Just Accepted

“Just Accepted” manuscripts have been peer-reviewed and accepted for publication. They are posted online prior to technical editing, formatting for publication and author proofing. The American Chemical Society provides “Just Accepted” as a free service to the research community to expedite the dissemination of scientific material as soon as possible after acceptance. “Just Accepted” manuscripts appear in full in PDF format accompanied by an HTML abstract. “Just Accepted” manuscripts have been fully peer reviewed, but should not be considered the official version of record. They are accessible to all readers and citable by the Digital Object Identifier (DOI®). “Just Accepted” is an optional service offered to authors. Therefore, the “Just Accepted” Web site may not include all articles that will be published in the journal. After a manuscript is technically edited and formatted, it will be removed from the “Just Accepted” Web site and published as an ASAP article. Note that technical editing may introduce minor changes to the manuscript text and/or graphics which could affect content, and all legal disclaimers and ethical guidelines that apply to the journal pertain. ACS cannot be held responsible for errors or consequences arising from the use of information contained in these “Just Accepted” manuscripts.

A binder-free cobalt phosphate hydrate ($\text{Co}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}$) multilayer nano/ microflakes structure is synthesized on nickel foam (NF) via a facile hydrothermal process. Four different concentrations (2.5 mM, 5mM, 10mM and 20mM) of the Co^{2+} and PO_4^{3-} were used to obtain different mass loading of cobalt phosphate on the nickel foam. The $\text{Co}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}$ modified NF electrode (2.5 mM) shows a maximum specific capacity of 868.3 C g^{-1} (capacitance of 1578.7 F g^{-1}) at a current density of 5 mA cm^{-2} and remains as high as 566.3 C g^{-1} (1029.5 F g^{-1}) at 50 mA cm^{-2} in 1 M NaOH. A supercapattery assembled using $\text{Co}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}/\text{NF}$ as positive and activated carbon/NF as negative electrode, delivers a gravimetric capacitance of 111.2 F g^{-1} (volumetric capacitance of 4.44 F cm^{-3}). Furthermore, the device offers a high specific energy of 29.29 Wh kg^{-1} (energy density of 1.17 mWh cm^{-3}) and a specific power of 4687 W kg^{-1} (power density of 187.5 mW cm^{-3}).

Introduction

Supercapattery, as the ideal electrochemical energy storage device, combines the high energy-storage capability of conventional batteries with the high power-delivery-capability of supercapacitors. A large amount of investigations have been carried out in the development of this hybrid energy storage device to combine the best of both worlds¹⁻⁴. Till date many researchers have classified their work to be capacitive which showed battery-like behaviour due to the misunderstanding of pseudocapacitor and supercapattery.⁵⁻⁸ “Pseudocapacitance” is used to describe the electrode materials with similar electrochemical properties to a capacitive carbon electrode, such as RuO₂ and MnO₂, which exhibits a rectangular cyclic voltammograms (CV) and a triangular charge-discharge curve⁹⁻¹⁰. The new terminology of supercapattery was created to define the electrochemical behaviour between capacitor-like and battery-like hybrids. In addition, the so-called asymmetric supercapacitors fabricated by using redox materials as positive electrode and carbon based materials as negative electrode were also miscalled, which should also be named hybrid supercapattery.^{8, 11}

In recent years, several groups proposed to apply transition metal phosphates and their composites as electrode materials for supercapattery due to their good performance as positive electrode materials for rechargeable ion-batteries.^{1, 12-14} However, for cobalt phosphate, only limited reports are available for supercapattery applications and none on a complete cell.

Li et al. fabricated a 3D Co₃(PO₄)₂·8H₂O architecture with a specific capacitance of 350 F g⁻¹ at an applied current of 1 A g⁻¹¹⁵ whereas, *Tang et al.* reported a honeycomb-like mesoporous Co₃(PO₄)₂·8H₂O nanospheres with a specific capacitance of 247.7 F g⁻¹ at a current of 0.25 A g⁻¹^{1, 16}. Three different cobalt based composites namely, Co₁₁(HPO₃)₈(OH)₆, CoHPO₃·3H₂O and NH₄CoPO₄·H₂O were fabricated using hydrothermal process, delivered a specific capacitance of

1
2
3 312, 413 and 369.4 F g⁻¹, respectively.¹⁷⁻¹⁹ . All these single electrodes showed a low specific
4 capacitance and thereby will not be able to deliver more energy density than existing carbon or
5 oxide based electrodes²⁰⁻²¹. Furthermore, *Wang et al.* reported a mesoporous uniform
6 NH₄NiPO₄·H₂O nanostructure with a specific capacitance of 1072 F g⁻¹ at a current of 1.5 A g⁻¹

In terms of complete cells, a capacitance of 80.5 F g⁻¹ was reported for an asymmetric
supercapacitor using Mn₃(PO₄)₂·3H₂O nanosheets as positive electrode and activated carbon
(AC) as negative electrode.²³ *Tang et al.* reported a cobalt nickel phosphate nanospheres // AC
hybrid supercapattery with a good capacitance of 149.6 F g⁻¹.¹⁶ *Gao et al.* investigated an
ultrathin hybridized phosphate ((NH₄)(Ni, Co)PO₄·0.67H₂O) nanoslices // AC hybrid device
exhibited a specific capacitance of 78 F g⁻¹.²³ Hierarchical 1D NH₄NiPO₄·H₂O microrods
achieved an aerial capacitance of 66 mF cm⁻² in a flexible all-solid-state supercapacitor.²⁴
Among these complete cells, the highest specific energy of 45.8 Wh kg⁻¹ was reported for
Co_{0.86}Ni_{2.14}(PO₄)₂ // AC but the cycle stability is quite low, which is only 66.5% after 1000
cycles.¹⁶

Herein, we report a cobalt phosphate hydrate (Co₃(PO₄)₂·8H₂O) multilayer nano/ microflakes
structure synthesized on nickel foam by a hydrothermal method. The electrochemical
performance of the material was tested as single electrode and as the positive electrode of a
supercapattery cell in 1.0 M NaOH electrolytes. The specific capacity of this binder-free
multilayer nano/ microflake structured material is 868.3 C g⁻¹ (241.2 mAh g⁻¹) at a current
density of 5 mA cm⁻², which is equivalent to a specific capacitance of 1578.7 F g⁻¹. The capacity
retention is 65.2% (566.3 C g⁻¹, 157.3 mAh g⁻¹, 1029.5 F g⁻¹) of the initial value at a current

1
2
3 density of 50 mA cm⁻². The hybrid device in a configuration of Co₃(PO₄)₂·8H₂O/NF // separator
4 // AC/NF delivers a high specific capacitance of 111.2 F g⁻¹ and a specific energy of 29.29 Wh
5
6 kg⁻¹ (energy density of 1.17 mWh cm⁻³) at a specific power of 468.75 W kg⁻¹ (power density of
7
8 18.75 mW cm⁻³), with an excellent cyclic stability of 77.9% after 1000 cycles. Compared to the
9
10 state of the art mono-metallic phosphate based electrode materials, our electrode showed
11
12 increased capacity (capacitance) and energy density with excellent cyclic stability.

Experimental Section

Material Synthesis:

$\text{Co}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}$ nano/ microflakes were synthesized by hydrothermal method on nickel foam (NF). In detail, nickel foam ($3 \times 3 \text{ cm}^2$) treated with 3 M HCl followed by washing with ethanol and deionized water for 15 minutes was used as substrate. Equal concentration (2.5 mM) of $\text{Co}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ and $\text{NH}_4\text{H}_2\text{PO}_4$ were dissolved in deionized (DI) water under stirring for 15 min. The solution was transferred to a 100 ml reaction vessel, which contained the pre-treated nickel foam substrate and was then kept at $120 \text{ }^\circ\text{C}$ for 8 h in oven. After this time, the reaction vessel was allowed to cool down to room temperature naturally. Finally, substrates covered with $\text{Co}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}$ were washed with DI water several times with the assistance of ultrasonication, and then dried in air. For the mass loading study, different concentrations (5 mM, 10 mM, 20 mM) of Co^{+2} and PO_4^{-3} were prepared using the same procedure. The amount of $\text{Co}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}$ was measured from the weight difference of the pure nickel foam and $\text{Co}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}$ grown nickel foam. Typical mass of the active electrode material is ~ 4 , ~ 8 , ~ 11 and $\sim 15 \text{ mg/cm}^2$, respectively. Figure S1 in the Electronic Supplementary Information (ESI) shows a photograph of $\text{Co}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}/\text{NF}$ samples prepared using different concentrations (2.5 mM, 5 mM, 10 mM, 20 mM).

Materials Characterization:

The crystal structures of $\text{Co}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}/\text{NF}$ samples were analysed using X-ray diffractometer (XRD Philips PW3710-MPD diffractometer with $\text{Cu K}\alpha$ radiation, $\lambda=1.54\text{\AA}$). The surface morphology and compositional analysis of $\text{Co}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}/\text{NF}$ samples were performed

1
2
3 by field emission scanning electron microscope (FEI QUANTA 650 HRSEM) with an energy
4
5 dispersive X-ray spectroscopy (EDX Oxford Instruments INCA energy system) and high
6
7 resolution transmission electron microscope (JEOL HRTEM-2100 at 200 kV). To avoid
8
9 contribution of Ni from the NF, the EDX and TEM measurements were carried out for the
10
11 powder samples scratched off from the NF. The Raman spectra of $\text{Co}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}/\text{NF}$ hybrid
12
13 structures were recorded with the Renishaw (RA 100) inVia confocal Raman Microscope at
14
15 514.5 nm excitation. The X-ray photoelectron spectroscopy (XPS) analysis was performed on a
16
17 Kratos Ultra DLD spectrometer with Al K α (1486.6 eV) as the X-ray source.

24 Electrochemical Measurement:

25
26
27
28 The electrochemical performance of the $\text{Co}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}/\text{NF}$ electrodes were investigated in a
29
30 three-electrode system at 25 °C. The nickel foam supported $\text{Co}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}$, platinum wire and
31
32 saturated calomel electrode (SCE) were used as working, counter and reference electrodes,
33
34 respectively. The electrolyte was 1.0 M NaOH solution. The electrochemical properties of hybrid
35
36 cell were evaluated in a two-electrode system using $\text{Co}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}/\text{NF}$ as positive electrode
37
38 and activated carbon/NF as negative electrode separated by Celgard separator in 1.0 M sodium
39
40 hydroxide solution. The activated carbon (AC) based electrode was prepared by mixing 90 wt%
41
42 AC and 10 wt% PVDF (polyvinylidene difluoride) and spreading the mixture on to a $3 \times 3 \text{ cm}^2$
43
44 nickel foam. Typical mass loading of 2, 4 and 6 mg cm^{-2} were used to fabricate activated carbon
45
46 electrode. Both positive and negative electrodes were cut into $1 \times 1 \text{ cm}^2$ then assembled into a
47
48 hybrid supercapattery. The electrochemical measurements, including cyclic voltammetry (CV),
49
50 chronopotentiometry, and A. C. impedance techniques were conducted using a CHI 660C
51
52 electrochemical workstation and a Bio-logic VSP Modular 5 channels potentiostat.

Results and Discussion

X-ray diffraction (XRD) and Raman spectroscopy were used to explore the phase structure of $\text{Co}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}$ nano/ microflakes. As shown in Figure 1(a), except the marked peaks of nickel foam (peaks at 44.6° , 51.9° and 76.6°) single phase of $\text{Co}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}$ were formed. All the other peaks can be indexed to the planes of cobalt phosphate hydrate (JCPDS NO. 41-0375). With increasing concentration, the peak intensity of $\text{Co}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}$ increased (Figure S2), while the peak intensity of nickel decreased due to larger mass loading for higher concentration samples. Figure 1(b) shows the Raman spectra of nickel foam and $\text{Co}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}/\text{NF}$. No obvious peaks were obtained from acid pre-treated pure nickel foam spectroscopy, because of no changes in polarization in the pure metal. In the spectroscopy of $\text{Co}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}/\text{NF}$, the peaks due to the Ni-O stretching at 560 cm^{-1} indicated the conversion of the nickel foam which is presented in Section 5 of the ESI.²⁵ O-Co-O bending appears at 260 and 370 cm^{-1} .²⁶ The O-P-O bending modes are located at 462 cm^{-1} ,²⁷⁻²⁸ while the symmetric O-P-O stretching vibrations are observed at 956 , 1023 and 1046 cm^{-1} .^{26 27-28} The asymmetric P-O-P stretching vibration was obtained at 894 cm^{-1} .²⁸ The external modes are found in the 160 - 250 region.²⁸⁻²⁹ All these modes confirm the formation of $\text{Co}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}$ composite on nickel foam^{26, 28, 30-31}.

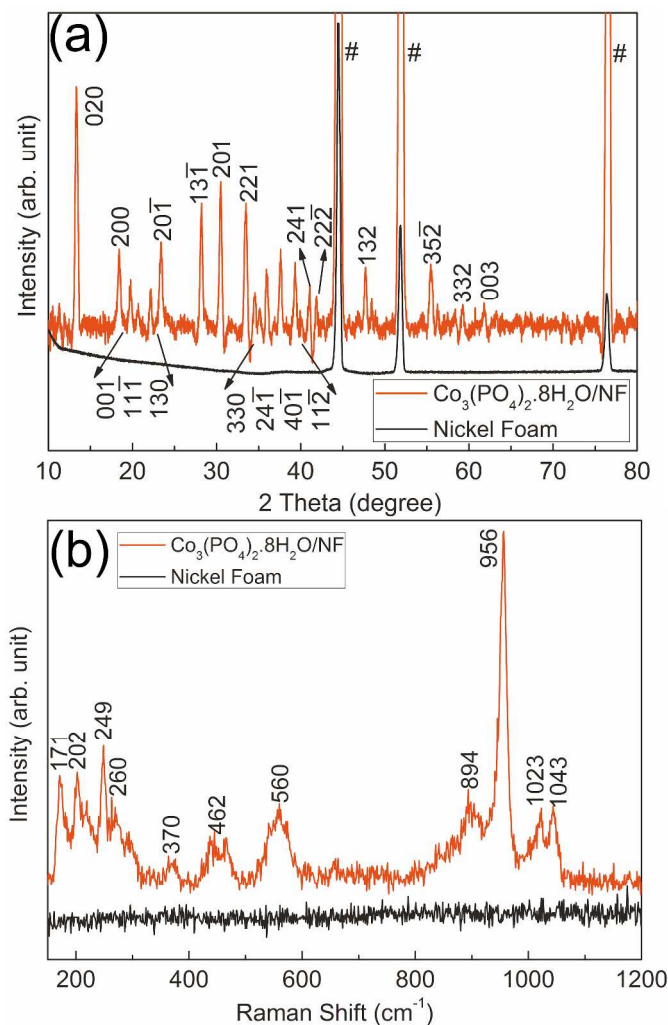

Figure 1. (a) XRD pattern and (b) Raman spectra of pure nickel foam and 2.5 mM $\text{Co}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}/\text{NF}$ nano/microstructure.

Figure 2 shows the SEM images of nickel foam supported $\text{Co}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}$ nano/microflakes at different magnifications fabricated from 2.5 mM concentration. Low magnification images (Figure 2a, b) shows the homogeneous growth of the $\text{Co}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}$ multilayer nano/microflakes. These nano/microflakes were formed layer by layer with an average thickness ranging from 400 nm to 1 μm as can be seen in Figure 2(c, d). With increasing concentration (from 2.5 to 20 mM), individual layer of the multilayer structures grew thicker (600 nm to 1.2

1
2
3 μm) in a disorderly fashion into different directions as can be observed in Figure S3-S4. Thicker
4
5 flakes easily block the interspace of the nickel foam and might reduce the overall surface area of
6
7 the electrode. To analyze the component in the nano/ microflakes structure, thin flake-powder
8
9 was scratched off from the nickel foam and stuck to the copper tape. The elemental mapping on
10
11 the flakes in Figure 2(e) clearly shows the distribution of Co, P and O, which is in good
12
13 agreement with the XRD and Raman analysis.
14

1
2
3 In addition, high-resolution transmission electron microscopy (HR-TEM) measurements were
4 carried out for the powder samples scratched off from the nickel foam to avoid the contribution
5 of the substrate. The HR-TEM and corresponding selected-area electron diffraction (SAED)
6 images are shown in Figure 3. Different thicknesses of scratched powder sample were selectively
7 analyzed. Figure 3(a) and (b) clearly show a single layer found at the edge of a thick sample
8 piece, which is comprised of several layers. Similarly, Figure 3(c) demonstrates the obvious
9 layer-by-layer structure, confirming the multilayer structure shown in the SEM images in Figure
10 2(c-d). The corresponding SAED pattern in Figure 3(d) shows the electron diffraction from
11 different planes and is consistent with XRD results.

8
9
10 To investigate the electrochemical performance of the $\text{Co}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}/\text{NF}$, a three electrode
11 system was used. Figure S7(a) shows the CV curves of pure nickel foam, 2.5, 5, 10 and 20 mM
12 $\text{Co}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}/\text{NF}$ at a scan rate of 2 mV/s in 1.0 M NaOH solution. The contribution of bare
13 nickel foam is negligible compare to the $\text{Co}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}$. Clear current peaks are observed in all
14 the samples, indicating the non-capacitive faradaic energy storage properties of the electrode
15 material. With increasing concentration (i.e., with increased mass loading of the active material),
16 the main peaks around 0.45 and 0.25 V broaden and the peak current varies. This may be due to
17 the higher mass loading, which results in more activate material to take part in the redox reaction
18 but on the other hand reduces the conductivity of the electrode as can be observed from the
19 Nyquist plots in Figure S8. The resistance of the electrodes are found to be 1.90, 1.94, 2.47 and
20 4.8 Ω with increased mass loading. The 2.5 and 5 mM CVs are nearly symmetrical, indicating
21 good redox property of the material. However, for higher concentration samples, the secondary
22 peaks (around 0.25 and 0.55 V) become more obvious because of the larger mass loading
23 enhanced the first step of the redox reactions (shown as equation 1). Two pairs of oxidation and
24 reduction peaks indicate the transform between the different states of Co^{2+} and Co^{3+} . Figure 4(a)
25 shows the CV curves of 2.5 mM sample at different scan rate from 1 to 50 mV/s. With increasing
26 scan rate, the oxidation and reduction peaks started to shift from each other, indicating quasi-
27 reversible reaction and the shape of the CVs tends to be asymmetric. Figure S7(b) shows that the
28 peak shift in 5 mM sample is less than 2.5 mM sample, which may be due to the larger loading
29 (2 \times compared to 2.5 mM) of cobalt phosphate, resulted in more active materials to be involved in
30 the faradaic reactions as follows³²⁻³³:

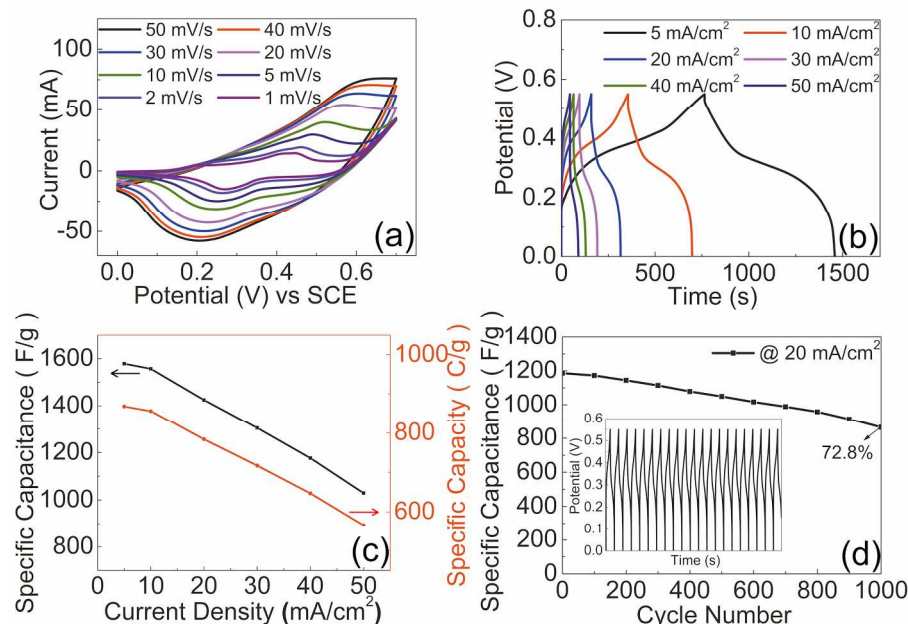

Figure 4. (a) Cyclic voltammograms of 2.5 mM $\text{Co}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}/\text{NF}$ at different scan rate from 1 to 50 mV/s in 1 M NaOH. (b) Charge-discharge profile of the electrode at different current densities. (c) Specific capacitance and capacity variation at different current densities. (d) Cyclic stability of the electrode. Inset represents continuous charge-discharge profile at 20 mA/cm².

Figure 4(b) shows the charge-discharge profile of 2.5 mM $\text{Co}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}/\text{NF}$. In both 2.5 and 5 mM discharging curves (Figure S7(c) and (d)), distinct potential plateaus are observed, which demonstrate the battery-like characteristics of the electrodes. The nearly symmetric charging and discharging curves at low current density indicate the reversible redox reaction. 5 mM sample shows nearly twice discharging time than the 2.5 mM sample at similar current density, which may be due to double mass loading in case of 5 mM sample. However, for 10 and

1
2
3 20 mM samples (Figure S7(e-f)), the discharge time does not increase with larger mass loading.
4
5 From SEM image analysis in Figure S4 we found that the multilayer structures for higher-
6
7 concentration samples grew thicker and larger in a disorderly fashion, which reduces the overall
8
9 surface area of the electrode accessible by the electrolyte and thereby less active material is
10
11 taking part in storing the charge. These results are in good agreement with the CV analysis
12
13 presented in Figure 4(a) and Figure S7(a).
14
15

16
17 Due to the non-capacitive faradaic (or battery) mechanism, the specific capacity in terms of C
18
19 g^{-1} or mAh g^{-1} was calculated using equations 1 and 2 as described in section 3 of ESI. A
20
21 maximum specific capacity of 868.3 C g^{-1} (241.2 mAh g^{-1}) at an applied current density of 5 mA
22
23 cm^{-2} was found for the 2.5 mM sample. The capacity variation as a function of current density is
24
25 shown in Figure 4(c). With a 10 times increase in the current density (from 5 to 50 mA cm^{-2}), the
26
27 capacity retention is 65.2% and 72.1% of the initial value for 2.5 and 5 mM samples, which are
28
29 much better than the state of the art (48%) cobalt phosphate electrodes.¹⁵
30
31
32
33

34 However, to be comparable with reported literatures, specific capacitance in terms of F g^{-1} was
35
36 calculated using equation 3 as shown in section 3 of ESI. An ultra-high specific capacitance of
37
38 1578.7 F g^{-1} was achieved from 2.5 mM $\text{Co}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}/\text{NF}$ at 5 mA cm^{-2} (1.25 A/g) and
39
40 1336.9 F g^{-1} was attained for 5 mM sample at 5 mA cm^{-2} (0.625 A/g), and reduced to 1029.5 F g^{-1}
41
42 (65.2%) for 2.5 mM and 963.6 F g^{-1} (72.1%) for 5 mM sample for a current density of 50
43
44 mA/cm^2 (Figure 4(c) and Figure S9). The reduction in specific capacitance in the 5 mM and
45
46 higher concentration samples are due to the larger mass loading, which resulted in a thicker layer
47
48 formation as compared to low concentration sample that ultimately reduced the active sites for
49
50 ion diffusion from the electrolyte. However, the specific capacitance for 2.5 mM electrode is
51
52 found to be better than the work reported by Tang et al., where a specific capacitance of 1409.8 F
53
54
55
56
57
58
59
60

1

g^{-1} at 0.25 A g^{-1} was obtained for a honeycomb-like mesoporous cobalt nickel phosphate nanospheres, whereas for $\text{Co}_3(\text{PO}_4)_2$, only 247.7 F g^{-1} was reported¹⁶. Similarly, *Li et al.* showed 350 F g^{-1} at 1 A g^{-1} for a 3D $\text{Co}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}$ architecture with flower-like morphologies assembled from 2D microsheets.¹⁵ Furthermore, *Pang et al.* reported three different phosphate microstructures, and achieved 312 F g^{-1} for $\text{Co}_{11}(\text{HPO}_3)_8(\text{OH})_6$ nanoribbons¹⁷, 413 F g^{-1} for $\text{CoHPO}_4 \cdot 3\text{H}_2\text{O}$ nanosheets and 369.4 F g^{-1} for $\text{NH}_4\text{CoPO}_4 \cdot \text{H}_2\text{O}$ nano/microstructures. Whereas, our 2.5 mM electrode showed ~ 4 times better specific capacitance as compared to the best reported cobalt phosphate based electrodes. Table S1 and Table S3 compares the specific capacity and capacitance of all the four different concentration electrodes fabricated in this work and other similar metal phosphate and cobalt oxide based electrode materials and from published literature.^{15-19, 22-24, 34} Another important requirement for supercapattery application is the long term cyclic stability. Figure 4(d) shows the cyclic stability of the 2.5 mM sample and the inset shows the continuous charge-discharge profile at 20 mA/cm^2 . The electrode exhibited a capacitance of 1149 F g^{-1} (72.8% retention) after 1000 cycles, which is more than twice of the best capacitance value reported for cobalt phosphate based electrodes.¹⁵⁻¹⁸ The decrease of the capacitance after 1000 charge-discharge cycles may be due to the morphology transformation and the dissolution of the active material as shown in Figure S16.

It is noteworthy that the observed specific capacity (or capacitance) is higher than the theoretical value (533 C g^{-1} or 969 F g^{-1} as calculated by Equation 8 and 9 as shown in section 3 of ESI³⁵) for the cobalt phosphate electrode. This may be attributed to the contribution of electric double layer capacitance in addition to the battery-like faradaic contributions.³⁶ When crystalline water is removed from the $\text{Co}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}$ during electrochemical reaction, a large amount of void space is available for redox reaction. The interconnected $\text{Co}_3(\text{PO}_4)_2$ nanosheets

are favorable for electrolyte penetration to the interior surfaces via the intercalated water molecules. After oxidation of crystalline water, there is a possibility of forming abundant pores within the $\text{Co}_3(\text{PO}_4)_2$ nano/ microsheets as can be seen in Figure S5 of ESI, which provide large surface area and numerous electroactive sites for effective ion adsorption.

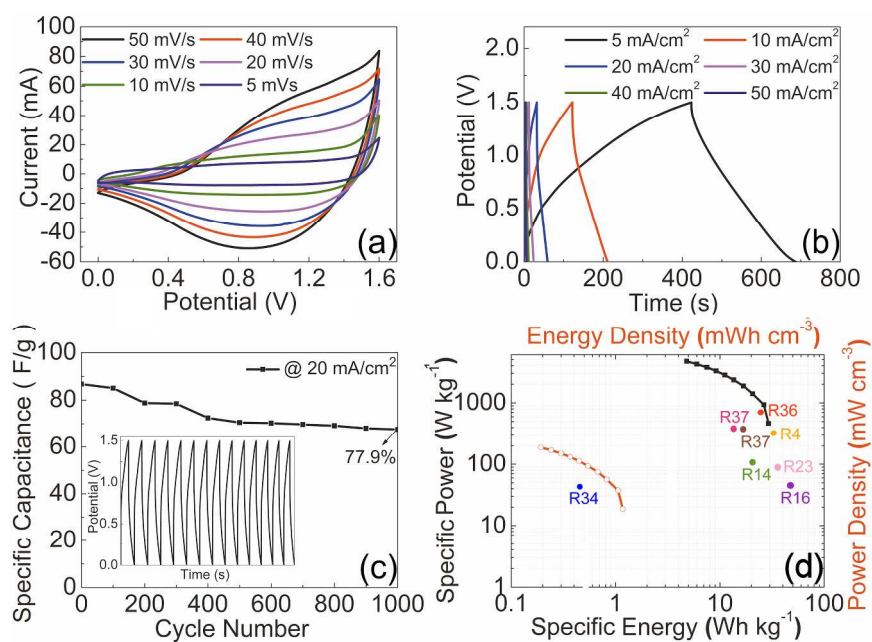

Figure 5. (a) Cyclic voltammograms of the $\text{Co}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O} // \text{AC}$ hybrid supercapattery at different scan rates in 1 M NaOH. (b) Charge-discharge curves of supercapattery at different current densities. (c) Cyclic stability of supercapattery. Inset represents continuous charge-discharge profile at 20 mA/cm^2 (d) Ragone plots of supercapattery.^{4, 14, 16, 23, 34, 36-37}

In order to evaluate the performance of our $\text{Co}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O} // \text{NF}$ electrode, a hybrid supercapattery ($\text{Co}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O} // \text{AC}$) was assembled with 2.5 mM $\text{Co}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O} // \text{NF}$ as positive electrode and AC/NF as negative electrode in 1 M NaOH solution. A brief discussion on the optimization of the positive and negative electrodes for the hybrid supercapattery is presented

1
2
3 in Section 4 of the ESI. Typical mass loading of 2, 4 and 6 mg cm⁻² were used to fabricate the
4
5 activated carbon electrode. Among those, 4 mg cm⁻² mass loading of activated carbon showed
6
7 the best performance due to the balance of the charge flow between the positive electrode and the
8
9 negative electrode. Figure 5(a) shows the CV curves of the Co₃(PO₄)₂·8H₂O//AC supercapattery
10
11 at different scan rates from 5 to 50 mV/s. The quasi-rectangle shapes of these CV curves
12
13 demonstrate the dominant capacitive behaviour rather than battery characteristic. The CV curves
14
15 retain the same shape with increasing scan rate, which exhibited a good rate capability of the
16
17 hybrid supercapattery. The individual CV curves of positive (Co₃(PO₄)₂·8H₂O/NF) and negative
18
19 (AC/NF) electrodes are shown in Figure S10 (c). The negative electrode demonstrated a typical
20
21 electric double layer charge-discharge profile, with hydrogen storage at deep cathodic
22
23 conditions. On the other hand, the positive electrode has a capacity of redox reversible reaction.
24
25 Thereby, a potential window of 1.6 V was achieved in this hybrid supercapattery. Figure 5(b)
26
27 shows the charge-discharge curves of the Co₃(PO₄)₂·8H₂O//AC supercapattery at different
28
29 current densities with a cell voltage up to 1.5 V. Quasi-lined charge and discharge curves rather
30
31 than potential plateaus confirm the capacitive characteristic of the hybrid supercapattery.
32
33 Specific capacitances at different current densities (Figure S11) were calculated by equation 4
34
35 and 5 (ESI), based on the total mass of both positive and negative active materials (~8 mg) or the
36
37 total measured volume of the hybrid supercapattery (0.2 cm³).
38
39

40
41 The device showed a specific capacitance of 111.2 F g⁻¹ (4.44 F cm⁻³) at a current density of 5
42
43 mA cm⁻². Even at 50 mA cm⁻², it showed a specific capacitance of 50.7 F g⁻¹ (2.03 F cm⁻³).
44
45 Thereby, our hybrid device could retain a remarkable 45.6% of the initial value for ten times of
46
47 initial current density. Furthermore, the hybrid supercapattery showed better cyclic stability of
48
49 77.9% (Figure 5(c)) after 1000 cycles as compared to the earlier reported work (66.5% and
50
51
52
53
54
55
56
57
58
59
60

1
2
3 57.8%)¹⁶. Compared to three electrode system, the hybrid supercapattery exhibits a better cyclic
4 stability, which may be due to the synergistic effect of the positive supercapattery electrode with
5 the negative carbon based electrode, which reduced the dissolution of active material.
6
7

8
9
10 Due to the non-linear function of the charge-discharge curves, the specific energy (density) and
11 specific power (density) were calculated by equations 6 and 7 as shown in the ESI. As in the
12 Ragone plots shown in Figure 5(d) and Table S2, the highest specific energy was found to be
13 29.29 Wh kg⁻¹ (energy density of 1.17 mWh cm⁻³) at a specific power of 468.75 W kg⁻¹ (power
14 density of 18.75 mW cm⁻³) for the hybrid device using 2.5 mM Co₃(PO₄)₂·8H₂O/NF as positive
15 and AC/NF as negative electrode. Even at a high specific power of 4687 W kg⁻¹ (power density
16 of 187.5 mW cm⁻³), the device could retain a specific energy of 5.33 Wh kg⁻¹ (energy density of
17 0.21 mWh cm⁻³). The Nyquist plot of the hybrid supercapattery before and after 1000 cycles is
18 shown in Figure S12. From the two plots, resistance was found to be only 0.80 Ω and 5.06 Ω for
19 the hybrid supercapattery before and after cyclability test, which indicate acceptable conductivity
20 for the device even after 1000 cycles.

34
35

36 Overall, cobalt phosphate hydrate multilayer nano/ microflakes structure showed interesting
37 properties as a positive electrode for supercapattery application. Lower concentration samples
38 exhibited better electrochemical performance due to the less mass loading and thinner layer and
39 showed state of the art specific capacitance for this composite. Formation of Co₃(PO₄)₂·8H₂O
40 nano/ microflakes coupled with mesoporous Ni foam resulted in a large contact area between
41 active materials and the electrolyte, leading to more efficient ion and charge transport, resulting
42 in significant increases in the specific capacitance and rate capability at high current densities.
43 Thereby, the hybrid device showed excellent specific capacitance with very good energy and
44 power density, acceptable retention capability and good cyclability.

Conclusions

In summary, we reported a binder-free $\text{Co}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}$ multilayer nano/ microflakes structure via simple hydrothermal technique on nickel foam substrate as a positive electrode for supercapattery application. Due to the different concentrations of the synthesis process, different mass loading of the active materials were achieved. Single phase of $\text{Co}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}$ were formed homogeneously over the nickel foam with an average thickness of 400 nm to 1 μm . Among all the samples, the highest specific capacity of 868.3 C g^{-1} (241.2 mAh g^{-1}) at a current density of 5 mA cm^{-2} was exhibited from 2.5 mM sample, with a rate capability of 65.2% for 10 times of the initial current density. A high performance hybrid supercapattery was fabricated using $\text{Co}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}/\text{NF}$ as positive and AC/NF as the negative electrode. A maximum specific energy of 29.29 Wh kg^{-1} (energy density of 1.17 mWh cm^{-3}) was obtained at a specific power of 468.75 W kg^{-1} (power density of 18.75 mW cm^{-3}), with good cyclic stability of 77.9% after 1000 cycles. Therefore, $\text{Co}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}$ can be a promising material for supercapattery application.
