Aims

There is a paucity of data on the performance of angiography-derived vessel fractional flow reserve (vFFR) in coronary artery lesions of patients presenting with non-ST-segment elevation acute coronary syndrome (NSTEMI-ACS). Optical coherence tomography (OCT) allows for visualization of lumen dimensions and plaque integrity with high resolution. The aim of this study was to define the association between vFFR and OCT findings in intermediate coronary artery lesions in patients presenting with NSTEMI-ACS.

Methods and results

The FAST OCT study was a prospective, multicenter, single-arm study. Patients presenting with NSTEMI-ACS with intermediate to severe coronary artery stenosis in one or multiple vessels with TIMI 3 flow suitable for OCT imaging were eligible. Complete pre-procedural vFFR and OCT data were available in 226 vessels (in 188 patients). A significant association between vFFR and minimal lumen area (MLA) was observed, showing an average decrease of 20.4% (95% CI –23.9% to –16.7%) in MLA per 0.10 decrease in vFFR (adjusted $P < 0.001$). $vFFR \leq 0.80$ showed a sensitivity of 56.7% and specificity of 92.5% to detect $MLA \leq 2.5 \text{ mm}^2$. Conversely, vFFR had a poor to moderate discriminative ability to detect plaque instability (sensitivity, 46.9%; specificity, 71.6%).

Conclusion

In patients with NSTEMI-ACS, vFFR is significantly associated with OCT-detected MLA, and $vFFR \leq 0.80$ is highly predictive of the presence of significant disease based on OCT. Conversely, the sensitivity of $vFFR \leq 0.80$ to detect OCT-assessed significant disease was low, indicating that the presence of significant OCT findings cannot be ruled out based on a negative vFFR.

Error bars represent 95% confidence intervals. MLA, minimal lumen area; %AS, percentage area stenosis; vFFR, vessel fractional flow reserve.

importance in the light of the results of the recent PREVENT trial, showing superior outcomes after preventive PCI as compared to optimal medical therapy in patients with non-flow limiting vulnerable coronary plaques.²⁰ Results of the ongoing COMBINE-INTERVENE (NCT05333068) and VULNERABLE (NCT05599061) trials are eagerly awaited to provide further insights into the utility of revascularization of non-ischemic vulnerable or unstable plaques as compared to guideline-directed medical treatment. In addition, the INTERCLIMA (NCT05027984) trial will demonstrate whether OCT is superior to FFR to guide clinical decision-making in non-culprit lesions in patients with ACS.

Finally, integrated assessment of (angiography-based) physiology and imaging may lead to improved risk stratification, as recently demonstrated in a sub-analysis of the FLAVOUR trial showing that a combination of plaque characteristics and low QFR best predicted clinical outcomes.²¹ Novel OCT-derived physiology indices may provide an appealing solution by combining anatomical and functional lesion assessments into one single assessment. Although pivotal validation studies on OCT derived physiology showed promising results, future research is warranted to prove their clinical value.^{22,23}

Limitations

A number of limitations need to be mentioned. First of all, vFFR analysis remains dependent on the quality of angiographic cine-images. As such, despite dedicated guidelines for acquisition of adequate angiographic projections, vFFR analysis could not be performed for 11 (5%) vessels. Secondly, the decision to perform revascularization was based on angiography and OCT data, whereas vFFR analyses were performed offline. Thirdly, no pressure-wire based FFR measurements were performed as reference, precluding any direct comparisons between vFFR and FFR in their association with OCT findings. Finally, this study was not powered to assess clinical outcomes.

Conclusion

In patients presenting with NSTEMI-ACS, vFFR is significantly associated with OCT-detected MLA, and a vFFR ≤ 0.80 is highly predictive of a small MLA based on OCT. Conversely, the diagnostic performance of vFFR to predict plaque instability was moderate to poor. Moreover, vFFR was unable to rule out the presence of significant disease based on OCT, underscoring the limitations of vFFR and the potential value of OCT in intermediate lesions of patients presenting with NSTEMI-ACS.
