ABSTRACT

"Darwin wasn't just provocative in saying that we descend from the apes—he didn't go far enough, we are apes in every way, from our long arms and tailless bodies to our habits and temperament." said Frans de Waal, a primate scientist at Emory University in Atlanta, Georgia. 1.3 million Species have been named and analyzed by scientists. This project focuses on capturing various nucleotide sequences of various species and determining the similarity and differences between them. Finite state automata have been used to accomplish this. The automata for a DNA genome is created using Alergia algorithm and is used as the foundation for comparing it to the other species DNA sequences.

ACKNOWLEDGEMENTS

I would like to take this opportunity to thank each and every person who has contributed towards the completion of this project. Working on this project was an exciting experience. Knowledge and experience gained from this project will remain with me as an ingratiating memory.

I would like to express my special thanks of gratitude to my project advisor Dr. T. Y. Lin who gave me this golden opportunity to this wonderful project. His guidance and cooperation have helped me in completing this project successfully. Thanks for the benevolent support and kind attention. I would also like to thank my committee members Dr. Tseng and Mr. Amit Sant for their support and patience.

I would also like to thank our department for providing us with the necessary software required in our project. I'm also thankful to the library for providing necessary books and materials required to learn different concepts for our project.

Last but not the least, sincere thanks to my parents for inspiration and blessings, to my brother's constant moral support and encouragement without which project completion would have been next to impossible. I would also like to take this opportunity to thank my friends Mona, Mini, Krupali and Nikhil for being there for whenever I needed them.

1. Introduction

DNA, or deoxyribonucleic acid, is the hereditary material in humans and almost all other organisms. Almost all the cells in a human body have the same DNA. Most DNA is found in the cell nucleus (where it is called nuclear DNA) however a small amount of DNA can also be discovered in the mitochondria (where it is called mitochondrial DNA or mtDNA). DNA molecules are double-stranded helices, consisting of two long biopolymers made of simpler units called nucleotides. DNA nucleobase contains 4 chemical bases: Adenine (A), Guanine (G), Cytosine (C) and Thymine (T) [15].

RNA or ribonucleic acid is an important molecule with long chains of nucleotides. A RNA nucleotide contains a nitrogenous base, a ribose sugar, and a phosphate [15]. RNA, just like DNA, is equally important for living beings. RNA is usually single stranded unlike DNA which is double stranded. RNA nucleobase is made up of 4 chemical bases: Adenine (A), Guanine (G), Cytosine (C) and Uracil (U) [2].

DNA chemical bases pair up with each other, A with T and C with G, forming units called base pairs. A sugar molecule and a phosphate molecule are attached to each base. DNA in humans contains around 3 billion bases and these are similar in two people for about 99% of the total bases. These bases are sequenced differently for different information that needs to be transmitted [15]. This is similar to the way that different sequences of letters form words and sequences of words form sentences.

The study of abstract machines and the computational difficulties that can be resolved using these abstract machines is called automata. Automata theory is closely related to formal language theory, as the automata are often classified by the class of formal languages they are able to recognize. A finite representation of a formal language that may be an infinite set can be automata [1].

Automata theory has been used to analyze the pattern of text data to find the writer and find the similarity and differences between him and others [5]. In biology, automata theory has been of vital importance. DNA nucleotide genomes have been symbolized using Cellular automata [13]. Hence, the study of DNA nucleobase pairs can be achieved using the automata theory.

A human DNA has approximately three billion base pairs. Searching a single gene from these vast base pairs that contribute to the human genome is known as DNA sequencing. In late 1970’s, primary technique for DNA sequencing was established however scientist could sequence very few base pairs.

An enormous volume of information can be captured from one million bases or more. Matching the dissimilarity between the vast DNA sequences can help in understanding evolution, adaptation and immunity. The Human Genome Project (HGP) was dedicated to evolving innovative and improved tools to obtain gene economically, more rapidly and practical for scientists to achieve. Its popular sequencing of the human genome has provided scientists with a fundamental design of the human being [12].

In this project, we will create the automata of the DNA nucleotide sequence by appropriately representing the base pair sequences in the form of numerical symbols. We will further create a PTA (Prefix Tree Acceptor) to compare the sequence with various other species.

2. DNA Sequencing

A segment of DNA that is transferred from parents to children is known as gene. They are systematized and wrapped in components called chromosomes. Humans have 23 pairs of chromosomes which makes them different from other creatures. A gene also codes for a single protein molecule also known as polypeptide which is also used for protein synthesis. It comprises of two steps: Transcription and Translation [9].

Transcription: The sequence of one gene is replicated in an RNA molecule [15].

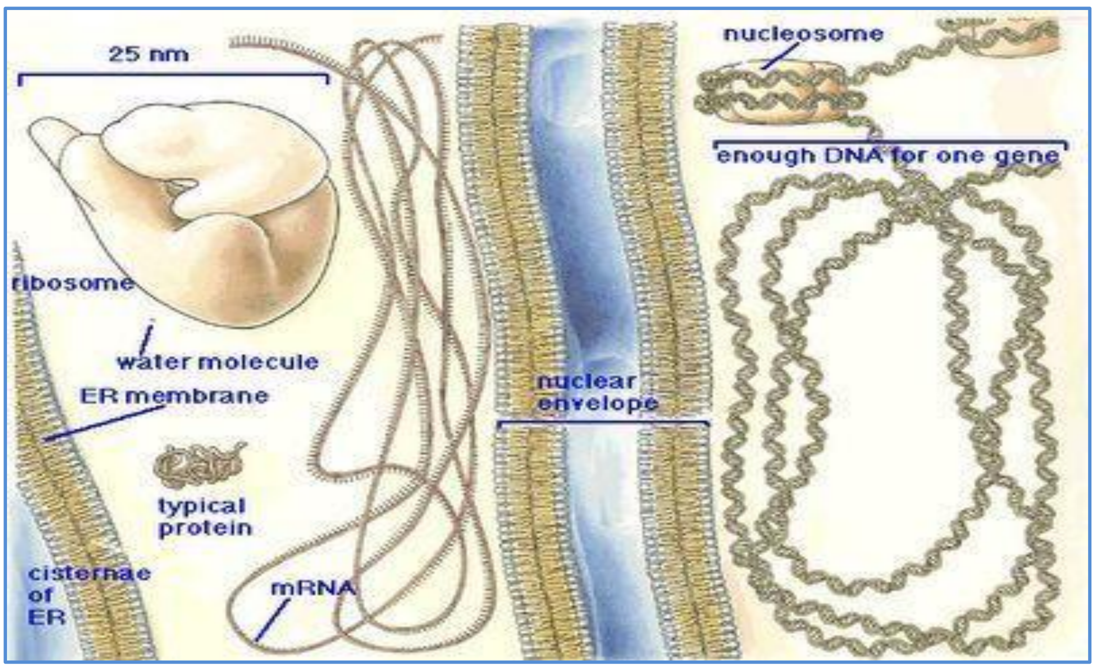

Figure 1: Process of Transcription [17]

Translation: The RNA molecule acts as a cypher for the formation of an amino-acid chain (a polypeptide) [15].

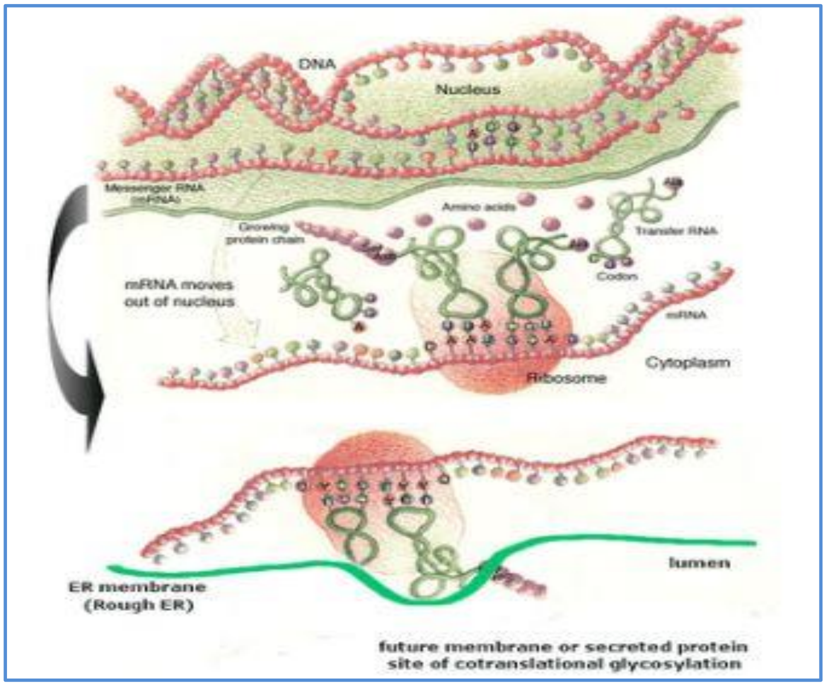

Figure 2: Process of Translation [17]

Translation of DNA to RNA into a sequence of amino acids marks the beginning of protein synthesis [9][15]. The main structure of protein is a thorough sequence of amino acids in a polypeptide string. A set of 20 naturally occurring amino acids exists today. Asparagine was discovered in 1806 followed by Cysteine, Leucine and Glucine [9].

Types of Amino Acids:

Amino Acid	one letter code	three letter code
L-alanine	A	Ala
L-arginine	R	Arg
L-asparagine	N	Asn
L-aspartic acid	D	Asp
L-cysteine	C	Cys
L-glutamine	Q	Gln
L-glutamic acid	E	Glu
glycine	G	Gly
L-histidine	H	His
L-isoleucine.	I	Ile
L-leucine	L	Leu
L-lysine	K	Lys
L-methionine	M	Met
L-phenylalanine	F	Phe
L-proline	P	Pro
L-serine	S	Ser
L-threonine	T	Thr
L-tryptophan	W	Trp
L-tyrosine	Y	Tyr
L-valine	V	Val

Table 1: List of Amino acids [2]

Amino acids are categorized into four major sets based on the properties of the "R" group in each amino acid. The types of amino acids are namely polar, nonpolar, positively charged, or negatively charged [9]. Polar amino acids have "R" groups that are hydrophilic, which hunt for contact with aqueous solutions. Nonpolar amino acids are the opposite of hydrophilic; they avoid contact with liquid [10].

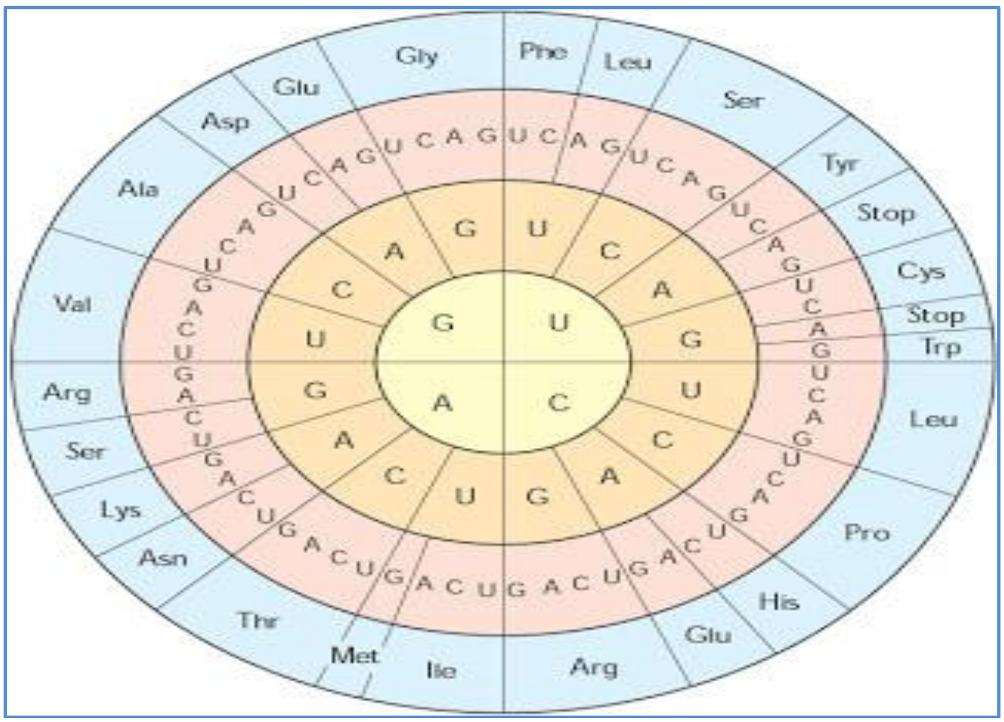

Figure 3: Amino Acids Chart [2]

There are 8 different types of essential amino acids: isoleucine, leucine, lysine, methionine, phenylalanine, threonine, tryptophan and valine. The remaining 12 are non-essential amino acids [10]. Essential amino acids perform various functions in your body including supervising insulin and maintaining healthy hair, skin, and nails.

They act as the elementary building blocks of the human body. Deficiency in amino acids can lead to lower energy levels. It could also slower the rate of metabolism and cause skin and hair loss, indigestion, insomnia, stress etc. Obesity can be avoided by getting all the required amino acid, which in turn can help in throwing waste away from the bloodstream.

3. Understanding Automata

In this section, we will understand the use of Finite Automata for representing DNA genomes [1] [3].

3.1. Finite automaton ‘A’ is defined as follows:

$$A=(S, P, i, \delta, T), \text{ where}$$

- S: is a finite set known as set of states
- P: finite input alphabet

$$P = \{A, C, G, T\} \text{ or } \{A, C, G, U\}$$

- i: fixed element of A called as initial state
- δ: is a function:

$$\delta: S \times A \rightarrow S$$

It is known as the transition function.

- T: is a subset of S known as terminal state.

3.2. Non-Deterministic Finite Automata:

Non-deterministic finite automata can be in various states at a single instance of time [14]. Transition from one state on an input can be to any set of states.

DFA vs NFA [14]

Deterministic Finite Automata	Non Deterministic Finite Automata
Characterized as a 5 tuple state: <S, A, T, s_0, F>	Characterized as a 5 tuple state: <S, A, T, s_0, F>
S is the set of states	S is the set of states
A is the alphabet	A is the alphabet
T is the transition function: $S \times A \rightarrow S$	T is the transition function: $S \times (A \cup \{\varepsilon\}) \rightarrow PS$
s_0 is the initial state	s_0 is the initial state
F is the set of accepting states.	F is the set of accepting states.

4. Alergia Algorithm

Our main focus is on an algorithm that can encode the strategy for understanding the DNA sequences. This algorithm belongs to the family of functions that can be determined as Stochastic Finite State Transducer (SFST) [16][18]. Stochastic Moore machine is nothing but the probabilistic distribution of symbols.

We will use Alergia algorithm for our DNA recognition which is discussed as follows.

```
Algorithm Alergia
Input:
        S: sample set of strings
        α: 1 – confidence level
Output:
        SFA
Begin
        A = stochastic prefix tree acceptor from S
        Do (for j = successor(first node(A) to last
        node(A))
             Do (for i = firstnode(A) to j)
                  If compatible(i,j)
                       Merge (A,i,j)
                       Determinize(A)
                       Exit (i loop)
                  End if
             End for
        End for
        Return A
End algorithm
```

There are 4 major groups of amino acids: Polar, Non polar, positively charged and negatively charged. To build automata we have to convert these to numerical.

Hence, we will enumerate them in the following way:

NonPolar-0

Glycine (G) – GGU, GGC, GGA, GGG;

Alanine (A) – GCU, GCC, GCA, GCG;

Valine (V) – GUU, GUC, GUA, GUG;

Leucine (L) – CUU, CUC, CUA, CUG, UUA, UUG;

Isoleucine (I) – AUU, AUC, AUA;

Proline (P) – CCU, CCC, CCA, CCG;

Methionine (M) – AUG;

Phenylalanine (F) – UUU, UUC;

Tryptophan (W) – UGG

Polar-1

Serine (S) – UCU, UCC, UCA, UCG;

Threonine (T) – ACU, ACC, ACA, ACG;

Cysteine (C) – UGU, UGC;

Asparagine (N) – GAU, GAC;

Glutamine (Q) – CAA, CAG;

Tyrosine (Y) – UAU, UAC

Polar Acidic-2

Aspartic Acid (D) – GAU, GAC;

Glutamic Acid (E) – GAA, GAG

Polar Basic-3

Lysine (K) – AAA, AAG;

Arginine (R) – CGU, CHC, CGA, CGG, AGA, AGG;

Histidine (H) – CAU, CAC

Figure 3 shows that UAA, UAG and UGA are stop codons. We will group them in the final stage as 4.

Stop Codons-4

UAA,

UAG,

UGA

5. Creating SFA using Algorithm Alergia

Let us assume there are 'n' strings, $S=\{s_0, s_1, s_2, s_3, \ldots s_n\}$ and $s_i = a_1 a_2 a_3 \ldots a_i$.

Once the SFA is build, we start merging the states [16]. Two states can be merged when they are compatible i.e. they have equal transition probabilities for every input $a \in A$ and the end nodes must be same as well.

$$q_i \equiv q_j \Rightarrow \forall a \in A, \text{ where } p_i(a) = p_j(a) \text{ and } \delta_i(a) \equiv \delta_j(a)$$

It's very difficult to find equal frequencies hence states are accepted to be same if they fall under a confidence range.

Given the probability p and frequency n for n values, a confidence range can be defined as:

$$\left|p - \frac{f}{n}\right| < \sqrt{\frac{1}{2n}\log\frac{2}{\alpha}} \text{ with probability larger than } (1-a).$$

The probabilities are calculated and these values of vital importance for the process of merging. Algorithm Alergia will reject the states if these values are greater than the confidence range.

$$\left|\frac{f}{n} - \frac{f'}{n'}\right| > \sqrt{\frac{1}{2}\log\frac{2}{\alpha}}\left(\frac{1}{\sqrt{n}} + \frac{1}{\sqrt{n'}}\right).$$

The above equation helps in merging the compatible states. After merging all the compatible states, we get a SFA [16] which is an estimate of the initial one.

A DNA nucleotide sequence can be represented in the form of numerical depending on the 4 groups of amino acids discussed in Chapter 4 as follows:

Sequence 1: AUG AGA CCA GCG AGG ACA CCU GAU GAA UGA

Input 1: 0 3 0 0 3 1 0 2 2 4

Sequence 2: AUG CUC CAU CAA UGG GAC AAA UUU UUC UGG

Input 2: 0 0 3 1 0 2 3 0 0 0

Sequence 3: AUG AUC ACC UGU GAU AAG GUU AUU CCU CAU

Input 3: 0 1 1 1 2 3 0 0 0 3

Sequence 4: AUG UCU GAG GAC GAA CGU UCU UGG GAU AAA

Input 4: 0 1 2 2 2 3 1 1 2 3

Sequence 5: AUG CCU CAU GAU AAG AUC UGU CAU GUU ACC

Input 5: 0 0 3 1 3 1 1 3 0 1

Sequence 6: AUG AUU CCC UAU GAU GAG AAG GAC AAA UCU

Input 6: 0 0 0 1 2 2 3 2 3 1

Sequence 7: AUG CAU UAU GAU CAU GAC AAA CCU AUC GAU

Input 7: 0 3 1 1 3 2 3 0 1 2

Sequence 8: AUG CCU GAU AUU UGU CAU GUU GAG UAU ACC

Input 8: 0 0 1 0 1 3 0 2 1 1

Sequence 9: AUG GAU AAG GAA AAA UCA GAC CUU CCC CAU

Input 9: 0 1 3 2 3 1 1 0 0 3

Sequence 10: AUG AAA AAG GAU UGU CAA GAU AUC GAG CAC

Input 10: 0 3 3 2 1 1 2 0 2 3

Above are a few examples of DNA sequences being represented numerically. Once this is done we can now use Algorithm Alergia to build a prefix tree acceptor (PTA) [3][16]. The algorithm then merges all the compatible states in PTA and creates stochastic finite automata [16][17][18]. This automaton is an estimate of the initial one.

6. DNA samples of living organisms

There are approximately 8.7 million species of species on our planet out of which 6.5 million are from land and the remaining from the seas [8].

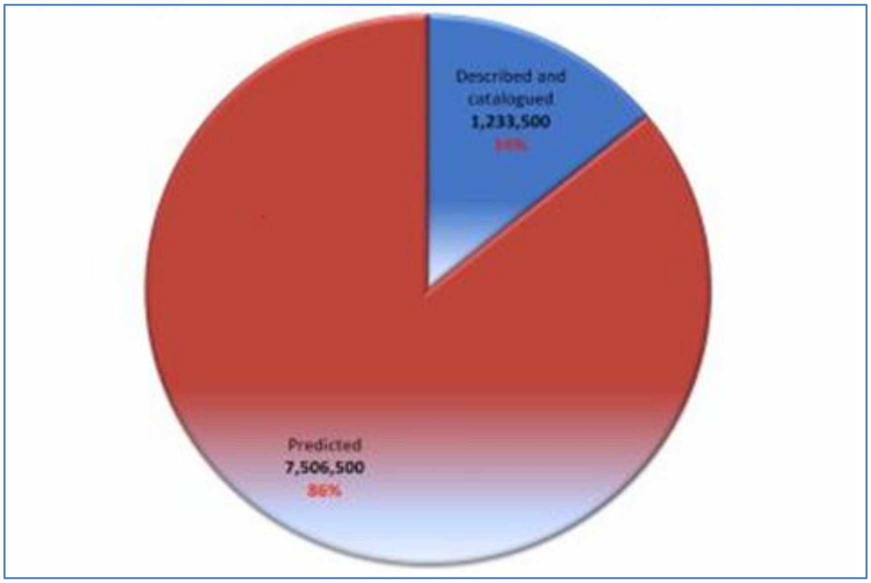

Figure 4: Total Number of Species on Earth [8]

As shown in the above figure, only 1.8 million species have been categorized and known to mankind. This clearly states that around 75-90% of them are yet to be discovered.

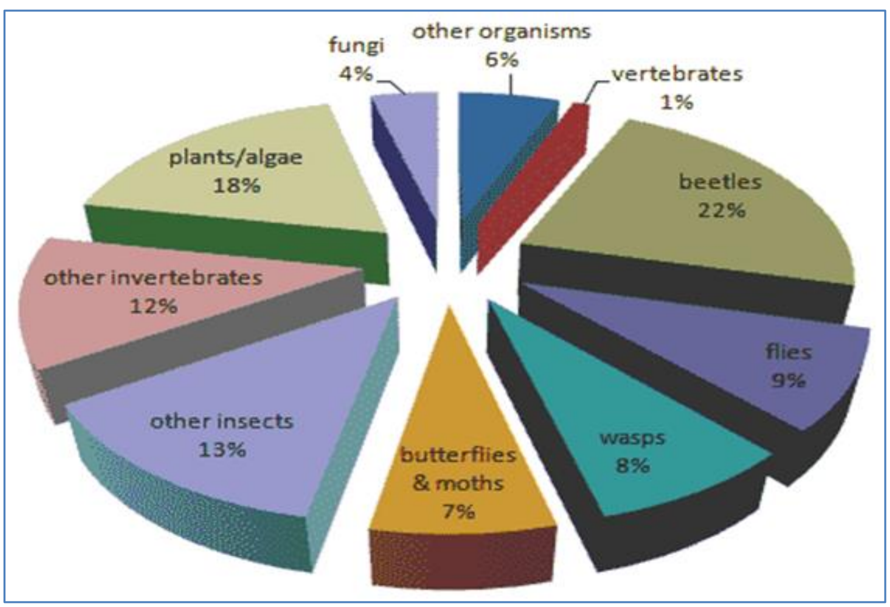

Figure 5: Relative Number of Named Species [7]

The above chart shows that there are approximately 12% of invertebrates such as arthropod, mollusk, annelid, coelenterate etc. Vertebrates, categorized by the existence of spinal cord, include mammals (human beings), birds, reptiles, amphibians etc. Our percentage is the lowest amongst all [7].

Our goal is to find the similarity between different species. Below are samples of DNA sequences [15][19] of some species:

7. Test Results

Comparison of Human, Chimpanzee and Banana

	Alpha	Human	Chimp	Banana
1	0.10	99.981	99.949	89.933
2	0.20	99.979	97.816	87.154
3	0.30	99.978	95.342	81.706
4	0.40	99.975	94.721	74.585
5	0.50	99.972	92.808	70.633
6	0.60	99.971	90.368	63.707
7	0.70	99.965	89.886	59.961
8	0.80	99.962	88.386	54.822
9	0.90	99.955	86.371	52.666
10	1.00	99.951	84.731	49.595

Table 2: Comparison of Human, Chimpanzee and Banana DNA

The above table shows that the DNA of chimpanzee has 84% similarity with Human DNA and DNA of banana is 49% similar to human DNA.

Comparing Human, Chimpanzee and Mouse

	Alpha	Human	Chimp	Mouse
1	0.10	99.981	99.949	97.933
2	0.20	99.979	97.816	97.154
3	0.30	99.978	95.342	96.706
4	0.40	99.975	94.721	94.585
5	0.50	99.972	92.808	93.633
6	0.60	99.971	90.368	92.707
7	0.70	99.965	89.886	91.961
8	0.80	99.962	88.386	89.822
9	0.90	99.955	86.371	82.666
10	1.00	99.951	84.731	81.595

Table 3: Comparison of Human, Chimpanzee and Mouse DNA

The above table shows that the DNA of chimpanzee has 84% similarity with Human DNA and DNA of banana is 81% similar to Mouse DNA.

Comparing Human, Monkey and Fruit Fly

	Alpha	Human	Monkey	Fruit Fly
1	0.10	99.981	99.941	79.103
2	0.20	99.979	97.814	72.974
3	0.30	99.978	95.360	66.286
4	0.40	99.975	94.722	64.605
5	0.50	99.972	92.800	61.993
6	0.60	99.971	90.363	57.127
7	0.70	99.965	89.898	53.581
8	0.80	99.962	88.545	49.232
9	0.90	99.955	86.371	46.116
10	1.00	99.951	84.931	44.685

Table 4: Comparison of Human, Monkey and Fruit Fly DNA

The above table shows that the DNA of monkey has 84% similarity with Human DNA and DNA of Fruit Fly is 44% similar to human DNA.

Comparing Human, Dog and E. Coli (bacteria)

	Alpha	Human	Dog	E. Coli
1	0.10	99.981	97.923	39.202
2	0.20	99.979	94.701	32.346
3	0.30	99.978	92.456	29.282
4	0.40	99.975	89.980	22.167
5	0.50	99.972	86.976	17.593
6	0.60	99.971	85.049	12.152
7	0.70	99.965	83.728	09.361
8	0.80	99.962	82.983	07.991
9	0.90	99.955	80.624	05.668
10	1.00	99.951	77.828	03.120

Table 5: Comparison of Human, Dog and E. Coli DNA

The above table shows that the DNA of Dog has 77% similarity with Human DNA and DNA of E. Coli is 3% similar to human DNA.

Comparing Human, Mouse and Yeast

	Alpha	Human	Mouse	Yeast
1	0.10	99.981	99.191	58.111
2	0.20	99.979	97.664	52.912
3	0.30	99.978	95.850	49.282
4	0.40	99.975	94.102	46.629
5	0.50	99.972	92.810	41.908
6	0.60	99.971	90.303	37.133
7	0.70	99.965	89.678	34.592
8	0.80	99.962	88.685	31.225
9	0.90	99.955	87.371	29.193
10	1.00	99.951	86.931	27.662

Table 6: Comparison of Human, Mouse and Yeast DNA

The above table shows that the DNA of Mouse has 86% similarity with Human DNA and DNA of Yeast is 27% similar to human DNA.

Comparing Human, Fruit fly and Weed

	Alpha	Human	Fruit Fly	Weed
1	0.10	99.981	78.717	58.125
2	0.20	99.979	71.285	52.936
3	0.30	99.978	67.453	49.222
4	0.40	99.975	64.636	46.695
5	0.50	99.972	62.125	42.901
6	0.60	99.971	59.984	33.198
7	0.70	99.965	55.920	29.598
8	0.80	99.962	52.615	25.233
9	0.90	99.955	48.331	22.180
10	1.00	99.951	44.231	18.690

Table 7: Comparison of Human, Fruit Fly and Weed DNA

The above table shows that the DNA of Fruit Fly has 44% similarity with Human DNA and DNA of Weed is 18% similar to human DNA.

Comparing Human, Cat and Cow

	Alpha	Human	Cat	Cow
1	0.10	99.981	98.717	97.989
2	0.20	99.979	98.219	96.026
3	0.30	99.978	95.420	94.894
4	0.40	99.975	93.685	92.695
5	0.50	99.972	91.133	89.430
6	0.60	99.971	89.993	88.925
7	0.70	99.965	88.913	86.686
8	0.80	99.962	86.215	82.135
9	0.90	99.955	85.931	79.248
10	1.00	99.951	84.231	76.666

Table 8: Comparison of Human, Cat and Cow DNA

The above table shows that the DNA of Cat has 84% similarity with Human DNA and DNA of Cow is 76% similar to human DNA.

Comparing Human, Dog and Mushroom

	Alpha	Human	Dog	Mushroom
1	0.10	99.981	97.923	89.471
2	0.20	99.979	94.701	82.895
3	0.30	99.978	92.456	79.346
4	0.40	99.975	89.980	77.908
5	0.50	99.972	86.976	69.786
6	0.60	99.971	82.049	66.012
7	0.70	99.965	78.728	61.623
8	0.80	99.962	76.983	54.979
9	0.90	99.955	75.624	49.801
10	1.00	99.951	77.828	42.213

Table 9: Comparison of Human, Dog and Mushroom DNA

The above table shows that the DNA of Dog has 77% similarity with Human DNA and DNA of Mushroom is 42% similar to human DNA.

Comparing Human, Dog and Rice

	Alpha	Human	Dog	Rice
1	0.10	99.981	97.923	58.309
2	0.20	99.979	94.701	46.786
3	0.30	99.978	92.456	41.523
4	0.40	99.975	89.980	37.960
5	0.50	99.972	86.976	33.986
6	0.60	99.971	82.049	29.112
7	0.70	99.965	78.728	25.011
8	0.80	99.962	76.983	22.951
9	0.90	99.955	75.624	18.208
10	1.00	99.951	74.828	15.420

Table 10: Comparison of Human, Dog and Rice DNA

The above table shows that the DNA of Dog has 74% similarity with Human DNA and DNA of Rice is 15% similar to human DNA.

Comparing Human, Cow and E. Coli(bacteria)

	Alpha	Human	Cow	E. Coli
1	0.10	99.981	97.130	39.202
2	0.20	99.979	94.195	32.346
3	0.30	99.978	92.222	29.282
4	0.40	99.975	89.900	22.167
5	0.50	99.972	86.928	17.593
6	0.60	99.971	82.022	12.152
7	0.70	99.965	81.123	09.361
8	0.80	99.962	79.646	07.991
9	0.90	99.955	77.186	05.668
10	1.00	99.951	76.925	03.120

Table 11: Comparison of Human, Cow and E. Coli DNA

The above table shows that the DNA of Cow has 76% similarity with Human DNA and DNA of E. Coli is 3% similar to human DNA.

Following is a table which shows the similarity between different species. For example, the Human and Chimps are 87% similar (84% according to our test result), Dog and Mouse are 82% similar (87% according to our test result). The results below are almost in accordance with the tests we have conducted.

Homologs	Human	Chimp	Dog	Mouse	Rat	Fruit Fly
Human	--	29529 87% 84%	27761 81% 77%	26830 79% 81%	23860 70% 73%	13276 39% 44%
Chimp	18898 87% 84%	--	16865 78% 71%	16194 75% 79%	14283 66% 68%	7673 35% 38%
Dog	28144 82% 77%	27139 89% 82%	--	26740 88% 91%	23816 78% 74%	22771 75% 69%
Mouse	16384 83% 81%	15674 82% 78%	16066 84% 87%	--	14067 74% 76%	7887 41% 45%
Rat	12409 70% 73%	11907 90% 92%	12184 92% 89%	12420 94% 91%	--	6592 50% 49%

Table: Homologous gene Summary Chart [21]

8. Future Work

Although 1.8 million species are discovered today, all their DNA nucleotides are not easily accessible to study the differences and the similarities between these organisms. Also, DNA can be represented in 3D structures [12][20] depending on the behavioral patterns of proteins in the amino acids. This can be achieved in future research.

9. Conclusion

Pattern recognition of sequential symbolic data using automata theory was proposed in 2005 by Dr. Lin [1] and is being researched since then by him and his students. His student, Nikhil Kalantri has proposed an approach for author identification using the Alergia algorithm for pattern recognition.

In this project, two or more species can be compared on the basis of their DNA genome. The nucleotide sequences help us understand and learn the theory of life and the evolution of living organisms by comparing two species or by comparing the two organisms of the same species. For mathematical results, theory of automata proves to be vital importance. A PTA formed by the use of Alergia helps us understand the DNA genome in a better way.
