Identification and characterization of kidney glomerulus-associated genes and proteins

AKADEMISK AVHANDLING

som för avläggande av medicine doktorexamen vid Karolinska
Institutet offentligen försvaras i Lennart Nilssonsalen, Nobels väg 15A

Fredagen den 31 augusti, 2012, kl 09.30

av

Perisic Ljubica

Huvudhandledare:

Professor Karl Tryggvason
Karolinska Institutet
Inst. för Medicinsk Biokemi och Biofysik

Bihandledare:

Assistant Professor Jaakko Patrakka
Karolinska Institutet
Inst. för Medicinsk Biokemi och Biofysik

Fakultetsopponent:

Professor emerita Anita Aperia
Karolinska Institutet
Inst. för kvinnors och barns hälsa

Betygsnämnd:

Professor Erik Larsson
Uppsala Universitetet
Inst. för immunologi, genetik och pathologi

Associate Professor Per Uhlen
Karolinska Institutet
Inst. för Medicinsk Biokemi och Biofysik

Professor Staffan Strömblad
Karolinska Institutet
Inst. för biotvetenskaper och näringslära

Stockholm 2012

SUMMARY

The kidney glomerulus is a micro-organ comprised of a molecular filtration barrier that prevents the loss of blood proteins into the primary filtrate. This function is dependent on the coordination of its three constituent layers: the endothelium, the glomerular basement membrane and the podocytes. While each of the three layers contributes to the permselectivity of the glomerular filtration barrier, the podocyte forms the final barrier to filtration.

Many glomerulus-enriched proteins have been implicated in pathogenesis of renal diseases. We have identified over 300 glomerulus-upregulated genes using expressed sequence tag profiling and microarray analysis, in order to discover new genes with important roles in glomerular filtration. Two of these proteins, *Plekhh2* and *Schip1*, were characterized further in this study.

Plekhh2 is an intracellular protein with two PH, MyTH and FERM domains, highly enriched in the podocytes and testes, for which no function has previously been ascribed. We studied by immunoelectron microscopy *Plekhh2* distribution in the human glomerular filter and found that its expression was reduced in focal segmental glomerulosclerosis. Heterologously expressed *Plekhh2* localizes to the peripheral regions of lamellipodia in cultured podocytes and its PH1 domain contains a PIP3 consensus-binding site. The N-terminal half of *Plekhh2* is not required for targeting to lamellipodia but it rather mediates *Plekhh2* self-association. By yeast two-hybrid we identified two *Plekhh2* interacting partners: *Hic-5*, a focal adhesion protein, and actin. *Plekhh2* and *Hic-5* coprecipitate and colocalize at the soles of podocyte foot processes in situ. Strikingly, endogenous *Hic-5* partially relocalizes from focal adhesions to lamellipodia in *Plekhh2*-expressing podocytes. We found also that *Plekhh2* stabilizes the cortical actin cytoskeleton by attenuating actin depolymerization. *Plekhh2*, *Hic5* and actin show parallel expression changes in two mouse models of glomerular damage.

Schip1 is a coiled-coil protein previously discovered through association studies with schwannomin (*Nf2*, merlin) in the mouse brain, shown to be responsive to PDGF β stimulation. We have identified *Schip1* as a highly enriched kidney glomerulus transcript in the podocytes, and investigated its functions in this context. We show that *Schip1* promotes migration of cells in response to PDGF β stimulation and accumulation of cortical actin. In cultured podocytes, *Schip1* localizes to lamellipodia periphery, closely overlapping the cortical actin. Actin disassembly by latrunculin A treatment, could not be prevented by *Schip1* expression, but the protein colocalized to remaining actin fibers. Strikingly, by yeast two-hybrid, coprecipitations and FRET we discovered that *Schip1* interacts with *Nherf2/ezrin*. This is a well characterized podocyte protein complex, forming a supporting net for docking actin filaments in the foot processes by binding to podocalyxin and/or PDGF β cytoplasmic tails. Furthermore, we show by comparative microarray studies, that the expression of *Schip1* and its associated proteins is affected in a similar manner in several mouse models of human glomerular diseases.

Our experiments suggest that both *Plekhh2* and *Schip1* are involved in actin assembly dynamics at the leading edge of cellular extensions. We propose that these proteins are associated to the complicated podocyte foot process actin network. The discovery and characterization of novel glomerular genes and proteins presented in this thesis, has contributed to our understanding of glomerular biology and pathophysiology of renal diseases.
