1 Supplementary Material

The supplementary material presented herein accompanies the main manuscript titled "Predicting Inmate Suicidal Behavior with an Interpretable Ensemble Machine Learning Approach in Smart Prisons" for PeerJ. This document aims to provide readers with additional details and visualizations that complement the findings discussed in the main paper.

```

The algorithms 1 and 2 are for subsections "Dimensionality Reduction via SHAP" and "Interpretation & Dimensionality Reduction via Anchor" respectively in the main paper.

In the algorithm 1, we represent our working with SHAP for generating feature importance values using the XGBoost classifier (XGB). We take our two processed datasets, one containing suicide ideation features (Suicide_D) and the other without such features (NonSuicide_D). For each of the datasets, we perform the following steps. We split the dataset into a training set (T) and a testing set (S) using an 80-20 split ratio. The XGBoost classifier is trained on the training set (T) and used to make predictions on the testing set (S).

To calculate the feature importance, the input dataset (X) is converted into a DataFrame (xFrame) with the same column structure as the training and testing sets. Then, the SHAP explainer is created using the trained XGBoost classifier. The explainer computes the SHAP values, which quantify the contribution of each feature to the predictions made by the XGBoost model.

The computed SHAP values (SHAPValues) are then visualized using a bar plot. This plot displays the importance of each feature, ranking them based on their impact on the model's predictions. The parameter "max display=27" specifies that only the top 27 features will be shown in the plot. Finally, we create two

Algorithm 2 Algorithm to obtain top anchored features using Anchor on XG-Boost

0: procedure ANCHOR(RDS)0: $XGB \leftarrow XGBClassifier$ for datasets D in RDS do 0: $T, S \leftarrow 80_20_split(D)$ 0: $XGB \leftarrow Fit(T)$ 0: 0: $XGB \leftarrow Pred(S)$ 0: $FeatureNames \leftarrow list(T.columns)$ $df \leftarrow DataFrame(T, FeatureNames)$ 0: $exp \leftarrow AnchorTabularExplainer(T.values, FeatureNames)$ 0: for each row r in S do 0: $INS \leftarrow S.iloc[r]$ 0: $P \leftarrow XGB.pred(X)$ 0: 0: $qenExp \leftarrow exp.explain_instance(P)$ $record/display Anchored \leftarrow genExp.names()$ 0: $record/display Precision \leftarrow qenExp.precision()$ 0: $record/display \ Coverage \leftarrow genExp.coverage()$ 0: end for 0: $FDS \leftarrow SelectData(genExp, RDS)$ 0: 0: end for return FDS 0: 0: end procedure=0

reduced datasets (RDS) having 27 features based on the feature importance values computed by the SHAP.

In the algorithm 2, for both of the reduced datasets (RDS) from SHAP analysis, we first split it into a training set (T) and a testing set (S) using an 80-20 split ratio. The XGBoost classifier (XGB) is then trained on the training set (T) and used to make predictions on the testing set (S).

To prepare the training set (T) for anchor explanations, we create a list of feature names (FeatureNames) from the columns of the training set. We then create a DataFrame (df) using the training set (T) and the feature names (FeatureNames). Next, an AnchorTabularExplainer is created using the values of the training set (T) and the feature names (FeatureNames). This explainer is responsible for generating anchor explanations based on the XGBoost model. We iterate over each row (r) in the testing set (S). For each row, it retrieves the instance (INS) from the testing set. The XGBoost model makes a prediction (P) on this instance. An explanation for the instance is generated using the explainer (exp) by calling the 'explain_instance()' method with the prediction (P) as input. The generated explanation (genExp) includes the anchor names, precision, and coverage.

We record and display the anchored rules, precision, and coverage for the gener-

ated explanation. This information helps to understand the rules or conditions under which the model makes its predictions. After iterating over all rows in the testing set (S), we analyze recorded generated rules and create a further reduced dataset having 12 features for suicide ideation and 19 features for without suicide ideation dataset.

Table 1: Important features for the dataset with suicidal ideation features, along with the count of how many times each feature was used as an anchor in explanations.

 ${\mathbf T}$ - Total usage count as an anchor

 $\mathbf{T^{NS}}$ - Usage count in non-suicidal class predictions

 $\mathbf{T}^{\mathbf{S}}$ - Usage count in suicidal class predictions

Feature Name	Т	T^{NS}	$\mathbf{T}^{\mathbf{S}}$
Lifetime Suicide Attempts due to Depressive Disorders	51	43	8
Suicide Thoughts Lifetime	42	38	4
Significant Problems with Suicidal Thoughts in Life	23	22	1
Personality Disorder - Borderline	15	14	1
Times Hospitalized for Psych Problems in Life	7	3	4
