Introduction

Olive latent virus 1 (OLV-1) is a necrovirus belonging to the family *Tombusviridae*. It is a small icosahedral plant virus, which encapsidates a single stranded positivesense RNA. This virus was first isolated from symptomless olive trees in Italy [7] and afterwards in Jordan and Portugal [10, 4]. OLV-1 was also isolated from symptomatic hosts, such as citrus trees in Turkey [11] and tulips in Japan [9]. Up to now, only one complete genome sequence of an OLV-1 citrus isolate has been determined [8]. This report describes the first full genomic sequence of an OLV-1 isolated from olive trees.
