Mental Health of Caregiving Grandparents

Barbie Vander Boegh, RN, BSN Student Jeri L. Bigbee, PhD, FNP-BC, FAAN, Jody DeMeyer Endowed Chair

<u>Purpose</u>

To assess the mental health of full-time custodial grandparents as compared with part-time caregiving grandparents

Background

Grandparents are stepping up to help raise their grandchildren while:

- Both parents hold two or more jobs
- Divorce rates are increasing
- •Single parents are working outside of the home
- •Substance abuse &/or child neglect /abuse are present

Mental health stressors:

- •Strained relationships with adult children
- •Responsibility of raising another family at an increased age
- ·Legal issues with adult children

Previous research suggests that caregiving grandparents may have lower levels of mental health

Methods

Conceptual Framework: Pender's Health Promotion Model

Comparative Descriptive Design

Sample:

- •11 frontier grandparents (5 grandfathers & 6 grandmothers)
 - •6 full-time custodial
 - •5 part-time caregiving

Instrument:

SF-36 Health Survey (composite mental health score)

Analysis:

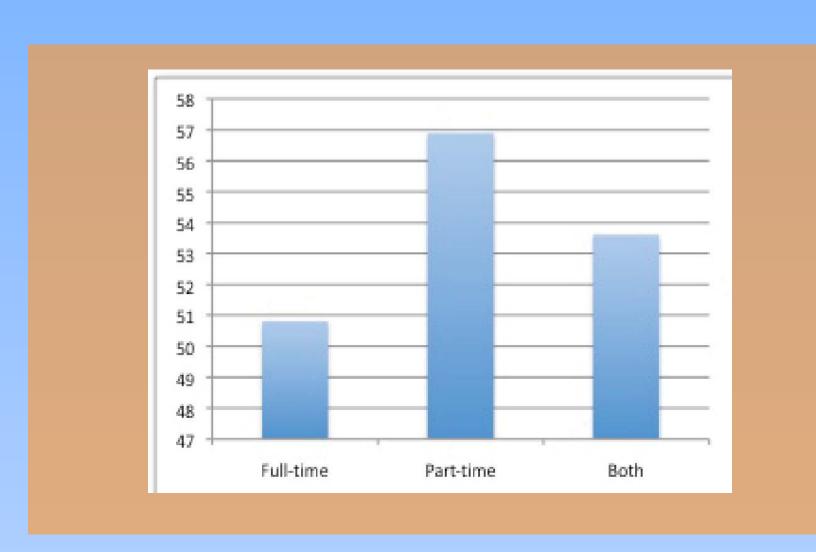

Non-parametric Mann-Whitney U

Funded by the Jody DeMeyer Endowment

Results

No statistically significant difference in mean mental health scores between caregiver groups

(range = 45 - 60, norm = 50)

Implications

Limitations

Small sample size

Findings suggest

- Frontier grandparents' mental health is higher than the norm
- •No difference between full-time
- & part-time caregiving grandparents' mental health

Differs with previous grandparent & rural/frontier research

Caregiving may promote mental health in frontier grandparents
