Résumé

Dans le présent travail, nous avons étudié sept communautés présentes dans les marais salés de l'ouest de la Péninsule Ibérique, principalement rattachées à la classe *Sarcocornietea fruticosae*. Trois nouveaux syntaxa sont décrits dans ce travail : *Myriolimo diffusi-Limonietum algarvensis*, *Triglochin maritimae-Sarcocornietum maritimae* subass. *puccinellietosum alpini* et *Limonion lanceolati-algarvensis*. Le premier est une association chamaephytique des marais limoneux secs thermoméditerranéens, seulement inondés par l'eau salée pendant les grandes marées ; il occupe des places bien drainées de l'Algarve (Province Lusitanien-Andalouse Côtier, Région Méditerranée), et est caractérisé par les endémiques ibériques *Myriolimon diffusum* et *Limonium algarvense*. Le deuxième est une communauté halophytique formée par *Sarcocornia perennis* subsp. *alpini*, *Halmione portulacoides*, *Triglochin maritima*, *Puccinellia maritima* et *Plantago maritima* sur des sites périodiquement inondés par des eaux salées, riches en sable et limon, au nord de la Ria de Aveiro (District Miniense, Sous-province Cantabrique-Atlantique, Province Atlantique-Européenne, Région Eurosibérienne). La dernière est une alliance composée de communautés thermoméditerranéennes de *Limonium sp. pl.* noyées par les marées plus élevées dans la Province Lusitanien-Andalouse Côtier. Nous présentons également quelques relevés des associations *Limonio vulgaris-Juncetum subulatum* et *Limonietum lanceolati*, et nous amplifions la distribution du *Puccinellio tenuifoliae-Limonietum plurisquamati* jusqu'à l'estuaire du Tage et du *Limonietum lanceolati* à l'estuaire du Sado. Nous proposons aussi la ségrégation entre *Myriolimetum ferulacei*, sur les falaises maritimes de l'Algarve, et *Inulo crithmoidis-Myriolimetum ferulacei*, dans les marais.

Summary

Coastal halophilous Limonium communities from West Iberian Peninsula.

In the present work, we studied seven communities occurring in salt marshes in the west of the Iberian Peninsula, mostly ascribable to *Sarcocornietea fruticosae* class. Three new syntaxa are described: *Myriolimo diffusi-Limonietum algarvensis*, *Triglochin maritimae-Sarcocornietum maritimae* subass. *puccinellietosum alpini* and *Limonion lanceolati-algarvensis*. The first one is a chamaephytic community existing on thermomediterranean dry salt marshes, only inundated during high tides; it occupies well-drained sands from the Algarve (Coastal Lusitanian-Andalusian Province, Mediterranean Region), which the director species are the Iberian endemisms *Myriolimon diffusum* and *Limonium algarvense*. The second one is a halophytic community formed by *Sarcocornia perennis* subsp. *alpini*, *Triglochin maritima*, *Halmione portulacoides*, *Puccinellia maritima*, and *Plantago maritima* on sites occasionally inundated by saltwater, rich in sand and silt, north of the Ria de Aveiro (Miniense District, Cantabrian-Atlantic Subprovince, Eurosiberian Region). The last one is the alliance *Limonion lanceolati-algarvensis*, formed by *Limonium sp. pl.* communities from the Coastal Lusitanian-Andalusian Province. We also extend the distribution area of *Puccinellio tenuifoliae-Limonietum plurisquamati* to the Tagus estuary. We propose the segregation between *Myriolimetum ferulacei*, from the Algarve sea cliffs, and *Inulo crithmoidis-Myriolimetum ferulacei*, from salt marshes.

Key words: salt marshes, phytosociology, biogeography, Portugal, Galicia

Introduction

Within the Iberian Peninsula context, the Portuguese salt marshes' vegetation is of great originality, as the boundary between the Eurosiberian and the Mediterranean Regions is found in Lusitanian territory (GÉHU & RIVAS-MARTÍNEZ 1983; COSTA *et al.* 2009). The separation may be related to the fact that salinization processes in the Mediterranean Sea shores are greatly influenced by the saline solution movements in the subsoil and by the presence of a saline phreatic sheet during summer time (CORRE, 1978), since tides are practically insignificant. On the Atlantic coast the main reason for the existence of halophytic areas is, on the contrary, soil submersion by seawater due to tides (SÁNCHEZ *et al.*, 1998). Regarding the southwestern Iberian

Peninsula, plant communities' distribution has been influenced by both the depth and salt content of the phreatic sheet and the seawater submersion period (COSTA *et al.*, 1996), which may explain the original combination of some Atlantic and Mediterranean plants and communities present on this area.

In this paper we deepen the study of recently described communities by COSTA *et al.* (2009), as well as, communities of *Limonium sp. pl.* which form a new alliance included in *Limonietalia* order. This order is characterized by littoral and inland temporary wet Mediterranean high saline *Limonium sp. pl.* and perennial grasses communities.

Material and methods

Phytosociological relevés and nomenclature were drawn up after the principles of the Zurich-Montpellier landscape and 'sigmatist' school (BRAUN-BLANQUET 1965, GÉHU & RIVAS-MARTÍNEZ 1980, WEBER *et al.* 2000 and RIVAS-MARTÍNEZ 2005). Bioclimatic and biogeographic nomenclature follows RIVAS-

MARTÍNEZ (2002) and COSTA *et al.* (1999). The taxonomic nomenclature follows the work of CASTROVIEJO *et al.* (1986-2010), FRANCO (1971, 1984), FRANCO & ROCHA AFONSO (1994, 1998, 2003), except for *Myriolimon diffusum* and *Myriolimon ferulaceum* that follows LLÉDO *et al.* (2005).

Results

1. *Limonio vulgaris-Juncetum subulati* J.C. Costa, Neto, T. Almeida & Lousã in J.C. Costa, Arsenio, Monteiro-Henriques, Neto, E. Pereira, T. Almeida & Izco 2009

[*Arthrocnemo glauci-Juncetum subulati* sensu RIVAS-MARTÍNEZ et al. (1980), COSTA et al. (1996) non *Arthrocnemo glauci-Juncetum subulati* Brullo & Furnari 1976]

Phytocoenoses dominated by *Juncus subulatus*, on depression or abandoned saltpans, flooded for a more or less long period by brackish water derived from autumn and winter rainfall, completely dried out during summer. It is found in saline-clayey soils, with a high sandy fraction, being the Iberian *Arthrocnemion macrostachyi* community that bear the longest period of flood. In its floristic characteristic composition are included: *Juncus subulatus*, *Halimione portulacoides*, *Sarcocornia fruticosa*, *Limonium vulgare*, *Aster tripolium* subsp. *pannonicus*, *Arthrocnemum macrostachyum*, *Sarcocornia perennis* subsp. *alpini*, *Polygonum equisetiforme*, *Myriolimon*

ferulaceum, *Inula crithmoides*, *Elytrigia elongata*, *Triglochin barrelieri*, etc. (Table 1). It occurs in the thermomediterranean dry bioclimate, within the Tagus and the Guadalquivir rivers, in the Coastal Lusitanian-Andalusian Province, Mediterranean Region (Fig. 1). Of difficult syntaxonomic positioning, as it contains plant species both form *Sarcocornietea fruticosae* (*H. portulacoides*, *S. fruticosa*, *A. macrostachyum*, *S. alpini*, *P. equisetiforme*, *M. ferulaceum*, *I. crithmoides*, *T. barrelieri*, *Suaeda vera*, *Cistanche phelypaea*, *Artemisia gallica*, *Limoniastrum monopetalum*, *M. diffusum*) and from *Juncetea maritimi* (*J. subulatus*, *L. vulgare*, *J. maritimus*, *A. tripolium* subsp. *pannonicus*, *E. elongata*, *F. laevis*), we decided to assign it to the former, within *Sarcocornietalia fruticosae* order, *Arthrocnemion macrostachyi* alliance, *Arthrocnemion macrostachyi* suballiance, as the characteristic species of *Sarcocornietea* are more frequent and because these communities occupy the higher parts of the salt marshes resisting to high salinity contents during summer. It corresponds to Natura 2000 natural habitat 1410.

2. *Triglochin maritimae-Sarcocornietum alpini* J.C. Costa, Neto, Izco in J.C. Costa, Arsénio, Monteiro-Henriques, Neto, E. Pereira, T. Almeida & Izco 2009

Halophytic community dominated by *S. perennis* subsp. *alpini*, *Triglochin maritima* and *H. portulacoides* (Table 2) occurring in salt marshes in areas north of the Tagus River, in sandy-silty zones, occasionally flooded by brackish water, in the meso-diterranean bioclimate, also in some salt-marshes placed in general thermotemperate bioclimate, but with local mediterranean influence. It is a geovarious of *Halimione portulacoides-Sarcocornietum alpini*, which belongs in the southwest of the Iberian Peninsula, south of the Tagus Estuary, in the thermomediterranean territories. It contacts at lower elevations with *Puccinellio maritimae-Sarcocornietum perennis* and with *Limonio-Juncetum maritimi* at higher quotas. We propose its inclusion in *Sarcocornienion alpini* suballiance because it occurs on salt marshes only exceptionally reached by tides. It corresponds to Natura 2000 natural habitat 1420.

This association has two subassociations: *sarcocornietum alpini* (table 2, relevés 1 to 7) and *puccinellietosum maritimae* J.C. Costa, Neto & Izco subass. *nova hoc loco* (Table 2, relevés 8 to 15). The first one is typical and characteristic of the Portuguese Dividing Sector, Coastal Lusitanian-Andalusian Province, Mediterranean Region, between Óbidos Lagoon and Mondego River (Fig. 1). The second, *puccinellietosum maritimae*, occurs north of the Ria de Aveiro reaching Galicia in the Northern Galician-Portuguese Subsector, Cantabrian-Atlantic Subprovince, Atlantic European Province, Eurosiberian Region (Fig. 1), with *Puccinellia maritima* and *Plantago maritima* as differential species (Table 2). Holotypus: relevé no. 13 of table 2, held in Corrubedo (Coruña, Spain).

Chamaephytic association on sandy-brackish soils, only occasionally touched by brackish water during equinoctial tides, although occasionally flooded by fresh water during winter or springtime. *Limonium plurisquamatum*, *Puccinellia tenuifolia*, *H. portulacoides*, *F. laevis*, *J. maritimus*, *M. ferulaceum* are the most reliable species (Table 3). It occurs in the

Portuguese Dividing Sector, Dividing Portuguese-Sadensean Subprovince, Coastal Lusitanian-Andalusian Province, Mediterranean Region, between the Tagus River and S. Martinho do Porto (Tornada River) (Fig. 1), in the thermomediterranean subhumid to dry bioclimate.

6. *Limonietum lanceolati* Arsénio, J.C. Costa, Neto & Monteiro-Henriques in Neto, Arsénio & J.C. Costa 2009

Hemicryptophytic association, dominated by *Limonium lanceolatum* and *M. ferulaceum* accompanied by several plants of *Sarcocornetea fruticosae* (Table 5). It occurs in clayey or silty soils rich in schistose debris, only inundated during the highest tides. It occupies places relatively higher than the *Inula crithmoidis-Arthrocnemetum glauci* and lower than the *Cistancho phelypaeae-Suaedetum verae*, in salt marshes from the Mira (Odemira) and Cerca rivers (Aljezur) (Fig. 1), which belong in the Coastal Vincentine District in the Coastal Lusitanian-Andalusian Province. Also noted in the Sado estuary (relevés 7 and 8, Table 5), in sandy areas in clearings of *Cistancho phelypaeae-Suaedetum verae*; this territory is included in the Sadensean District of the same Province. It is in the thermomediterranean dry belt.

7. *Myriolimo diffusi-Limonietum algarvensis* J.C. Costa, Lousã, Caperta & Neto ass. nova hoc loco

[holotypus relevé nº 3, Table 6]

The communities dominated by the chamaephytes *Myriolimon diffusum* (Pourr.) Lledó, Erben & Crespo (= *Limonium diffusum* (Pourr.) O. Kunze) and *Limonium algarvense* found in the Algarve are here designated as *Myriolimo diffusi-Limonietum algarvensis* (Table 6). This phytocoenosis occurs in sandy well-drained soils, inundated only during the highest tides, under the thermomediterranean dry bioclimate. It occupies places relatively lower than the occupied by the *Polygono equisetiformis-Limoniastrum monopetalii* association, usually between this and *Cistancho phelypaeae-Suaedetum verae*. Therefore, the presence of *L. monopetalum* and *S. vera* is understandable. Its area of distribution, so far, is restricted to the salt marshes of the Algarve, in the Algarvian District, Coastal Lusitanian-Andalusian Province (Fig. 1).

To join these associations of *Limonium* sp. pl. from the west and southwest of the Iberian Peninsula, the alliance *Limonion lanceolati-algarvensis* All. nova [Holotypus: *Limonietum lanceolati* Arsénio, J.C. Costa, Neto & Monteiro-Henriques in Neto, Arsénio & J.C. Costa 2009 in Quercetae 9: 96-97 tb. XXII, 2009] is proposed, based on ecological and floristical criteria included in *Limonietalia* order. This alliance is formed by halophilous thermomediterranean Coastal Lusitan-Andalusian communities, with rosulate and prostrate chamaephytes that colonize the upper tideland of salt marshes reached by the sea water only during the highest tides. *L. algarvense*, *L. daveui*, *L. lanceolatum* and *M. diffusi* are their characteristic species. *Inulo crithmoidis-Myriolimetum ferulacei*, *Puccinellio tenuifoliae-Limonietum plurisquamati*, *Limonietum lanceolati* and *Myriolimo diffusi-Limonietum algarvensis* are the associations that form this new alliance (corresponding to Natura 2000 natural habitat 1510*).

The proposed nom. mut. in this work will be sent to the commission of the international code of phytosociological nomenclature in accordance with article 45.

Table 7
Diagnostic species and chorology of the study associations

Discussion

In Table 7 we present the characteristic, differential species and the chorology of the associations studied in this work. *Limonio vulgaris-Juncetum subulati* is distinguished from *Arthrocnemo glauci-Juncetum subulati* and *Elymo elongati-Juncetum subulati* by the differential species *L. vulgare* and *M. ferulaceum*.

Triglochin maritimae-Sarcocornietum alpini have as differential species *T. maritima* and *A. tripolium* subsp. *pannonicus*, on the other hand, the Mediterranean species *Puccinellia iberica*, *C. phelypaeae* and *A. gallica* are absent from the floristic composition, but these two are present in *Halimono portulacoides-Sarcocornietum alpini*.

We accepted the segregation of *Inulo crithmoidis-Myriolimetum ferulacei* from *Myriolimetum ferulacei* because the ecology of the communities is quite different (the first one occurs on salt marshes and the second on sea cliffs), as well as the floristic composition, with many differential species (*H. portulacoides*, *P. iberica*, *A. gallica*, *L. monopetalum*, *T. barrelieri*, *L. vulgare*, *L. algarvense*, *J. subulatus* in the first one and *L. ovalifolium*, *C. maritimum*, *F. laevis*, *P. coronopus* subsp. *occidentalis*, *D. marina*, *A. maritimus*, *D. halophilus*, *L. virgatum*, *S. australis*, etc. in the second).

The new alliance *Limonion lanceolati-algarvensis* corresponds to the coastal chamaephytic communities reached by the sea waters only during the highest tides. The atlantic species *F. laevis*, *L. ovalifolium* are the differential species to the other alliances of the order *Limonietalia*, on the other hand *M. ferulaceum*, *T. barrelieri*, *A. gallica*, *P. equisetiforme*, *P. iberica*, *L. monopetalum* and *S. vera* are the differential species to Cantabrian-Atlantic alliance *Limonio ovalifolii-Frankenion laevis* (*Glaucop-Puccinellieta*, *Juncetea maritimae*).

Puccinellio tenuifoliae-Limonietum plurisquamati stands between *Limonio vulgaris-Juncetum subulati*, *Juncetea maritimae* and *Sarcocornietea fruticosae*; however, we propose its inclusion in the latter due to the presence of *M. ferulaceum*, *A. gallica*. Although *Myriolimo diffusi-Limonietum algarvensis* resembles the *Inulo crithmoidis-Myriolimetum ferulacei* association, its ecology is quite distinct as the latter occurs on clayey or silty soils and the first one on sandy soils. These two associations, *Inulo crithmoidis-Myriolimetum ferulacei* and *Limonietum lanceolati* are included *Limonion lanceolati-algarvensis* alliance due to their ecology, short time inundated, and floristic composition where *Sarcocornietea fruticosae* species dominate.
