Limestone and Nitrogen Application Influence on Cotton Yields and Soil Tests

IN PORTAGEVILLE CLAY SOIL IN SOUTHEAST MISSOURI

James A. Roth and Thomas E. Fisher

(Publication authorized February 24, 1972)

COLUMBIA, MISSOURI

SUMMARY

Seed cotton yields were increased by the application of agricultural limestone on a Portageville clay soil with an initial pHs of 5.8. The addition of four tons or above resulted in a significant increase of seed cotton of the eight crops grown as compared to the check treatment. Five hundred pounds of fine lime applied annually increased yields but the increase over the check was not statistically significant.

The application of limestone, as measure by the soil test, decreased the exchangeable potassium as compared to the check. It apparently did not influence phosphate content of the soil but reduced neutralizable acidity and pHs. Cation exchange capacity was increased, except within the eight-ton application, as limestone was increased.

Over the eight crops of cotton, 113 pounds of nitrogen produced the highest yield, averaging 1670 pounds of seed cotton. This was significantly higher than yields obtained with either the 38 or 63-pound rates of nitrogen. Nitrogen did not increase acidity of the soil significantly although there was a small reduction in pHs over the ten-year period.

ACKNOWLEDGEMENT

The study reported in this publication was begun under the direction of Dr. G. E. Smith, Chairman, Department of Soils, and completed under the guidance of Dr. Roger Mitchell, Chairman, Department of Agronomy. This research was one of the experiments of Project Number 7033-2670 "Soil Fertility and Cotton Production," University of Missouri Agricultural Experiment Station.

Limestone and Nitrogen Application Influence on Cotton Yields and Soil Tests

IN PORTAGEVILLE CLAY SOIL IN SOUTHEAST MISSOURI

James A. Roth¹ and Thomas E. Fisher

Cotton requirements for agricultural limestone and nitrogen have been of concern to farmers of southeast Missouri for several years. With the application of each pound of nitrogen as ammonium nitrate, 1.8 (2) to 3.57 (4) of calcium carbonate are required to neutralize the acid produced in the soil by the chemical reaction. Thus, a question arises of the need to control soil acidity to create a more favorable soil environment for making plant nutrients available to cotton.

According to Neal and Lovett, as reported in Hunger Signs in *Crops* (5), a low pH causes "crinkle leaf" (Manganese toxicity), which results in an excess of water-soluble manganese in the soil solution on some soils. Raising the pH by the addition of limestone eliminates the causes of "crinkle leaf." Finding what level the pHs* should be was one of the objectives of this study. Another was to determine the effect of nitrogen on the acidity of the soil over a period of years. In addition, opportunity to observe changes in soil test values was provided.

EXPERIMENTAL PROCEDURE

A field experiment was established on a Portageville clay soil located seven miles southeast of Portageville, Mo. The Portageville soil series consists of deep, poorly drained, level to depressional soils which occur in oxbows, lakebeds, and meanders left by former channels of the Mississippi River (1). The soil texture consisted of approximately 1 percent sand, 38 percent silt, and 61 percent clay. Soil samples (0-6 inches) were obtained from each plot prior to any soil treatment. These tests are reported in Table 1.

A split plot design was used; the main blocks consisted of five rates of limestone and a check block divided each with three subplots of three rates of nitrogen sidedressed. A recommended cotton variety was planted in 38 inch rows as near May 1 as soil conditions permitted. Three replications of four-row plots 90

¹Associate Professor and Technician, respectively, Department of Agronomy, University of Missouri-Columbia, Delta Center, Portageville, Missouri 63873.

*Refers to salt pH (pHs) as measured in 1:1 soil : 0.01M CaCl₂ suspension.

feet long were included in each subplot. Agricultural calcium carbonate limestone¹ from Jonesboro, Ill. was applied, disced, and plowed down at the beginning of the experiment. No additional limestone was applied throughout the experiment except the annual treatment. Limestone used for the annual treatment was fine lime² (100 mesh or less) obtained from Ste. Genevieve and applied in a band near the row.

The cotton was irrigated by the row method as needed throughout the experiment. This averaged only one irrigation per season. It was very difficult on this soil to prevent an excessive amount of water per irrigation due to large cracks which developed as the soil dried out.

Harvesting the two center rows of each plot was accomplished by a spindle picker, usually in two pickings. Samples of seed cotton were obtained to determine percent lint, staple, and bolls per pound. Quality-of-lint data is not included in this publication as differences were not statistically significant.

After each harvest except 1962, soil samples were obtained from each plot and analyzed according to methods used in the soil testing laboratories of Missouri (3). Results of soil tests after each harvest are reported in Tables 3 through 9. Soil samples were also obtained after completion of the experiment and reported in Table 10.

The data was evaluated statistically by Duncan's New Multiple Range Test (5% level of significance) as a split block design.

RESULTS AND DISCUSSION

The application of limestone increased the soil pH as the rate of limestone was increased. The results of the eight-year average yield data indicated the most optimum pHs for cotton on this soil ranged from 6.1 to 7.1. All limestone treated plots had as high or higher pHs after ten years than they had initially, which indicates that a limestone application may last longer than anticipated. The pHs increased to a maximum in five to six years, after which there was a decline, but only the two-ton rate of application declined to the initial level of acidity (Figure 1). All other limestone treatments were above the initial pHs at the conclusion of the experiment.

Nitrogen applications over the ten-year period did not reduce the pHs of the soil (Table 12). There was no significant difference between the pHs of the 38, 63, and 113 pound rates of nitrogen application. To change the pHs significantly would require higher rates of nitrogen than would be advisable in cotton production in Southeast Missouri.

Soil Tests Results

Organic Matter: Percent of organic matter changed over the ten year period from 2.88% to 2.59% or an average change of minus 0.30% (Table 11). In con-

¹98.2% calcium carbonate with 56.5% passing through a 40 mesh sieve.

²98.5% calcium carbonate with 100% passing through a 100 mesh sieve and 80% through a 200 mesh sieve.

sideration of treatments there appeared to be no relationship except to the fact that over a period of time the organic matter has decreased under a system of continued row cropping of cotton.

Phosphate: Over the nine year period a total of 450 pounds of phosphate was added (50 pounds annually) to the soil which increased the soil test an average of 257 pounds (Table 11). The rate of limestone or nitrogen application did not apparently effect the available phosphate over the ten year period.

Potassium: The soil test for potassium increased an average of 86 pounds following applications of a total of 374 pounds over the ten-year period (Table 11). Limestone applications reduced the available potassium. On the no-treatment plot the potassium soil test increased two times or 178 pounds over the ten-year period. On the plots on which limestone was applied the increase varied from 40 to 95 pounds, depending on rate of limestone application.

Magnesium: No magnesium was added during the experiment but the soil test data indicated an increase of 136 pounds over the ten-year period. Neither limestone nor nitrogen applications appeared to have any effect on available magnesium (Table 11).

Calcium: Pounds of exchangeable calcium in the soil test increased as the rates of limestone were increased. Over the ten-year period exchangeable calcium decreased 442 pounds on the no-treatment plot, whereas, in the plot on which 24 tons was applied the calcium increased 2,995 pounds (Table 11).

N.A.: Neutralizable acidity increased on the plots on which no limestone was applied; where limestone was applied a decrease in N.A. occurred. On the plot receiving a 24-ton limestone application N.A. decreased to zero in 1964, followed by an increase to 0.3 in 1970 (Tables 4 and 10).

pHs: The pHs of the soil increased with the application of limestone. On the check plot the pHs remained about constant throughout the ten-year period. On plots on which limestone was applied the pHs increased but on the plot receiving 24 tons, the pHs reached 7.2 in 1966, then decreased to 6.8 in 1970 (Figure 1). The pHs on all limestone treated plots reached maximum level five to six years after application and then declined. The check plot maintained the initial pHs over the ten year period.

Seed Cotton Yields: In only one year (1962) did limestone applications increase yields of seed cotton significantly over the check. In the summary of eight years of data (Table 10 and Table 12), however, the 4, 8, 12, and 24-ton rates of application of limestone significantly increased first picking and total yields of seed cotton over the check and the 2-ton application.

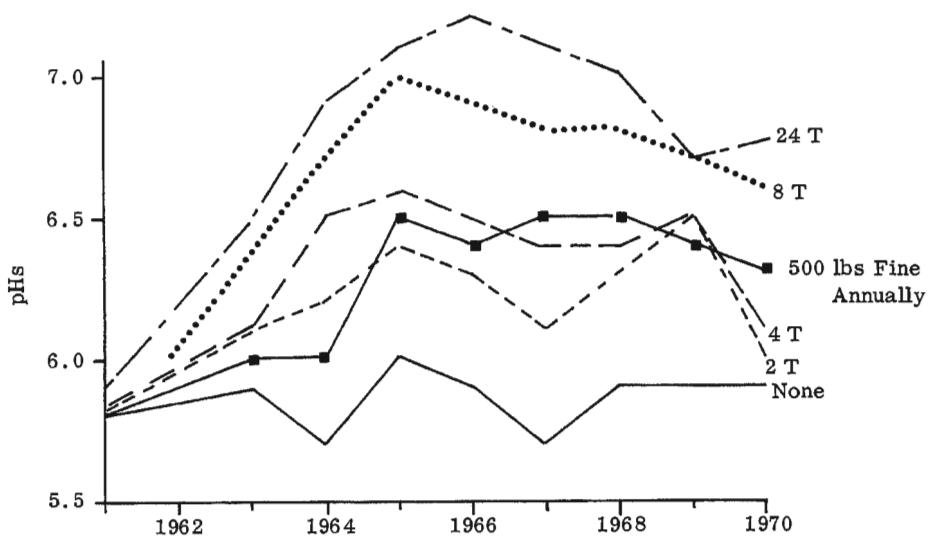

Fig. 1—Influence of limestone on pHs over ten-year period (1961-70) on a Portageville clay soil.

Seed cotton yields increased as the rate of nitrogen was increased (Tables 10 and 12) over the eight-year period. Only one year, 1963, (Table 3) did the 25 pounds of nitrogen sidedress average higher in yield than the 50 and 100 pound applications on this soil type. In seven of the eight years the sidedress of 100 pounds of nitrogen produced highest yield but not always significantly higher than the 50 pound rate of applications.

1/ Agricultural limestone (calcium carbonate) applied April 1961.

2/ Fine lime (calcium carbonate less than 100 mesh) applied annually.

3/ Annual fertilizer N+P₂O₅+K₂O.

(1) 38 pounds of nitrogen per acre.

(2) 63 pounds of nitrogen per acre.

(3) 113 pounds of nitrogen per acre.
