## Introduction

Practical work (PW) has had, since long ago, a fundamental role in the education of Chemistry students (Woolnough, 1991; Miguéns & Garrett, 1991). However, doubts have sometimes been raised about its importance as a means for promoting significant learning of Chemistry (Hodson, 1990; 1993).

In order to make PW relevant, it is necessary that it can motivate the students and contribute to the development of a set of skills and competencies that are fundamental in tertiary education (Figueiredo, Viana & Maia, 2001).

The work here presented, developed in that context, is the result of a research project carried out at the University of Évora (Portugal), on the use of PW as an investigative activity of problem solving. This project also had a didactic purpose. It aimed at contributing to the increase in the success of students in chemistry courses included in non-chemistry science degrees, as well as to a revalorization of PW as a privileged strategy for the teaching of chemistry.

## Methodology

An initial characterization of students of different courses according to their success in examinations (fig. 1) and also concerning their former preparation (fig.2), done through a questionnaire, including a diagnostic test, gave the basis for the choice of the course in which the experimental intervention should be implemented (Geological Resources Engineering – ERG, the one with lowest results), and of the course used as control group (Hydrologic Resources Engineering – ERH).
