(20 \mathrm{~mL})$ were stirred under $\mathrm{N}_{2}$ at room temperature. Chromatography on silica gel eluting with dichloromethane afforded dendrimer 110 (81 $\mathrm{mg}, 77 \%)$ as an orange solid. $\mathrm{Mp}>250{ }^{\circ} \mathrm{C} .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta(\mathrm{ppm})=9.26(\mathrm{~s}, 3 \mathrm{H}) 8.64$ $(\mathrm{s}, 3 \mathrm{H}) 8.14(\mathrm{~s}, 6 \mathrm{H}) 7.6(\mathrm{~m}, 24 \mathrm{H}) 7.2(\mathrm{~m}, 24 \mathrm{H}) 5.03(\mathrm{~s}, 12 \mathrm{H}) 2.08(\mathrm{~s}, 18 \mathrm{H}) 1.83(\mathrm{~s}, 36 \mathrm{H})$. IR ( KBr ): $v=1729,1520,1444,1213,754,675,644 \mathrm{~cm}^{-1} . \mathrm{UV} / \mathrm{Vis}\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right): \lambda_{\max }(\lg \varepsilon)$ 368 (5.03), 436 (5.27). MS (MALDI-TOF): $\mathrm{M}+=3308 . \mathrm{C}_{177} \mathrm{H}_{126} \mathrm{O}_{18} \mathrm{~S}_{24}$, (3310.47): calcd. C 64.22, H 3.84; found C 63.81, H 4.05.

## Dendron wedge 111.

Following the same procedure as for compound 108, alcohol 109 ( $550 \mathrm{mg}, 0.52 \mathrm{mmol}$ ), dichloride $107(100 \mathrm{mg}, 0.26 \mathrm{mmol})$ and triethylamine ( $0.14 \mathrm{ml}, 1.04 \mathrm{mmol}$ ) afforded 111 ( $450 \mathrm{mg}, 72 \%$ ) as an orange solid. Mp $230^{\circ} \mathrm{C}$ (black powder above $200^{\circ} \mathrm{C}$ ). ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta(\mathrm{ppm})=8.62(\mathrm{~m}, 3 \mathrm{H}) 8.11(\mathrm{~d}, \mathrm{~J}=1 \mathrm{~Hz}, 4 \mathrm{H}) 7.89(\mathrm{~d}, \mathrm{~J}=1 \mathrm{~Hz}, 4 \mathrm{H}) 7.6(\mathrm{~m}, 16 \mathrm{H})$ $7.2(\mathrm{~m}, 16 \mathrm{H}) 5.02(\mathrm{~s}, 8 \mathrm{H}) 2.09(\mathrm{~s}, 12 \mathrm{H}) 1.85(\mathrm{~s}, 24 \mathrm{H}) 1.03(\mathrm{~s}, 9 \mathrm{H}) 0.29(\mathrm{~s}, 6 \mathrm{H}) . \mathrm{UV} / \mathrm{Vis}$ $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right): \lambda_{\text {max }}(\lg \varepsilon) 368$ (4.85), 436 (5.12). IR (KBr): $v=1728,1519,1444,1215,756$, $675,644 \mathrm{~cm}^{-1}$. MS (MALDI-TOF): $\mathrm{M}+=2362 . \mathrm{C}_{126} \mathrm{H}_{100} \mathrm{O}_{13} \mathrm{~S}_{16} \mathrm{Si}(2363.28)$.

10-(4,5-Dimethyl-1,3-dithiol-2-ylidene)-9,10-dihydroxy-9-(4-chloromethyl-5-methyl-1,3-dithiol-2-ylidene)anthracene (112).

112

To a stirred solution of alcohol $47(2000 \mathrm{mg}, 4.4 \mathrm{mmol})$ in dry acetonitrile ( 50 mL ) was added triphenylphosphine ( $1.25 \mathrm{~g}, 4.8 \mathrm{mmol}$ ) and carbontetrachloride ( 20 mL ). The reaction was carried out at reflux, following by TLC until completion after $c a$. Ih in which time the colour changed from orange to dark brown. The reaction mixture was filtered through a plug of silica gel, eluting with ethyl acetate and concentrated in vacuo. Flash chromatography of the residue on silica gel eluting with ethyl acetate/hexane (1:2) afforded compound $112(2 \mathrm{~g}, 95 \%)$ as an orange solid.

Note: this compound is easily decomposed on silica and especially in solvents like dichloromethane, and also in acid conditions. Mp decomp. to black powder at $225{ }^{\circ} \mathrm{C}$. ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta(\mathrm{ppm})=7.66-7.59(\mathrm{~m}, 4 \mathrm{H}) 7.29-7.25(\mathrm{~m}, 4 \mathrm{H}) 4.27(\mathrm{~s}, 2 \mathrm{H}) 2.03(\mathrm{~s}, 3 \mathrm{H})$ 1.93 ( $\mathrm{s}, 6 \mathrm{H}$ ). UV/Vis (EtOAc): $\lambda_{\max }(\mathrm{lg} \varepsilon) 364$ (4.24), 428 (4.49). IR (KBr): $v=1512,1456$, 1445, 755, 675, $644 \mathrm{~cm}^{-1} . \mathrm{C}_{24} \mathrm{H}_{19} \mathrm{ClS}_{4}$ (471.12): calcd. C 61.18, H 4.06; found C $61.26, \mathrm{H}$ 4.13.

## Dendron wedge 114.

114

To a stirred solution of chloride $112(2 \mathrm{~g}, 4.2 \mathrm{mmol})$ in dry THF ( 50 mL ) was added 3,5-dihydroxybenzyl alcohol ( $298 \mathrm{mg}, 2.1 \mathrm{mmol}$ ), $\mathrm{K}_{2} \mathrm{CO}_{3}(640 \mathrm{mg}, 4.2 \mathrm{mmol})$ and 18 - . crown- $6(112 \mathrm{mg}, 0.4 \mathrm{mmol})$. The resulting mixture was heated at reflux under $\mathrm{N}_{2}$ and vigorously stirred for 24 h . Solvents were evaporated in vacuo. Water ( 100 mL ) was added to the residue and the crude product extracted with chloroform ( $3 \times 50 \mathrm{~mL}$ ). Combined organic layers were dried over $\mathrm{MgSO}_{4}$ and evaporated to dryness. The residue was chromatographed on a silica gel column (eluent: dichloromethane) to afford 14 ( 600 mg , $28 \%)$ as an orange solid. Mp ca. $240^{\circ} \mathrm{C}$. ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta(\mathrm{ppm})=7.65-7.61(\mathrm{~m}, 8 \mathrm{H})$ $7.28-7.23(\mathrm{~m}, 8 \mathrm{H}) 6.56(\mathrm{~s}, 2 \mathrm{H}) 6.42(\mathrm{~s}, 1 \mathrm{H}) 4.64(\mathrm{~s}, 4 \mathrm{H}) 4.61(\mathrm{~s}, 2 \mathrm{H}) 1.98(\mathrm{~s}, 6 \mathrm{H}) 1.90(\mathrm{~s}$, 12H). IR (KBr): $v=3450$ (br.) $1595,1520,1456,1444,1281,1144,755,675,644 \mathrm{~cm}^{-1}$. UV/Vis $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right): \lambda_{\max }(\lg \varepsilon) 368$ (4.56), 436 (4.80). MS (MALDI-TOF): $\mathrm{M}+=1009$.

## Dendrimer 115.

By analogy with the preparation of 108, alcohol 114 ( $100 \mathrm{mg}, 0.1 \mathrm{mmol}$ ), 1,3,5benzenetricarbonyl trichloride ( $8.4 \mathrm{mg}, 0.03 \mathrm{mmol}$ ) and triethylamine ( $26 \mu \mathrm{l}, 0.2 \mathrm{mmol}$ ) in dry dichloromethane ( 10 mL ) were stirred under $\mathrm{N}_{2}$ at room temperature. Chromatography on silica gel eluting with dichloromethane afforded dendrimer $115(60 \mathrm{mg}, 57 \%)$ as an orange solid. $\mathrm{Mp} 242-245{ }^{\circ} \mathrm{C}$. ${ }^{\mathrm{H}} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta(\mathrm{ppm})=8.92(\mathrm{~s}, 3 \mathrm{H}) 7.62-7.54(\mathrm{~m}$, 24H) 7.26-7.21 (m, 24H) $6.52(\mathrm{~s}, 6 \mathrm{H}) 6.37(\mathrm{~s}, 3 \mathrm{H}) 5.22(\mathrm{~s}, 6 \mathrm{H}) 4.51(\mathrm{~s}, 12 \mathrm{H}) 1.84$ (bs, $54 \mathrm{H})$. UV/Vis $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right): \lambda_{\max }(\mathrm{lg} \varepsilon) 368$ (4.99), 436 (5.24). MS (MALDI-TOF): $\mathrm{M}+=3184$. $\mathrm{C}_{174} \mathrm{H}_{132} \mathrm{O}_{12} \mathrm{~S}_{24}$ (3184.49): calcd. C 65.63, H 4.18; found C 65.42, H 4.03.

## Dendron wedge 116.

Following the same procedure as for compound 108, alcohol 114 ( $300 \mathrm{mg}, 0.3 \mathrm{mmol}$ ), dichloride $6(54 \mathrm{mg}, 0.15 \mathrm{mmol})$ and triethylamine $(80 \mu \mathrm{~L}, 0.6 \mathrm{mmol})$ afforded $116(220$ $\mathrm{mg}, 65 \%)$ as an orange solid. Mp 243-246 ${ }^{\circ} \mathrm{C} .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta(\mathrm{ppm})=8.34(\mathrm{bs}, 1 \mathrm{H})$ $7.73(\mathrm{~s}, 2 \mathrm{H}) 7.65-7.54(\mathrm{~m}, 16 \mathrm{H}) 7.29-7.22(\mathrm{~m}, 16 \mathrm{H}) 6.54(\mathrm{bs}, 4 \mathrm{H}) 6.37(\mathrm{bs}, 2 \mathrm{H}) 5.20(\mathrm{bs}$, $4 \mathrm{H}) 4.51(\mathrm{bs}, 8 \mathrm{H}) 1.84(\mathrm{bs}, 36 \mathrm{H}) 0.99(\mathrm{~s}, 9 \mathrm{H}) 0.23(\mathrm{~s}, 6 \mathrm{H})$. IR (KBr): $v=1725,1595,1520$, $1444,1216,1144,754,675,644 \mathrm{~cm}^{-1}$. UV/Vis $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right): \lambda_{\max }(\mathrm{lg} \varepsilon) 368$ (4.81), 436 (5.03). MS (MALDI-TOF): $\mathrm{M}+=2278 . \mathrm{C}_{124} \mathrm{H}_{104} \mathrm{O}_{9} \mathrm{~S}_{16} \mathrm{Si}$ (2279.3): calcd. C 65.34, H 4.60; found C 65.43, H 4.73.

## Dendron wedge 117.

Following the same procedure as for compound 109, dendron 116 ( $200 \mathrm{mg}, 0.09 \mathrm{mmol}$ ) was dissolved in dry THF. Tetrabutylammonium fluoride ( 1 M in THF, $0.09 \mathrm{~mL}, 0.09$ mmol ) was added and the resultant mixture was stirred during 1 h . The solvents were removed by evaporation in vacuo and the residue was purified by chromatography on silica gel with dichloromethane as eluent, to afford 117 (133 mg, 70\%) as an orange solid mp decomp. to black powder at $245^{\circ} \mathrm{C} .{ }^{\mathrm{H}} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta(\mathrm{ppm})=8.3(\mathrm{bs}, 1 \mathrm{H}) 7.71(\mathrm{~s}$, 2H) 7.65-7.54 (m, 16H) 7.27-7.17 (m, 16H) $6.52(b s, 4 H) 6.37(b s, 2 H) 5.20(b s, 4 H) 4.52$ (bs, 8H) 1.84 (bs, 36 H ). IR (KBr): $v=3450$ (br.), 1726, 1596, 1520, 1445, 1222, 1146, 755, $675,644 \mathrm{~cm}^{-1}$. UV/Vis $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right): \lambda_{\max }(\mathrm{lg} \varepsilon) 368$ (4.85), 436 (5.09). MS (MALDI-TOF): $\mathrm{M}+=2164 . \mathrm{C}_{118} \mathrm{H}_{90} \mathrm{O}_{9} \mathrm{~S}_{16}$ (2165.0): calcd. $\left(+2 \mathrm{~mol}\right.$ of $\left.\mathrm{H}_{2} \mathrm{O}\right) \mathrm{C} 64.39, \mathrm{H} \mathrm{4.30}$; found C 64.15, H 4.23.

## Dendrimer 118.

By analogy with the preparation of 108, alcohol 117 (130 mg, 0.06 mmol ), 1,3,5benzenetricarbonyl trichloride ( $5.3 \mathrm{mg}, 0.02 \mathrm{mmol}$ ) and triethylamine ( $16 \mu \mathrm{l}, 0.12 \mathrm{mmol}$ ) in dry dichloromethane ( 10 mL ) were stirred under $\mathrm{N}_{2}$ at room temperature. Chromatography on silica gel eluting with dichloromethane afforded dendrimer $\mathbf{1 8}$ ( 72 mg , $54 \%$ ) as an orange solid. Mp decomp. to black powder at $240{ }^{\circ} \mathrm{C}$. ${ }^{1} \mathrm{H} \operatorname{NMR}\left(\mathrm{CDCl}_{3}\right): \delta$ $(\mathrm{ppm})=9.05(\mathrm{~s}, 3 \mathrm{H}) 8.69(\mathrm{~s}, 3 \mathrm{H}) 8.14(\mathrm{~s}, 6 \mathrm{H}) 7.59-7.46(\mathrm{~m}, 48 \mathrm{H}) 7.28-7.18(\mathrm{~m}, 48 \mathrm{H}) 6.51$ ( $\mathrm{s}, 12 \mathrm{H}) 6.33(\mathrm{~s}, 6 \mathrm{H}) 5.22(\mathrm{bs}, 12 \mathrm{H}) 4.50(\mathrm{~m}, 24 \mathrm{H}) 1.82-1.79(\mathrm{bs}, 108 \mathrm{H}) . \mathrm{IR}(\mathrm{KBr}): v=$ 1731, 1596, 1520, 1444, 1222, 1146, 753, 675, $644 \mathrm{~cm}^{-1}$. UV/Vis $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right): \lambda_{\max }(\mathrm{lg} \varepsilon) 368$ (5.27), 436 (5.51). MS (MALDI-TOF): $\mathrm{M}+=6648 . \mathrm{C}_{363} \mathrm{H}_{270} \mathrm{O}_{30} \mathrm{~S}_{48}$ (6651.2): calcd. C 65.55, H 4.09; found C 65.37, H 4.23.

## Appendix One

## Dynamic NMR Studies.

Determination

## of the Activation Enthalpy $\Delta \boldsymbol{H}^{\ddagger}$

and the Activation Entropy $\Delta S^{\ddagger}$
${ }^{1}$ H NMR studies performed on 47, showed a difference in chemical shift for the two protons $\mathbf{H}_{\mathrm{a}}$ and $\mathbf{H}_{\mathrm{b}}$ in $\alpha$-position of the hydroxyl group (Figure 2.3), observed at $20^{\circ} \mathrm{C}$ in $\mathrm{d}_{6}$-DMSO, giving a four-line AB system $\left(\mathrm{J}_{\mathrm{AB}}=c a .13 \mathrm{~Hz}\right)$. This four-line AB system is coalescing into a singlet with increasing of temperature, consistent with the increase of interconversion between the two forms A and B . The rate exchange corresponding to this interconversion can be studied by looking at the variation of the chemical shift of protons $H_{a}$ and $H_{b}$ for a range of temperature until coalescence. Simulations of the process have been performed by Dr Paul Hazendonk, currently working in the Solid State NMR department of the University of Durham, and gave accurate values of rate exchange for each studied temperature (Table A1.1).

Table A1.1 Calculated rate exchange for the interconversion process.

The Eyring equation is linking directly this rate exchange to the activation energy, $\mathrm{E}_{\mathrm{a}}$, of the system.

$$
\begin{equation*}
\mathrm{r}=\frac{\mathrm{k}_{\mathrm{b}} \mathrm{~T}}{\mathrm{~h}} \exp \left(\frac{-\mathrm{E}_{\mathrm{a}}}{\mathrm{RT}}\right) \tag{1}
\end{equation*}
$$

$r$ is the rate exchange, $k_{b}$ is the Boltzmann constant, $h$ is the Plank constant, $R$ is the ideal gas constant and T is the temperature $\left(\mathrm{h}=6.6210^{-34} \mathrm{Js}\right.$ and $\left.\mathrm{K}_{\mathrm{b}}=1.3810^{-23} \mathrm{~J} \mathrm{~K}^{-1}\right)$.

The activation energy can be decomposed in activation enthalpy of and activation entropy:

$$
\begin{equation*}
\mathrm{E}_{\mathrm{a}}=\Delta \mathrm{H}^{\ddagger}-\mathrm{T} \Delta \mathrm{~S}^{\ddagger} \tag{2}
\end{equation*}
$$

Thus, the Eyring equation can be written:

$$
\begin{equation*}
\ln \left(\frac{\mathrm{r}}{\mathrm{~T}}\right)=\ln \left(\frac{\mathrm{k}_{\mathrm{b}}}{\mathrm{~h}}\right)+\frac{\Delta \mathrm{S}^{\ddagger}}{\mathrm{R}}-\frac{\Delta \mathrm{H}^{\ddagger}}{\mathrm{RT}} \tag{3}
\end{equation*}
$$

Consequently, when $\ln (r / T)$ is plotted as a function of $1 / T$, the slope of the obtained linear variation is $-\Delta \mathrm{H}^{\ddagger} / \mathrm{R}$ and the intercept obtained by extrapolating to $1 / \mathrm{T}=0$ is $\ln \left(\mathrm{k}_{\mathrm{b}} / \mathrm{h}\right)$ $+\Delta \mathrm{S}^{\ddagger} / \mathrm{R}$ (Figure Al.1). However, there can be large extrapolation errors due to small errors in the slope: To minimise extrapolation error, it is essential to have data over as large a temperature range as possible. Unfortunately for this interconversion process studied, the melting temperature of $\mathrm{d}_{6}$ - DMSO (in which the separation of the AB system is the wider), the coalescence temperature and the boiling temperature of $\mathrm{d}_{6}$ - DMSO are limiting the number of experiments in our case between $\mathrm{T}=24^{\circ} \mathrm{C}$ and $\mathrm{T}=80^{\circ} \mathrm{C}$, and, the error obtained in $\Delta S^{\ddagger}$ is too large for reliable interpretation.

## Eyring Plot

Figure A1.1 Eyring plot relative to the interconversion process.

Using Eyring equation and the linear equation obtained by the Eyring plot (Figure Al.I), the activation enthalpy $\Delta \mathrm{H}^{\ddagger}$ is found to be equal to $75.3 \mathrm{~kJ} \mathrm{~mol}^{-1}$ and the activation entropy $\Delta \mathrm{S}^{\ddagger}$ equal to 11.5 J mol-1 $\mathrm{K}^{-1}$ with standard deviations of $0.9 \mathrm{~kJ} \mathrm{~mol}^{-1}$ and 8.4 J $\mathrm{mol}^{-1} \mathrm{~K}^{-1}$ respectively, which is not reliable for the activation entropy as we discuss previously.

## Appendix Two

## Molecular Modelling Studies.

## A 2.1 Software and Calculation Procedures.

All structures studied were modelled and optimised in the gas phase and without consideration of the counter ions using Hyperchem 5.02: Hyperchem, Inc., 1115 NW $4^{\text {th }}$ Street, Gainesville, FL 32601 (USA). For compounds 77c and 78c only (ferrocenyl diacid chloride and ferrocenyl bridge), Hyperchem 6.0 was used, the PM3 method having being configured for transition metals as un update of Hyperchem 5.02.

For all the diacid chlorides (77a-f) and the anthracenediylidene derivatives studied ((E) 76 , (Z) 76, 78a-d and their dicationic oxided species), the optimisation was performed by semi-empirical calculations using the PM3 method. These calculations solve the Schrödinger equation, with certain approximations, to describe the electron properties of atoms and molecules.

For the dendritic molecules, the optimisation was performed by molecular mechanics calculations using the MM+ method. The total number of orbitals for these molecules was too high to use semi-empirical calculations. Molecular mechanical calculations treat atoms as Newtonian particles interacting through a potential energy function. Potential energy depends on bond lengths, bond angles, torsion angles, and nonbonded interactions (van der Waals forces, electrostatic interactions, and hydrogen bonds).

In all cases, the same algorithm was used (Polak-Ribiere), which attempts to lower the energy of a molecular system by adjusting its geometry. The same final condition of convergence was also used (RMS gradient of $0.001 \mathrm{kcal} / \AA \AA \mathrm{mol}$ ).

## A 2.2 Diacid chloride derivatives.

Terephthaloyl chloride (77a) and Thiophene dicarbonyl chloride (77b)

Ferrocenyl dicarbonyl dichloride (77c) and oxybis(carbonyl chloride) (77d):

77e and 77f

## A 2.3 Anthracenediylidene derivatives.

Calculations were performed on the neutral forms of $(E) 76$ and $(Z) 76$ to compare the intramolecular distance between the two oxygen atoms in an attempt to explain the selectivity of the cyclisation reaction (Chapter Three).

9,10-bis[(4-hydroxymethyl-5-methyl)-1,3-dithiol-2-ylidene]-9,10-dihydroanthracene

Modelling studies of the dication species can be performed by semi-empirical calculations adding a global charge of +2 on the molecule. On the converged structure, the charges are then distributed mainly on the sulfur atoms of the dithiolium rings.

All the bridged derivative (78a-d) and their corresponding oxidised form have been studied following the same procedure as for 76.

## A 2.4 Dendrimers.

Modelling studies performed on dendrimers 110, were realised by adding to the energy-minimised conformation of the core (Figure A2.1), the energy-minimised conformation of the units (Figure A2.2) at its periphery. The resulting structure was then energy-minimised by molecular mechanics using the MM+ method. Depending on the starting positions of the units around the core (attached angles), several converged structures have been obtained, most of them asymmetric, presenting $\pi-\pi$ interactions between the units. The presented structure of 110 (See Chapter Four) was obtained with a final energy comparable to the other asymmetric structures.

Figure A2.1. Energy minimised conformation of the core obtained by semi-empirical calculations (PM3 method)

Figure A2.2. Energy minimised conformation of the unit obtained by semi-empirical calculations (PM3 method).

For dendrimer 118, the starting structure was obtained by adding to the energyminimised conformation of the core, the energy-minimised conformation of dimer 119 (Figure A2.3). The energy of the presented structure (see chapter Four) was the lowest observed for the obtained conformations on an average number of 10 different starting structures (by varying the attached angles between the core and the dimer).

Figure A2.3. Energy minimised conformation of 119 obtained by Molecular mechanics calculations (MM+ method).

For the oxidised forms $110^{12+}$ and $118^{24+}$, only one converged structure was obtained for each dendrimer due to Coulombic repulsion which forces the cationic units to be placed as far as possible from each other with, therefore, the maximum space expansion between them. The calculations were performed using partial atomic charges to calculate non-bonded electrostatic interactions.

## Oxobisphenyl cyclophane (78d)

Table 1. Crystal data and structure refinement

| Identification code |  |
| :---: | :---: |
| Empirical formula | $\mathrm{C}_{38} \mathrm{H}_{26} \mathrm{O}_{5} \mathrm{~S}_{4} \cdot 3 \mathrm{CH}_{2} \mathrm{Cl}_{2}$ |
| Formula weight | 945.61 |
| Temperature | 120(2) K |
| Wavelengch | 0.71073 A |
| Crystal system | Triclinic |
| Space group | P $\overline{1} \quad$ (No. 2) |
| Unit cell dimensions | $a=11.535(3) \dot{A} \quad \alpha=72.46(1)^{\circ}$ |
|  | $b=13.215(3) \dot{\mathrm{A}} \quad \beta=79.85(1)^{\circ}$ |
|  | $c=14.744(3) \dot{A} \quad \gamma=89.50(1)^{\circ}$ |
| Volume | 2107.1(8) $\dot{\text { d }}^{3}$ |
| Z | 2 |
| Density (calculated) | $1.490 \mathrm{~g} / \mathrm{cm}^{3}$ |
| Absorption coefficient | $0.650 \mathrm{~mm}^{-1}$ |
| F(000) | 968 |
| Crystal size | $0.7 \times 0.4 \times 0.35 \mathrm{~mm}^{3}$ |
| $\theta$ range for data collection | 1.4 to $29.0^{\circ}$. |
| Index ranges | $-15 \leq h \leq 15,-18 \leq k \leq 17,-20 \leq l \leq 19$ |
| Reflections collected | 25443 |
| Independent reflections | $10988[\mathrm{R}(\mathrm{int})=0.0184]$ |
| Reflections with $\mathrm{I}>2 \sigma$ (I) | 9748 |
| Completeness to $\theta=29.0^{\circ}$ | 98.1\% |
| Absorption correction | Semi-empirical from equivalents |
| Max. and min. transmission | 0.8015 and 0.7154 |
| Refinement method | Full-matrix least-squares on $\mathrm{F}^{2}$ |
| Data / restraints / parameters | 10988/6/536 |
| Largest final shifte.s.d. ratio | 0.010 |
| Goodness-of-fit on $\mathrm{F}^{2}$ | 1.016 |
| Final R indices [ $\mathrm{I}>2 \sigma$ ( I ] | $\mathrm{R}_{1}=0.0507, \mathrm{wR}_{2}=0.1278$ |
| R indices (all data) | $\mathrm{R}_{1}=0.0569, \mathrm{wR}_{2}=0.1336$ |
| Largest diff. peak and hole | 1.484 and -0.955 e. $\mathrm{A}^{-3}$ |

Table 2. Atomic coordinates ( $\times 10^{5}$ ) and equivalent isotropic displacement parameters $\left(A^{2} \times 10^{\circ}\right)$
$U(\mathrm{sq})$ is delined as one third of the trace of the orthogonalized $\mathrm{U}_{n}$, tensor.

Largest diff. peak and hole
$\mathrm{R}_{1}=0.1128, \mathrm{wR}_{2}=0.1096$
1.420 and $-1.133 \mathrm{e} . \mathrm{A}^{-3}$

In the DCM molecule $\mathrm{Cl}(3) \mathrm{C}(40) \mathrm{Cl}(4)$ the C atom is disordered between two positions, and Cl atoms between three positions each. DCM molecule $\mathrm{Cl}(5) \mathrm{C}(41) \mathrm{Cl}\left(5^{\prime}\right)$ is located near an inversion centre, so that the two Cl atoms are related via this centre, and the C atom is disordered between 2 positions, related by this centre (the C site occupancies are 0.25 , the Cl site 0.5 ).

Table 2. Atomit coordinates ( $\times 10^{4}$ ) and equivalent isotropic displacement parameters $\left(\dot{A}=\times 10^{3}\right)$ $U(e q)$ is detined as one third of the trace of the orthogonalized Uij tensor.

[^1]
[^0]:    ${ }^{\dagger}$ During the writing of this thesis, the first doubly-bridged derivative has been synthesised in our group by C.A. Christensen and both the cation radical and dication states are observed in cyclic voltammetry experiments.

[^1]:    Symmetry transformations used to generare equivalent atoms (primed): $-\mathbf{x} \cdot \mathbf{- y}+1,-z+1$
