**Cellulose production in *Pseudomonas syringae* pv. *syringae*:
a compromise between epiphytic and pathogenic lifestyles**

Journal:	<i>FEMS Microbiology Ecology</i>
Manuscript ID:	FEMSEC-14-11-0635.R3
Manuscript Type:	Research Paper
Date Submitted by the Author:	19-Jun-2015
Complete List of Authors:	Arrebola, Eva; Universidad de Málaga, Microbiology Carrion, Victor; Universidad de Málaga, Microbiology Gutierrez-Barranquero, Jose; Universidad de Málaga, Microbiology Pérez-García, Alejandro; University of Malaga, Departament of Microbiology Rodriguez-Palenzuela, Pablo; Universidad Politecnica de Madrid, Bioquimica Cazorla, Francisco; Universidad de Málaga, Microbiología de Vicente, Antonio; Universidad de Málaga, Microbiología
Keywords:	Virulence, Biofilm, Phyllosphere, Woody plants, Bacterial EPS

19 **Keywords:** virulence, biofilm, phyllosphere, woody plants, bacterial EPS

20 **Running title:** Cellulose is involved in the epiphytic fitness of UMAF0158

22 Abstract

23

24 Genome sequencing and annotation have revealed a putative cellulose
25 biosynthetic operon in the strain *Pseudomonas syringae* pv. *syringae*
26 UMAF0158, the causal agent of bacterial apical necrosis. Bioinformatics
27 analyses and experimental methods were used to confirm the functionality of
28 the cellulose biosynthetic operon. In addition, the results showed the
29 contribution of the cellulose operon to important aspects of *P. syringae* pv.
30 *syringae* biology, such as the formation of biofilms and adhesion to mango leaf
31 surface, suggesting that this operon increases epiphytic fitness. However,
32 based on the incidence and severity of the symptoms observed in tomato
33 leaflets, cellulose expression reduces virulence, as cellulose-deficient mutants
34 increased the area of necrosis, whereas the cellulose-overproducing strain
35 decreased the area of necrosis compared to the wild type. In conclusion, the
36 results of this study show that the epiphytic and pathogenic stages of the *P.*
37 *syringae* pv. *syringae* UMAF0158 lifestyle are intimately affected by cellulose
38 production.

39

40 Introduction

41 Cellulose is a homo-polysaccharide consisting of glucose units linked by β 1-4
42 glycosidic bonds and is the most abundant organic polymer present on Earth
43 (Delmer & Amor, 1995). Cellulose is produced by many bacterial species
44 including *Gluconacetobacter xylinus* (*Acetobacter xylinus*) (Coucheron *et al.*,

1
2
3 45 1991). The polymer has been identified as a primary component of the
4
5 46 extracellular matrix produced by a diversity of biofilm-forming bacteria (Le
6
7 47 Quéré & Ghigo, 2009; Zogaj *et al.*, 2003; Lu *et al.*, 2012), including
8
9 48 environmental and plant pathogen pseudomonads (Ude *et al.*, 2006; Robertson
10
11 49 *et al.*, 2013). The expression of large amounts of cellulose, like many other
12
13 50 exopolysaccharides, may protect cells in biofilms and lead to biocide resistance
14
15 51 (O'Toole *et al.* 2000). Furthermore, bacterial cellulose has been shown to be
16
17 52 required for cell adhesion to host tissues (Matthysse *et al.*, 1981).

18
19
20 53 Cellulose-based biofilm formation has also been associated with the virulence
21
22 54 of several human and animal diseases (Fux *et al.*, 2005; Yildiz, 2007) such as
23
24 55 the enteric bacteria *Escherichia coli* (Weiss-Muszkat *et al.*, 2010) and
25
26 56 *Salmonella enterica* (Lu *et al.*, 2012). Pellicle formation by the plant pathogen
27
28 57 *Dickeya dadantii* is dependent on cellulose production (Jahn *et al.*, 2011;
29
30 58 Pringent-Combaret *et al.*, 2012) encoded by the bacterial cellulose synthase
31
32 59 (*bcs*) operon (Wong *et al.*, 1990). Furthermore, cellulose production in *D.*
33
34 60 *dadantii* favours plant surface colonisation and a mutation in the *bcs* operon
35
36 61 also decreases resistance to chlorine stresses (Pringent-Combaret *et al.*, 2012).
37
38 62 *Pseudomonas putida* mt2 has a similar *bcs* operon involved in cell-surface and
39
40 63 cell-cell interactions necessary for biofilm formation and which also contributes
41
42 64 to rhizosphere fitness (Nielsen *et al.*, 2011). *Pseudomonas fluorescens* SBW25
43
44 65 also encodes a *bsc*-like *wss* operon, and an over-producing cellulose mutant
45
46 66 known as the "Wrinkly Spreader" colonises the air-liquid interface of static
47
48 67 microcosms through the formation of self-supporting biofilms (Spiers *et al.*,
49
50 68 2002; Spiers *et al.*, 2003; Spiers, 2014). Cellulose has also been identified as a
51
52
53
54
55
56
57
58
59
60

69 matrix component in other *Pseudomonas* spp. biofilms, including *P. syringae*
70 (*Ude et al.*, 2006).

71 *P. syringae* is a wide host range pathogen, affecting both herbaceous and
72 woody plants and causing serious diseases in crops (*Hirano & Upper*, 1990,
73 *Cazorla et al.*, 1998; *Kennelly et al.*, 2007; *Gutiérrez-Barranquero et al.*, 2011).

74 Recently we sequenced the complete genome of *P. syringae* pv. *syringae*
75 UMAF0158 (under submission; GenBank CP005970), isolated from the necrotic
76 tissue of a mango tree (*Cazorla et al.*, 1998); among other traits, we have
77 identified a gene cluster orthologous to the *P. fluorescens* SBW25 *wss* operon.
78 Because cellulose production is directly involved in biofilm formation and is
79 directly or indirectly associated with other aspects of plant-pathogenic bacteria,
80 the aim of our present study is to clarify the role of cellulose in this woody plant
81 pathogen.

84 **Materials and Methods**

86 **Bacterial strains and growth conditions**

87 For standard maintenance, *P. fluorescens* SBW25 (*Spiers et al.*, 2002), *P.*
88 *syringae* pv. *syringae* UMAF0158 (*Arrebola et al.*, 2003) and B728a (*Hirano &*
89 *Upper*, 2000) were grown in King's medium B (KB) (*King et al.*, 1954) and
90 incubated at 28°C for 48 h. UMAF0158::wssB and UMAF0158::wssE were
91 maintained with 50 µg mL⁻¹ kanamycin. The conditions used for plant
92 experiments are specified in the corresponding sections.

93

94

95 **Bioinformatics**

96 Database searches were performed using the NCBI
97 (<http://www.ncbi.nlm.nih.gov>) and ASAP
98 (<http://asap.ahabs.wisc.edu/asap/ASAP1.htm>) websites. Homology searches
99 and analyses of conserved domains were performed using the NCBI BLAST
100 and the Pfam database (<http://pfam.sanger.ac.uk>). A complementary search of
101 the protein pattern was performed using the PROSITE™ database
102 (<http://prosite.expasy.org>). GC analyses, promoter, terminator and IS analyses,
103 and primer design were performed using a GC calculator
104 (http://www.genomicsplace.com/gc_calc.html), SoftBerry
105 (<http://linux1.softberry.com/berry.phtml>), IS Finder (<http://www-is.biotoul.fr>) and
106 Primer3 (<http://primer3.sourceforge.net>).

107

108 **Phylogenetic Analysis**

109 Phylogenetic analysis of different *Pseudomonas spp.* strains was performed
110 using *E. coli* K-12, *S. typhimurium* LT2 and *E. amylovora* 273 as out groups
111 (Supplementary material, Table S3). Sequences were aligned using ClustalW
112 (Larkin *et al.*, 2007). The cellulose synthase subunits *wssB*, *wssC* and *wssE*
113 (Spiers *et al.*, 2002) and the housekeeping genes *fruK*, *gapA*, *gltA*, *pgi*, *recA*,
114 *rpoA*, *rpoB* and *rpoD* were used for phylogenetic comparison. Phylogenetic
115 analysis was performed using MEGA 5.0 software (Tamura *et al.*, 2007, 2011).
116 Phylogenetic trees were constructed using maximum likelihood fits based on a
117 data-specific model (Nei & Kumar, 2000).

118

119 **Strain manipulation and molecular assays**

120 Insertional inactivation mutagenesis of *P. syringae* UMAF0158 was used to
121 suppress cellulose production by inserting disruption vectors into the different
122 ORFs of the cellulose operon via single-crossover homologous recombination.
123 The PCR reaction, pCR2.1-TOPO[®] (Invitrogen Life Tech, USA) cloning and
124 plasmid purification were performed using standard procedures and primers are
125 listed in the Supplementary material, Table S5. Plasmids were transformed into
126 the wild-type strain UMAF0158 using electroporation. The correct insertions of
127 disruption vectors were analysed by PCR and the bacterial growth curves were
128 obtained in KB to confirm similarities with the wild type (data not shown).

129 The wild-type strain UMAF0158 was transformed with the kanamycin-resistant,
130 self-replicating plasmid pVSP61-WspR19 to produce a strain over-producing
131 cellulose (Ude *et al.*, 2006).

132 Total RNA was isolated (Castillo *et al.*, 2007) and RT-PCR was performed using
133 the Titan OneTube RT-PCR system (Roche Diagnostics, Basel, Switzerland)
134 and primers are listed in the Supplementary material, Table S5. The
135 transcription start point for the *wss* operon was determined using the 5'-RACE
136 method (Maruyama *et al.* 1995; Filiatrault *et al.*, 2010, 2011; Carrión *et al.*,
137 2012).

138

139 **Microscopy**

140 Bacterial suspensions were made in sterile distilled water and adjusted to 10⁸
141 cfu mL⁻¹, and then were sprayed onto mango buds and left for three days on
142 plants maintained in a greenhouse. Mango buds were fixed in 2.5%
143 glutaraldehyde and dehydrated by increasing the ethanol concentration. The

1
2
3 144 samples were maintained in 100% ethanol until processing for Scanning
4
5 145 Electronic Microscopy (SEM). At least three replicates for every sample were
6
7 146 observed.
8

9
10 147

11 148 ***In vitro* analysis of cellulose production**

12
13
14 149 Strains were grown in KB medium supplemented with FeCl₃ (0.25 g L⁻¹) to avoid
15
16 150 siderophore production and 10 μM Calcofluor (SIGMA Fluorescent Whitener 28)
17
18 151 for 3 days at 28°C before visualization and images analysis (See
19
20 152 Supplementary material and methods section). The pictures were processed
21
22 153 using Visilog 5.0 software (Noesis Vision Inc., France). The colour images were
23
24 154 transformed to grey scale pictures. The measured area for each colony was
25
26 155 17202 pixels (0.1388 mm²). At least three colonies per image and six images
27
28 156 per strain and experiment were analysed. Five independent experiments were
29
30 157 performed to obtain the cellulose production results. The values were obtained
31
32 158 as arbitrary units (a.u.), defined as the value obtained according to a grey scale
33
34 159 ranging from 0.0 (pure black) to 255 (pure white) in a 0.1388 mm² area.
35
36
37
38
39

40 160

41 161 **Biofilm quantification**

42
43 162 Liquid cultures were adjusted to 10⁸ cfu mL⁻¹ and incubated at 28°C overnight in
44
45 163 96-well microtiter plates to assay biofilm formation. Biofilm quantification were
46
47 164 performed as previously described (Peeters *et al.*, 2008). The absorbance of
48
49 165 the eluted Crystal violet was measured at 595 nm. At least 24 wells per strain
50
51 166 and experiment were used, and four independent experiments were performed
52
53 167 to obtain the biofilm results.
54
55

56 168
57
58
59
60

1
2
3 169 **Adhesion assay on mango leaves**

4
5 170 For adhesion experiments, bacterial suspensions were adjusted to 10^8 cfu mL⁻¹.
6
7 171 Drops (10 µL) of each strain were inoculated onto mango leaves wiped with
8
9 172 70% ethanol. After 30 min the leaves were washed with sterile water and the
10
11 173 inoculated region removed for processing. The leaf pieces were placed into
12
13 174 sterile bags with 1 mL of sterile water, homogenised for 3 min, and plated onto
14
15 175 KB plates to determine bacterial numbers. Three plates per strain were used,
16
17 176 with three replicates per experiment and three independent experiments
18
19 177 performed.
20
21
22

23 178

24
25 179 **Pathogenesis and competitive index evaluation**

26
27 180 The assayed strains were inoculated onto detached tomato leaflets (*Solanum*
28
29 181 *lycopersicum* L. cv. Hellfrucht-Früstamm) to evaluate virulence, as previously
30
31 182 described (Arrebola *et al.*, 2007, 2009; Carrión *et al.*, 2014). The appearance of
32
33 183 necrotic symptoms was monitored by using visual analysis to evaluate disease
34
35 184 incidence (number of inoculated points showing necrotic symptoms equal or
36
37 185 greater than 0.5 cm in diameter). The total necrotic area per leaflet induced at
38
39 186 the last day (10th day) of the experiment (severity) was determined from six
40
41 187 leaflets over three independent experiments using the image analysis software
42
43 188 Visilog 5.0 (Noesis Vision Inc., France). In addition, two inoculated leaflets were
44
45 189 used every day for seven days to estimate the total bacterial population in every
46
47 190 strain used.
48
49

50
51
52 191 Additional experiments to obtain a competitive index were performed using
53
54 192 tomato leaflets maintained *in vitro*. A bacterial suspension of the wild type
55
56 193 UMAF0158 strain was mixed at 1:1 ratio with cellulose-defective mutants, and
57
58
59
60

1
2
3 194 the cellulose overproducer strain suspensions was adjusted to 10^8 cfu mL⁻¹, and
4
5 195 then processed similarly to the pathogenicity test. The leaflets were processed
6
7 196 after 1 h to observe the initial symptom points and after 7 days to observe the
8
9 197 final symptom points. Three leaflets per strain and experiment and three
10
11 198 independent experiments were performed to obtain competitive index results.
12
13
14
15

16 200 **Statistical Analysis**

17
18 201 Statistical analyses were performed using IBM.SPSS 19 software (IBM®
19
20 202 Company, Armonk, NY). One factor ANOVA was used for the analysis of the
21
22 203 means with $p=0.05$, homogeneity test data were analysed by the Levene test,
23
24 204 and statistic descriptive effects homogeneity was analysed by Brown-Forsythe
25
26 205 Welch test, with post hoc analysis by LSD $\alpha= 0.05$ and a 95% confidence
27
28 206 interval. The statistical analysis of incidence of necrotic symptoms was
29
30 207 performed using SAS9.2 software (SAS Institute Inc., Cary, NC, USA) in the
31
32 208 Enterprise Guide 4.2 program with generalised linear model analysis.
33
34
35
36
37

38 210 **Results**

39 211 40 41 42 212 **Bioinformatics analysis of a cellulose biosynthetic operon from *P.*** 43 44 213 ***syringae* pv. *syringae* UMAF0158.**

45
46 214 The complete genomic sequences of UMAF0158 containing the cellulose
47
48 215 synthase operon have been deposited in GenBank under the accession number
49
50 216 CP005970 (Martínez-García *et al.* Direct Submission). A gene cluster of 14,642
51
52 217 bp (chromosome section 4684145–4696189 bp; corresponding genes from
53
54 218 PsyrMG_20805 to PsyrMG_20845), consisting of nine genes, was annotated
55
56
57
58
59
60

1
2
3 219 with putative functions associated with cellulose production and acetylation
4
5 220 (Table 1; Supplementary material Table S1).

6
7 221 The *wss* cluster located in *P. syringae* pv. *syringae* UMAF0158 had an
8
9 222 arrangement similar to the cellulose operons of other *Pseudomonas* strains
10
11 223 (Fig. 1). Further sequence analysis using the cellulose operons reported in
12
13 224 *Pseudomonas* spp. strains showed high sequence similarity in all ORFs
14
15 225 (Supplementary material, Table S2). The only exceptions were *P. syringae* pv.
16
17 226 *aesculi* 2250, which showed no similarity with the *wssB* and *wssI* genes, and *P.*
18
19 227 *fluorescens* SBW25, which showed the lowest similarity with the whole *wss*
20
21 228 operon at the nucleotide level.

22
23
24
25 229 To obtain insight into the evolutionary history of the cellulose operon of
26
27 230 *Pseudomonas* spp., three concatenated genes (*wssB*, *wssC* and *wssE*),
28
29 231 corresponding to three of the four cellulose synthase subunits, were used to
30
31 232 construct phylogenetic trees. *E. coli*, *S. typhimurium* and *Erwinia amylovora*
32
33 233 were used as out-groups (Fig. 2a; Supplementary material, Table S3). A
34
35 234 phylogenetic tree was also constructed using eight different housekeeping
36
37 235 genes (Fig. 2b). The phylogenetic relationship of the cellulose genes did not
38
39 236 reveal important variations with respect to the phylogenetic relationship of the
40
41 237 housekeeping, but notably, the absence/presence of the cellulose cluster was
42
43 238 distributed among pathogens and non-pathogens (Fig. 2).

44
45
46
47 239 Additionally, the sequences of the cellulose operon and flanking regions were
48
49 240 compared between *P. syringae* UMAF0158, *P. syringae* pv *tomato* DC3000, *P.*
50
51 241 *syringae* pv. *aesculi* 2250 and *P. savastanoi* pv. *savastanoi* NCPPB3335, and
52
53 242 two *P. syringae* strains, that lacked cellulose operons, pv. *syringae* B728a and
54
55 243 pv. *phaseolicola* 1448A. The results showed identical localisation in all cellulose
56
57
58
59
60

1
2
3 244 operon-containing *P. syringae* strains. Notably, in the strains lacking cellulose
4
5 245 operons, the equivalent genomic region showed a sequence with high identity
6
7 246 to the flanking regions of the cellulose operon of UMAF0158, suggesting that
8
9 247 this region represents the remnants of a cellulose operon. Indeed, in *P.*
10
11 248 *syringae* pv. *phaseolicola* 1448A, this region showed 83% identity with a non-
12
13 249 coding region upstream of *wssA* and 72% identity with a 116-bp region at the 3'-
14
15 250 end of *wssI* in the strain UMAF0158. Similarly, *P. syringae* pv. *syringae* B728a
16
17 251 contains a hypothetical protein (P syr_0881) with 89% identity to the 3'-end
18
19 252 (24% of the total sequence) of *wssI* in the strain UMAF0158.
20
21
22
23

24
25 254 **Operon structure of the cellulose cluster in the *P. syringae* pv. *syringae***
26
27 255 **UMAF0158 strain.**

28
29 256 RT-PCR amplifying 17 fragments across the *wss* operon confirmed that the
30
31 257 genes were co-transcribed as a single polycistronic RNA transcript (Fig. 3a).
32
33 258 Bioinformatics analysis of the non-coding sequence upstream of *wssA* revealed
34
35 259 -10 and -35 boxes corresponding to a putative promoter, and the RpoD sigma
36
37 260 transcription factor was also detected (Fig. 3b). In addition, an analysis of the
38
39 261 potential insertion sequences (IS) was performed for this 246-nucleotide DNA
40
41 262 fragment, showing eight different sequences (Fig. 3b; Supplementary material,
42
43 263 Table S4). 5'-RACE analysis of the promoter revealed nucleotide +1 73 bp
44
45 264 upstream of the first ATG codon of *wssA*, and a Shine-Dalgarno (SD) sequence
46
47 265 (Chen *et al.*, 1994) located 9 bp upstream of the start codon (Fig. 3b). A 363-
48
49 266 nucleotide DNA sequence located downstream of *wssI* was identified as a
50
51 267 terminator sequence with a typical terminator hairpin secondary structure.
52
53 268 Further RT-PCR analysis confirmed that the transcription of this operon stopped
54
55
56
57
58
59
60

1
2
3 269 after the *wssI* gene (Fig. 3c). Finally, thirteen different IS sequences were found
4
5 270 at the end of the *wss* operon of UMAF0158 (Fig. 3c; Supplementary material,
6
7 271 Table S4).

11 273 ***P. syringae* pv. *syringae* UMAF0158 cellulose production and its role in**
12
13
14 274 **biofilm formation and plant surface colonisation.**

15
16 275 To confirm the functionality of the *wss* operon in UMAF0158, mutants in two of
17
18 276 the essential conserved genes were constructed: UMAF0158::*wssB*, and
19
20 277 UMAF0158::*wssE*, both of which are critical subunits in the cellulose synthase
21
22 278 complex (Spiers *et al.* 2013; Spiers, 2014). As expected, these two mutants
23
24 279 were defective in cellulose production (Fig. 4). Additionally, UMAF0158
25
26 280 transformed with the plasmid pVS61-WsR19, containing *wspR19* from *P.*
27
28 281 *fluorescens* SBW25 (Ude *et al.*, 2006), had a cellulose overproduction
29
30 282 phenotype. Clear differences were seen in cellulose production between wild-
31
32 283 type UMAF0158, cellulose defective mutants and the overproducing strain (Fig.
33
34 284 4a), confirming that cellulose production required a functional *wss* operon.
35
36

37
38 285 In addition, the role of cellulose in biofilm formation was also analysed. A
39
40 286 relationship between the presence and absence of the *wss* operon, cellulose
41
42 287 production and biofilm formation was observed by Crystal violet staining of
43
44 288 bacteria adhering to microtiter plates in an *in vitro* assay of biofilm formation
45
46 289 (Fig. 4b). Scanning electron microscopy of colonising bacteria on mango buds
47
48 290 also showed differences among the strains with or without active *wss* operons,
49
50 291 consistent with the results described above, confirming matrix production in
51
52 292 epiphytic colonisation (Fig. 5). Notably, it was possible to observe micro-
53
54 293 colonies of the wild-type and overproducer UMAF0158 strains immersed in the
55
56
57
58
59
60

1
2
3 294 extracellular matrix. In contrast, the cellulose-defective mutants showed much
4
5 295 less matrix production (Fig. 5).
6

7 296 To evaluate the influence of cellulose production on the *P. syringae* pv. *syringae*
8
9 297 UMAF0158 epiphytic lifestyle, adhesion experiments on mango leaves were
10
11 298 performed (Fig. 6). This showed that the amount of bacteria recovered from the
12
13 299 surface of mango leaves were significantly higher in strains with an active *wss*
14
15 300 operon. Altogether, these results confirmed the functionality of the *wss* operon
16
17 301 and the role of cellulose production in biofilm formation and leaf colonisation.
18
19
20

21 302

22
23 303 **Involvement of cellulose production in the virulence of *P. syringae* pv.**
24
25 304 ***syringae* UMAF0158.**

26
27 305 Evaluation of the virulence was performed on tomato leaflets (Arrebola *et al.*,
28
29 306 2007, 2009), which is a more reliable plant model for pathogenicity. Growth
30
31 307 curves for strains with or without an active *wss* operon were obtained from
32
33 308 inoculated tomato leaflets. Bacterial counts displayed similar growth patterns
34
35 309 (Fig. 7a). The number of necrotic points developed (incidence) in the cellulose
36
37 310 defective mutants was not significantly different from that observed with the wild
38
39 311 type. However, the overproducer strain had a delayed onset and a lower
40
41 312 number of necrotic symptoms (Fig. 7b). To complete the virulence study, the
42
43 313 overall necrotic area (severity) for each strain was also estimated in these
44
45 314 experiments (Fig. 7c and d). The results demonstrated significant differences
46
47 315 between the defective mutants, the overproducer and the wild-type strains.
48
49 316 Indeed, both cellulose-defective mutants had the highest amount of necrotic
50
51 317 areas and the overproducer strain showed the lowest amount of necrotic area,
52
53 318 (Fig. 7d), suggesting the negative influence of cellulose production on the
54
55
56
57
58
59
60

1
2
3 319 virulence of this bacterium. Moreover, the competitive indices of the cellulose-
4
5 320 defective mutants and overproducer strain were determined with respect to the
6
7 321 wild-type strain (Fig. 8). Only the overproducer strain had a significantly lower
8
9 322 competitive index, in agreement with the low virulence shown in the
10
11 323 pathogenicity test.
12
13
14 324

17 325 **Discussion**

18
19
20 326 The annotation of the completely mapped genome of this strain and the
21
22 327 bioinformatics analysis confirmed the sequence similarity of the identified
23
24 328 cellulose biosynthetic operon with other available and characterised cellulose
25
26 329 operons (Wong *et al.*, 1990; Sofia *et al.*, 1994; Zogaj *et al.*, 2001, Spiers *et al.*,
27
28 330 2002; Ude *et al.*, 2006; Smits *et al.*, 2010) and provided strong support for an
29
30 331 operon-like structural organisation which was subsequently confirmed, as well
31
32 332 as its functionality. Sequence analysis of this operon showed motifs for polymer
33
34 333 acetylation in *P. syringae* UMAF0158, which provides more stability and
35
36 334 robustness to the produced cellulose (Spiers & Rainey, 2005). In *P. fluorescens*
37
38 335 SBW25, four genes involved in cellulose acetylation (*wssFGHI*) have been
39
40 336 reported (Spiers, 2014). The orthologous genes in UMAF0158 have been also
41
42 337 identified. To the best of our knowledge, SBW25, DC3000 and UMAF0158 are
43
44 338 the only pseudomonads to be identified as having *wssFGHI*, which makes the
45
46 339 partial acetylation of cellulose by these strains as unique (Spiers *et al.*, 2013).
47
48 340 The phylogenetic relationships and their locations in the genomes among
49
50 341 *Pseudomonas* spp. *wss* operons were compared, showing a common ancestor
51
52 342 even for *P. syringae* strains that do not currently contain the *wss* operon. The
53
54 343 presence of a large number of insertion sequences (IS) in the cellulose operon
55
56
57
58
59
60

1
2
3 344 flanking regions suggest the potential instability of the *wss* operon (Coucheron
4
5 345 *et al.*, 1991) and present an explanation for why the *wss* operon is not present
6
7 346 in all *P. syringae* pathovars and strains.
8
9

10 347 To determine whether cellulose production of UMAF0158 is involved in plant
11
12 348 colonisation, the phenotypes of two cellulose production-defective mutants, a
13
14 349 cellulose overproducer strain and the wild-type strain were compared. The
15
16 350 results showed the clear involvement of cellulose in biofilm formation and plant
17
18 351 surface adhesion, consistent with previous studies (Matthysse *et al.*, 1981; Gal
19
20 352 *et al.*, 2003; Spiers *et al.* 2003; Le Quéré & Ghigo, 2009; Nielsen *et al.*, 2011).
21
22 353 The overproducer strain drove increased biofilm formation, resulting from the
23
24 354 increased expression of polysaccharides and secreted adhesion proteins,
25
26 355 promoting auto-aggregation (O'Toole *et al.*, 2000). This cellulose
27
28 356 overproduction occurs through the unregulated expression of *wspR19 in trans*,
29
30 357 which produces an increase in the c-di GMP levels, causing higher activation of
31
32 358 *wss* transcription (Spiers *et al.*, 2002) as well as increased cellulose expression
33
34 359 and biofilm formation (Spiers *et al.*, 2003; Ude *et al.*, 2006; Giddens *et al.*, 2007;
35
36 360 Nielsen *et al.*, 2011). These results support the involvement of cellulose in the
37
38 361 epiphytic fitness of *P. syringae* UMAF0158, similar to *P. fluorescens* SWB25
39
40 362 during plant root colonisation (Gal *et al.*, 2003). However, the fact that
41
42 363 UMAF0158 cells are able to stick on the mango leaf surface during the epiphytic
43
44 364 phase contradict the data found with B728a by Yu *et al.* (2013). These authors
45
46 365 found that flagellar motility was favoured during the epiphytic stage through a
47
48 366 global transcriptome profiling. These results demonstrate the diversity of
49
50 367 strategies in the same pathovar to live on/in the host plant; this could even
51
52 368 explain why B728a lacks the *wss* operon.
53
54
55
56
57
58
59
60

1
2
3 369 *P. syringae* UMAF0158 is also a pathogenic bacterium, and cellulose
4
5 370 production could influence its pathogenicity, similar to *Enterobacteriaceae* (Lu *et*
6
7 371 *al.*, 2012). The analysis of the symptoms did not show evident differences
8
9 372 among the cellulose-defective mutants and the wild-type strain; however, the
10
11 373 mutants had a significant increase in the induced necrotic area (severity)
12
13 374 compared with the wild-type strain. In contrast, the overproducer strain showed
14
15 375 a significant decrease. The assessment of these two parameters, incidence and
16
17 376 severity, demonstrated that the virulence of this pathogen is higher in the
18
19 377 absence of cellulose production, because mobility was not increased in these
20
21 378 mutants (data not shown). Notably, when the amount of cellulose in the
22
23 379 exopolysaccharide layer is high (overproducer strain), the virulence of these
24
25 380 bacteria is significantly decreased. Additionally, the competitive index revealed
26
27 381 that only the overproduction of cellulose resulted in a reduction in
28
29 382 competitiveness with wild-type bacteria during the infection of plant tissues,
30
31 383 supporting the previous results. These results suggest that the produced
32
33 384 cellulose material is not a virulence factor but could even act negatively on
34
35 385 virulence. The cellulose overproducer cells could be attached more strongly in
36
37 386 the epiphytic biofilm and it could result in less cells leaving biofilm to roam
38
39 387 through the apoplast to cause disease.

40
41 388 Consistent with these data, the presence or absence of cellulose production in
42
43 389 different strains of *P. syringae* pathovars may determine the lifestyle of the
44
45 390 strain studied, favouring each strain for the prevalence of the epiphytic or
46
47 391 pathogenic lifestyles. Thus, a highly specialised pathogenic strain that does not
48
49 392 produce cellulose would be favoured. Bacteria that cause disease on plants are
50
51 393 typically much better colonisers of the plant than those that do not (Hirano &
52
53
54
55
56
57
58
59
60

1
2
3 394 Upper, 2000). The plant host of *P. syringae* pv. *syringae* UMAF0158 is the
4
5 395 mango tree (*Mangifera indica* L.), producing a typical disease known as
6
7 396 bacterial apical necrosis of mango. This disease is characterised by epiphytic
8
9 397 bacterial survival during the spring and summer and is made evident by
10
11 398 symptom development during the autumn and winter (Cazorla *et al.*, 1998). We
12
13 399 recently described a new phylotype including primarily pv. *syringae* strains
14
15 400 adapted to mango trees and other woody hosts (Gutiérrez-Barranquero *et al.*,
16
17 401 2013). It is likely that this bacterium maintained cellulose production as an
18
19 402 adaptation and specialisation during leaf and bud colonisation, although these
20
21 403 adaptation reduced virulence; this observation implies an adjusted regulation
22
23 404 process of the *wss* operon depending on the stage of life of the bacterium on
24
25 405 the plant host, whereby cellulose production is induced in the epiphytic phase
26
27 406 and repressed during the pathogenic phase. In fact, the second messenger c-
28
29 407 di-GMP is a known regulator between the sessile and mobile phases in a huge
30
31 408 range of bacterial species (Römling *et al.*, 2013). This relevant role of cellulose
32
33 409 production in the *P. syringae* ecology could help to understand also its role in
34
35 410 the biofilm formation, surface colonization and ecology of other cellulose-
36
37 411 producing bacteria.

1 Figure Legends

2 **Fig. 1.** Genomic organisation of bacterial cellulose biosynthesis gene
3 clusters. The cellulose biosynthetic operons of *Gluconacetobacter xylinus* strain
4 (I) (*bcs*), *Escherichia coli* strain K-12, *Salmonella typhimurium* strain LT2 (*yhj*),
5 *Erwinia amylovora* strain ATCC49946 (putative operon *bcs*), *Pseudomonas*
6 *fluorescens* strain SBW25, *Pseudomonas syringae* pv. *tomato* strain DC3000
7 (*wss*), and *Pseudomonas syringae* pv. *syringae* strain UMAF0158 are
8 schematically shown. Each operon contains three genes related to the essential
9 subunits of cellulose synthase, represented as black arrows. The figure has
10 been adapted from Spiers *et al.*, (2002).

11 **Fig. 2.** *Pseudomonas* spp. strain phylogenetic analysis. *Escherichia coli* K-
12 12, *Salmonella typhimurium* LT2 and *Erwinia amylovora* 273 have been used as
13 out groups. The evolutionary history was inferred using the maximum likelihood
14 method based on a previously described data-specific model (Nei & Kumar,
15 2000). (a) Phylogenetic tree using three concatenated genes for cellulose
16 synthase subunits (*wssB*, *wssC* and *wssE*). (b) Phylogenetic tree using eight
17 concatenated housekeeping genes *fruK*, *gapA*, *gltA*, *pgi*, *recA*, *rpoA*, *rpoB* and
18 *rpoD*. The strains with the conserved cellulose operon are marked in a grey
19 background. The *P. syringae* Cit7 strain (marked with asterisk) was not included
20 in the cellulose phylogenetic tree because a contiguous and complete *wss*
21 operon was not found within this draft genome, despite evidence of its
22 presence.

23 **Fig. 3.** The cellulose operon of *Pseudomonas syringae* pv. *syringae* strain
24 UMAF0158. (a) Organisation of the nine genes (grey arrows) that constitute the
25 *wss* operon in UMAF0158: *wssABCDEFGHI*. Mutations in *wssB* and *wssE* are

1
2
3 26 represented with a black triangle (▼). The promoter (P) and terminator (T)
4
5 27 locations are indicated in the non-coding region. Double-headed arrows show
6
7 28 the overlapping amplifications along the cellulose operon. Agarose gels
8
9 29 displaying the PCR products obtained from genomic DNA or mRNA (RT-PCR)
10
11 30 of wild-type UMAF0158. (b) The nucleotide sequence (246 bp) located
12
13 31 upstream of *wssA* was analysed, showing a putative promoter (*in silico* -35 and
14
15 32 -10 boxes indicated with solid-lined boxes) and a putative transcriptional
16
17 33 element for *rpoD16* (indicated with a dashed-line box). The transcript initiation
18
19 34 site is indicated as nucleotide +1 with a black point under the nucleotide, and
20
21 35 the Shine-Dalgarno (SD) sequence is indicated in bold letters. The insertion
22
23 36 sequences (IS) analysed *in silico* are indicated as bold red letters (Table S3).
24
25 37 (c) The terminal region of the cellulose operon located downstream of *wssl*,
26
27 38 depicting the secondary structure and its location of the putative Rho-
28
29 39 independent terminator sequence. The insertion sequences (IS) are indicated
30
31 40 as bold red letters (Table S3). Diagram of the experiment designed to confirm
32
33 41 the functionality of the cellulose operon terminator: the amplicon sizes and
34
35 42 primer directions are indicated. Agarose electrophoresis gels show the results
36
37 43 of the RT-PCR experiments. Hyperladder I (Bioline) was used in these
38
39 44 experiments.

45
46 **Fig. 4.** Cellulose production and biofilm formation by *Pseudomonas*
47
48 *syringae* UMAF0158, defective mutants and derivative overproducer-strain. (a)
49
50 47 Determination of cellulose production measured as fluorescence intensity
51
52 48 through calcofluor staining. The fluorescence intensity is given as arbitrary units
53
54 49 (a.u.), defined as the value obtained from the image analysis according to a
55
56 50 grey scale ranging from pure black to pure white. (b) Biofilm formation was

1
2
3 51 estimated as the absorbance at 595 nm after 15 min of crystal violet staining.
4
5 52 Both experiments were performed using *P. syringae* pv. *syringae* UMAF0158
6
7 53 containing the vector pVSP61 and *P. syringae* pv. *syringae* B728 and *P.*
8
9 54 *fluorescens* SBW25 as controls for cellulose production. Different letters
10
11 55 represent significant differences, $p=0.05$. Error bars show standard deviation.

28

29
30 **Fig. 6.** Bacterial cell counts obtained from adhesion experiments on
31
32 63 mango leaves. Drops of bacterial suspension were deposited onto mango
33
34 64 leaves, and after incubation for 30 min, the leaves were softly washed, and the
35
36 65 adhered cells were recovered and counted. In this experiment, wild type
37
38 66 *Pseudomonas syringae* pv. *syringae* UMAF0158, cellulose-defective mutants
39
40 67 UMAF0158::*wssB* and UMAF0158::*wssE*, and cellulose-overproducing strain
41
42 68 UMAF0158 + pVSP61-WspR19 were assayed. Different letters represent
43
44 69 significant differences, $p=0.05$. Error bars show standard deviation.
45
46

47
48 **Fig. 7.** Analysis of cellulose as a putative virulence factor of *Pseudomonas*
49
50 71 *syringae* pv. *syringae* UMAF0158. (a) Growth time course of wild type *P.*
51
52 72 *syringae* pv. *syringae* UMAF0158 (●), the cellulose-defective mutants
53
54 73 UMAF0158::*wssB* (○) and UMAF0158::*wssE* (▼) and the cellulose-
55
56 74 overproducing strain UMAF0158+pVSP61-WspR19 (Δ) inoculated onto tomato
57
58
59
60

1
2
3 75 leaflets after piercing and maintained *in vitro* for ten days at 22°C under a 16-h
4
5 76 photoperiod. (b) The development of necrotic symptoms in tomato leaflets
6
7 77 inoculated with the four strains. The incidence of necrotic symptoms is
8
9 78 represented as an accumulative number of inoculated points developing
10
11 79 necrotic areas higher than 5 mm in diameter. The symptoms were monitored
12
13 80 and counted for 0, 3, 6 and 10 days, obtaining a total of 108 inoculated points
14
15 81 from each strain. Significant differences from wild-type UMAF0158 are indicated
16
17 82 with an asterisk (*). Error bars show standard deviation. (c) Representative
18
19 83 pictures of tomato leaflets maintained *in vitro* and inoculated with the four
20
21 84 strains, showing symptoms developed at 10 days post-inoculation. (d) Severity
22
23 85 of necrotic symptoms: the total necrotic area (mm²) per leaflet with 6 inoculated
24
25 86 points in 3 independent experiments was measured 10 days after inoculation.
26
27 87 Six inoculated leaflets in each independent experiment were analysed, and 3
28
29 88 independent experiments were performed. Different letters represent significant
30
31 89 differences $p=0.05$ according to analysis of variance. Error bars show standard
32
33 90 deviation.
34
35
36
37
38

39 **Fig. 8.** The competitive index (CI) score for *Pseudomonas syringae* pv.
40
41 *syringae* UMAF0158::*wssB*, UMAF0158::*wssE* and UMAF0158 + pVSP61-
42
43 WspR19 relative to the co-inoculated wild type *P. syringae* pv. *syringae*
44
45 UMAF0158. Three leaflets per strain were analysed, and three independent
46
47 94 experiments were performed to obtain the competitive index values. A CI score
48
49 95 of 1 denotes no difference compared with the wild type. Additional analysis of
50
51 96 the average data from three independent experiments was performed using
52
53 97 analysis of variance ($p=0.05$). Different letters indicate statistical significance.
54
55 98 Error bars show standard deviation.

Fig. 6. Bacterial cell counts obtained from adhesion experiments on mango leaves. Drops of bacterial suspension were deposited onto mango leaves, and after incubation for 30 min, the leaves were softly washed, and the adhered cells were recovered and counted. In this experiment, wild type *Pseudomonas syringae* pv. *syringae* UMAF0158, cellulose-defective mutants UMAF0158::wssB and UMAF0158::wssE, and cellulose-overproducing strain UMAF0158 + pVSP61-WspR19 were assayed. Different letters represent significant differences, $p=0.05$. Error bars show standard deviation.

773x740mm (96 x 96 DPI)

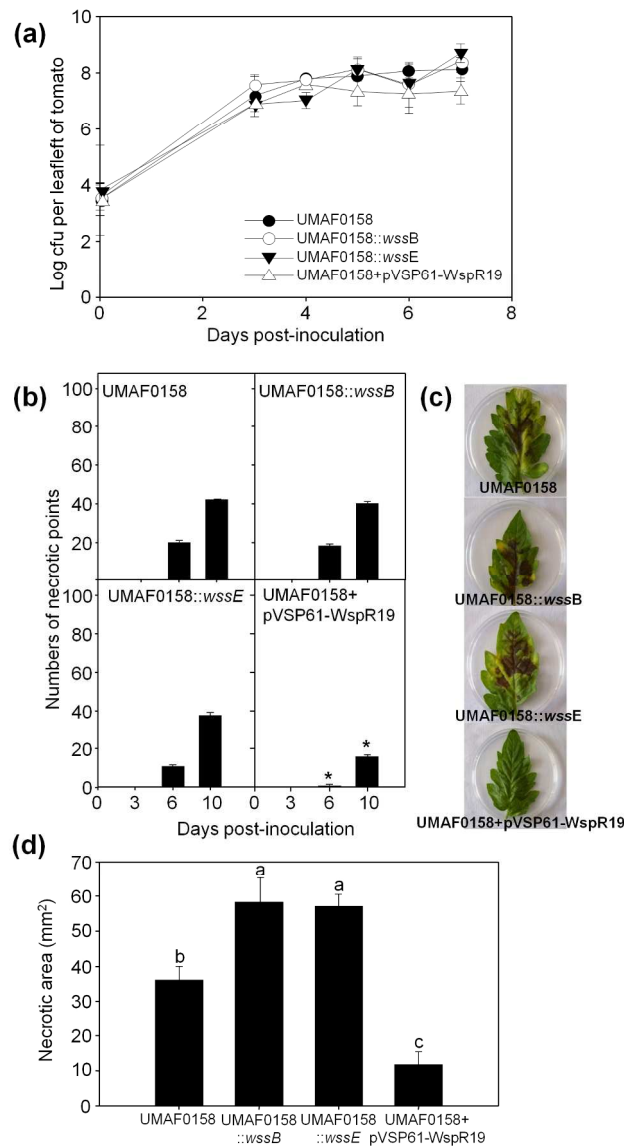

Fig. 7. Analysis of cellulose as a putative virulence factor of *Pseudomonas syringae* pv. *syringae* UMAF0158. (a) Growth time course of wild type *P. syringae* pv. *syringae* UMAF0158 (●), the cellulose-defective mutants UMAF0158::wssB (○) and UMAF0158::wssE (▼) and the cellulose-overproducing strain UMAF0158+pVSP61-WspR19 (△) inoculated onto tomato leaflets after piercing and maintained in vitro for ten days at 22°C under a 16-h photoperiod. (b) The development of necrotic symptoms in tomato leaflets inoculated with the four strains. The incidence of necrotic symptoms is represented as an accumulative number of inoculated points developing necrotic areas higher than 5 mm in diameter. The symptoms were monitored and counted for 0, 3, 6 and 10 days, obtaining a total of 108 inoculated points from each strain. Significant differences from wild-type UMAF0158 are indicated with an asterisk (*). Error bars show standard deviation. (c) Representative pictures of tomato leaflets maintained in vitro and inoculated with the four strains, showing symptoms developed at 10 days post-inoculation. (d) Severity of necrotic symptoms: the total necrotic area (mm²) per leaflet with 6 inoculated points in 3 independent experiments was measured 10 days after inoculation. Six inoculated leaflets in each independent experiment were analysed, and 3 independent

1
2
3 experiments were performed. Different letters represent significant differences $p=0.05$ according to analysis
4 of variance. Error bars show standard deviation.

For Peer Review

Fig. 8. The competitive index (CI) score for *Pseudomonas syringae* pv. *syringae* UMAF0158::wssB, UMAF0158::wssE and UMAF0158 + pVSP61-WspR19 relative to the co-inoculated wild type *P. syringae* pv. *syringae* UMAF0158. Three leaflets per strain were analysed, and three independent experiments were performed to obtain the competitive index values. A CI score of 1 denotes no difference compared with the wild type. Additional analysis of the average data from three independent experiments was performed using analysis of variance ($p=0.05$). Different letters indicate statistical significance. Error bars show standard deviation.

530x554mm (55 x 55 DPI)

1 Supplemental Materials and Methods

3 Bacterial strains and growth conditions

4 For standard maintenance, *P. fluorescens* SBW25 (Spiers *et al.*, 2002), *P.*
5 *syringae* pv. *syringae* UMAF0158 (Arrebola *et al.*, 2003) and B728a (Hirano &
6 Upper, 2000) were grown in King's medium B (KB) (King *et al.*, 1954) and
7 incubated at 28°C for 48 h. Defective mutants UMAF0158::wssB and
8 UMAF0158::wssE were maintained with 50 µg mL⁻¹ kanamycin. The conditions
9 used for plant experiments are specified in the corresponding sections.

11 Phylogenetic Analysis

12 Phylogenetic analysis of different *Pseudomonas spp.* strains was performed
13 using *E. coli* K-12, *S. typhimurium* LT2 and *E. amylovora* 273 as out groups
14 (Supplementary material, Table S3). The selected sequences were analysed
15 using ContigExpress in Vector NTI Advance 10 software to generalise the
16 sequence size. Thereafter, the group sequences of the genes selected for
17 phylogenetic analysis were joined for multilocus treatment and aligned using
18 ClustalW software (Larkin *et al.*, 2007). The cellulose synthase subunits *wssB*,
19 *wssC* and *wssE* (Spiers *et al.*, 2002) and the housekeeping genes *fruK*, *gapA*,
20 *gltA*, *pgi*, *recA*, *rpoA*, *rpoB* and *rpoD* from the selected strains were used for
21 phylogenetic comparison. Phylogenetic analysis of the tested strains was
22 performed using MEGA 5.0 software (Tamura *et al.*, 2007, 2011). Phylogenetic
23 trees were constructed using maximum likelihood fits based on a data-specific
24 model (Nei & Kumar, 2000) of 24 different nucleotide-substitution models.
25 Evolutionary distances were computed using the best model according to the

1
2
3 26 previous assessment, including the General Time Reversible method using
4
5 27 discrete Gamma distribution (GTR+G) for the cellulose multilocus, and the
6
7 28 Tamura-Nei method using discrete Gamma distribution and assuming that a
8
9 29 certain fraction of the site was evolutionarily invariable (TN93+G+I) for the
10
11 30 housekeeping multilocus. The bootstrap consensus trees were inferred from
12
13 31 1000 replicates, and branches corresponding to partitions reproduced in less
14
15 32 than 50% bootstrap replicates were collapsed. The tree with the highest log
16
17 33 likelihood (-46080.6247) is shown for the cellulose phylogenetic tree, and (-
18
19 34 40441.1534) is shown for the housekeeping phylogenetic tree. The percentage
20
21 35 of trees in which the associated taxa clustered together is shown next to the
22
23 36 branches. Initial tree(s) for the heuristic search were automatically obtained.
24
25 37 When the number of common sites was < 100 or less than one fourth of the
26
27 38 total number of sites, the maximum parsimony method was used, otherwise the
28
29 39 BIONJ method with the MCL distance matrix was used. Evolutionary analyses
30
31 40 were conducted in MEGA5 (Tamura *et al.*, 2007). The cellulose multilocus tree
32
33 41 has been drawn to scale, with branch lengths measured in the number of
34
35 42 substitutions per site. The analysis involved 24 nucleotide sequences. The
36
37 43 1st+2nd+3rd+Noncoding codon positions were included. All positions containing
38
39 44 gaps and missing data were eliminated. There were a total of 5210 positions in
40
41 45 the final dataset. A discrete Gamma distribution was used for the housekeeping
42
43 46 multilocus to model evolutionary rate differences among sites (5 categories (+G,
44
45 47 parameter = 0.6416). The rate variation model allowed for some sites to be
46
47 48 evolutionarily invariable ([+I], 28.5912% sites). The tree is drawn to scale, with
48
49 49 branch lengths measured in the number of substitutions per site. The analysis
50
51 50 involved 45 nucleotide sequences. The 1st+2nd+3rd+Noncoding codon
52
53
54
55
56
57
58
59
60

1
2
3 51 positions were included. All positions containing gaps and missing data were
4
5 52 eliminated. A total of 5588 positions were included in the final dataset. The *P.*
6
7 53 *syringae* Cit7 strain (marked with an asterisk in Fig. 2b) was not included in the
8
9 54 cellulose phylogenetic tree (Fig. 2a) because a contiguous and complete
10
11 55 biosynthetic operon was not found within this draft genome, despite evidence of
12
13 56 its presence.
14
15
16
17

18 **Strain manipulation and molecular assays**

19
20
21 59 Insertional inactivation mutagenesis of *P. syringae* UMAF0158 was used to
22
23 60 suppress cellulose production by inserting disruption vectors into the different
24
25 61 ORFs of the cellulose operon via single-crossover homologous recombination.
26
27 62 The PCR using sequence-specific primers was performed to construct
28
29 63 integrative plasmid DNA fragments of the two different genes (*wssB* and *wssE*).
30
31 64 The PCR reaction, pCR2.1-TOPO[®] (Invitrogen Life Tech, USA) cloning and
32
33 65 plasmid purification were performed using standard procedures and primers are
34
35 66 listed in the Supplementary material, Table S5. Plasmids were transformed into
36
37 67 the wild-type strain UMAF0158 using electroporation. Both types of mutants
38
39 68 (UMAF0158::*wssB* and UMAF0158::*wssE*) were analysed by PCR using in and
40
41 69 out primers of the cloned sequence locating the correct insertion of the
42
43 70 disruption vectors. Additionally, bacterial growth curves were obtained in KB
44
45 71 broth to confirm similarities with the wild type (data not shown).
46
47
48
49 72 The wild-type strain UMAF0158 was transformed with the kanamycin-resistant
50
51 73 self-replicating plasmid pVSP61-WspR19 to produce an over-producing
52
53 74 cellulose strain. UMAF0158 was also transformed with the vector pVSP61 as a
54
55 75 control. (Ude *et al.*, 2006).
56
57
58
59
60

1
2
3 76 Total RNA was isolated from a bacterial culture as previously described
4
5 77 (Castillo *et al.*, 2007). The RNA concentration was determined using a
6
7 78 Nanodrop ND-1000 (NanoDrop Technologies Wilmington, DE) and brought to
8
9
10 79 50 ng μL^{-1} . The RNA sample integrity was assessed through agarose gel
11
12 80 electrophoresis. RT-PCR was performed with 100 ng RNA in a final volume of
13
14 81 50 μL using the Titan OneTube RT-PCR system, according to the
15
16 82 manufacturer's instructions (Roche Diagnostics, Basel, Switzerland), with
17
18 83 primers designed to include the neighbouring ends of the analysed genes and
19
20
21 84 listed in the Supplementary material, Table S5. Positive control reactions,
22
23 85 containing DNA isolated from the corresponding bacteria strain, were included
24
25 86 in every assay. The transcription start point for the *wss* operon was determined
26
27 87 using the 5'-RACE method (Maruyama *et al.* 1995; Filiatrault *et al.*, 2010, 2011;
28
29 88 Carrión *et al.*, 2012). The synthesis of single-stranded cDNA was performed
30
31 89 using Total DNA-free RNA, which was obtained from cultures grown in KB broth
32
33 90 for 48 h at 28°C. One microgram of this RNA was used as a template to
34
35 91 synthesise first-strand cDNA using a cDNA synthesis kit (SMART™ RACE
36
37 92 cDNA Amplification Kit, Clontech, Takara Bio Company© 2012, USA) and a
38
39 93 gene-specific oligonucleotide primer designed to anneal within the coding
40
41 94 region of the gene (Primers listed in Supplementary material, Table S5). The
42
43 95 reactions were performed for 90 min at 42°C and subsequently diluted 10-fold in
44
45 96 water. A total of 1 μl of these dilutions was added to 20 μl of PCR mixture. The
46
47 97 cycling profile included 5 cycles for 30 s at 94°C; 3 min at 72°C; 5 cycles for 30
48
49 98 s at 94°C; 30 s at 70°C; 3 min 72°C; 25 cycles for 30 s at 94°C; 30 s at 68°C;
50
51 99 and a final extension for 3 min at 72°C. The amplification products were cloned
52
53
54
55
56
57
58
59
60

1
2
3 100 into the pGEM®-T Easy Vector (Promega Corporation, Madison, WI) and
4
5 101 confirmed through sequencing.
6
7

8 102
9

10 103 **Microscopy**

11
12 104 The bacterial cultures were incubated for 48 h at 28°C in KB medium. Bacterial
13
14 105 suspensions were made in sterile distilled water and adjusted to 10⁸ cfu mL⁻¹.
15

16
17 106 The suspensions were sprayed onto mango buds (*Mangifera indica* L. var
18

19 107 Osteen) and left for three days on plants maintained in a greenhouse. Mango
20

21 108 buds were fixed in 2.5% glutaraldehyde in phosphate buffer for 24 h at 4°C in
22

23 109 the dark. Finally, the samples were dehydrated by increasing the ethanol
24

25 110 concentration from 0% to 100%, and the samples were kept in each ethanol
26

27 111 solution for at least 20 min. The samples were maintained in 100% ethanol until
28

29 112 processing for Scanning Electronic Microscopy (SEM). At least three replicates
30

31 113 for every sample were observed.
32
33
34
35
36

37 115 ***In vitro* analysis of cellulose production**

38
39 116 Strains were grown in KB medium supplemented with FeCl₃ (0.25 g L⁻¹) to avoid
40
41 117 siderophore production. Calcofluor (SIGMA Fluorescent Whitener 28) was
42

43 118 added to the medium at 10 μM for fluorescent staining of the colonies. The
44

45
46 119 bacteria were grown for 3 days at 28°C then subsequently observed and
47

48 120 photographed using a binocular microscope with a 2x objective, 640x480 focus
49

50 121 and 1 s exposure time under UV light. The pictures in Tiff format were
51

52 122 processed using Visilog 5.0 software (Noesis Vision Inc., France). The colour
53

54 123 images were transformed to grey scale pictures, whereby the fluorescent color
55

56 124 is transformed to white color; thus, highly fluorescent colonies will be closer to
57
58
59
60

1
2
3 125 white in color than colonies with little fluorescence. Using the image processor,
4
5 126 the amount of white in the colonies were measured and transformed to data.
6
7 127 The measured area for each colony was 17202 pixels (0.1388 mm²). At least
8
9 128 three colonies per image and six images per strain and experiment were
10
11 129 analysed. Five independent experiments were performed to obtain the cellulose
12
13 130 production results. The values were obtained as arbitrary units (a.u.), defined as
14
15 131 the value obtained according to a grey scale ranging from 0.0 (pure black) to
16
17 132 255 (pure white) in a 0.1388 mm² area.
18
19
20
21
22

23 134 **Biofilm quantification**

24
25 135 Liquid cultures of UMAF0158, the cellulose-defective mutants
26
27 136 UMAF0158::*wssB* and UMAF0158::*wssE*, and the overproducing strain
28
29 137 (overproducer type) were adjusted to 10⁸ cfu mL⁻¹ and incubated at 28°C
30
31 138 overnight to assay biofilm formation. The negative control was cultured using
32
33 139 KB broth. Biofilm formation and quantification were performed as previously
34
35 140 described (Peeters *et al.*, 2008). Briefly, one hundred microliters of each strain
36
37 141 culture were pipetted into several wells of a 96-well microtiter plate and
38
39 142 incubated at 28°C for 24 h to facilitate cell attachment and biofilm formation.
40
41 143 The culture was discarded after incubation to remove any loosely associated or
42
43 144 planktonic bacteria. For biofilm fixation, 100 µL of methanol was added to each
44
45 145 well of a 96-well microtiter plate. After 15 min, the methanol was removed, and
46
47 146 the plate was air-dried. The biofilms were quantified using a crystal violet assay.
48
49 147 The wells were stained with 100 µL of 0.5% crystal violet and incubated at room
50
51 148 temperature for 15 min, followed by washing under running tap water. The
52
53 149 bound crystal violet was released after adding 150 µL of 33% of acetic acid
54
55
56
57
58
59
60

1
2
3 150 (SIGMA-Aldrich, Bandai, Fukushima, Japan). The 96-well microtiter plates were
4
5 151 measured at 595 nm using a micro-plate reader. At least 24 wells per strain and
6
7 152 experiment were used, and four independent experiments were performed to
8
9 153 obtain the biofilm results.
10

11
12 154

13 14 155 **Adhesion assay on mango leaves**

15
16 156 For adhesion experiments, bacterial suspensions using KB plates from strains
17
18 157 grown for 48 h at 28°C were adjusted to 10^8 cfu mL⁻¹. Drops (10 µL) of each
19
20 158 strain were inoculated onto mango leaves wiped with 70% ethanol and painted
21
22 159 onto dividing lines to avoid mixtures. After 30 min, the leaves were carefully
23
24 160 washed with sterile water, cut from the mango tree and dissected according to
25
26 161 the painted lines for processing. The leaf pieces were placed into sterile bags
27
28 162 with 1 mL of sterile water and homogenised for 3 min. One hundred microliters
29
30 163 from every bag was plated onto a KB plates to determine bacterial numbers.
31
32 164 Three plates per strain were used, with three replicates per experiment and
33
34 165 three independent experiments performed to obtain the adhesion results.
35
36 166

37
38
39 166

40 41 167 **Pathogenesis and competitive index evaluation**

42
43 168 Wild-type UMAF0158, the cellulose-defective mutants UMAF0158::*wssB* and
44
45 169 UMAF0158::*wssE*, and the overproducer strains were inoculated onto detached
46
47 170 tomato leaflets (*Solanum lycopersicum* L. cv. Hellfrucht-Früstamm) to evaluate
48
49 171 virulence, as previously described (Arrebola *et al.*, 2007, 2009; Carrión *et al.*,
50
51 172 2014). Bacterial suspensions from exponentially growing cultures were adjusted
52
53 173 to 10^8 cfu mL⁻¹. Detached leaflets were inoculated with six 10 µL drops of
54
55 174 bacterial suspension at six different points on each leaflet. For inoculation, the
56
57
58
59
60

1
2
3 175 leaves were pierced with bacterial droplets using a sterile entomological pin.
4
5 176 The leaflets were maintained in Murashige & Skoog (MS) media at 22 °C for a
6
7 177 16-h photoperiod. Six tomato leaflets were used for each strain and each
8
9 178 independent experiment. Non-infected detached leaflets inoculated with sterile
10
11 179 distilled water were included in all experiments as a control. These experiments
12
13 180 were repeated three times.

14
15
16 181 The development of necrotic symptoms at the inoculation points was
17
18 182 determined using two different methods. First, the appearance of necrotic
19
20 183 symptoms was monitored for 0, 3, 6 and 10 days using visual analysis to
21
22 184 evaluate disease incidence (number of inoculated points with symptoms of
23
24 185 necrosis), considering points with areas equal or greater than 0.5 cm in
25
26 186 diameter to be necrotic. Second, the total necrotic area per leaflet induced by
27
28 187 the inoculated strains on the last day (10th day) of the experiment (severity) was
29
30 188 determined from six leaflets over three independent experiments using the
31
32 189 image analysis software Visilog 5.0 (Noesis Vision Inc., France).

33
34
35
36 190 In addition, two inoculated leaflets were used every day for seven days to
37
38 191 estimate the total bacterial density in every strain used. The tomato leaflets
39
40 192 were homogenised in 10 ml of sterile water, and the bacteria were serially
41
42 193 diluted and counted on KB plates after incubation at 28°C for 48 h.

43
44
45 194 Additional experiments to obtain a competitive index were performed using
46
47 195 tomato leaflets maintained *in vitro*. A bacterial suspension of the wild type
48
49 196 UMAF0158 strain was mixed at a 1:1 ratio with cellulose-defective mutants, and
50
51 197 the cellulose overproducer strain suspensions was adjusted to 10⁸ cfu mL⁻¹.
52
53 198 Similar to the pathogenicity, six drops of the mixture were inoculated on the
54
55 199 tomato leaflets at six different places and maintained in MS medium at 22°C
56
57
58
59
60

1
2
3 200 during the experiment. The leaflets were processed after 1 h to observe the
4
5 201 initial symptom points and after 7 days to observe the final symptom points. The
6
7 202 same suspension from tomato leaflet processing was inoculated in KB medium
8
9 203 with and without kanamycin ($50\mu\text{g mL}^{-1}$). The titers were calculated for every
10
11 204 strain at initial and final points. The competitive indices were obtained after
12
13 205 dividing the analysed strain by the wild type at each point (initial and final), and
14
15 206 dividing again the data obtained from the final point per the data from the initial
16
17 207 point in every mutant and overproductive strain. Three leaflets per strain and
18
19 208 experiment and three independent experiments were performed to obtain
20
21 209 competitive index results.
22
23
24
25
26

27 **Statistical Analysis**

28
29 212 Statistical analyses of *in vitro* cellulose production, the biofilm quantification
30
31 213 adhesion assay on mango leaves, the competitive index and analysis of the
32
33 214 necrotic area, were performed using IBM.SPSS 19 software (IBM® Company,
34
35 215 Armonk, NY). One factor ANOVA was used for the analysis of the means with
36
37 216 $p=0.05$: homogeneity test data were analysed by the Levene test, and statistic
38
39 217 descriptive effects homogeneity was analysed by the Brown-Forsythe Welch
40
41 218 test, with post hoc analysis by LSD $\alpha= 0.05$ and a 95% confidence interval. The
42
43 219 statistical analysis of incidence of necrotic symptoms was performed using
44
45 220 SAS9.2 software (SAS Institute Inc., Cary, NC, USA) in the Enterprise Guide
46
47 221 4.2 program with generalised linear model analysis.
48

a: Search protein patterns on the amino acid sequence template based on PROSITE™ database

(<http://prosite.expasy.org/>)

b: ATP/GTP binding site motif A (P-Loop)

c: N-myristoylation site

d: Casein kinase II phosphorylation site

e: Protein kinase C phosphorylation site

f: N-glycosylation site (glycosylation of asparagine)

g: Cell attachment sequence

h: Amidation site

i: cAMP and cGMP-dependent protein kinase phosphorylation site

1 **Table S2.** Sequence coverage (Cov) and identity (Ident) of genes belonging to cellulose operon located in *Pseudomonas syringae*
 2 *pv.syringae* UMAF0158 with the orthologous genes located in sequenced *Pseudomonas spp.* strains. The three common genes
 3 present in every cellulose operon (Fig. 1), are colored in grey.

Table S5. DNA primers used in this study.

PRIMERS	SEQUENCE 5'→3'	USE
Construction of insertional mutants using integrative plasmids (pCR2.1-TOPO)		
wssB-F	CCGACCGTCGATGTGTTTAT	Amplify a <i>wssB</i> fragment (794bp) that cloned into pCR2.1 TOPO vector was used to construct insertional mutant in <i>wssB</i>
wssB-R	AGGCCGTAAAAGAAGTGCAG	
wssE-F	CCTGAAGGATGCGGTAAAA	Amplify a <i>wssB</i> fragment (826bp) that cloned into pCR2.1 TOPO vector was used to construct insertional mutant in <i>wssB</i>
wssE-R	CAGGAGTACTTGC GGATCGT	
Allocation <i>wss</i> genes in mRNA by RT-PCR (see Fig. 3a)		
Cel-1F	GTGATTGCCTGGCTGACC	Amplify overlapping sequence between AMN-31 and <i>wssA</i> (1367bp)
Cel-1R	GAGATCGATCGCCAGTGTCT	
Cel-2F	CACGCGTAACTGATCAATCG	Amplify overlapping sequence between <i>wssA</i> and <i>wssB</i> (1351bp)
Cel-2R	GTCCAGCCAGTTGTCTGAAAT	
Cel-3F	TTGTCATGACCAACCTGTCTG	Amplify <i>wssB</i> internal sequence (1373bp)
Cel-3R	AAGGTGCGGCAACACATAG	
Cel-4F	GTGGTGTGGCCACTGAAAC	Amplify overlapping sequence between <i>wssB</i> and <i>wssC</i> (1313bp)
Cel-4R	ACAACGCACAAGCCAACAG	
Cel-5F	GGCACTCGTTTCGATGATCT	Amplify overlapping sequence between <i>wssB</i> and <i>wssC</i> (1341bp)
Cel-5R	AACCGGAGACGTTGAGTTTG	
Cel-6F	CAACGCACTGGTATTGCTCA	Amplify <i>wssC</i> internal sequence (1288bp)
Cel-6R	TACCTTGTCGCTGCTGCTC	
Cel-7F	GACCGGTGTGTCGGTTATTC	Amplify overlapping sequence between <i>wssC</i> and <i>wssD</i> (1315bp)
Cel-7R	AACCCAATCGGCGATAAAG	
Cel-8F	GACCTGTGGATCGTCTACGC	Amplify overlapping sequence between <i>wssD</i> and <i>wssE</i> (1359bp)
Cel-8R	AAAACAACGCCAGAATCGAG	
Cel-9F	CGCAGACTTACTTGGCTCGT	Amplify <i>wssE</i> internal sequence (1377bp)
Cel-9R	ACAGCAACGCACTGGTGTAG	
Cel-10F	AGGCGGGCTATCGTCAAGT	Amplify <i>wssE</i> internal sequence (1309bp)
Cel-10R	GCGAACGGATTGGACGAC	
Cel-11F	GTCCGGACGACATTCAGG	Amplify <i>wssE</i> internal sequence (1310bp)
Cel-11R	ACTCTGGTCGTTGGCGTAAC	
Cel-12F	AGAGGGCCTCAAGGCTGATA	Amplify overlapping sequence between <i>wssE</i> and <i>wssF</i> (1334bp)
Cel-12R	CAGGAACTGCGACATCAACT	
Cel-13F	GATCAGCAAGAAGGTCGATTG	Amplify overlapping sequence between <i>wssF</i> , <i>wssG</i> and <i>wssH</i> (1367bp)
Cel-13R	ACCACGGTCAGCAGCATGT	
Cel-14F	CGACCTGTTCAAGTCCGGTTG	Amplify overlapping sequence between <i>wssG</i> and <i>wssH</i> (1296bp)
Cel-14R	CTTGGAACAGCAGGCAGATT	
Cel-15F	CGTACTCGCTGCAACTGTTT	Amplify overlapping sequence between <i>wssH</i> and <i>wssI</i> (1340bp)
Cel-15R	TACGCAGGTAAGCTGTTTCG	
Cel-16F	GGCGAAGTGA CTCACTCAACT	Amplify overlapping sequence between <i>wssH</i> , <i>wssI</i> and 3'end (1269bp)
Cel-16R	AAATTTGTCCCAACCACGAA	
Cel-17F	TGTGGCGATCGAAAAGTTAG	Amplify overlapping sequence between <i>wssI</i> and AMN-42 (1299bp)
Cel-17R	CGGAAAGAATGCTGGACCT	

Allocation transcriptional start point (5' RACE analysis)		
GSPcel-1	TCAGGCACCGATTGATCAGTTACGC	Reverse amplification 130bp from ATG of <i>wssA</i>
GSPcel-2	CGTACTTTTACCCACACCGCCCTTG	Reverse amplification 386bp from ATG of <i>wssA</i>
GSPcel-3	ACCAGCCAGTGTGGATCGTTTCCT	Reverse amplification 677bp from ATG of <i>wssA</i>
GSPcel-4	CGCAGCGTCAATTCCAGATTCAGAC	Forward amplification 452bp to TAA of <i>wssI</i>
GSPcel-5	ACGACCTGTTTCGGCGACAGTAACCT	Forward amplification 253bp to TAA of <i>wssI</i>
GSPcel-6	GTCTACTTCGACAACCCGGCCTTCC	Forward amplification 98bp to TAA of <i>wssI</i>
