*Dedicated to Professor Khalifa Trimèche,  
on the occasion of his 60th anniversary*

### Abstract

Using a convolution structure on the real line associated with the Jacobi-Dunkl differential-difference operator  $\Lambda_{\alpha,\beta}$  given by:

$$\Lambda_{\alpha,\beta}f(x) = f'(x) + ((2\alpha + 1) \coth x + (2\beta + 1) \tanh x) \left( \frac{f(x) - f(-x)}{2} \right),$$

$\alpha \geq \beta \geq -\frac{1}{2}$ , we define mean-periodic functions associated with  $\Lambda_{\alpha,\beta}$ . We characterize these functions as an expansion series intervening appropriate elementary functions expressed in terms of the derivatives of the eigenfunction of  $\Lambda_{\alpha,\beta}$ . Next, we deal with the Pompeiu type problem and convolution equations for this operator.

*2000 Mathematics Subject Classification:* 34K99, 44A15, 44A35, 42A75, 42A63

*Key Words and Phrases:* Jacobi-Dunkl operator, mean periodic function, Jacobi-Dunkl expansion, Pompeiu problem

### 0. Introduction

For  $\alpha \geq \beta \geq -\frac{1}{2}$ , we consider the Jacobi-Dunkl operator  $\Lambda_{\alpha,\beta}$  defined on  $C^1(\mathbb{R})$  by

$$\Lambda_{\alpha,\beta}f(x) = f'(x) + ((2\alpha + 1) \coth x + (2\beta + 1) \tanh x) \left( \frac{f(x) - f(-x)}{2} \right).$$

We point out that the operator  $\Lambda_{\alpha,\beta}$  coincides with the Heckman-Opdam operator, known also as the Dunkl-Heckman operator:

$$D_\xi = \partial_\xi + \frac{1}{2} \sum_{\alpha \in \mathcal{R}_+} k_\alpha a(\xi) \frac{1 + e^{-a}}{1 - e^{-a}} (1 - r_\alpha),$$

on  $\mathbb{R}$ , with  $\mathcal{R}_+ = \{2, 4\}$  and suitable choice of  $k_\alpha$ 's (see [17] and the references cited therein).

The eigenfunction of this operator, satisfying  $\Lambda_{\alpha,\beta} f(x) = i\lambda f(x)$ ,  $\lambda \in \mathcal{C}$  and  $f(0) = 1$ , can be expressed in terms of the Jacobi functions  $\varphi_\mu^{\alpha,\beta}$  and  $\varphi_\mu^{\alpha+1,\beta+1}$ , namely:

$$\Psi_\lambda^{\alpha,\beta}(x) = \varphi_\mu^{\alpha,\beta}(x) + \frac{i\lambda}{2(\alpha+1)} \sinh x \cosh x \varphi_\mu^{\alpha+1,\beta+1}(x),$$

where

$$\lambda^2 = \mu^2 + \rho^2 \quad \text{with} \quad \rho = \alpha + \beta + 1,$$

and

$$\varphi_\mu^{\alpha,\beta}(x) = {}_2F_1\left(\frac{\rho + i\mu}{2}, \frac{\rho - i\mu}{2}; \alpha + 1; -\sinh^2 x\right).$$

We note that in [2], the authors have established a product formula for the eigenfunction  $\Psi_\lambda^{\alpha,\beta}$ ,  $\lambda \in \mathcal{C}$ : For  $x, y \in \mathbb{R}$

$$\Psi_\lambda^{\alpha,\beta}(x) \Psi_\lambda^{\alpha,\beta}(y) = \int_{\mathbb{R}} \Psi_\lambda^{\alpha,\beta}(z) d\mu_{x,y}^{\alpha,\beta}(z),$$

where  $\mu_{x,y}^{\alpha,\beta}$  is a real uniformly bounded measure with compact support, which may not be positive. This leads in a natural way to define the translation operators, denoted  $T_x^{\alpha,\beta}$ ,  $x \in \mathbb{R}$ , by

$$\forall y \in \mathbb{R}, T_x^{\alpha,\beta} f(y) = \int_{\mathbb{R}} f(z) d\mu_{x,y}^{\alpha,\beta}(z).$$

Here  $f$  is a measurable function on  $\mathbb{R}$ .

We point out that in [10], the authors have shown that for all  $\lambda \in \mathcal{C}$ , the eigenfunction  $\Psi_\lambda^{\alpha,\beta}$ , admits an integral representation which permits to define an intertwining operator  $V_{\alpha,\beta}$  on  $\mathcal{E}(\mathbb{R})$ , the space of  $C^\infty$ -functions on  $\mathbb{R}$ , by

$$V_{\alpha,\beta} f(x) = \begin{cases} \int_{-|x|}^{|x|} K(x,y) f(y) dy, & \text{if } x \in \mathbb{R} \setminus \{0\}, \\ f(0), & \text{if } x = 0, \end{cases}$$

where  $K(x, \cdot)$  is a positive function on  $\mathbb{R}$ , continuous on  $] -|x|, |x|[$  and supported in  $[-|x|, |x|]$ ,  $V_{\alpha, \beta}$  intertwines  $\Lambda_{\alpha, \beta}$  and the usual derivative  $D = \frac{d}{dx}$ :  $\Lambda_{\alpha, \beta} V_{\alpha, \beta} = V_{\alpha, \beta} D$ .

This intertwining operator leads also to define  $T_x^{\alpha, \beta} f$  as follows

$$T_x^{\alpha, \beta} f(y) = V_{\alpha, \beta, x} V_{\alpha, \beta, y} (V_{\alpha, \beta}^{-1}(f)(x + y)).$$

Of course, the two formulas defining  $T_x^{\alpha, \beta} f$  coincide on  $\mathcal{E}(\mathbb{R})$ .

A function  $f$  in  $\mathcal{E}(\mathbb{R})$  is called mean-periodic associated with the operator  $\Lambda_{\alpha, \beta}$ , if there exists a non zero distribution  $\mu \in \mathcal{E}'(\mathbb{R})$ , such that

$$\mu *_{\alpha, \beta} f(x) = 0,$$

where, for all  $x \in \mathbb{R}$ ,

$$\mu *_{\alpha, \beta} f(x) = \langle \mu_y, T_{-x}^{\alpha, \beta} \check{f}(y) \rangle,$$

here  $\check{f}(u) = f(-u)$ .

Using the operator  $V_{\alpha, \beta}$  and the results of L. Schwartz in [19] for the classical case, we give a representation of a mean-periodic function  $f$  in  $\mathcal{E}(\mathbb{R})$ , associated with  $\Lambda_{\alpha, \beta}$ , in terms of a series intervening elementary functions  $\Psi_{\lambda, l}^{\alpha, \beta}(x)$ , defined by  $\frac{d^l}{dt^l} (\Psi_{-it}^{\alpha, \beta}(x))_{t=i\lambda} = V_{\alpha, \beta}(x^l e^{i\lambda x})$ , which we call exponential-monomials associated with  $\Lambda_{\alpha, \beta}$ . Namely, we have (formally)

$$f(x) = \sum_{(\lambda, l)} \sum_{0 \leq j \leq l-1} c_{\lambda, j} \Psi_{\lambda, j}^{\alpha, \beta}(x), \quad c_{\lambda, j} \in \mathcal{C},$$

the summation is extended over the distinct roots of  $\mathcal{F}_{\alpha, \beta}(\mu)$  counted with multiplicities  $l$ , where  $\mathcal{F}_{\alpha, \beta}(\mu)$  is the Jacobi-Dunkl transform of  $\mu$  defined by

$$\mathcal{F}_{\alpha, \beta}(\mu)(\lambda) = \langle \mu, \Psi_{-\lambda}^{\alpha, \beta} \rangle.$$

For general  $\mu$  one can get convergence of the series expansion in the topology of  $\mathcal{E}(\mathbb{R})$  only if one groups the terms and then uses the Abel summability. For a wide class of distributions  $\mu$  the Abelian summation process is not necessary. More precisely, if one assumes that  $\mu \in \mathcal{E}'(\mathbb{R})$  is slowly-decreasing in the following mean: there are  $A, \varepsilon > 0$  such that for any  $x \in \mathbb{R}$

$$\text{Max}\{|\mathcal{F}_{\alpha, \beta}(\mu)(y)|, y \in \mathbb{R}, |x - y| \leq A \log(1 + |x|^2)\} \geq \varepsilon(1 + |x|)^{-\frac{1}{\varepsilon}},$$

then the Abel summation procedure can be dispensed.

Next, for  $\mu, \nu \in \mathcal{E}'(\mathbb{R})$  and  $g, h \in \mathcal{E}(\mathbb{R})$ , we are interesting to establish the uniqueness and existence of solutions  $f \in \mathcal{E}(\mathbb{R})$  of the system

$$(S) \quad \begin{cases} \mu *_{\alpha, \beta} f = g, \\ \nu *_{\alpha, \beta} f = h, \end{cases}$$

where  $*_{\alpha, \beta}$  is the convolution associated with  $\Lambda_{\alpha, \beta}$ .

The uniqueness turns out to prove that  $f = 0$  is the unique solution in  $\mathcal{E}(\mathbb{R})$  of the system

$$(S_0) \quad \begin{cases} \mu *_{\alpha, \beta} f = 0, \\ \nu *_{\alpha, \beta} f = 0. \end{cases}$$

This leads naturally to study the Pompeiu problem in this context, which consists to characterize compactly supported distributions  $\mu_1, \mu_2$  such that  $f = 0$  is the unique smooth function satisfying

$$\mu_i *_{\alpha, \beta} f = 0, \text{ for } i = 1, 2.$$

In other words,  $f = 0$  is the unique smooth function which is mean periodic relatively to  $\mu_1$  and  $\mu_2$ .

The paper is organized as follows. The first section is devoted to introduce some results about harmonic analysis associated with  $\Lambda_{\alpha, \beta}$  which will be used later. In Section 2, we introduce the notion of a mean periodic function associated to the operator  $\Lambda_{\alpha, \beta}$  called  $(\alpha, \beta)$ -mean-periodic function. Next, we summarize the essential fact about these functions namely their series expansion in terms of  $(\alpha, \beta)$ -exponential monomial  $\Psi_{\lambda, l}^{\alpha, \beta}$ . Then we determine their coefficients, for that purpose we construct a biorthogonal system. In Sections 3 and 4, we introduce the Pompeiu problem related to  $(\alpha, \beta)$ -mean-periodic function and we give the resolution of a system of convolution equations associated with the Jacobi-Dunkl operator.

## 1. Preliminaries

In the following, we begin by introducing some useful spaces:

-  $\mathcal{D}(\mathbb{R})$  is the spaces of  $C^\infty$ -functions on  $\mathbb{R}$ , with compact support, we have

$$\mathcal{D}(\mathbb{R}) = \bigcup_{a>0} \mathcal{D}_a(\mathbb{R}),$$

where  $\mathcal{D}_a(\mathbb{R})$  is the space of  $C^\infty$ -functions on  $\mathbb{R}$ , with support in the closed interval  $[-a, a]$ . We provide  $\mathcal{D}_a(\mathbb{R})$  with the topology of uniform convergence of functions and their derivatives. For this topology  $\mathcal{D}_a(\mathbb{R})$  is a Fréchet space.

The space  $\mathcal{D}(\mathbb{R})$  is provided with the inductive limit topology.

-  $\mathcal{E}(\mathbb{R})$  the space of  $C^\infty$ -functions on  $\mathbb{R}$ , endowed with the usual topology of uniform convergence of the functions and their derivatives of all order on compact subsets of  $\mathbb{R}$ .

-  $\mathcal{E}'(\mathbb{R})$  the space of distributions on  $\mathbb{R}$  with compact support.

-  $\mathcal{H}(\mathcal{C})$  the space of entire functions on  $\mathcal{C}$ , rapidly decreasing of exponential type. We have

$$\mathcal{H}(\mathcal{C}) = \bigcup_{a>0} \mathcal{H}_a(\mathcal{C}),$$

$$\mathcal{H}_a(\mathcal{C}) = \left\{ \psi \text{ entire, } \forall m \in \mathbb{N}, \varrho_m(\psi) = \sup_{\lambda \in \mathcal{C}} |(1 + |\lambda|^2)^m \psi(\lambda) e^{-a|\mathcal{I}m\lambda}| < +\infty \right\}.$$

We provide  $\mathcal{H}_a(\mathcal{C})$  with the topology defined by the seminorms  $\varrho_m, m \in \mathbb{N}$ .

The space  $\mathcal{H}(\mathcal{C})$  is equipped with the inductive limit topology.

-  $\mathcal{H}(\mathcal{C})$  the space of entire functions on  $\mathcal{C}$ , slowly increasing of exponential type, i.e.  $\exists m \in \mathbb{N}, \exists R > 0$ , such that

$$\sup_{\lambda \in \mathcal{C}} |(1 + |\lambda|^2)^{-m} \psi(\lambda) e^{-R|\mathcal{I}m\lambda}| < +\infty.$$

### 1.1. The function $\Psi_\lambda^{\alpha,\beta}$

For  $\alpha \geq \beta \geq -\frac{1}{2}$ , we consider the Jacobi-Dunkl operator  $\Lambda_{\alpha,\beta}$  given by

$$\Lambda_{\alpha,\beta} f(x) = f'(x) + ((2\alpha+1)\coth x + (2\beta+1)\tanh x) \left( \frac{f(x) - f(-x)}{2} \right), \quad f \in C^1(\mathbb{R}).$$

The eigenfunction  $\Psi_\lambda^{\alpha,\beta}$  of  $\Lambda_{\alpha,\beta}$  satisfying

$$\begin{cases} \Lambda_{\alpha,\beta} u = i\lambda u, \quad \lambda \in \mathcal{C}, \\ u(0) = 1, \end{cases}$$

is related to the Jacobi functions  $\varphi_\mu^{\gamma,\delta}$  and it is given by

$$\Psi_\lambda^{\alpha,\beta}(x) = \varphi_\mu^{\alpha,\beta}(x) + i \frac{\lambda}{2(\alpha+1)} \sinh x \cosh x \varphi_\mu^{\alpha+1,\beta+1}(x), \quad x \in \mathbb{R},$$

where  $\lambda^2 = \mu^2 + \rho^2$  and  $\rho = \alpha + \beta + 1$ . We recall that  $\varphi_\mu^{\gamma,\delta}$  is defined in terms of the Gauss hypergeometric function  ${}_2F_1$  by

$$\varphi_{\mu}^{\gamma, \delta}(x) = {}_2F_1\left(\frac{\gamma + \delta + 1 + i\mu}{2}, \frac{\gamma + \delta + 1 - i\mu}{2}; \gamma + 1; -\sinh^2 x\right), \quad x \in \mathbb{R}.$$

For  $x \in \mathbb{R} \setminus \{0\}$  and  $\lambda \in \mathcal{C}$ , the function  $\Psi_{\lambda}^{\alpha, \beta}$  admits the following integral representation

$$\Psi_{\lambda}^{\alpha, \beta}(x) = \int_{-|x|}^{|x|} K(x, y) e^{i\lambda y} dy, \quad (1)$$

where  $K(x, \cdot)$  is a positive function on  $\mathbb{R}$ , continuous on  $] -|x|, |x| [$ , supported in  $[-|x|, |x|]$ . For the explicit form, one can see formula (3.4) in [10].

Also, the function  $\Psi_{\lambda}^{\alpha, \beta}$  verifies the following properties (see, [3] and [10]):

i) For all  $n \in \mathbb{N} \setminus \{0\}$ ,  $x \in \mathbb{R} \setminus \{0\}$  and  $\lambda \in \mathcal{C}$ , then

$$\frac{d^n}{dx^n} \Psi_{\lambda}^{\alpha, \beta}(x) = P_x^n(\lambda) \Psi_{\lambda}^{\alpha, \beta}(x) + Q_x^{n-1}(\lambda) \Psi_{\lambda}^{\alpha, \beta}(-x),$$

where  $P_x^n$  (resp.  $Q_x^n$ ) is a polynomial in  $\lambda$  of degree  $n$  (resp. of degree  $\leq n - 1$ ). Its coefficients are bounded independently on  $x$ ,  $|x| \geq x_0$ , where  $x_0 > 0$ .

ii) For all  $n \in \mathbb{N}$ , there exists a constant  $c_n > 0$  such that for all  $x \in \mathbb{R}$  and  $\lambda \in \mathbb{R} \setminus \{0\}$ ,

$$\left| \frac{d^n}{dx^n} \Psi_{\lambda}^{\alpha, \beta}(x) \right| \leq c_n (1 + |x|) \frac{(1 + \rho + |\lambda|)^{n+1}}{|\lambda|}.$$

iii) For all  $n \in \mathbb{N}$ ,  $x \in \mathbb{R}$  and  $\lambda \in \mathcal{C}$ , we have

$$\left| \frac{d^n}{d\lambda^n} \Psi_{\lambda}^{\alpha, \beta}(x) \right| \leq |x|^n e^{Im \lambda |x|}.$$

Formula (1) permits to define the Jacobi- Dunkl intertwining operator on  $\mathcal{E}(\mathbb{R})$  by

$$V_{\alpha, \beta} f(x) = \begin{cases} \int_{-|x|}^{|x|} K(x, y) f(y) dy, & \text{if } x \in \mathbb{R} \setminus \{0\}, \\ f(0), & \text{if } x = 0. \end{cases}$$

It is a topological automorphism of  $\mathcal{E}(\mathbb{R})$  verifying

$$V_{\alpha, \beta}(Df) = \Lambda_{\alpha, \beta}(V_{\alpha, \beta} f), \quad f \in \mathcal{E}(\mathbb{R}),$$

$D$  is the usual derivative operator.

The dual operator  ${}^tV_{\alpha,\beta}$  of the operator  $V_{\alpha,\beta}$  is defined on  $\mathcal{D}(\mathbb{R})$  by

$${}^tV_{\alpha,\beta}(g)(y) = \int_{|x| \geq |y|} K(x, y)g(x)A_{\alpha,\beta}(x)dx.$$

It is a topological isomorphism of  $\mathcal{D}(\mathbb{R})$  and satisfies the transmutation relation

$$D({}^tV_{\alpha,\beta}g) = {}^tV_{\alpha,\beta}(\Lambda_{\alpha,\beta}g), \quad g \in \mathcal{D}(\mathbb{R}).$$

To complete, we recall that the dual operator  ${}^tV_{\alpha,\beta}$  of the operator  $V_{\alpha,\beta}$  is defined on  $\mathcal{E}'(\mathbb{R})$  by

$$\langle {}^tV_{\alpha,\beta}(\mu), f \rangle = \langle \mu, V_{\alpha,\beta}(f) \rangle,$$

and it is an isomorphism of  $\mathcal{E}'(\mathbb{R})$ .

We point out that from the properties of the intertwining operator  $V_{\alpha,\beta}$  and its inverse, we have

$$\forall \mu \in \mathcal{E}', \text{supp} \mu \subset [-a, a] \iff \text{supp} {}^tV_{\alpha,\beta}(\mu) \subset [-a, a]. \quad (2)$$

### 1.2. The Jacobi-Dunkl transform and the convolution product

We recall some notions related to the Jacobi-Dunkl transform, which will be used later (see [2], [3] and [10]).

The Jacobi-Dunkl transform is defined on  $\mathcal{D}(\mathbb{R})$ , (resp.  $\mathcal{E}'(\mathbb{R})$ ) by

$$\mathcal{F}_{\alpha,\beta}(f)(\lambda) = \int_{\mathbb{R}} f(x)\Psi_{-\lambda}^{\alpha,\beta}(x)A_{\alpha,\beta}(x)dx, \quad \lambda \in \mathcal{C},$$

$$\text{(resp. } \mathcal{F}_{\alpha,\beta}(\mu)(\lambda) = \langle \mu, \Psi_{-\lambda}^{\alpha,\beta} \rangle \text{)}.$$

Here,  $A_{\alpha,\beta}(x) = 2^{2\rho}(\sinh |x|)^{2\alpha+1}(\cosh x)^{2\beta+1}$ .

It is connected to the usual Fourier transform  $\mathcal{F}$  by the relations

$$\begin{aligned} \forall f \in \mathcal{D}(\mathbb{R}) \quad , \quad \mathcal{F}_{\alpha,\beta}(f) &= \mathcal{F} \circ {}^tV_{\alpha,\beta}(f), \\ \forall \mu \in \mathcal{E}'(\mathbb{R}) \quad , \quad \mathcal{F}_{\alpha,\beta}(\mu) &= \mathcal{F} \circ {}^tV_{\alpha,\beta}(\mu), \end{aligned} \quad (3)$$

where

$$\mathcal{F}(f)(\lambda) = \int_{\mathbb{R}} f(x) e^{-i\lambda x} dx, \quad \lambda \in \mathcal{C},$$

$$\text{(resp. } \mathcal{F}(\mu)(\lambda) = \langle \mu, e^{-i\lambda \cdot} \rangle, \quad \lambda \in \mathcal{C} \text{)}.$$

From the relations (3) and the classical Paley-Wiener type theorems associated with the transformation  $\mathcal{F}$ , we deduce the following Paley-Wiener type theorems associated with the operator  $\Lambda_{\alpha,\beta}$  (see [10]):

The Jacobi-Dunkl transform  $\mathcal{F}_{\alpha,\beta}$  is a topological isomorphism from  $\mathcal{D}(\mathbb{R})$ , (resp.  $\mathcal{E}'(\mathbb{R})$ ) onto  $\mathcal{H}(\mathbb{C})$ , (resp.  $\mathcal{TH}(\mathbb{C})$ ).

In [2] the authors have established a product formula for the function  $\Psi_\lambda^{\alpha,\beta}$ ,  $\lambda \in \mathcal{C}$ :

$$\Psi_\lambda^{\alpha,\beta}(x)\Psi_\lambda^{\alpha,\beta}(y) = \int_{\mathbb{R}} \Psi_\lambda^{\alpha,\beta}(z)d\mu_{x,y}^{\alpha,\beta}(z), \quad x, y \in \mathbb{R},$$

where  $\mu_{x,y}^{\alpha,\beta}$  is a real uniformly bounded measure with compact support, which may not be positive.

The translation operators  $T_x^{\alpha,\beta}$ ,  $x \in \mathbb{R}$ , associated with the Jacobi-Dunkl operator is defined by

$$T_x^{\alpha,\beta} f(y) = \int_{\mathbb{R}} f(z)d\mu_{x,y}^{\alpha,\beta}(z), \quad x, y \in \mathbb{R},$$

here  $f$  is a measurable function.

This formula coincides on  $\mathcal{E}(\mathbb{R})$  with

$$\forall y \in \mathbb{R}, T_x^{\alpha,\beta} f(y) = V_{\alpha,\beta,x} V_{\alpha,\beta,y} (V_{\alpha,\beta}^{-1}(f)(x + y)). \tag{4}$$

The last formula was given as a definition of  $T_x^{\alpha,\beta}$  on  $\mathcal{E}(\mathbb{R})$ , see [10].

Also, the operator  $T_x^{\alpha,\beta}$ , satisfies:

- (i) For all  $x \in \mathbb{R}$ ,  $T_x^{\alpha,\beta}$  is linear and continuous from  $\mathcal{E}(\mathbb{R})$  into itself.
- (ii) For all  $f \in \mathcal{E}(\mathbb{R})$ , we have

$$\begin{aligned} T_x^{\alpha,\beta} f(y) &= T_y^{\alpha,\beta} f(x) \quad , \quad T_0^{\alpha,\beta} f(y) = f(y) \\ T_x^{\alpha,\beta} T_y^{\alpha,\beta} &= T_y^{\alpha,\beta} T_x^{\alpha,\beta} \quad , \quad T_x^{\alpha,\beta} \Lambda_{\alpha,\beta} = \Lambda_{\alpha,\beta} T_x^{\alpha,\beta}. \end{aligned}$$

- (iii) For all  $x, y \in \mathbb{R}$  and  $\lambda \in \mathcal{C}$ , we have the following product formula:

$$T_x^{\alpha,\beta}(\Psi_\lambda^{\alpha,\beta})(y) = \Psi_\lambda^{\alpha,\beta}(x)\Psi_\lambda^{\alpha,\beta}(y).$$

- (iv) For all  $f \in \mathcal{D}_a(\mathbb{R})$ ,  $a > 0$ , we have

$$\forall x \in \mathbb{R}, T_x^{\alpha,\beta} f \in \mathcal{D}_{a+|x|}(\mathbb{R}),$$

$$\forall \lambda \in \mathcal{C}, \mathcal{F}_{\alpha,\beta}(T_x^{\alpha,\beta} f)(\lambda) = \Psi_\lambda^{\alpha,\beta}(x)\mathcal{F}_{\alpha,\beta}(f)(\lambda).$$

To complete this section, we give the following definitions:

(i) We define the convolution of two distributions  $\mu, \nu \in \mathcal{E}'(\mathbb{R})$  by

$$\langle \mu *_{\alpha, \beta} \nu, f \rangle = \langle \mu_x, \langle \nu_y, T_x^{\alpha, \beta} f(y) \rangle \rangle, f \in \mathcal{E}(\mathbb{R}).$$

(ii) The convolution of  $\mu \in \mathcal{E}'(\mathbb{R})$  and  $f \in \mathcal{E}(\mathbb{R})$  is the function  $\mu *_{\alpha, \beta} f \in \mathcal{E}(\mathbb{R})$  given by

$$\mu *_{\alpha, \beta} f(x) = \langle \mu_y, T_{-x}^{\alpha, \beta} \check{f}(y) \rangle,$$

here  $\check{f}(u) = f(-u)$ .

(iii) The convolution of two functions  $f$  and  $g$  in  $\mathcal{D}(\mathbb{R})$  is defined by the relation

$$f *_{\alpha, \beta} g(x) = \int_{\mathbb{R}} T_{-x}^{\alpha, \beta} \check{f}(y) g(y) A_{\alpha, \beta}(y) dy.$$

Obviously, we have the following properties:

**I)** Let  $\mu, \nu$  be two distributions in  $\mathcal{E}'(\mathbb{R})$  and let  $f, g$  be two functions in  $\mathcal{D}(\mathbb{R})$ , then we have

$$\begin{aligned} \mathcal{F}_{\alpha, \beta}(\mu *_{\alpha, \beta} \nu) &= \mathcal{F}_{\alpha, \beta}(\mu) \mathcal{F}_{\alpha, \beta}(\nu), \\ \mathcal{F}_{\alpha, \beta}(\mu *_{\alpha, \beta} f) &= \mathcal{F}_{\alpha, \beta}(\mu) \mathcal{F}_{\alpha, \beta}(f), \\ \mathcal{F}_{\alpha, \beta}(f *_{\alpha, \beta} g) &= \mathcal{F}_{\alpha, \beta}(f) \mathcal{F}_{\alpha, \beta}(g). \end{aligned} \tag{5}$$

**II)** Let  $\mu, \nu$  be two distributions in  $\mathcal{E}'(\mathbb{R})$  and  $f$  be in  $\mathcal{E}(\mathbb{R})$  we have

$$\mu *_{\alpha, \beta} (\nu *_{\alpha, \beta} f) = (\mu *_{\alpha, \beta} \nu) *_{\alpha, \beta} f. \tag{6}$$

Also, this convolution and the ordinary convolution  $*$  are related by the following:

Let  $\mu, \nu$  be two distributions in  $\mathcal{E}'(\mathbb{R})$  and  $f$  be a function in  $\mathcal{E}(\mathbb{R})$  we have

$$\begin{aligned} ({}^tV_{\alpha, \beta})^{-1}(\mu) *_{\alpha, \beta} V_{\alpha, \beta}(f) &= V_{\alpha, \beta}(\mu * f), \\ {}^tV_{\alpha, \beta}(\mu) * V_{\alpha, \beta}^{-1}(f) &= V_{\alpha, \beta}^{-1}(\mu *_{\alpha, \beta} f), \\ {}^tV_{\alpha, \beta}(\mu *_{\alpha, \beta} \nu) &= {}^tV_{\alpha, \beta}(\mu) * {}^tV_{\alpha, \beta}(\nu). \end{aligned} \tag{7}$$

## 2. Mean-periodic functions associated with the Jacobi-Dunkl operators

### 2.1. Mean-periodic functions

DEFINITION 2.1. A function  $f$  in  $\mathcal{E}(\mathbb{R})$  is called mean-periodic associated with the operator  $\Lambda_{\alpha,\beta}$ , if there exists a non zero distribution  $\mu \in \mathcal{E}'(\mathbb{R})$ , such that for all  $x \in \mathbb{R}$

$$\mu *_{\alpha,\beta} f(x) = 0. \quad (8)$$

Henceforth we shall denote  $(\alpha, \beta)$ -mean-periodic function for the mean periodic function associated with  $\Lambda_{\alpha,\beta}$ . If we want to emphasize the equation satisfied by  $f$  we will say that  $f$  is  $(\alpha, \beta)$ -mean-periodic with respect to  $\mu$  or  $\mu_{-(\alpha, \beta)}$ -mean-periodic function.

If  $\alpha = \beta = -1/2$ , we recover the definition of the classical mean-periodic function, (see [19]).

As in [5], Proposition 6.1.2, we can prove the following proposition.

PROPOSITION 2.2. *The set  $\mathcal{M}_{\alpha,\beta} = \{f \in \mathcal{E}(\mathbb{R}), \mu *_{\alpha,\beta} f = 0\}$  is a closed subspace of  $\mathcal{E}(\mathbb{R})$  which is invariant under translations  $T_x^{\alpha,\beta}$ ,  $x \in \mathbb{R}$ .*

According to the Hahn-Banach theorem, we have the following proposition.

PROPOSITION 2.3. *A function  $f \in \mathcal{E}(\mathbb{R})$  is  $(\alpha, \beta)$ -mean periodic for at least one  $\mu \neq 0$ ,  $\mu \in \mathcal{E}'(\mathbb{R})$ , if and only if  $\mathcal{Z}^{\alpha,\beta}(f) \neq \mathcal{E}(\mathbb{R})$ .*

$\mathcal{Z}^{\alpha,\beta}(f)$  is the closure of the subspace of  $\mathcal{E}(\mathbb{R})$  spanned by  $T_{-x}^{\alpha,\beta} \check{f}$ ,  $x \in \mathbb{R}$ .

#### Examples:

(i) Given  $a \in \mathbb{R}$ ,  $a \neq 0$ , every function  $f$  in  $\mathcal{E}(\mathbb{R})$  such that

$$T_{-x}^{\alpha,\beta} \check{f}(a) = f(x), \text{ for all } x \in \mathbb{R}$$

is  $(\alpha, \beta)$ -mean-periodic with respect to  $\mu = \delta_a - \delta_0$ , where  $\delta_x$  denotes the Dirac point measure at  $x$ .

(ii) If  $f \in \mathcal{D}(\mathbb{R})$ ,  $f \neq 0$ , then  $f$  is not mean periodic.

**Notations:** For  $\lambda \in \mathbb{C}$ ,  $x \in \mathbb{R}$  and  $l \in \mathbb{N}$ , we put

- $\Psi_\lambda(x) := \Psi_{\lambda^{-\frac{1}{2}}, -\frac{1}{2}}(x) = e^{i\lambda x}$ .
- $\Psi_{\lambda,l}(x) := \frac{d^l}{dt^l}(\Psi_{-it}(x))_{t=i\lambda} = x^l e^{i\lambda x}$ .
- $\Psi_{\lambda,l}^{\alpha,\beta}(x) := V_{\alpha,\beta}(\Psi_{\lambda,l})(x) = \frac{d^l}{dt^l}(\Psi_{-it}^{\alpha,\beta}(x))_{t=i\lambda}$ .

For  $\mu \in \mathcal{E}'(\mathbb{R})$ , as in the classical case, (see [5]), one can show that

$$\mu *_{\alpha, \beta} \Psi_{\lambda, j}^{\alpha, \beta}(x) = \sum_{s=0}^j \binom{j}{s} \Psi_{\lambda, j-s}^{\alpha, \beta}(x) (-i)^s \mathcal{F}_{\alpha, \beta}^{(s)}(\mu)(\lambda), \quad \mu \in \mathcal{E}'(\mathbb{R}), \quad 0 \leq j \leq l-1. \tag{9}$$

Thus, if we choose  $\mu \in \mathcal{E}'(\mathbb{R})$  such that  $\lambda$  is a root of order at least  $l$  of  $\mathcal{F}_{\alpha, \beta}(\mu)$ , we conclude that  $x \rightarrow \Psi_{\lambda, l}^{\alpha, \beta}(x)$  is  $\mu - (\alpha, \beta)$ -mean-periodic.

DEFINITION 2.4.  $\Psi_{\lambda, l}^{\alpha, \beta}$  are called  $(\alpha, \beta)$ -exponential-monomials.

By using relation (9), one can see the following proposition.

PROPOSITION 2.5. *The functions  $\Psi_{\lambda, j}^{\alpha, \beta}$ ,  $0 \leq j \leq l-1$ , belong to  $\mathcal{Z}^{\alpha, \beta}(\check{f})$  if and only if, for each distribution  $\mu \in \mathcal{E}'(\mathbb{R})$  verifying*

$$\mu *_{\alpha, \beta} f = 0, \quad \text{for all } x \in \mathbb{R},$$

we have

$$\mathcal{F}_{\alpha, \beta}^{(j)}(\mu)(\lambda) = 0, \quad \text{for } j = 0, \dots, l-1.$$

DEFINITION 2.6. We call spectrum of a  $(\alpha, \beta)$ -mean-periodic function  $f$  in  $\mathcal{E}(\mathbb{R})$ , denoted by  $\text{sp}(f)$ , the set of pairs  $(\lambda, l)$ ,  $\lambda \in \mathcal{C}$ ,  $l \in \mathbb{N}$ , such that the functions  $\Psi_{\lambda, j}^{\alpha, \beta}$  belong to  $\mathcal{Z}^{\alpha, \beta}(\check{f})$  for  $0 \leq j \leq l-1$  and not for  $j = l$ .

From the last proposition, we can conclude that the spectrum is composed by the common zeros of the Jacobi-Dunkl transform of elements in  $\mathcal{E}'(\mathbb{R})$ , which are orthogonal to  $\mathcal{Z}^{\alpha, \beta}(f)$ , each zero being counted with its order of multiplicity.

There is a relationship between  $(\alpha, \beta)$ -mean-periodic functions and classical mean-periodic as shown in the following result which is deduced from the relation

$${}^tV_{\alpha, \beta}(\mu) * V_{\alpha, \beta}^{-1}(f) = V_{\alpha, \beta}^{-1}(\mu *_{\alpha, \beta} f).$$

PROPOSITION 2.7. *A function  $f$  in  $\mathcal{E}(\mathbb{R})$  is  $(\alpha, \beta)$ -mean-periodic with respect to  $\mu$  if and only if the function  $V_{\alpha, \beta}^{-1}(f)$  is classical mean periodic with respect to  ${}^tV_{\alpha, \beta}(\mu)$ .*

From the work of L. Schwartz ([19]) about classical mean-periodic functions on  $\mathbb{R}$  and Proposition 2.7, we deduce the following characterization of the  $(\alpha, \beta)$ -mean-periodic functions.

THEOREM 2.8. *Every  $(\alpha, \beta)$ -mean-periodic function  $f$  in  $\mathcal{E}(\mathbb{R})$ , can be approximated in the topology of  $\mathcal{E}(\mathbb{R})$  by finite linear combinations of*

functions of the type  $\Psi_{\lambda,l}^{\alpha,\beta}$ ,  $(\lambda, l) \in \text{sp}(f)$ . More precisely, we can find finite sets  $\Lambda_n \subseteq \text{sp}(f)$  and  $c_{\lambda,j} \in \mathcal{C}$ , such that

$$f(x) = \lim_{n \rightarrow +\infty} \sum_{(\lambda,l) \in \Lambda_n} \sum_{0 \leq j \leq l-1} c_{\lambda,j} \Psi_{\lambda,j}^{\alpha,\beta}(x), \tag{10}$$

the coefficients  $c_{\lambda,j}$  are uniquely determined.

REMARK. One can see that the space  $\mathcal{M}_{\alpha,\beta}$ , defined in Proposition 2.2, is generated by the  $(\alpha, \beta)$ -exponential monomials  $\Psi_{\lambda,j}^{\alpha,\beta}$ , for  $j \in \{0, 1, 2, \dots, l-1\}$  and  $(\lambda, l) \in \text{sp}(f)$ .

EXAMPLE. Let  $\Lambda_{\alpha,\beta}^n \delta_0$ ,  $n \in \mathbb{N}$ , the element of  $\mathcal{E}'(\mathbb{R})$  defined by

$$\langle \Lambda_{\alpha,\beta}^n \delta_0, f \rangle = (-1)^n (\Lambda_{\alpha,\beta}^n f)(0) \quad \text{and} \quad \mu = \sum_{n=0}^N c_n \Lambda_{\alpha,\beta}^n \delta_0, \quad c_n \in \mathcal{C}, \quad N \in \mathbb{N},$$

then  $\mu *_{\alpha,\beta} f = 0$  means that  $f$  is a solution of the homogeneous differential-difference equation with constant coefficients, namely the equation

$$c_N \Lambda_{\alpha,\beta}^N f(x) + \dots + c_0 f(x) = 0.$$

Then the solution of this equation is given by finite sums of the form

$$f(x) = \sum_{(\lambda,l) \in \text{sp}(f)} \sum_{0 \leq j \leq l-1} a_{\lambda,j} \Psi_{\lambda,j}^{\alpha,\beta}(x) \quad , \quad a_{\lambda,j} \in \mathcal{C},$$

where  $\text{sp}(f)$  is the set of the roots  $\lambda$  of the algebraic equation

$$\mathcal{F}_{\alpha,\beta}(\mu)(\lambda) = \sum_{n=0}^N c_n (i\lambda)^n = 0.$$

If  $\alpha = \beta = -1/2$ , this corresponds to the classical result of Euler.

### 2.2. Biorthogonal system associated with $(\alpha, \beta)$ -exponential monomials

**Notation.** Let  $\mu \in \mathcal{E}'(\mathbb{R})$ ,  $\mu \neq 0$ , we put  
 -  $Z(\mathcal{F}_{\alpha,\beta}(\mu)) = \{(\lambda_n, l_n), n \in \mathbb{N}, l_n \in \mathbb{N}\}$ ,  
 where  $\lambda_n$  is a zero of order  $l_n$  of the entire function  $\mathcal{F}_{\alpha,\beta}(\mu)$ .

As in the classical case [12], [19] and [5] (see also [20] and [4]), we construct a family of distributions  $\mu_{n,m} \in \mathcal{E}'(\mathbb{R})$  verifying

$$\langle \mu_{n,m}, \Psi_{-\lambda_s,j}^{\alpha,\beta} \rangle = (-1)^j \delta_{n,s} \delta_{m,j}, \tag{11}$$

where  $(\lambda_n, l_n) \in Z(\mathcal{F}_{\alpha, \beta}(\mu))$ ,  $0 \leq m \leq l_n - 1$  and  $0 \leq j \leq l_s - 1$ , here  $\delta_{r,s}$  denotes the Kronecker symbol. This formula permits to compute the coefficients  $c_{\lambda,j}$  of the development of a  $\mu$ - $(\alpha, \beta)$ -mean-periodic function  $f \in \mathcal{E}(\mathbb{R})$ , respect to the  $(\alpha, \beta)$ -exponential monomials defined in (10).

Let  $f$  be a function in  $\mathcal{E}(\mathbb{R})$ , for all  $n \in N$ , we put

$$I_n(f)(x) := \int_0^x f(t)e^{-i\lambda_n(x-t)}dt.$$

It is known that the general solution in  $\mathcal{E}(\mathbb{R})$  of the equation

$$(D + i\lambda_n)^{l_n}g = f,$$

is given by

$$g(x) = \sum_{j=0}^{l_n-1} \beta_j x^j e^{-i\lambda_n x} + \overbrace{I_n \circ \dots \circ I_n}^{l_n \text{ times}}(f)(x) \quad , \quad \beta_j \in \mathcal{C}.$$

It follows that the general solution in  $\mathcal{E}(\mathbb{R})$  of the equation

$$(\Lambda_{\alpha, \beta} + i\lambda_n)^{l_n}g = f,$$

is given by

$$g(x) = \sum_{j=0}^{l_n-1} \beta_j \Psi_{-\lambda_n, j}^{\alpha, \beta}(x) + V_{\alpha, \beta} \overbrace{I_n \circ \dots \circ I_n}^{l_n \text{ times}}(V_{\alpha, \beta}^{-1}(f))(x), \beta_j \in \mathcal{C},$$

**Notation.**

- If  $G$  is a meromorphic function, having  $\gamma$  as a pole, we denote by  $[G(\lambda)]_\gamma$  the singular part of  $G(\lambda)$  in a neighborhood of  $\gamma$ , hence  $G(\lambda) - [G(\lambda)]_\gamma$  is holomorphic in a neighborhood of  $\gamma$ .

LEMMA 2.9.

(i) The distribution  $q_n$  in  $\mathcal{E}'(\mathbb{R})$  whose the Jacobi-Dunkl transform is

$$\mathcal{F}_{\alpha, \beta}(q_n)(\lambda) = (\lambda - \lambda_n)^{l_n} \left[ \frac{1}{\mathcal{F}_{\alpha, \beta}(\mu)(\lambda)} \right]_{\lambda_n}$$

has a support concentrated at the origin.

(ii) The distribution  $\mu_{n,0} \in \mathcal{E}'(\mathbb{R})$ ,  $n \in \mathbb{N}$ , whose the Jacobi-Dunkl transform is given by

$$\mathcal{F}_{\alpha,\beta}(\mu_{n,0})(\lambda) = \begin{cases} \mathcal{F}_{\alpha,\beta}(\mu)(\lambda) \left[ \frac{1}{\mathcal{F}_{\alpha,\beta}(\mu)(\lambda)} \right]_{\lambda_n} & , \text{ if } \lambda \neq \lambda_n, \\ 1 & , \text{ if } \lambda = \lambda_n, \end{cases}$$

satisfies

$$\langle \mu_{n,0}, f \rangle = (-i)^{l_n} \langle q_n *_{\alpha,\beta} \mu, V_{\alpha,\beta} \overbrace{I_n \circ \dots \circ I_n}^{l_n \text{ times}} (V_{\alpha,\beta}^{-1}(f)) \rangle, \text{ for all } f \in \mathcal{E}(\mathbb{R}).$$

**P r o o f.**

(i) Since the function  $(\lambda - \lambda_n)^{l_n} \left[ \frac{1}{\mathcal{F}_{\alpha,\beta}(\mu)(\lambda)} \right]_{\lambda_n}$  is a polynomial and using the relation (2), we can conclude that the distribution  $q_n$  has a support concentrated at the origin.

(ii) By the Jacobi-Dunkl transform, it is clear that

$$(-i)^{l_n} (\Lambda_{\alpha,\beta} - i\lambda_n)^{l_n} \mu_{n,0} = q_n *_{\alpha,\beta} \mu.$$

For all  $g$  in  $\mathcal{E}(\mathbb{R})$ , we have

$$\langle q_n *_{\alpha,\beta} \mu, g \rangle = (i)^{l_n} \langle \mu_{n,0}, (\Lambda_{\alpha,\beta} + i\lambda_n)^{l_n} g \rangle.$$

Now the general solution of the equation

$$(\Lambda_{\alpha,\beta} + i\lambda_n)^{l_n} g = f \quad , \quad f \in \mathcal{E}(\mathbb{R}),$$

is given by

$$g(x) = \sum_{j=0}^{l_n-1} \beta_j \Psi_{-\lambda_n,j}^{\alpha,\beta}(x) + V_{\alpha,\beta} \overbrace{I_n \circ \dots \circ I_n}^{l_n \text{ times}} (V_{\alpha,\beta}^{-1}(f))(x), \beta_j \in \mathbb{C}.$$

Hence,

$$\langle \mu_{n,0}, f \rangle = (-i)^{l_n} \langle q_n *_{\alpha,\beta} \mu, V_{\alpha,\beta} I_n \circ \dots \circ I_n (V_{\alpha,\beta}^{-1}(f)) \rangle.$$

**REMARK.** If the zeros  $\lambda_n$  of  $\mathcal{F}_{\alpha,\beta}(\mu)$  are simple, then the distribution  $q_n$  is given by

$$q_n = \frac{1}{(\mathcal{F}_{\alpha,\beta}(\mu))'(\lambda_n)} \delta_0$$

and

$$\mathcal{F}_{\alpha,\beta}(\mu_{n,0})(\lambda) = \begin{cases} \frac{\mathcal{F}_{\alpha,\beta}(\mu)(\lambda)}{(\mathcal{F}_{\alpha,\beta}(\mu))'(\lambda_n)(\lambda - \lambda_n)} & , \text{ if } \lambda \neq \lambda_n, \\ 1 & , \text{ if } \lambda = \lambda_n. \end{cases}$$

Then, for all  $f \in \mathcal{E}(\mathbb{R})$ ,

$$\langle \mu_{n,0}, f \rangle = \frac{(-i)}{(\mathcal{F}_{\alpha,\beta}(\mu))'(\lambda_n)} \langle \mu, V_{\alpha,\beta} I_n (V_{\alpha,\beta}^{-1}(f)) \rangle.$$

In the same way as in [19] (see also [5] and [4]), we can prove the following proposition.

PROPOSITION 2.10. For  $\mu \in \mathcal{E}'(\mathbb{R}), \mu \neq 0$ , there exists a distribution  $\mu_{n,m}, 0 \leq m \leq l_n - 1$ , in  $\mathcal{E}'(\mathbb{R})$  satisfying the relation (11). It is given by

$$\mu_{n,m} = \frac{1}{m!} (\Lambda_{\alpha,\beta} - i\lambda_n)^m \mu_{n,0} + \tau_{n,m} *_{\alpha,\beta} \mu,$$

where  $\tau_{n,m}$  is the distribution in  $\mathcal{E}'(\mathbb{R})$ , with support concentrated at the origin, for  $m \neq 0$  its Jacobi-Dunkl transform is given by

$$\mathcal{F}_{\alpha,\beta}(\tau_{n,m})(\lambda) = \frac{(i)^m}{m!} \left\{ \left[ \frac{(\lambda - \lambda_n)^m}{\mathcal{F}_{\alpha,\beta}(\mu)(\lambda)} \right]_{\lambda_n} - (\lambda - \lambda_n)^m \left[ \frac{1}{\mathcal{F}_{\alpha,\beta}(\mu)(\lambda)} \right]_{\lambda_n} \right\}.$$

Moreover, if  $[a, b]$  is the smallest closed interval containing the support of  $\mu$ , then  $\text{supp}(\mu_{n,m}) \subset [a, b]$ .

COROLLARY 2.11. Let  $f \in \mathcal{E}(\mathbb{R})$  and  $\mu \in \mathcal{E}'(\mathbb{R})$ , assume that

$$f(x) = \sum_{n \geq 0} \sum_{0 \leq l \leq l_n - 1} c_{n,l} \Psi_{\lambda_n,l}^{\alpha,\beta}(x),$$

with  $(\lambda_n, l_n) \in Z(\mathcal{F}_{\alpha,\beta}(\mu))$  and the series converges in the topology of  $\mathcal{E}(\mathbb{R})$ . Then  $f$  is  $\mu$ - $(\alpha, \beta)$ -mean-periodic and the coefficients  $c_{n,l}$  can be computed by the formula

$$c_{n,l} = \langle \mu_{n,l}, \check{f} \rangle = \frac{1}{l!} \langle (\Lambda_{\alpha,\beta} - i\lambda_n)^l \mu_{n,0}, \check{f} \rangle. \tag{12}$$

**2.3. Jacobi-Dunkl expansion of  $(\alpha, \beta)$ -mean-periodic functions**

Let  $f$  be a  $(\alpha, \beta)$ -mean-periodic function in  $\mathcal{E}(\mathbb{R})$  with respect to  $\mu \in \mathcal{E}'(\mathbb{R})$ . We will be interested in the convergence, which will be defined, of the series expansion

$$\sum_{(\lambda_n, l_n) \in Z(\mathcal{F}_{\alpha, \beta}(\mu))} \sum_{0 \leq l \leq l_n - 1} c_{n,l} \Psi_{\lambda_n, l}^{\alpha, \beta}, \tag{13}$$

to  $f$ , where the coefficients  $c_{n,l}, 0 \leq l \leq l_n - 1, n \in \mathbb{N}$ , are given by the relation (12).

DEFINITION 2.12. The series (13) converges to  $f$  in  $\mathcal{E}(\mathbb{R})$  by means of grouping of terms and Abel convergence factors, if there are disjoint finite subsets  $Z_j$  ( groupings ) such that  $Z(\mathcal{F}_{\alpha, \beta}(\mu)) = \bigcup_1^{+\infty} Z_j$  and for every  $\varepsilon > 0$  the series expansion

$$\sum_{j=1}^{+\infty} \left[ \sum_{(\lambda_n, l_n) \in Z_j} \left( \sum_{0 \leq l \leq l_n - 1} c_{n,l} \Psi_{\lambda_n, l}^{\alpha, \beta}(x + i\sigma\varepsilon) \right) \right],$$

converges to a function  $f_\varepsilon$ , satisfying  $\lim_{\varepsilon \rightarrow 0} f_\varepsilon = f$ , where both the series and the limit are in the topology of  $\mathcal{E}(\mathbb{R})$ .

Here,  $\sigma = -1$  for  $\text{Re}\lambda_n > 0$ ,  $\sigma = 1$  for  $\text{Re}\lambda_n < 0$  and  $\sigma = 0$  for  $\text{Re}\lambda_n = 0$ .

From the results of L. Schwartz ([19]) about the Fourier-expansion of classical mean-periodic functions on  $\mathbb{R}$ , we deduce, similarly as in [4] the following result for the Jacobi-Dunkl expansion of  $(\alpha, \beta)$ -mean-periodic functions relatively to a distribution in  $\mathcal{E}'(\mathbb{R})$ .

THEOREM 2.13. *Let  $f$  be a  $(\alpha, \beta)$ -mean-periodic function with respect to  $\mu \in \mathcal{E}'(\mathbb{R})$ , then the series expansion defined in (13) whose coefficients are given by the relation (12), converges to  $f$  in  $\mathcal{E}(\mathbb{R})$  by means of grouping of terms and Abel convergence factors.*

L. Ehrenpreis [13] (see also [7]), showed in the classical case that for a wide class of distributions  $\mu$  the abelian summation process is not necessary. Naturally, we can extend it for  $(\alpha, \beta)$ - mean-periodic functions.

DEFINITION 2.14. A distribution  $\mu \in \mathcal{E}'(\mathbb{R})$  is called  $(\alpha, \beta)$ -slowly-decreasing, if there are positive constants  $A, \varepsilon$ , such that for any  $x \in \mathbb{R}$

$$\text{Max} \{ |\mathcal{F}_{\alpha, \beta}(\mu)(y)|, y \in \mathbb{R}, |x - y| \leq A \log(1 + |x|) \} \geq \varepsilon(1 + |x|)^{-1/\varepsilon}.$$

It turns out that:

- i) if  $\alpha = \beta = -1/2$ , we have the definition of slowly decreasing distribution (see [7] p.123).
- ii)  $\mu$  is  $(\alpha, \beta)$ -slowly-decreasing if and only if  ${}^tV_{\alpha, \beta}(\mu)$  is a slowly decreasing.

By using the result of L. Ehrenpreis for the Fourier expansion of classical mean-periodic functions on  $\mathbb{R}$  (see [13]) and Proposition 2.7, we deduce the following theorem.

**THEOREM 2.15.** *If  $\mu$  is  $(\alpha, \beta)$ -slowly-decreasing, there exists a finite grouping  $Z_j$  of  $Z(\mathcal{F}_{\alpha, \beta}(\mu))$  such that for any  $f \in \mathcal{E}(\mathbb{R})$  satisfying  $\mu *_{\alpha, \beta} f = 0$ , the series*

$$\sum_{j=1}^{+\infty} \left[ \sum_{(\lambda_n, l_n) \in Z_j} \left( \sum_{0 \leq l \leq l_n - 1} c_{n, l} \Psi_{\lambda_n, l}^{\alpha, \beta}(x) \right) \right], \tag{14}$$

converges to  $f$  in  $\mathcal{E}(\mathbb{R})$ , where the coefficients  $c_{n, l}$ ,  $0 \leq l \leq l_n - 1$ ,  $n \in \mathbb{N}$  are given by the relation (12).

By imposing other conditions on the  $(\alpha, \beta)$ -slowly-decreasing distribution  $\mu$ , we can show as follows that the series expansion defined in the relation (13) converges in  $\mathcal{E}(\mathbb{R})$  without the grouping of terms (i.e., for which we have  $\text{card}(Z_j) = 1$  in (14) for all  $j$ ).

It follows from the results of C. A. Berenstein and B. A. Taylor [7] (see also [6], p.214), in the classical case and Proposition 2.7, the following result.

**THEOREM 2.16.** *Given a  $(\alpha, \beta)$ -mean-periodic function  $f$  in  $\mathcal{E}(\mathbb{R})$  relatively to a distribution  $\mu$  in  $\mathcal{E}'(\mathbb{R})$  which is  $(\alpha, \beta)$ -slowly-decreasing, a necessary and sufficient condition for which the Jacobi-Dunkl series representation defined in the relation (13) converges to  $f$  in  $\mathcal{E}(\mathbb{R})$  without groupings is that for some  $\varepsilon, c > 0$ , we have*

$$|\mathcal{F}_{\alpha, \beta}^{(l)}(\mu)(\lambda)| \geq \varepsilon \frac{\exp(-c|\text{Im}\lambda|)}{(1 + |\lambda|)^c}, \tag{15}$$

where  $(\lambda, l) \in Z(\mathcal{F}_{\alpha, \beta}(\mu))$ .

### 3. Pompeiu problem associated with the Jacobi-Dunkl operators

The Pompeiu problem extensively studied by several authors (see, [9] and [1]), is very closely related to the theory of mean periodic functions, see [6].

Let us first recall that a family  $\mathcal{R}$  of compactly supported Radon measures is said to have the Pompeiu property associated with the Jacobi-Dunkl operator, (see [18]), if there is no non trivial function  $f \in C(\mathbb{R})$  or  $\mathcal{E}(\mathbb{R})$  satisfying

$$f *_{\alpha,\beta} \mu = 0, \quad \text{for all } \mu \in \mathcal{R}. \quad (16)$$

Similarly, a collection  $\mathcal{K}$  of bounded measurable subsets of  $\mathbb{R}$  is said to have the Pompeiu property, if there is no non trivial function  $f \in C(\mathbb{R})$  such that:

$$f *_{\alpha,\beta} 1_D(x) = \int_D T_{-x}^{\alpha,\beta} \check{f}(y) A_{\alpha,\beta}(y) dy \equiv 0, \quad \text{for all } D \in \mathcal{K}.$$

Analogously, we say that a family  $\mathcal{R}$  of compactly supported distributions has the Pompeiu property, if there is no non trivial smooth function satisfying:  $\mu *_{\alpha,\beta} f = 0$ , for all  $\mu \in \mathcal{R}$ .

**THEOREM 3.1.** *Two distributions  $\mu, \nu$  of  $\mathcal{E}'(\mathbb{R})$  have the Pompeiu property if and only if  $\mathcal{F}(\mu)$  and  $\mathcal{F}(\nu)$  have no common zero.*

**P r o o f.** The system

$$\begin{cases} \mu *_{\alpha,\beta} f = 0, \\ \nu *_{\alpha,\beta} f = 0, \end{cases}$$

is clearly equivalent to the following

$$\begin{cases} {}^t V_{\alpha,\beta}(\mu) * V_{\alpha,\beta}^{-1}(f) = 0, \\ {}^t V_{\alpha,\beta}(\nu) * V_{\alpha,\beta}^{-1}(f) = 0, \end{cases}$$

which leads to  $V_{\alpha,\beta}^{-1}(f) = 0$ , (see [6], p. 206), and to  $f = 0$ .

Conversely, let  $\lambda \in \mathcal{C}$  such that  $\mathcal{F}_{\alpha,\beta}(\mu)(\lambda) = \mathcal{F}_{\alpha,\beta}(\nu)(\lambda) = 0$ , then

$$\mu *_{\alpha,\beta} \Psi_{\lambda}^{\alpha,\beta}(x) = \nu *_{\alpha,\beta} \Psi_{\lambda}^{\alpha,\beta}(x) = 0, \quad \text{for all } x \in \mathbb{R}.$$

On the other hand,  $\Psi_{\lambda}^{\alpha,\beta}(0) = 1$ , hence  $\mu$  and  $\nu$  do not satisfy the Pompeiu problem, this finished the proof.  $\blacksquare$

**Applications**

PROPOSITION 3.2. For  $r_1 > r_2 > 0$  a necessary and sufficient condition such that there is no non trivial  $f \in C(\mathbb{R})$  satisfying

$$\forall x \in \mathbb{R}, \int_{-r_i}^{r_i} T_{-x}^{\alpha, \beta} \check{f}(y) A_{\alpha, \beta}(y) dy = 0, \quad (i = 1, 2), \tag{17}$$

is that the functions  $\mu \rightarrow \varphi_{\mu}^{\alpha+1, \beta+1}(r_1)$  and  $\mu \rightarrow \varphi_{\mu}^{\alpha+1, \beta+1}(r_2)$ , have no common zeros.

P r o o f. If we denote by  $\sigma_r = 1_{]-r, r[}(x) A_{\alpha, \beta}(x) dx$ , the relation (17) is equivalent to the following

$$\forall x \in \mathbb{R}, \sigma_{r_i} *_{\alpha, \beta} f(x) = 0 \quad (i = 1, 2). \tag{18}$$

So by Theorem 3.1 there is no non trivial function satisfying (17) if and only if the functions  $\lambda \rightarrow \mathcal{F}_{\alpha, \beta}(\sigma_{r_1})(\lambda)$  and  $\lambda \rightarrow \mathcal{F}_{\alpha, \beta}(\sigma_{r_2})(\lambda)$  have no common zero. But we have

$$\frac{d}{dx} \left[ (\sinh 2x)^{-1} A_{\alpha+1, \beta+1}(x) \varphi_{\mu}^{\alpha+1, \beta+1}(x) \right] = 16(\alpha + 1) A_{\alpha, \beta}(x) \varphi_{\mu}^{\alpha, \beta}(x),$$

([15], p.148). It follows that  $(\lambda^2 = \mu^2 + \rho^2)$ ,

$$\mathcal{F}_{\alpha, \beta}(\sigma_{r_i})(\lambda) = \frac{2^{2\rho}}{\alpha + 1} (\sinh r_i)^{2(\alpha+1)} (\cosh r_i)^{2(\beta+1)} \varphi_{\mu}^{\alpha+1, \beta+1}(r_i),$$

and this gives the result. ■

By applying Theorem 3.1, for the measures  $\mu_i = \frac{1}{2}(\delta_{r_i} + \delta_{-r_i})$ ,  $i = 1, 2$ , we obtain the following proposition.

PROPOSITION 3.3. For  $r_1, r_2 > 0$ , a necessary and sufficient condition such that there is no non trivial function  $f \in C(\mathbb{R})$  satisfying

$$\forall x \in \mathbb{R}, T_{r_i} f(x) + T_{-r_i} f(x) = 0, \quad (i = 1, 2)$$

is that the functions  $\mu \rightarrow \varphi_{\mu}^{\alpha+1, \beta+1}(r_1)$  and  $\mu \rightarrow \varphi_{\mu}^{\alpha+1, \beta+1}(r_2)$ , have no common zeros.

### 4. Convolution equations

For  $\mu, \nu \in \mathcal{E}'(\mathbb{R})$ ,  $\mu$  being  $(\alpha, \beta)$ -slowly-decreasing, we consider the system of  $(\alpha, \beta)$ -convolution equation

$$(S) \quad \begin{cases} \mu *_{\alpha, \beta} f = g, \\ \nu *_{\alpha, \beta} f = h, \end{cases}$$

where  $g, h \in \mathcal{E}(\mathbb{R})$  and the unknown function  $f$  is also sought in  $\mathcal{E}(\mathbb{R})$ . For the classical case one can see [7].

There is clearly compatibility condition, namely:

$$\mu *_{\alpha, \beta} h = \nu *_{\alpha, \beta} g.$$

**PROPOSITION 4.1.** *Assume that  $\mathcal{F}_{\alpha, \beta}(\mu)$  and  $\mathcal{F}_{\alpha, \beta}(\nu)$  have no common zeros. The necessary and sufficient condition for the previous system (S) to have a solution for every pair  $(g, h)$  satisfying the compatibility condition, is the existence of  $\mu_1, \nu_1 \in \mathcal{E}'(\mathbb{R})$  such that*

$$\mu_1 *_{\alpha, \beta} \mu + \nu_1 *_{\alpha, \beta} \nu = \delta_0. \tag{19}$$

*In this case the solution is unique.*

**P r o o f.** From relation (7), the system (S) is equivalent to

$$\begin{cases} {}^tV_{\alpha, \beta}(\mu) * V_{\alpha, \beta}^{-1}(f) = V_{\alpha, \beta}^{-1}(g), \\ {}^tV_{\alpha, \beta}(\nu) * V_{\alpha, \beta}^{-1}(f) = V_{\alpha, \beta}^{-1}(h). \end{cases}$$

Using the classical result ([6], p. 219) and the fact that  ${}^tV_{\alpha, \beta}^{-1}(\delta_0) = \delta_0$ , we deduce the result. ■

By using Theorem 3.1, one can remark that if  $f$  is a solution of the system (S), then  $f$  is unique.

**COROLLARY 4.2.** *If the hypotheses of Proposition 4.1 hold, then the necessary and sufficient condition for the existence of a solution  $f$  of the previous system (S) for every pair satisfying the compatibility condition is the existence of constants  $\varepsilon > 0$  and  $C > 0$ , such that*

$$|\mathcal{F}_{\alpha, \beta}(\mu)(\xi)| + |\mathcal{F}_{\alpha, \beta}(\nu)(\xi)| \geq \varepsilon \frac{\exp(-C|\mathcal{I}m\xi|)}{(1 + |\xi|)^C}, \text{ for all } \xi \in \mathcal{C}. \tag{20}$$

**P r o o f.** The proof of the corollary is based on Proposition 4.1, the relation (7) and the result in the classical case (see [6] p. 220). ■

REMARKS.

i) If we denote by

$$P_{\mu,\nu} : \mathcal{E} \rightarrow \mathcal{E}(\mathbb{R}) \times \mathcal{E}(\mathbb{R}), \quad f \rightarrow (\mu *_{\alpha,\beta} f, \nu *_{\alpha,\beta} f),$$

called Pompeiu transform under the assumption that  $\mathcal{F}_{\alpha,\beta}(\mu), \mathcal{F}_{\alpha,\beta}(\nu)$  have no common zero, then  $P_{\mu,\nu}$  is injective.

ii) Let  $\mu, \nu \in \mathcal{E}'(\mathbb{R})$  satisfying (19), the solution  $f$  of the system (S) is given by

$$f = \mu_1 *_{\alpha,\beta} g + \nu_1 *_{\alpha,\beta} h.$$
